  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--stub-tags`

  Use stubs instead of real tags (default $WERF_STUB_TAGS)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

Default:
- $WERF_SYNCHRONIZATION, or
- :local if --repo is not specified, or
- https://delivery-sync.deckhouse.ru if --repo has been specified.

The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only

- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit compose run

Usage:

```
d8 delivery-kit compose run [IMAGE_NAME...] [options] [--docker-compose-options="OPTIONS"] [--docker-compose-command-options="OPTIONS"] -- SERVICE [COMMAND] [ARGS...]
```

Run docker-compose run command with forwarded image names.

Show more...

Run docker-compose run command with forwarded image names.
Image environment name format: $WERF_<FORMATTED_WERF_IMAGE_NAME>_DOCKER_IMAGE_NAME ($WERF_DOCKER_IMAGE_NAME for nameless image).
<FORMATTED_WERF_IMAGE_NAME> is werf image name from werf.yaml modified according to the following rules:
- all characters are uppercase (app -> APP);
- charset /- is replaced with _ (DEV/APP-FRONTEND -> DEV_APP_FRONTEND).
If one or more IMAGE_NAME parameters specified, werf will build and forward only these images.
Given the following werf configuration:

```
# werf.yaml
project: x
configVersion: 1
---
image: frontend
dockerfile: frontend.Dockerfile
---
image: geodata-backend
dockerfile: backend.Dockerfile
```

Use described images as follows in your docker compose configuration:

```
# docker-compose.yaml
services:
  frontend:
    image: $WERF_FRONTEND_DOCKER_IMAGE_NAME
  backend:
    image: $WERF_GEODATA_BACKEND_DOCKER_IMAGE_NAME
```

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images

until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)

- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and

development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project's werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--docker-compose-bin-path`

  DEPRECATED: "docker compose" command always used now, this option is ignored. Define docker-compose bin path (default $WERF_DOCKER_COMPOSE_BIN_PATH)
- `--docker-compose-command-options`

  Define docker-compose command options (default $WERF_DOCKER_COMPOSE_COMMAND_OPTIONS)
- `--docker-compose-options`

  Define docker-compose options (default $WERF_DOCKER_COMPOSE_OPTIONS)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read and pull images from the specified repo
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--dry-run`

  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or false by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)

- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name, -N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

Choose repo container registry implementation.
The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).

- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--stub-tags`

  Use stubs instead of real tags (default $WERF_STUB_TAGS)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or

- :local if --repo is not specified, or
- https://delivery-sync.deckhouse.ru if --repo has been specified.

The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only

- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit compose up

Usage:

```
d8 delivery-kit compose up [IMAGE_NAME...] [options] [--docker-compose-options="OPTIONS"] [--docker-compose-command-options="OPTIONS"] [--] [SERVICE...]
```

Run docker-compose up command with forwarded image names.

Show more...

Run docker-compose up command with forwarded image names.
Image environment name format: $WERF_<FORMATTED_WERF_IMAGE_NAME>_DOCKER_IMAGE_NAME ($WERF_DOCKER_IMAGE_NAME for nameless image).
<FORMATTED_WERF_IMAGE_NAME> is werf image name from werf.yaml modified according to the following rules:
- all characters are uppercase (app -> APP);
- charset /- is replaced with _ (DEV/APP-FRONTEND -> DEV_APP_FRONTEND).
If one or more IMAGE_NAME parameters specified, werf will build and forward only these images.
Given the following werf configuration:
werf.yaml
project: x
configVersion: 1
---
image: frontend
dockerfile: frontend.Dockerfile
---
image: geodata-backend
dockerfile: backend.Dockerfile
Use described images as follows in your docker compose configuration:
docker-compose.yaml
services:
  frontend:
    image: $WERF_FRONTEND_DOCKER_IMAGE_NAME
  backend:
    image: $WERF_GEODATA_BACKEND_DOCKER_IMAGE_NAME

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or

$WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)

- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")

- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--docker-compose-bin-path`

  DEPRECATED: "docker compose" command always used now, this option is ignored. Define docker-compose bin path (default $WERF_DOCKER_COMPOSE_BIN_PATH)
- `--docker-compose-command-options`

  Define docker-compose command options (default $WERF_DOCKER_COMPOSE_COMMAND_OPTIONS)
- `--docker-compose-options`

  Define docker-compose options (default $WERF_DOCKER_COMPOSE_OPTIONS)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read and pull images from the specified repo
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--dry-run`

  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or false by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)

- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).

- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--stub-tags`

  Use stubs instead of real tags (default $WERF_STUB_TAGS)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

Default:
- $WERF_SYNCHRONIZATION, or
- :local if --repo is not specified, or
- https://delivery-sync.deckhouse.ru if --repo has been specified.

The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only

- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit config

Usage:

```
d8 delivery-kit config [options]
```

Work with werf.yaml

d8 delivery-kit config graph

Usage:

```
d8 delivery-kit config graph [IMAGE_NAME...] [options]
```

Print dependency graph for images in werf.yaml.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go,

$WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project's werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or false by default)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit config list

Usage:

```
d8 delivery-kit config list [options]
```

List image and artifact names defined in werf.yaml.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

Custom path for storing rendered configuration file

- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Show only final images
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--images-only`

  Show only final images
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions

- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit config render

Usage:

```
d8 delivery-kit config render [IMAGE_NAME...] [options]
```

Render werf.yaml.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).

- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit converge

Usage:

```
d8 delivery-kit converge [options]
```

Build and push images, then deploy application into Kubernetes

Show more...

Build and push images, then deploy application into Kubernetes.

The result of converge command is an application deployed into Kubernetes for current git state.
Command will create release and wait until all resources of the release will become ready.

Environment is a required param for the deploy by default, because it is needed to construct Helm
Release name and Kubernetes Namespace. Either --env or $WERF_ENV should be specified for command.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g.
  $WERF_ADD_ANNOTATION_1=annoName1=annoValue1,
  $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-custom-tag`

  Set tag alias for the content-based tag.
  The alias may contain the following shortcuts:
  - %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
  - %image_content_based_tag% to use a content-based tag.
  For cleaning custom tags and associated content-based tag are treated as one.
  Also can be defined with $WERF_ADD_CUSTOM_TAG_* (e.g. $WERF_ADD_CUSTOM_TAG_1="%image%-tag1", $WERF_ADD_CUSTOM_TAG_2="%image%-tag2")
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)

- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--atomic`

  Enable auto rollback of the failed release to the previous deployed release version when current deploy process have failed ($WERF_ATOMIC by default)
- `--auto-rollback`, `-R`

  Enable auto rollback of the failed release to the previous deployed release version when current deploy process have failed ($WERF_AUTO_ROLLBACK by default)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=...,

$WERF_CACHE_REPO_2=...)

- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--delete-propagation`

  Set default delete propagation strategy (default $WERF_DELETE_PROPAGATION or Foreground).
- `--deno-binary-path`

  Path to the Deno binary to use instead of auto-downloading (default $WERF_DENO_BINARY_PATH)
- `--deploy-graph-path`

  Save deploy graph path to the specified file (by default $WERF_DEPLOY_GRAPH_PATH). Extension must be .dot or not specified. If extension not specified, then .dot is used
- `--deploy-report-path`

  Change deploy report path and format (by default $WERF_DEPLOY_REPORT_PATH or ".werf-deploy-report.json" if not set). Extension must be .json for JSON format. If extension not specified, then .json is used
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-default-values`

  Do not use values from the default .helm/values.yaml file (default $WERF_DISABLE_DEFAULT_VALUES or false)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo, to pull base images
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)

- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or true by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--force-adoption`

  Always adopt resources, even if they belong to a different Helm release (default $WERF_FORCE_ADOPTION or false)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--hooks-status-progress-period`

  No-op
- `--ignore-bundle-js`

  Do not use the existing bundle.js file. Requires TypeScript source files and Deno to rebuild (default $WERF_IGNORE_BUNDLE_JS)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--insecure-helm-dependencies`

  Allow insecure oci registries to be used in the Chart.yaml dependencies configuration (default $WERF_INSECURE_HELM_DEPENDENCIES)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

  Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

  Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)
- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

  Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)
- `--kube-key-data`

Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)

- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--network-parallelism`

  Parallelize some network operations (default $WERF_NETWORK_PARALLELISM or 30)
- `--no-create-namespace`

  Don't create the release namespace (default $WERF_NO_CREATE_NAMESPACE)
- `--no-final-tracking`

  By default disable tracking operations that have no create/update/delete resource operations after them, which are most tracking operations, to speed up the release (default $WERF_NO_FINAL_TRACKING)
- `--no-install-crds`

  Do not install CRDs from "crds/" directories of installed charts (default $WERF_NO_INSTALL_CRDS)
- `--no-notes`

  Don't show release notes at the end of the release (default $WERF_NO_NOTES)
- `--no-pod-logs`

  Disable Pod logs collection and printing (default $WERF_NO_POD_LOGS or false)
- `--no-remove-manual-changes`

  Don't remove fields added manually to the resource in the cluster if fields aren't present in the manifest (default $WERF_NO_REMOVE_MANUAL_CHANGES)

- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--plan-lifetime`

  How long plan artifact is valid
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--provenance-keyring`

  Path to keyring containing public keys to verify chart provenance (default $WERF_PROVENANCE_KEYRING)
- `--provenance-strategy`

  Strategy for provenance verifying (default $WERF_PROVENANCE_STRATEGY).
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--release`

  Use specified Helm release name (default [[project]]-[[env]] template or deploy.helmRelease custom template from werf.yaml or $WERF_RELEASE)
- `--release-info-annotations`

  Add annotations to release metadata (default $WERF_RELEASE_INFO_ANNOTATIONS)
- `--release-label`

  Add Helm release labels (can specify multiple). Kind of labels depends or release storage driver.
  Format: labelName=labelValue.
  Also, can be specified with $WERF_RELEASE_LABEL_* (e.g. $WERF_RELEASE_LABEL_1=labelName1=labelValue1, $WERF_RELEASE_LABEL_2=labelName2=labelValue2)
- `--release-storage`

  How releases should be stored (default $WERF_RELEASE_STORAGE)
- `--release-storage-sql-connection`

  SQL Connection String for Helm SQL Storage (default $WERF_RELEASE_STORAGE_SQL_CONNECTION)
- `--releases-history-max`

  Max releases to keep in release storage ($WERF_RELEASES_HISTORY_MAX or 5 by default)
- `--render-subchart-notes`

  If set, render subchart notes along with the parent (by default $WERF_RENDER_SUBCHART_NOTES or false)
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)

- `--rollback-graph-path`

  Save rollback graph path to the specified file (by default $WERF_ROLLBACK_GRAPH_PATH). Extension must be .dot or not specified. If extension not specified, then .dot is used
- `--runtime-annotations`

  Add annotations which will not trigger resource updates to all resources (default $WERF_RUNTIME_ANNOTATIONS)
- `--runtime-labels`

  Add labels which will not trigger resource updates to all resources (default $WERF_RUNTIME_LABELS)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--save-deploy-report`

  Save deploy report (by default $WERF_SAVE_DEPLOY_REPORT or false). Its path and format configured with --deploy-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

  Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)
- `--set`

  Set helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_* (e.g. $WERF_SET_1=key1=val1, $WERF_SET_2=key2=val2)
- `--set-docker-config-json-value`

  Shortcut to set current docker config into the .Values.global.werf.dockerconfigjson
- `--set-file`

  Set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2).
  Also, can be defined with $WERF_SET_FILE_* (e.g. $WERF_SET_FILE_1=key1=path1, $WERF_SET_FILE_2=key2=val2)
- `--set-json`

  Set new values, where the key is the value path and the value is JSON (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_JSON_* (e.g. $WERF_SET_JSON_1=key1=val1, $WERF_SET_JSON_2=key2=val2)
- `--set-literal`

  Set new values, where the key is the value path and the value is the value. The value will always become a literal string (can specify multiple or separate values with commas: key1=val1,key2=val2).)
  Also, can be defined with $WERF_SET_LITERAL_* (e.g. $WERF_SET_LITERAL_1=key1=val1, $WERF_SET_LITERAL_2=key2=val2)
- `--set-root-json`

  Set new keys in arbitrary things in the global root context ("$"), where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you REALLY know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_ROOT_JSON_* (e.g. $WERF_SET_ROOT_JSON_1=key1=val1, $WERF_SET_ROOT_JSON_2=key2=val2)
- `--set-runtime-json`

  Set new keys in $.Runtime, where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.

Also, can be defined with $WERF_SET_RUNTIME_JSON_* (e.g. $WERF_SET_RUNTIME_JSON_1=key1=val1, $WERF_SET_RUNTIME_JSON_2=key2=val2)

- `--set-string`

  Set STRING helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_STRING_* (e.g. $WERF_SET_STRING_1=key1=val1, $WERF_SET_STRING_2=key2=val2)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-dependencies-repo-refresh`, `-L`

  Do not refresh helm chart repositories locally cached index
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-helm-dependencies`

  Skip TLS certificate validation when accessing a Helm charts repository (default $WERF_SKIP_TLS_VERIFY_HELM_DEPENDENCIES)
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--templates-allow-dns`

  Allow performing DNS requests in templating (default $WERF_TEMPLATES_ALLOW_DNS)
- `--timeout`, `-t`

  Resources tracking timeout in seconds ($WERF_TIMEOUT by default)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)

- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--use-custom-tag`

  Use a tag alias in helm templates instead of an image content-based tag (NOT RECOMMENDED).
  The alias may contain the following shortcuts:
  - %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
  - %image_content_based_tag% to use a content-based tag.
  For cleaning custom tags and associated content-based tag are treated as one.
  Also, can be defined with $WERF_USE_CUSTOM_TAG (e.g. $WERF_USE_CUSTOM_TAG="%image%-tag")
- `--use-plan`

  Use the gzip-compressed JSON plan file from the specified path during release install
- `--values`

  Specify helm values in a YAML file or a URL (can specify multiple). Also, can be defined with $WERF_VALUES_* (e.g. $WERF_VALUES_1=.helm/values_1.yaml, $WERF_VALUES_2=.helm/values_2.yaml)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit cr

Usage:

```
d8 delivery-kit cr [options]
```

Authenticate with container registry.

d8 delivery-kit cr login

Usage:

```
d8 delivery-kit cr login registry [options]
```

Login into remote registry.

Show more...

Login into remote registry.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

Disable explanatory output (default $WERF_LOG_QUIET).

- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--password`, `-p`

  Use specified password for login (default $WERF_PASSWORD)
- `--password-stdin`

  Read password from stdin for login (default $WERF_PASSWORD_STDIN)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--username`, `-u`

  Use specified username for login (default $WERF_USERNAME)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit cr logout

Usage:

```
d8 delivery-kit cr logout registry [options]
```

Logout from a remote registry.

Show more...

Logout from a remote registry.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

Enable verbose output (default $WERF_LOG_VERBOSE).

- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit dismiss

Usage:

```
d8 delivery-kit dismiss [options]
```

Delete werf release from Kubernetes

Show more...

Delete application from Kubernetes.

Helm Release will be purged and optionally Kubernetes Namespace.

Environment is a required param for the dismiss by default, because it is needed to construct Helm Release name and Kubernetes Namespace. Either --env or $WERF_ENV should be specified for command.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)

- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--deploy-report-path`

  Change deploy report path and format (by default $WERF_DEPLOY_REPORT_PATH or ".werf-deploy-report.json" if not set). Extension must be .json for JSON format. If extension not specified, then .json is used
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)

- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--hooks-status-progress-period`

  No-op
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

  Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

  Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)
- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)

- `--kube-key-data`

  Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)
- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--network-parallelism`

  Parallelize some network operations (default $WERF_NETWORK_PARALLELISM or 30)
- `--no-final-tracking`

  By default disable tracking operations that have no create/update/delete resource operations after them, which are most tracking operations, to speed up the release (default $WERF_NO_FINAL_TRACKING)
- `--no-pod-logs`

  Disable Pod logs collection and printing (default $WERF_NO_POD_LOGS or false)
- `--no-remove-manual-changes`

  Don't remove fields added manually to the resource in the cluster if fields aren't present in the manifest (default $WERF_NO_REMOVE_MANUAL_CHANGES)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

Disable explanatory output (default $WERF_QUIET).

- `--release`

  Use specified Helm release name (default [[project]]-[[env]] template or deploy.helmRelease custom template from werf.yaml or $WERF_RELEASE)
- `--release-storage`

  How releases should be stored (default $WERF_RELEASE_STORAGE)
- `--release-storage-sql-connection`

  SQL Connection String for Helm SQL Storage (default $WERF_RELEASE_STORAGE_SQL_CONNECTION)
- `--releases-history-max`

  Max releases to keep in release storage ($WERF_RELEASES_HISTORY_MAX or 5 by default)
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--timeout`, `-t`

  Resources tracking timeout in seconds ($WERF_TIMEOUT by default)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-deploy-report`

  Use deploy report, previously saved with --save-deploy-report (by default $WERF_USE_DEPLOY_REPORT or

false). Its path and format configured with --deploy-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--with-hooks`

  Delete Helm Release hooks getting from existing revisions (default $WERF_WITH_HOOKS or true)
- `--with-namespace`

  Delete Kubernetes Namespace after purging Helm Release (default $WERF_WITH_NAMESPACE)

d8 delivery-kit export

Usage:

```
d8 delivery-kit export [IMAGE_NAME...] [options]
```

Export images

Show more...

Export images to an arbitrary repository according to a template specified by the --tag option
(build if needed).
The tag may contain the following shortcuts:
- %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
- %image_content_based_tag% to use a content-based tag.
All meta-information related to werf is removed from the exported images, and then images are completely under the user's responsibility.

Options

- `--add-label`

  Add label to exported images (can specify multiple).
  Format: labelName=labelValue[labelName=labelValue ...]. The default separator is a newline ("\n"), but it can be customized using the --add-label-separator flag.
  Also, can be specified with $WERF_EXPORT_ADD_LABEL_* (e.g. $WERF_EXPORT_ADD_LABEL_1=labelName1=labelValue1, $WERF_EXPORT_ADD_LABEL_2=labelName2=labelValue2)
- `--add-label-separator`

  Separator for --add-label values (default $WERF_EXPORT_ADD_LABEL_SEPARATOR or "\n")
- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo.
  Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)

- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read and pull images from the specified repo
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or true by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)

- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

  Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).

- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)

- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tag`

  Set a tag template (can specify multiple).
  It is necessary to use image name shortcut %image% or %image_slug% if multiple images are exported (e.g. REPO:TAG-%image% or REPO-%image%:TAG)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)

d8 delivery-kit helm

Usage:

```
d8 delivery-kit helm [options]
```

Manage application deployment with helm

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--hooks-status-progress-period`

  No-op
- `--insecure-helm-dependencies`

  Allow insecure oci registries to be used in the Chart.yaml dependencies configuration (default $WERF_INSECURE_HELM_DEPENDENCIES)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)

- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--releases-history-max`

  Max releases to keep in release storage ($WERF_RELEASES_HISTORY_MAX or 5 by default)
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm create

Usage:

```
d8 delivery-kit helm create NAME [options]
```

create a new chart with the given name

Show more...

This command creates a chart directory along with the common files and
directories used in a chart.

For example, 'helm create foo' will create a directory structure that looks
something like this:

```
foo/
├── .helmignore   # Contains patterns to ignore when packaging Helm charts.
├── Chart.yaml    # Information about your chart
├── values.yaml   # The default values for your templates
├── charts/       # Charts that this chart depends on
└── templates/    # The template files
    └── tests/    # The test files
```

'helm create' takes a path for an argument. If directories in the given path
do not exist, Helm will attempt to create them as it goes. If the given
destination exists and there are files in that directory, conflicting files
will be overwritten, but other files will be left alone.

Options

- `--starter`, `-p`

  the name or absolute path to Helm starter scaffold

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm dependency

Aliases: `dep`, `dependencies`

Usage:

```
d8 delivery-kit helm dependency update|build|list [options]
```

manage a chart's dependencies

Show more...

Manage the dependencies of a chart.

Helm charts store their dependencies in 'charts/'. For chart developers, it is
often easier to manage dependencies in 'Chart.yaml' which declares all

dependencies.

The dependency commands operate on that file, making it easy to synchronize
between the desired dependencies and the actual dependencies stored in the
'charts/' directory.

For example, this Chart.yaml declares two dependencies:

```
# Chart.yaml
dependencies:
- name: nginx
  version: "1.2.3"
  repository: "https://example.com/charts"
- name: memcached
  version: "3.2.1"
  repository: "https://another.example.com/charts"
```

The 'name' should be the name of a chart, where that name must match the name
in that chart's 'Chart.yaml' file.

The 'version' field should contain a semantic version or version range.

The 'repository' URL should point to a Chart Repository. Helm expects that by
appending '/index.yaml' to the URL, it should be able to retrieve the chart
repository's index. Note: 'repository' can be an alias. The alias must start
with 'alias:' or '@'.

Starting from 2.2.0, repository can be defined as the path to the directory of
the dependency charts stored locally. The path should start with a prefix of
"file://". For example,

```
# Chart.yaml
dependencies:
- name: nginx
  version: "1.2.3"
  repository: "file://../dependency_chart/nginx"
```

If the dependency chart is retrieved locally, it is not required to have the
repository added to helm by "helm add repo". Version matching is also supported
for this case.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or
  $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140

- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm dependency build

Usage:

```
d8 delivery-kit helm dependency update|build|list build CHART [options]
```

rebuild the charts/ directory based on the Chart.lock file

Show more...

Build out the charts/ directory from the Chart.lock file.

Build is used to reconstruct a chart's dependencies to the state specified in
the lock file. This will not re-negotiate dependencies, as 'helm dependency update'
does.

If no lock file is found, 'helm dependency build' will mirror the behavior
of 'helm dependency update'.

Options

- `--keyring`

  keyring containing public keys
- `--skip-refresh`

  do not refresh the local repository cache
- `--verify`

  verify the packages against signatures

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).

- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm dependency list

Alias: `ls`

Usage:

```
d8 delivery-kit helm dependency update|build|list list CHART [options]
```

list the dependencies for the given chart

Show more...

List all of the dependencies declared in a chart.

This can take chart archives and chart directories as input. It will not alter
the contents of a chart.

This will produce an error if the chart cannot be loaded.

Options

- `--max-col-width`

  maximum column width for output table

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.

- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm dependency update

Alias: `up`

Usage:

```
d8 delivery-kit helm dependency update|build|list update CHART [options]
```

update charts/ based on the contents of Chart.yaml

Show more...

Update the on-disk dependencies to mirror Chart.yaml.

This command verifies that the required charts, as expressed in 'Chart.yaml',
are present in 'charts/' and are at an acceptable version. It will pull down
the latest charts that satisfy the dependencies, and clean up old dependencies.

On successful update, this will generate a lock file that can be used to
rebuild the dependencies to an exact version.

Dependencies are not required to be represented in 'Chart.yaml'. For that
reason, an update command will not remove charts unless they are (a) present
in the Chart.yaml file, but (b) at the wrong version.

Options

- `--keyring`

  keyring containing public keys
- `--skip-refresh`

  do not refresh the local repository cache
- `--verify`

  verify the packages against signatures

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm env

Usage:

```
d8 delivery-kit helm env [options]
```

helm client environment information

Show more...

Env prints out all the environment information in use by Helm.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get

Usage:

```
d8 delivery-kit helm get [options]
```

download extended information of a named release

Show more...

This command consists of multiple subcommands which can be used to
get extended information about the release, including:

- The values used to generate the release
- The generated manifest file
- The notes provided by the chart of the release
- The hooks associated with the release
- The metadata of the release

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get all

Usage:

```
d8 delivery-kit helm get all RELEASE_NAME [options]
```

download all information for a named release

Show more...

This command prints a human readable collection of information about the
notes, hooks, supplied values, and generated manifest file of the given release.

Options

- `--revision`

  get the named release with revision
- `--template`

  go template for formatting the output, eg: {{.Release.Name}}

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or

$WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get hooks

Usage:

```
d8 delivery-kit helm get hooks RELEASE_NAME [options]
```

download all hooks for a named release

Show more...

This command downloads hooks for a given release.

Hooks are formatted in YAML and separated by the YAML '---\n' separator.

Options

- `--revision`

  get the named release with revision

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or

$WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get manifest

Usage:

```
d8 delivery-kit helm get manifest RELEASE_NAME [options]
```

download the manifest for a named release

Show more...

This command fetches the generated manifest for a given release.

A manifest is a YAML-encoded representation of the Kubernetes resources that were generated from this release's chart(s). If a chart is dependent on other charts, those resources will also be included in the manifest.

Options

- `--revision`

  get the named release with revision

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get metadata

Usage:

```
d8 delivery-kit helm get metadata RELEASE_NAME [options]
```

This command fetches metadata for a given release

Options

- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--revision`

  specify release revision

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get notes

Usage:

```
d8 delivery-kit helm get notes RELEASE_NAME [options]
```

download the notes for a named release

Show more...

This command shows notes provided by the chart of a named release.

Options

- `--revision`

  get the named release with revision

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

Set log color mode.
Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
Default $WERF_LOG_COLOR_MODE or auto mode.

- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get values

Usage:

```
d8 delivery-kit helm get values RELEASE_NAME [options]
```

download the values file for a named release

Show more...

This command downloads a values file for a given release.

Options

- `--all`, `-a`

  dump all (computed) values
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--revision`

  get the named release with revision

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

Kubernetes config context (default $WERF_KUBE_CONTEXT)

- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm get-autogenerated-values

Usage:

```
d8 delivery-kit helm get-autogenerated-values [IMAGE_NAME...] [options]
```

Get service values yaml generated by werf for helm chart during deploy

Show more...

Get service values generated by werf for Helm chart during deploy.

These values includes project name, Docker images IDs and other.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo.

Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)

- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo and to pull base images
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or true by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)

- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

  Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--parallel, -p`

Run in parallel (default $WERF_PARALLEL or true)

- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--set-docker-config-json-value`

  Shortcut to set current docker config into the .Values.global.werf.dockerconfigjson
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--stub-tags`

  Use stubs instead of real tags (default $WERF_STUB_TAGS)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or

- https://delivery-sync.deckhouse.ru if --repo has been specified.

The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only

- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--use-custom-tag`

  Use a tag alias in helm templates instead of an image content-based tag (NOT RECOMMENDED).
  The alias may contain the following shortcuts:
  - %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
  - %image_content_based_tag% to use a content-based tag.
  For cleaning custom tags and associated content-based tag are treated as one.
  Also, can be defined with $WERF_USE_CUSTOM_TAG (e.g. $WERF_USE_CUSTOM_TAG="%image%-tag")
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm get-namespace

Usage:

```
d8 delivery-kit helm get-namespace [options]
```

Print Kubernetes Namespace that will be used in current configuration with specified params.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

Enable debug (default $WERF_DEBUG).

- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm get-release

Usage:

```
d8 delivery-kit helm get-release [options]
```

Print Helm Release name that will be used in current configuration with specified params.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)

- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm history

Alias: `hist`

Usage:

```
d8 delivery-kit helm history RELEASE_NAME [options]
```

fetch release history

Show more...

History prints historical revisions for a given release.

A default maximum of 256 revisions will be returned. Setting '--max'
configures the maximum length of the revision list returned.

The historical release set is printed as a formatted table, e.g:

```
$ helm history angry-bird
REVISION    UPDATED                     STATUS          CHART           APP VERSION     DESCRIPTION
1           Mon Oct 3 10:15:13 2016     superseded      alpine-0.1.0    1.0             Initial install
2           Mon Oct 3 10:15:13 2016     superseded      alpine-0.1.0    1.0             Upgraded successfully
3           Mon Oct 3 10:15:13 2016     superseded      alpine-0.1.0    1.0             Rolled back to 2
4           Mon Oct 3 10:15:13 2016     deployed        alpine-0.1.0    1.0             Upgraded successfully
```

Options

- `--max`

  maximum number of revision to include in history
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm install

Usage:

```
d8 delivery-kit helm install [NAME] [CHART] [options]
```

install a chart

Show more...

This command installs a chart archive.

The install argument must be a chart reference, a path to a packaged chart,
a path to an unpacked chart directory or a URL.

To override values in a chart, use either the '--values' flag and pass in a file
or use the '--set' flag and pass configuration from the command line, to force
a string value use '--set-string'. You can use '--set-file' to set individual
values from a file when the value itself is too long for the command line
or is dynamically generated. You can also use '--set-json' to set json values
(scalars/objects/arrays) from the command line.

    $ helm install -f myvalues.yaml myredis ./redis

or

    $ helm install --set name=prod myredis ./redis

or

    $ helm install --set-string long_int=1234567890 myredis ./redis

or

    $ helm install --set-file my_script=dothings.sh myredis ./redis

or

    $ helm install --set-json 'master.sidecars=
[{"name":"sidecar","image":"myImage","imagePullPolicy":"Always","ports":
[{"name":"portname","containerPort":1234}]}]' myredis ./redis

You can specify the '--values'/'-f' flag multiple times. The priority will be given to the
last (right-most) file specified. For example, if both myvalues.yaml and override.yaml
contained a key called 'Test', the value set in override.yaml would take precedence:

    $ helm install -f myvalues.yaml -f override.yaml myredis ./redis

You can specify the '--set' flag multiple times. The priority will be given to the
last (right-most) set specified. For example, if both 'bar' and 'newbar' values are
set for a key called 'foo', the 'newbar' value would take precedence:

    $ helm install --set foo=bar --set foo=newbar myredis ./redis

Similarly, in the following example 'foo' is set to '["four"]':

    $ helm install --set-json='foo=["one", "two", "three"]' --set-json='foo=["four"]' myredis ./redis

And in the following example, 'foo' is set to '{"key1":"value1","key2":"bar"}':

    $ helm install --set-json='foo={"key1":"value1","key2":"value2"}' --set-json='foo.key2="bar"' myredis ./redis

To check the generated manifests of a release without installing the chart,
the --debug and --dry-run flags can be combined.

The --dry-run flag will output all generated chart manifests, including Secrets
which can contain sensitive values. Please carefully consider how and when this
flag is used.

If --verify is set, the chart MUST have a provenance file, and the provenance
file MUST pass all verification steps.

There are six different ways you can express the chart you want to install:

1. By chart reference: helm install mymaria example/mariadb
2. By path to a packaged chart: helm install mynginx ./nginx-1.2.3.tgz
3. By path to an unpacked chart directory: helm install mynginx ./nginx
4. By absolute URL: helm install mynginx https://example.com/charts/nginx-1.2.3.tgz
5. By chart reference and repo url: helm install --repo https://example.com/charts/ mynginx nginx
6. By OCI registries: helm install mynginx --version 1.2.3 oci://example.com/charts/nginx

CHART REFERENCES

A chart reference is a convenient way of referencing a chart in a chart repository.

When you use a chart reference with a repo prefix ('example/mariadb'), Helm will look in the local
configuration for a chart repository named 'example', and will then look for a
chart in that repository whose name is 'mariadb'. It will install the latest stable version of that chart
until you specify '--devel' flag to also include development version (alpha, beta, and release candidate releases),
or
supply a version number with the '--version' flag.

To see the list of chart repositories, use 'helm repo list'. To search for
charts in a repository, use 'helm search'.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g.
  $WERF_ADD_ANNOTATION_1=annoName1=annoValue1,
  $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1,
  $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--atomic`

  if set, the installation process deletes the installation on failure. The --wait flag will be set automatically if --atomic is used
- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--cleanup-on-fail`

  allow deletion of new resources created in this installation when install fails
- `--create-namespace`

  create the release namespace if not present
- `--dependency-update`

  update dependencies if they are missing before installing the chart
- `--deploy-report-path`

  save deploy report in JSON to the specified path
- `--description`

  add a custom description
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default
  $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-openapi-validation`

  if set, the installation process will not validate rendered templates against the Kubernetes OpenAPI Schema
- `--dry-run`

  simulate an install. If --dry-run is set with no option being specified or as '--dry-run=client', it will not attempt cluster connections. Setting '--dry-run=server' allows attempting cluster connections.
- `--enable-dns`

  enable DNS lookups when rendering templates
- `--force`

force resource updates through a replacement strategy
- `--generate-name`, `-g`

  generate the name (and omit the NAME parameter)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--labels`, `-l`

  Labels that would be added to release metadata. Should be divided by comma.
- `--name-template`

  specify template used to name the release
- `--no-hooks`

  prevent hooks from running during install
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--post-renderer`

  the path to an executable to be used for post rendering. If it exists in $PATH, the binary will be used, otherwise it will try to look for the executable at the given path
- `--post-renderer-args`

  an argument to the post-renderer (can specify multiple)
- `--render-subchart-notes`

  if set, render subchart notes along with the parent
- `--replace`

  re-use the given name, only if that name is a deleted release which remains in the history. This is unsafe in production
- `--repo`

  chart repository url where to locate the requested chart
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

  Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)
- `--set`

  set values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--set-file`

  set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2)
- `--set-json`

  set JSON values on the command line (can specify multiple or separate values with commas: key1=jsonval1,key2=jsonval2)
- `--set-literal`

  set a literal STRING value on the command line
- `--set-string`

  set STRING values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--skip-crds`

if set, no CRDs will be installed. By default, CRDs are installed if not already present
- `--timeout`

  time to wait for any individual Kubernetes operation (like Jobs for hooks)
- `--username`

  chart repository username where to locate the requested chart
- `--values`, `-f`

  specify values in a YAML file or a URL (can specify multiple)
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used
- `--wait`

  if set, will wait until all Pods, PVCs, Services, and minimum number of Pods of a Deployment, StatefulSet, or ReplicaSet are in a ready state before marking the release as successful. It will wait for as long as --timeout
- `--wait-for-jobs`

  if set and --wait enabled, will wait until all Jobs have been completed before marking the release as successful. It will wait for as long as --timeout

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to

$WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm lint

Usage:

```
d8 delivery-kit helm lint PATH [options]
```

examine a chart for possible issues

Show more...

This command takes a path to a chart and runs a series of tests to verify that
the chart is well-formed.

If the linter encounters things that will cause the chart to fail installation,
it will emit [ERROR] messages. If it encounters issues that break with convention
or recommendation, it will emit [WARNING] messages.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g.
  $WERF_ADD_ANNOTATION_1=annoName1=annoValue1,
  $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1,
  $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default
  $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--kube-version`

  Kubernetes version used for capabilities and deprecation checks
- `--quiet`

  print only warnings and errors
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

  Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with
  $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml,
  $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)
- `--set`

  set values on the command line (can specify multiple or separate values with commas:
  key1=val1,key2=val2)
- `--set-file`

  set values from respective files specified via the command line (can specify multiple or separate values
  with commas: key1=path1,key2=path2)
- `--set-json`

  set JSON values on the command line (can specify multiple or separate values with commas:
  key1=jsonval1,key2=jsonval2)
- `--set-literal`

  set a literal STRING value on the command line
- `--set-string`

set STRING values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--strict`

  fail on lint warnings
- `--values`, `-f`

  specify values in a YAML file or a URL (can specify multiple)
- `--with-subcharts`

  lint dependent charts

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm list

Alias: `ls`

Usage:

```
d8 delivery-kit helm list [options]
```

list releases

Show more...

This command lists all of the releases for a specified namespace (uses current namespace context if namespace not specified).

By default, it lists only releases that are deployed or failed. Flags like '--uninstalled' and '--all' will alter this behavior. Such flags can be combined: '--uninstalled --failed'.

By default, items are sorted alphabetically. Use the '-d' flag to sort by release date.

If the --filter flag is provided, it will be treated as a filter. Filters are regular expressions (Perl compatible) that are applied to the list of releases. Only items that match the filter will be returned.

```
$ helm list --filter 'ara[a-z]+'
NAME                UPDATED                                 CHART
maudlin-arachnid    2020-06-18 14:17:46.125134977 +0000 UTC  alpine-0.1.0
```

If no results are found, 'helm list' will exit 0, but with no output (or in the case of no '-q' flag, only headers).

By default, up to 256 items may be returned. To limit this, use the '--max' flag. Setting '--max' to 0 will not return all results. Rather, it will return the server's default, which may be much higher than 256. Pairing the '--max' flag with the '--offset' flag allows you to page through results.

Options

- `--all`, `-a`

  show all releases without any filter applied
- `--all-namespaces`, `-A`

  list releases across all namespaces
- `--date`, `-d`

  sort by release date
- `--deployed`

  show deployed releases. If no other is specified, this will be automatically enabled
- `--failed`

  show failed releases
- `--filter`, `-f`

  a regular expression (Perl compatible). Any releases that match the expression will be included in the results
- `--max`, `-m`

  maximum number of releases to fetch
- `--no-headers`

  don't print headers when using the default output format
- `--offset`

  next release index in the list, used to offset from start value
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--pending`

  show pending releases
- `--reverse`, `-r`

  reverse the sort order
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Works only for secret(default) and configmap storage backends.
- `--short`, `-q`

  output short (quiet) listing format
- `--superseded`

  show superseded releases
- `--time-format`

  format time using golang time formatter. Example: --time-format "2006-01-02 15:04:05Z0700"
- `--uninstalled`

  show uninstalled releases (if 'helm uninstall --keep-history' was used)
- `--uninstalling`

show releases that are currently being uninstalled

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm package

Usage:

```
d8 delivery-kit helm package [CHART_PATH] [...] [options]
```

package a chart directory into a chart archive

Show more...

This command packages a chart into a versioned chart archive file. If a path
is given, this will look at that path for a chart (which must contain a
Chart.yaml file) and then package that directory.

Versioned chart archives are used by Helm package repositories.

To sign a chart, use the '--sign' flag. In most cases, you should also

provide '--keyring path/to/secret/keys' and '--key keyname'.

```
$ helm package --sign ./mychart --key mykey --keyring ~/.gnupg/secring.gpg
```

If '--keyring' is not specified, Helm usually defaults to the public keyring
unless your environment is otherwise configured.

Options

- `--app-version`

  set the appVersion on the chart to this version
- `--dependency-update`, `-u`

  update dependencies from "Chart.yaml" to dir "charts/" before packaging
- `--destination`, `-d`

  location to write the chart.
- `--key`

  name of the key to use when signing. Used if --sign is true
- `--keyring`

  location of a public keyring
- `--passphrase-file`

  location of a file which contains the passphrase for the signing key. Use "-" in order to read from stdin.
- `--sign`

  use a PGP private key to sign this package
- `--version`

  set the version on the chart to this semver version

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request

- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm plugin

Usage:

```
d8 delivery-kit helm plugin [options]
```

install, list, or uninstall Helm plugins

Show more...

Manage client-side Helm plugins.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm plugin install

Alias: `add`

Usage:

```
d8 delivery-kit helm plugin install [options] <path|url>...
```

install one or more Helm plugins

Show more...

This command allows you to install a plugin from a url to a VCS repo or a local path.

Options

- `--version`
  specify a version constraint. If this is not specified, the latest version is installed

Global options

- `--debug`
  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`
  No-op
- `--kube-config`
  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`
  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`
  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`
  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`
  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`
  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`
  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`
  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`
  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`
  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`
  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`
  namespace scope for this request
- `--quiet`
  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`
  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm plugin list

Alias: `ls`

Usage:

```
d8 delivery-kit helm plugin list [options]
```

list installed Helm plugins

Global options

- `--debug`
  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`
  No-op
- `--kube-config`
  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`
  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`
  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`
  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`
  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`
  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`
  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`
  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`
  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`
  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`
  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`
  namespace scope for this request
- `--quiet`
  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`
  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`
  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm plugin uninstall

Aliases: `rm`, `remove`

Usage:

```
d8 delivery-kit helm plugin uninstall <plugin>... [options]
```

uninstall one or more Helm plugins

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm plugin update

Alias: `up`

Usage:

```
d8 delivery-kit helm plugin update <plugin>... [options]
```

update one or more Helm plugins

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)

- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm pull

Alias: `fetch`

Usage:

```
d8 delivery-kit helm pull [chart URL | repo/chartname] [...] [options]
```

download a chart from a repository and (optionally) unpack it in local directory

Show more...

Retrieve a package from a package repository, and download it locally.

This is useful for fetching packages to inspect, modify, or repackage. It can
also be used to perform cryptographic verification of a chart without installing
the chart.

There are options for unpacking the chart after download. This will create a
directory for the chart and uncompress into that directory.

If the --verify flag is specified, the requested chart MUST have a provenance
file, and MUST pass the verification process. Failure in any part of this will
result in an error, and the chart will not be saved locally.

Options

- `--ca-file`

verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--destination`, `-d`

  location to write the chart. If this and untardir are specified, untardir is appended to this
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored.
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--prov`

  fetch the provenance file, but don't perform verification
- `--repo`

  chart repository url where to locate the requested chart
- `--untar`

  if set to true, will untar the chart after downloading it
- `--untardir`

  if untar is specified, this flag specifies the name of the directory into which the chart is expanded
- `--username`

  chart repository username where to locate the requested chart
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

Set log terminal width.
Defaults to:
* $WERF_LOG_TERMINAL_WIDTH
* interactive terminal width or 140

- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm registry

Usage:

```
d8 delivery-kit helm registry [options]
```

login to or logout from a registry

Show more...

This command consists of multiple subcommands to interact with registries.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).

- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm registry login

Usage:

```
d8 delivery-kit helm registry login [host] [options]
```

login to a registry

Show more...

Authenticate to a remote registry.

Options

- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify registry client using this SSL certificate file
- `--insecure`

  allow connections to TLS registry without certs
- `--key-file`

  identify registry client using this SSL key file
- `--password`, `-p`

  registry password or identity token
- `--password-stdin`

  read password or identity token from stdin
- `--username`, `-u`

  registry username

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm registry logout

Usage:

```
d8 delivery-kit helm registry logout [host] [options]
```

logout from a registry

Show more...

Remove credentials stored for a remote registry.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm repo

Usage:

```
d8 delivery-kit helm repo add|remove|list|index|update [ARGS] [options]
```

add, list, remove, update, and index chart repositories

Show more...

This command consists of multiple subcommands to interact with chart repositories.

It can be used to add, remove, list, and index chart repositories.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).

- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm repo add

Usage:

```
d8 delivery-kit helm repo add|remove|list|index|update [ARGS] add [NAME] [URL] [options]
```

add a chart repository

Options

- `--allow-deprecated-repos`

  by default, this command will not allow adding official repos that have been permanently deleted. This disables that behavior
- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--force-update`

  replace (overwrite) the repo if it already exists
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the repository
- `--key-file`

  identify HTTPS client using this SSL key file
- `--no-update`

  Ignored. Formerly, it would disabled forced updates. It is deprecated by force-update.
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password
- `--password-stdin`

  read chart repository password from stdin
- `--username`

  chart repository username

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

Set log color mode.

Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

Default $WERF_LOG_COLOR_MODE or auto mode.

- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm repo index

Usage:

```
d8 delivery-kit helm repo add|remove|list|index|update [ARGS] index [DIR] [options]
```

generate an index file given a directory containing packaged charts

Show more...

Read the current directory and generate an index file based on the charts found.

This tool is used for creating an 'index.yaml' file for a chart repository. To
set an absolute URL to the charts, use '--url' flag.

To merge the generated index with an existing index file, use the '--merge'
flag. In this case, the charts found in the current directory will be merged
into the existing index, with local charts taking priority over existing charts.

Options

- `--json`

  output in JSON format
- `--merge`

  merge the generated index into the given index
- `--url`

  url of chart repository

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm repo list

Alias: `ls`

Usage:

```
d8 delivery-kit helm repo add|remove|list|index|update [ARGS] list [options]
```

list chart repositories

Options

- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm repo remove

Alias: `rm`

Usage:

```
d8 delivery-kit helm repo add|remove|list|index|update [ARGS] remove [REPO1 [REPO2 ...]] [options]
```

remove one or more chart repositories

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).

- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm repo update

Alias: `up`

Usage:

```
d8 delivery-kit helm repo add|remove|list|index|update [ARGS] update [REPO1 [REPO2 ...]] [options]
```

update information of available charts locally from chart repositories

Show more...

Update gets the latest information about charts from the respective chart repositories.
Information is cached locally, where it is used by commands like 'helm search'.

You can optionally specify a list of repositories you want to update.
 $ helm repo update <repo_name> ...
To update all the repositories, use 'helm repo update'.

Options

- `--fail-on-repo-update-fail`

  update fails if any of the repository updates fail

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.

Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
Default $WERF_LOG_COLOR_MODE or auto mode.

- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm rollback

Usage:

```
d8 delivery-kit helm rollback <RELEASE> [REVISION] [options]
```

roll back a release to a previous revision

Show more...

This command rolls back a release to a previous revision.

The first argument of the rollback command is the name of a release, and the
second is a revision (version) number. If this argument is omitted or set to
0, it will roll back to the previous release.

To see revision numbers, run 'helm history RELEASE'.

Options

- `--cleanup-on-fail`

  allow deletion of new resources created in this rollback when rollback fails
- `--deploy-report-path`

  save deploy report in JSON to the specified path
- `--dry-run`

  simulate a rollback
- `--force`

  force resource update through delete/recreate if needed
- `--history-max`

  limit the maximum number of revisions saved per release. Use 0 for no limit
- `--no-hooks`

  prevent hooks from running during rollback
- `--recreate-pods`

  performs pods restart for the resource if applicable

- `--timeout`

  time to wait for any individual Kubernetes operation (like Jobs for hooks)
- `--wait`

  if set, will wait until all Pods, PVCs, Services, and minimum number of Pods of a Deployment, StatefulSet, or ReplicaSet are in a ready state before marking the release as successful. It will wait for as long as --timeout
- `--wait-for-jobs`

  if set and --wait enabled, will wait until all Jobs have been completed before marking the release as successful. It will wait for as long as --timeout

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm search

Usage:

```
d8 delivery-kit helm search [keyword] [options]
```

search for a keyword in charts

Show more...

Search provides the ability to search for Helm charts in the various places
they can be stored including the Artifact Hub and repositories you have added.
Use search subcommands to search different locations for charts.

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or
  $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to
  $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm search hub

Usage:

```
d8 delivery-kit helm search [keyword] hub [KEYWORD] [options]
```

search for charts in the Artifact Hub or your own hub instance

Show more...

Search for Helm charts in the Artifact Hub or your own hub instance.

Artifact Hub is a web-based application that enables finding, installing, and

publishing packages and configurations for CNCF projects, including publicly available distributed charts Helm charts. It is a Cloud Native Computing Foundation sandbox project. You can browse the hub at https://artifacthub.io/

The [KEYWORD] argument accepts either a keyword string, or quoted string of rich query options. For rich query options documentation, see https://artifacthub.github.io/hub/api/?urls.primaryName=Monocular%20compatible%20search%20API#/Monocular/get_api_chartsvc_v1_charts_search

Previous versions of Helm used an instance of Monocular as the default 'endpoint', so for backwards compatibility Artifact Hub is compatible with the Monocular search API. Similarly, when setting the 'endpoint' flag, the specified endpoint must also be implement a Monocular compatible search API endpoint. Note that when specifying a Monocular instance as the 'endpoint', rich queries are not supported. For API details, see https://github.com/helm/monocular

Options

- `--endpoint`

  Hub instance to query for charts
- `--fail-on-no-result`

  search fails if no results are found
- `--list-repo-url`

  print charts repository URL
- `--max-col-width`

  maximum column width for output table
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm search repo

Usage:

```
d8 delivery-kit helm search [keyword] repo [keyword] [options]
```

search repositories for a keyword in charts

Show more...

Search reads through all of the repositories configured on the system, and
looks for matches. Search of these repositories uses the metadata stored on
the system.

It will display the latest stable versions of the charts found. If you
specify the --devel flag, the output will include pre-release versions.
If you want to search using a version constraint, use --version.

Examples:

```
# Search for stable release versions matching the keyword "nginx"
$ helm search repo nginx

# Search for release versions matching the keyword "nginx", including pre-release versions
$ helm search repo nginx --devel

# Search for the latest stable release for nginx-ingress with a major version of 1
$ helm search repo nginx-ingress --version ^1.0.0
```

Repositories are managed with 'helm repo' commands.

Options

- `--devel`

  use development versions (alpha, beta, and release candidate releases), too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--fail-on-no-result`

  search fails if no results are found
- `--max-col-width`

  maximum column width for output table
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--regexp`, `-r`

  use regular expressions for searching repositories you have added
- `--version`

  search using semantic versioning constraints on repositories you have added
- `--versions`, `-l`

  show the long listing, with each version of each chart on its own line, for repositories you have added

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or

$WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm secret

Usage:

```
d8 delivery-kit helm secret [options]
```

Work with secrets

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).

- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm secret decrypt

Usage:

```
d8 delivery-kit helm secret decrypt [options]
```

Decrypt data

Show more...

Decrypt data from standard input.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).

- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--output-file-path`, `-o`

  Write to file instead of stdout
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret encrypt

Usage:

```
d8 delivery-kit helm secret encrypt [options]
```

Encrypt data

Show more...

Encrypt data from standard input.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and

development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project's werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--output-file-path`, `-o`

  Write to file instead of stdout
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to

$WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret file

Usage:

```
d8 delivery-kit helm secret file [options]
```

Work with secret files

Global options

- `--debug`
  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`
  No-op
- `--kube-config`
  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`
  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`
  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`
  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`
  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`
  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`
  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`
  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`
  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`
  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`
  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`
  namespace scope for this request
- `--quiet`
  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`
  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`
  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm secret file decrypt

Usage:

```
d8 delivery-kit helm secret file decrypt [FILE_PATH] [options]
```

Decrypt secret file data

Show more...

Decrypt data from FILE_PATH or pipe.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--output-file-path`, `-o`

  Write to file instead of stdout
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret file edit

Usage:

```
d8 delivery-kit helm secret file edit FILE_PATH [options]
```

Edit or create new secret file

Show more...

Edit or create new secret file.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).

- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret file encrypt

Usage:

```
d8 delivery-kit helm secret file encrypt [FILE_PATH] [options]
```

Encrypt file data

Show more...

Encrypt data from FILE_PATH or pipe.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).

- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--output-file-path`, `-o`

  Write to file instead of stdout
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret generate-secret-key

Usage:

```
d8 delivery-kit helm secret generate-secret-key [options]
```

Generate hex encryption key

Show more...

Generate hex encryption key.
For further usage, the encryption key should be saved in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.

- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret rotate-secret-key

Usage:

```
d8 delivery-kit helm secret rotate-secret-key [EXTRA_SECRET_VALUES_FILE_PATH...] [options]
```

Regenerate secret files with new secret key

Show more...

Regenerate Secret files with new Secret key.

Old key should be specified in the $WERF_OLD_SECRET_KEY.
New key should reside either in the $WERF_SECRET_KEY or .werf_secret_key file.

Command will extract data with the old key, generate new secret data and rewrite files:
* standard raw Secret files in the .helm/secret folder;
* standard secret Values YAML file .helm/secret-values.yaml;
* additional secret Values YAML files specified with EXTRA_SECRET_VALUES_FILE_PATH params

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)

- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret values

Usage:

```
d8 delivery-kit helm secret values [options]
```

Work with secret values files

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

Enable verbose output (default $WERF_LOG_VERBOSE).

- `--namespace, -n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm secret values decrypt

Usage:

```
d8 delivery-kit helm secret values decrypt [FILE_PATH] [options]
```

Decrypt secret values file data

Show more...

Decrypt data from FILE_PATH or pipe.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

Enable verbose output (default $WERF_LOG_VERBOSE).

- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--output-file-path`, `-o`

  Write to file instead of stdout
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret values edit

Usage:

```
d8 delivery-kit helm secret values edit FILE_PATH [options]
```

Edit or create new secret values file

Show more...

Edit or create new secret values file.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm secret values encrypt

Usage:

```
d8 delivery-kit helm secret values encrypt [FILE_PATH] [options]
```

Encrypt values file data

Show more...

Encrypt data from FILE_PATH or pipe.
Encryption key should be in $WERF_SECRET_KEY or .werf_secret_key file.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and

development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project's werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--output-file-path`, `-o`

  Write to file instead of stdout
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

Global options

- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--namespace`, `-n`

  namespace scope for this request
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to

$WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds

d8 delivery-kit helm show

Alias: `inspect`

Usage:

```
d8 delivery-kit helm show [options]
```

show information of a chart

Show more...

This command consists of multiple subcommands to display information about a chart

Global options

- `--debug`
  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`
  No-op
- `--kube-config`
  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`
  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`
  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`
  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`
  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`
  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`
  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`
  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`
  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`
  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`
  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`
  namespace scope for this request
- `--quiet`
  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`
  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`
  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm show all

Usage:

```
d8 delivery-kit helm show all [CHART] [options]
```

show all information of the chart

Show more...

This command inspects a chart (directory, file, or URL) and displays all its content
(values.yaml, Chart.yaml, README)

Options

- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--repo`

  chart repository url where to locate the requested chart
- `--username`

  chart repository username where to locate the requested chart
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

Disable explanatory output (default $WERF_LOG_QUIET).

- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm show chart

Usage:

```
d8 delivery-kit helm show chart [CHART] [options]
```

show the chart's definition

Show more...

This command inspects a chart (directory, file, or URL) and displays the contents
of the Chart.yaml file

Options

- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--repo`

  chart repository url where to locate the requested chart
- `--username`

  chart repository username where to locate the requested chart
- `--verify`

  verify the package before using it
- `--version`

specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm show crds

Usage:

```
d8 delivery-kit helm show crds [CHART] [options]
```

show the chart's CRDs

Show more...

This command inspects a chart (directory, file, or URL) and displays the contents
of the CustomResourceDefinition files

Options

- `--ca-file`

verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--repo`

  chart repository url where to locate the requested chart
- `--username`

  chart repository username where to locate the requested chart
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).

- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm show readme

Usage:

```
d8 delivery-kit helm show readme [CHART] [options]
```

show the chart's README

Show more...

This command inspects a chart (directory, file, or URL) and displays the contents
of the README file

Options

- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--repo`

  chart repository url where to locate the requested chart
- `--username`

  chart repository username where to locate the requested chart
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)

- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm show values

Usage:

```
d8 delivery-kit helm show values [CHART] [options]
```

show the chart's values

Show more...

This command inspects a chart (directory, file, or URL) and displays the contents
of the values.yaml file

Options

- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--jsonpath`

  supply a JSONPath expression to filter the output
- `--key-file`

identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--repo`

  chart repository url where to locate the requested chart
- `--username`

  chart repository username where to locate the requested chart
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to

$WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm status

Usage:

```
d8 delivery-kit helm status RELEASE_NAME [options]
```

display the status of the named release

Show more...

This command shows the status of a named release.
The status consists of:
- last deployment time
- k8s namespace in which the release lives
- state of the release (can be: unknown, deployed, uninstalled, superseded, failed, uninstalling, pending-install, pending-upgrade or pending-rollback)
- revision of the release
- description of the release (can be completion message or error message, need to enable --show-desc)
- list of resources that this release consists of (need to enable --show-resources)
- details on last test suite run, if applicable
- additional notes provided by the chart

Options

- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--revision`

  if set, display the status of the named release with revision
- `--show-desc`

  if set, display the description message of the named release
- `--show-resources`

  if set, display the resources of the named release

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140

- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm template

Usage:

```
d8 delivery-kit helm template [NAME] [CHART] [options]
```

locally render templates

Show more...

Render chart templates locally and display the output.

Any values that would normally be looked up or retrieved in-cluster will be
faked locally. Additionally, none of the server-side testing of chart validity
(e.g. whether an API is supported) is done.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g. $WERF_ADD_ANNOTATION_1=annoName1=annoValue1, $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--api-versions`, `-a`

  Kubernetes api versions used for Capabilities.APIVersions
- `--atomic`

  if set, the installation process deletes the installation on failure. The --wait flag will be set automatically if --atomic is used
- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--cleanup-on-fail`

  allow deletion of new resources created in this installation when install fails
- `--create-namespace`

  create the release namespace if not present
- `--dependency-update`

  update dependencies if they are missing before installing the chart
- `--deploy-report-path`

  save deploy report in JSON to the specified path
- `--description`

add a custom description
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-openapi-validation`

  if set, the installation process will not validate rendered templates against the Kubernetes OpenAPI Schema
- `--dry-run`

  simulate an install. If --dry-run is set with no option being specified or as '--dry-run=client', it will not attempt cluster connections. Setting '--dry-run=server' allows attempting cluster connections.
- `--enable-dns`

  enable DNS lookups when rendering templates
- `--force`

  force resource updates through a replacement strategy
- `--generate-name`, `-g`

  generate the name (and omit the NAME parameter)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--include-crds`

  include CRDs in the templated output
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--is-upgrade`

  set .Release.IsUpgrade instead of .Release.IsInstall
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--kube-version`

  Kubernetes version used for Capabilities.KubeVersion
- `--labels`, `-l`

  Labels that would be added to release metadata. Should be divided by comma.
- `--name-template`

  specify template used to name the release
- `--no-hooks`

  prevent hooks from running during install
- `--output-dir`

  writes the executed templates to files in output-dir instead of stdout
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--post-renderer`

  the path to an executable to be used for post rendering. If it exists in $PATH, the binary will be used, otherwise it will try to look for the executable at the given path
- `--post-renderer-args`

  an argument to the post-renderer (can specify multiple)
- `--release-name`

  use release name in the output-dir path.
- `--render-subchart-notes`

  if set, render subchart notes along with the parent
- `--replace`

  re-use the given name, only if that name is a deleted release which remains in the history. This is unsafe in production
- `--repo`

chart repository url where to locate the requested chart
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

  Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)
- `--set`

  set values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--set-file`

  set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2)
- `--set-json`

  set JSON values on the command line (can specify multiple or separate values with commas: key1=jsonval1,key2=jsonval2)
- `--set-literal`

  set a literal STRING value on the command line
- `--set-string`

  set STRING values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--show-only`, `-s`

  only show manifests rendered from the given templates
- `--skip-crds`

  if set, no CRDs will be installed. By default, CRDs are installed if not already present
- `--skip-tests`

  skip tests from templated output
- `--timeout`

  time to wait for any individual Kubernetes operation (like Jobs for hooks)
- `--username`

  chart repository username where to locate the requested chart
- `--validate`

  validate your manifests against the Kubernetes cluster you are currently pointing at. This is the same validation performed on an install
- `--values`, `-f`

  specify values in a YAML file or a URL (can specify multiple)
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used
- `--wait`

  if set, will wait until all Pods, PVCs, Services, and minimum number of Pods of a Deployment, StatefulSet, or ReplicaSet are in a ready state before marking the release as successful. It will wait for as long as --timeout
- `--wait-for-jobs`

  if set and --wait enabled, will wait until all Jobs have been completed before marking the release as successful. It will wait for as long as --timeout

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm test

Usage:

```
d8 delivery-kit helm test [RELEASE] [options]
```

run tests for a release

Show more...

The test command runs the tests for a release.

The argument this command takes is the name of a deployed release.
The tests to be run are defined in the chart that was installed.

Options

- `--filter`

  specify tests by attribute (currently "name") using attribute=value syntax or '!attribute=value' to exclude a test (can specify multiple or separate values with commas: name=test1,name=test2)
- `--logs`

  dump the logs from test pods (this runs after all tests are complete, but before any cleanup)
- `--timeout`

  time to wait for any individual Kubernetes operation (like Jobs for hooks)

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm uninstall

Aliases: `del`, `delete`, `un`

Usage:

```
d8 delivery-kit helm uninstall RELEASE_NAME [...] [options]
```

uninstall a release

Show more...

This command takes a release name and uninstalls the release.

It removes all of the resources associated with the last release of the chart
as well as the release history, freeing it up for future use.

Use the '--dry-run' flag to see which releases will be uninstalled without actually
uninstalling them.

Options

- `--cascade`

  Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents. Defaults to background.

- `--description`

  add a custom description
- `--dry-run`

  simulate a uninstall
- `--ignore-not-found`

  Treat "release not found" as a successful uninstall
- `--keep-history`

  remove all associated resources and mark the release as deleted, but retain the release history
- `--no-hooks`

  prevent hooks from running during uninstallation
- `--timeout`

  time to wait for any individual Kubernetes operation (like Jobs for hooks)
- `--wait`

  if set, will wait until all the resources are deleted before returning. It will wait for as long as --timeout

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm upgrade

Usage:

```
d8 delivery-kit helm upgrade [RELEASE] [CHART] [options]
```

upgrade a release

Show more...

This command upgrades a release to a new version of a chart.

The upgrade arguments must be a release and chart. The chart
argument can be either: a chart reference('example/mariadb'), a path to a chart directory,
a packaged chart, or a fully qualified URL. For chart references, the latest
version will be specified unless the '--version' flag is set.

To override values in a chart, use either the '--values' flag and pass in a file
or use the '--set' flag and pass configuration from the command line, to force string
values, use '--set-string'. You can use '--set-file' to set individual
values from a file when the value itself is too long for the command line
or is dynamically generated. You can also use '--set-json' to set json values
(scalars/objects/arrays) from the command line.

You can specify the '--values'/'-f' flag multiple times. The priority will be given to the
last (right-most) file specified. For example, if both myvalues.yaml and override.yaml
contained a key called 'Test', the value set in override.yaml would take precedence:

```
$ helm upgrade -f myvalues.yaml -f override.yaml redis ./redis
```

You can specify the '--set' flag multiple times. The priority will be given to the
last (right-most) set specified. For example, if both 'bar' and 'newbar' values are
set for a key called 'foo', the 'newbar' value would take precedence:

```
$ helm upgrade --set foo=bar --set foo=newbar redis ./redis
```

You can update the values for an existing release with this command as well via the
'--reuse-values' flag. The 'RELEASE' and 'CHART' arguments should be set to the original
parameters, and existing values will be merged with any values set via '--values'/'-f'
or '--set' flags. Priority is given to new values.

```
$ helm upgrade --reuse-values --set foo=bar --set foo=newbar redis ./redis
```

The --dry-run flag will output all generated chart manifests, including Secrets
which can contain sensitive values. Please carefully consider how and when this
flag is used.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g.
  $WERF_ADD_ANNOTATION_1=annoName1=annoValue1,
  $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1,
  $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--atomic`

  if set, upgrade process rolls back changes made in case of failed upgrade. The --wait flag will be set
  automatically if --atomic is used
- `--ca-file`

  verify certificates of HTTPS-enabled servers using this CA bundle
- `--cert-file`

  identify HTTPS client using this SSL certificate file
- `--cleanup-on-fail`

  allow deletion of new resources created in this upgrade when upgrade fails
- `--create-namespace`

  if --install is set, create the release namespace if not present

- `--dependency-update`

  update dependencies if they are missing before installing the chart
- `--deploy-report-path`

  save deploy report in JSON to the specified path
- `--description`

  add a custom description
- `--devel`

  use development versions, too. Equivalent to version '>0.0.0-0'. If --version is set, this is ignored
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-openapi-validation`

  if set, the upgrade process will not validate rendered templates against the Kubernetes OpenAPI Schema
- `--dry-run`

  simulate an install. If --dry-run is set with no option being specified or as '--dry-run=client', it will not attempt cluster connections. Setting '--dry-run=server' allows attempting cluster connections.
- `--enable-dns`

  enable DNS lookups when rendering templates
- `--force`

  force resource updates through a replacement strategy
- `--history-max`

  limit the maximum number of revisions saved per release. Use 0 for no limit
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--insecure-skip-tls-verify`

  skip tls certificate checks for the chart download
- `--install`, `-i`

  if a release by this name doesn't already exist, run an install
- `--key-file`

  identify HTTPS client using this SSL key file
- `--keyring`

  location of public keys used for verification
- `--labels`, `-l`

  Labels that would be added to release metadata. Should be separated by comma. Original release labels will be merged with upgrade labels. You can unset label using null.
- `--no-hooks`

  disable pre/post upgrade hooks
- `--output`, `-o`

  prints the output in the specified format. Allowed values: table, json, yaml
- `--pass-credentials`

  pass credentials to all domains
- `--password`

  chart repository password where to locate the requested chart
- `--plain-http`

  use insecure HTTP connections for the chart download
- `--post-renderer`

  the path to an executable to be used for post rendering. If it exists in $PATH, the binary will be used, otherwise it will try to look for the executable at the given path
- `--post-renderer-args`

  an argument to the post-renderer (can specify multiple)
- `--recreate-pods`

  performs pods restart for the resource if applicable
- `--render-subchart-notes`

  if set, render subchart notes along with the parent
- `--repo`

  chart repository url where to locate the requested chart
- `--reset-then-reuse-values`

  when upgrading, reset the values to the ones built into the chart, apply the last release's values and merge

in any overrides from the command line via --set and -f. If '--reset-values' or '--reuse-values' is specified, this is ignored
- `--reset-values`

  when upgrading, reset the values to the ones built into the chart
- `--reuse-values`

  when upgrading, reuse the last release's values and merge in any overrides from the command line via --set and -f. If '--reset-values' is specified, this is ignored
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

  Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)
- `--set`

  set values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--set-file`

  set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2)
- `--set-json`

  set JSON values on the command line (can specify multiple or separate values with commas: key1=jsonval1,key2=jsonval2)
- `--set-literal`

  set a literal STRING value on the command line
- `--set-string`

  set STRING values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2)
- `--skip-crds`

  if set, no CRDs will be installed when an upgrade is performed with install flag enabled. By default, CRDs are installed if not already present, when an upgrade is performed with install flag enabled
- `--timeout`

  time to wait for any individual Kubernetes operation (like Jobs for hooks)
- `--username`

  chart repository username where to locate the requested chart
- `--values`, `-f`

  specify values in a YAML file or a URL (can specify multiple)
- `--verify`

  verify the package before using it
- `--version`

  specify a version constraint for the chart version to use. This constraint can be a specific tag (e.g. 1.1.1) or it may reference a valid range (e.g. ^2.0.0). If this is not specified, the latest version is used
- `--wait`

  if set, will wait until all Pods, PVCs, Services, and minimum number of Pods of a Deployment, StatefulSet, or ReplicaSet are in a ready state before marking the release as successful. It will wait for as long as --timeout
- `--wait-for-jobs`

  if set and --wait enabled, will wait until all Jobs have been completed before marking the release as successful. It will wait for as long as --timeout

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

Kubernetes config context (default $WERF_KUBE_CONTEXT)

- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout's file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm verify

Usage:

```
d8 delivery-kit helm verify PATH [options]
```

verify that a chart at the given path has been signed and is valid

Show more...

Verify that the given chart has a valid provenance file.

Provenance files provide cryptographic verification that a chart has not been
tampered with, and was packaged by a trusted provider.

This command can be used to verify a local chart. Several other commands provide
'--verify' flags that run the same validation. To generate a signed package, use
the 'helm package --sign' command.

Options

- `--keyring`

  keyring containing public keys

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit helm version

Usage:

```
d8 delivery-kit helm version [options]
```

print the client version information

Show more...

Show the version for Helm.

This will print a representation the version of Helm.
The output will look something like this:

version.BuildInfo{Version:"v3.2.1", GitCommit:"fe51cd1e31e6a202cba7dead9552a6d418ded79a",
GitTreeState:"clean", GoVersion:"go1.13.10"}

- Version is the semantic version of the release.
- GitCommit is the SHA for the commit that this version was built from.
- GitTreeState is "clean" if there are no local code changes when this binary was
  built, and "dirty" if the binary was built from locally modified code.
- GoVersion is the version of Go that was used to compile Helm.

When using the --template flag the following properties are available to use in
the template:

- .Version contains the semantic version of Helm
- .GitCommit is the git commit
- .GitTreeState is the state of the git tree when Helm was built
- .GoVersion contains the version of Go that Helm was compiled with

For example, --template='Version: {{.Version}}' outputs 'Version: v3.2.1'.

Options

- `--client`, `-c`

  display client version information
- `--short`

  print the version number
- `--template`

  template for version string format

Global options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--hooks-status-progress-period`

  No-op
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--namespace`, `-n`

  namespace scope for this request
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit host

Usage:

```
d8 delivery-kit host [options]
```

Work with werf cache and data of all projects on the host machine

d8 delivery-kit host cleanup

Usage:

```
d8 delivery-kit host cleanup [options]
```

Cleanup old unused werf cache and data of all projects on host machine.

Show more...

Cleanup old unused werf cache and data of all projects on host machine.

The data include:
* Lost Docker containers and images from interrupted builds.
* Old service tmp dirs, which werf creates during every build, converge and other commands.
* Local cache:
  * remote Git clones cache;
  * Git worktree cache.

It is safe to run this command periodically by automated cleanup job in parallel with other werf commands such as build, converge and cleanup.

Options

- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")

- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--dry-run`

  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--force`

  Force deletion of images which are being used by some containers (default $WERF_FORCE)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit host purge

Usage:

```
d8 delivery-kit host purge [options]
```

Purge werf images, cache and other data for all projects on host machine

Show more...

Purge werf images, cache and other data for all projects on host machine.

The data include:
* Old service tmp dirs, which werf creates during every build, converge and other commands.
* Local cache:
  * remote Git clones cache;
  * Git worktree cache.
* Shared context:
  * Mounts which persists between several builds (mounts from build_dir).

WARNING: Do not run this command during any other werf command is working on the host machine. This command is supposed to be run manually.

Options

- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
- `--dry-run`

  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--force`

  First remove containers that use werf docker images which are going to be deleted
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit includes

Usage:

```
d8 delivery-kit includes [options]
```

Work with werf includes

d8 delivery-kit includes get-file

Usage:

```
d8 delivery-kit includes get-file [FILE_NAME] [options]
```

Display file content that will be used by werf according to the includes overlay rules.

Show more...

Display file content that will be used by werf according to the includes overlay rules.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

Enable debug (default $WERF_DEBUG).

- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

Disable explanatory output (default $WERF_QUIET).

- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit includes ls-files

Usage:

```
d8 delivery-kit includes ls-files [GLOB...] [options]
```

List files in the project according to the includes overlay rules.

Show more...

List files in the project according to the includes overlay rules.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--filter`

  Filter by source, e.g. --filter=source=local,remoteRepo (default $WERF_INCLUDES_LIST_FILTER or all sources).
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default

$WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--ssh-key`

  Use only specific ssh key(s).

  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).

  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit includes update

Usage:

```
d8 delivery-kit includes update [options]
```

Create or update includes lock file (default: werf-includes.lock).

Show more...

Create or update includes lock file by resolving git references in the includes config to their latest commits (default: werf-includes.lock).

Options

- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)

- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit kube-run

Usage:

```
d8 delivery-kit kube-run [options] [IMAGE_NAME] [-- COMMAND ARG...]
```

Run container for project image in Kubernetes

Show more...

Run container in Kubernetes for specified project image from werf.yaml (build if needed).

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g. $WERF_ADD_ANNOTATION_1=annoName1=annoValue1, $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--auto-pull-secret`

  Automatically create docker config secret in the namespace and plug it via pod's imagePullSecrets for private registry access (default $WERF_AUTO_PULL_SECRET or true if not specified)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo.
  Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)

- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--copy-from`

  Copy file/dir from container to local machine after user command execution. Example: "/from/file:to". Can be specified multiple times. Can also be defined with "$WERF_COPY_FROM_*", e.g. "WERF_COPY_FROM_1=from:to".
- `--copy-to`

  Copy file/dir from local machine to container before user command execution. Example: "from:/to/file". Can be specified multiple times. Can also be defined with "$WERF_COPY_TO_*", e.g. "WERF_COPY_TO_1=from:to".
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read and pull images from the specified repo
- `--dry-run`

  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--extra-options`

  Pass extra options to "kubectl run" command, which will create a Pod (default $WERF_EXTRA_OPTIONS)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--interactive`, `-i`

  Enable interactive mode (default $WERF_INTERACTIVE or false if not specified)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).

- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--overrides`

  Inline JSON to override/extend any fields in created Pod, e.g. to add imagePullSecrets field (default $WERF_OVERRIDES). %pod_name%, %container_name%, and %container_image% will be replaced with the names of the created pod, container, and container image, respectively.
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--pod`

  Set created pod name (default $WERF_POD or autogenerated if not specified)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--rm`

  Remove pod and other created resources after command completion (default $WERF_RM or true if not specified)
- `--rm-with-namespace`

  Remove also a namespace after command completion (default $WERF_RM_WITH_NAMESPACE or false if not specified)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option

- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--tty`, `-t`

  Allocate a TTY (default $WERF_TTY or false if not specified)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false).
  Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)

d8 delivery-kit lint

Usage:

```
d8 delivery-kit lint [IMAGE_NAME...] [options]
```

Lint Helm chart

Show more...

Lint Helm chart. This command will calculate digests and build (if needed) all images defined in the werf.yaml.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g. $WERF_ADD_ANNOTATION_1=annoName1=annoValue1,

$WERF_ADD_ANNOTATION_2=annoName2=annoValue2)

- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo.
  Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--delete-propagation`

  Set default delete propagation strategy (default $WERF_DELETE_PROPAGATION or Foreground).
- `--deno-binary-path`

  Path to the Deno binary to use instead of auto-downloading (default $WERF_DENO_BINARY_PATH)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-default-values`

Do not use values from the default .helm/values.yaml file (default $WERF_DISABLE_DEFAULT_VALUES or false)

- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo and to pull base images
- `--env`

  Use specified environment (default $WERF_ENV)
- `--extra-apiversions`

  Extra Kubernetes API versions passed to $.Capabilities.APIVersions. Can be also set with $WERF_EXTRA_APIVERSIONS_* environment variables, values can be comma-separated
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or true by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--force-adoption`

  Always adopt resources, even if they belong to a different Helm release (default $WERF_FORCE_ADOPTION or false)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--ignore-bundle-js`

  Do not use the existing bundle.js file. Requires TypeScript source files and Deno to rebuild (default $WERF_IGNORE_BUNDLE_JS)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--insecure-helm-dependencies`

  Allow insecure oci registries to be used in the Chart.yaml dependencies configuration (default $WERF_INSECURE_HELM_DEPENDENCIES)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

  Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

  Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)
- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

  Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)
- `--kube-key-data`

Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)

- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--kube-version`

  Set specific Capabilities.KubeVersion (default $WERF_KUBE_VERSION)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--lookup-resources`

  Manifest files used as a cluster stub for the lookup template function in non-remote mode. Multi-document and kind:List supported. Namespaced resources must set metadata.namespace, otherwise namespace-scoped lookups ignore the requested namespace. Can be also set with $WERF_LOOKUP_RESOURCES_* environment variables (can specify multiple)
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--network-parallelism`

  Parallelize some network operations (default $WERF_NETWORK_PARALLELISM or 30)
- `--no-final-tracking`

  By default disable tracking operations that have no create/update/delete resource operations after them, which are most tracking operations, to speed up the release (default $WERF_NO_FINAL_TRACKING)
- `--no-remove-manual-changes`

  Don't remove fields added manually to the resource in the cluster if fields aren't present in the manifest (default $WERF_NO_REMOVE_MANUAL_CHANGES)
- `--parallel`, `-p`

Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--provenance-keyring`

  Path to keyring containing public keys to verify chart provenance (default $WERF_PROVENANCE_KEYRING)
- `--provenance-strategy`

  Strategy for provenance verifying (default $WERF_PROVENANCE_STRATEGY).
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--release`

  Use specified Helm release name (default [[project]]-[[env]] template or deploy.helmRelease custom template from werf.yaml or $WERF_RELEASE)
- `--release-storage`

  How releases should be stored (default $WERF_RELEASE_STORAGE)
- `--release-storage-sql-connection`

  SQL Connection String for Helm SQL Storage (default $WERF_RELEASE_STORAGE_SQL_CONNECTION)
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--runtime-annotations`

  Add annotations which will not trigger resource updates to all resources (default $WERF_RUNTIME_ANNOTATIONS)
- `--runtime-labels`

  Add labels which will not trigger resource updates to all resources (default $WERF_RUNTIME_LABELS)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)

- `--set`

  Set helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_* (e.g. $WERF_SET_1=key1=val1, $WERF_SET_2=key2=val2)
- `--set-docker-config-json-value`

  Shortcut to set current docker config into the .Values.global.werf.dockerconfigjson
- `--set-file`

  Set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2).
  Also, can be defined with $WERF_SET_FILE_* (e.g. $WERF_SET_FILE_1=key1=path1, $WERF_SET_FILE_2=key2=val2)
- `--set-json`

  Set new values, where the key is the value path and the value is JSON (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_JSON_* (e.g. $WERF_SET_JSON_1=key1=val1, $WERF_SET_JSON_2=key2=val2)
- `--set-literal`

  Set new values, where the key is the value path and the value is the value. The value will always become a literal string (can specify multiple or separate values with commas: key1=val1,key2=val2).)
  Also, can be defined with $WERF_SET_LITERAL_* (e.g. $WERF_SET_LITERAL_1=key1=val1, $WERF_SET_LITERAL_2=key2=val2)
- `--set-root-json`

  Set new keys in arbitrary things in the global root context ("$"), where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you REALLY know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_ROOT_JSON_* (e.g. $WERF_SET_ROOT_JSON_1=key1=val1, $WERF_SET_ROOT_JSON_2=key2=val2)
- `--set-runtime-json`

  Set new keys in $.Runtime, where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_RUNTIME_JSON_* (e.g. $WERF_SET_RUNTIME_JSON_1=key1=val1, $WERF_SET_RUNTIME_JSON_2=key2=val2)
- `--set-string`

  Set STRING helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_STRING_* (e.g. $WERF_SET_STRING_1=key1=val1, $WERF_SET_STRING_2=key2=val2)
- `--skip-dependencies-repo-refresh`, `-L`

  Do not refresh helm chart repositories locally cached index
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-helm-dependencies`

  Skip TLS certificate validation when accessing a Helm charts repository (default $WERF_SKIP_TLS_VERIFY_HELM_DEPENDENCIES)
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--stub-tags`

Use stubs instead of real tags (default $WERF_STUB_TAGS)

- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--templates-allow-dns`

  Allow performing DNS requests in templating (default $WERF_TEMPLATES_ALLOW_DNS)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--use-custom-tag`

  Use a tag alias in helm templates instead of an image content-based tag (NOT RECOMMENDED).
  The alias may contain the following shortcuts:
  - %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
  - %image_content_based_tag% to use a content-based tag.
  For cleaning custom tags and associated content-based tag are treated as one.
  Also, can be defined with $WERF_USE_CUSTOM_TAG (e.g. $WERF_USE_CUSTOM_TAG="%image%-tag")
- `--validate`

  Validate your manifests against the Kubernetes cluster you are currently pointing at (default $WERF_VALIDATE)
- `--values`

  Specify helm values in a YAML file or a URL (can specify multiple). Also, can be defined with $WERF_VALUES_* (e.g. $WERF_VALUES_1=.helm/values_1.yaml, $WERF_VALUES_2=.helm/values_2.yaml)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit managed-images

Usage:

```
d8 delivery-kit managed-images [options]
```

Work with managed images which will be preserved during cleanup procedure

d8 delivery-kit managed-images add

Usage:

```
d8 delivery-kit managed-images add [options]
```

Add image record to the list of managed images which will be preserved during cleanup procedure.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--cache-repo`

Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)

- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read and write images to the specified repo
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)

- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit managed-images ls

Usage:

```
d8 delivery-kit managed-images ls [options]
```

List managed images which will be preserved during cleanup procedure.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo.
  Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file

- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read images from the specified repo
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)

- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)

- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit managed-images rm

Usage:

```
d8 delivery-kit managed-images rm [options]
```

Remove image record from the list of managed images which will be preserved during cleanup procedure.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo.
  Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)

- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project's werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read and write images to the specified repo
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-tls-verify-registry`

Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)

- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}

- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only

- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)

- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit plan

Usage:

```
d8 delivery-kit plan [options]
```

Prepare deploy plan and show how resources in a Kubernetes cluster would change on next deploy

Show more...

Prepare deploy plan and show how resources in a Kubernetes cluster would change on next deploy.

Environment is a required param by default, because it is needed to construct Helm Release name and Kubernetes Namespace. Either --env or $WERF_ENV should be specified for command.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g. $WERF_ADD_ANNOTATION_1=annoName1=annoValue1, $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)

- `--add-custom-tag`

  Set tag alias for the content-based tag.
  The alias may contain the following shortcuts:
  - %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
  - %image_content_based_tag% to use a content-based tag.
  For cleaning custom tags and associated content-based tag are treated as one.
  Also can be defined with $WERF_ADD_CUSTOM_TAG_* (e.g. $WERF_ADD_CUSTOM_TAG_1="%image%-tag1", $WERF_ADD_CUSTOM_TAG_2="%image%-tag2")

- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)

- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or

$WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)

- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--delete-propagation`

  Set default delete propagation strategy (default $WERF_DELETE_PROPAGATION or Foreground).
- `--deno-binary-path`

  Path to the Deno binary to use instead of auto-downloading (default $WERF_DENO_BINARY_PATH)
- `--deploy-graph-path`

  Save deploy graph path to the specified file (by default $WERF_DEPLOY_GRAPH_PATH). Extension must be .dot or not specified. If extension not specified, then .dot is used
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--diff-context-lines`

  Show N lines of context around diffs ($WERF_DIFF_CONTEXT_LINES by default)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-default-values`

  Do not use values from the default .helm/values.yaml file (default $WERF_DISABLE_DEFAULT_VALUES or false)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo, to pull base images
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--exit-code`

  Return exit code 0 if no changes, 1 if error, 2 if any changes planned (default $WERF_EXIT_CODE or false)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or true by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)

- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--follow`

  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--force-adoption`

  Always adopt resources, even if they belong to a different Helm release (default $WERF_FORCE_ADOPTION or false)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--hooks-status-progress-period`

  No-op
- `--ignore-bundle-js`

  Do not use the existing bundle.js file. Requires TypeScript source files and Deno to rebuild (default $WERF_IGNORE_BUNDLE_JS)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--insecure-helm-dependencies`

  Allow insecure oci registries to be used in the Chart.yaml dependencies configuration (default $WERF_INSECURE_HELM_DEPENDENCIES)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

  Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME

* specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec

- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

  Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

  Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)
- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

  Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)
- `--kube-key-data`

  Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)
- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used

to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--network-parallelism`

  Parallelize some network operations (default $WERF_NETWORK_PARALLELISM or 30)
- `--no-final-tracking`

  By default disable tracking operations that have no create/update/delete resource operations after them, which are most tracking operations, to speed up the release (default $WERF_NO_FINAL_TRACKING)
- `--no-install-crds`

  Do not install CRDs from "crds/" directories of installed charts (default $WERF_NO_INSTALL_CRDS)
- `--no-remove-manual-changes`

  Don't remove fields added manually to the resource in the cluster if fields aren't present in the manifest (default $WERF_NO_REMOVE_MANUAL_CHANGES)
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--provenance-keyring`

  Path to keyring containing public keys to verify chart provenance (default $WERF_PROVENANCE_KEYRING)
- `--provenance-strategy`

  Strategy for provenance verifying (default $WERF_PROVENANCE_STRATEGY).
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).

- `--release`

  Use specified Helm release name (default [[project]]-[[env]] template or deploy.helmRelease custom template from werf.yaml or $WERF_RELEASE)
- `--release-info-annotations`

  Add annotations to release metadata (default $WERF_RELEASE_INFO_ANNOTATIONS)
- `--release-label`

  Add Helm release labels (can specify multiple). Kind of labels depends or release storage driver.
  Format: labelName=labelValue.
  Also, can be specified with $WERF_RELEASE_LABEL_* (e.g.
  $WERF_RELEASE_LABEL_1=labelName1=labelValue1,
  $WERF_RELEASE_LABEL_2=labelName2=labelValue2)
- `--release-storage`

  How releases should be stored (default $WERF_RELEASE_STORAGE)
- `--release-storage-sql-connection`

  SQL Connection String for Helm SQL Storage (default $WERF_RELEASE_STORAGE_SQL_CONNECTION)
- `--releases-history-max`

  Max releases to keep in release storage ($WERF_RELEASES_HISTORY_MAX or 5 by default)
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--runtime-annotations`

  Add annotations which will not trigger resource updates to all resources (default $WERF_RUNTIME_ANNOTATIONS)
- `--runtime-labels`

  Add labels which will not trigger resource updates to all resources (default $WERF_RUNTIME_LABELS)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--save-plan`

  Save the gzip-compressed JSON install plan to the specified file
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=...,
  $WERF_SECONDARY_REPO_2=...)
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)

- `--set`

  Set helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_* (e.g. $WERF_SET_1=key1=val1, $WERF_SET_2=key2=val2)
- `--set-docker-config-json-value`

  Shortcut to set current docker config into the .Values.global.werf.dockerconfigjson
- `--set-file`

  Set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2).
  Also, can be defined with $WERF_SET_FILE_* (e.g. $WERF_SET_FILE_1=key1=path1, $WERF_SET_FILE_2=key2=val2)
- `--set-json`

  Set new values, where the key is the value path and the value is JSON (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_JSON_* (e.g. $WERF_SET_JSON_1=key1=val1, $WERF_SET_JSON_2=key2=val2)
- `--set-literal`

  Set new values, where the key is the value path and the value is the value. The value will always become a literal string (can specify multiple or separate values with commas: key1=val1,key2=val2).)
  Also, can be defined with $WERF_SET_LITERAL_* (e.g. $WERF_SET_LITERAL_1=key1=val1, $WERF_SET_LITERAL_2=key2=val2)
- `--set-root-json`

  Set new keys in arbitrary things in the global root context ("$"), where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you REALLY know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_ROOT_JSON_* (e.g. $WERF_SET_ROOT_JSON_1=key1=val1, $WERF_SET_ROOT_JSON_2=key2=val2)
- `--set-runtime-json`

  Set new keys in $.Runtime, where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_RUNTIME_JSON_* (e.g. $WERF_SET_RUNTIME_JSON_1=key1=val1, $WERF_SET_RUNTIME_JSON_2=key2=val2)
- `--set-string`

  Set STRING helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_STRING_* (e.g. $WERF_SET_STRING_1=key1=val1, $WERF_SET_STRING_2=key2=val2)
- `--show-insignificant-diffs`

  Show insignificant diff lines ($WERF_SHOW_INSIGNIFICANT_DIFFS by default)
- `--show-plan`

  Show plan artifact planned changes
- `--show-sensitive-diffs`

  Show sensitive diff lines ($WERF_SHOW_SENSITIVE_DIFFS by default)
- `--show-verbose-crd-diffs`

  Show verbose CRD diff lines ($WERF_SHOW_VERBOSE_CRD_DIFFS by default)
- `--show-verbose-diffs`

  Show verbose diff lines ($WERF_SHOW_VERBOSE_DIFFS by default)
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)

- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-dependencies-repo-refresh`, `-L`

  Do not refresh helm chart repositories locally cached index
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-helm-dependencies`

  Skip TLS certificate validation when accessing a Helm charts repository (default $WERF_SKIP_TLS_VERIFY_HELM_DEPENDENCIES)
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--status-progress-period`

  No-op
- `--stub-tags`

  Use stubs instead of real tags (default $WERF_STUB_TAGS)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--templates-allow-dns`

  Allow performing DNS requests in templating (default $WERF_TEMPLATES_ALLOW_DNS)
- `--timeout`, `-t`

  No-op
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--use-custom-tag`

  Use a tag alias in helm templates instead of an image content-based tag (NOT RECOMMENDED).
  The alias may contain the following shortcuts:
  - %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
  - %image_content_based_tag% to use a content-based tag.
  For cleaning custom tags and associated content-based tag are treated as one.
  Also, can be defined with $WERF_USE_CUSTOM_TAG (e.g. $WERF_USE_CUSTOM_TAG="%image%-tag")
- `--values`

Specify helm values in a YAML file or a URL (can specify multiple). Also, can be defined with $WERF_VALUES_* (e.g. $WERF_VALUES_1=.helm/values_1.yaml, $WERF_VALUES_2=.helm/values_2.yaml)

- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit purge

Usage:

```
d8 delivery-kit purge [options]
```

Purge all project images in the container registry

Show more...

Purge all project images in the container registry.

WARNING: Images that are being used in the Kubernetes cluster will also be deleted.

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo.

Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)

- `--cleanup-report-path`

  Change cleanup report path (by default $WERF_CLEANUP_REPORT_PATH or ".werf-cleanup-report.json" if not set). Extension must be .json for JSON format. If extension not specified, then .json is used
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to delete images from the specified repo
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--dry-run`

  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`

  No-op
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)

- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--save-cleanup-report`

  Save cleanup report (by default $WERF_SAVE_CLEANUP_REPORT or false). Its path configured with --cleanup-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit render

Usage:

```
d8 delivery-kit render [IMAGE_NAME...] [options]
```

Render Kubernetes templates

Show more...

Render Kubernetes templates. This command will calculate digests and build (if needed) all images defined in the werf.yaml.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g. $WERF_ADD_ANNOTATION_1=annoName1=annoValue1, $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo.
  Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--deno-binary-path`

  Path to the Deno binary to use instead of auto-downloading (default $WERF_DENO_BINARY_PATH)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development

- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project's werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-default-secret-values`

  Do not use secret values from the default .helm/secret-values.yaml file (default $WERF_DISABLE_DEFAULT_SECRET_VALUES or false)
- `--disable-default-values`

  Do not use values from the default .helm/values.yaml file (default $WERF_DISABLE_DEFAULT_VALUES or false)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo and to pull base images
- `--elf-pgp-private-key-base64`

  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`

  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`

  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--extra-apiversions`

  Extra Kubernetes API versions passed to $.Capabilities.APIVersions. Can be also set with $WERF_EXTRA_APIVERSIONS_* environment variables, values can be comma-separated
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or true by default)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--force-adoption`

  Always adopt resources, even if they belong to a different Helm release (default $WERF_FORCE_ADOPTION or false)

- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--hooks-status-progress-period`

  No-op
- `--ignore-bundle-js`

  Do not use the existing bundle.js file. Requires TypeScript source files and Deno to rebuild (default $WERF_IGNORE_BUNDLE_JS)
- `--ignore-secret-key`

  Disable secrets decryption (default $WERF_IGNORE_SECRET_KEY)
- `--include-crds`

  Include CRDs in the templated output (default $WERF_INCLUDE_CRDS)
- `--insecure-helm-dependencies`

  Allow insecure oci registries to be used in the Chart.yaml dependencies configuration (default $WERF_INSECURE_HELM_DEPENDENCIES)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

  Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

  Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)
- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

  Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)
- `--kube-key-data`

  Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)
- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--kube-version`

  Set specific Capabilities.KubeVersion (default $WERF_KUBE_VERSION)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).

- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--lookup-resources`

  Manifest files used as a cluster stub for the lookup template function in non-remote mode. Multi-document and kind:List supported. Namespaced resources must set metadata.namespace, otherwise namespace-scoped lookups ignore the requested namespace. Can be also set with $WERF_LOOKUP_RESOURCES_* environment variables (can specify multiple)
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--network-parallelism`

  Parallelize some network operations (default $WERF_NETWORK_PARALLELISM or 30)
- `--output`

  Write render output to the specified file instead of stdout ($WERF_RENDER_OUTPUT by default)
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--provenance-keyring`

  Path to keyring containing public keys to verify chart provenance (default $WERF_PROVENANCE_KEYRING)
- `--provenance-strategy`

  Strategy for provenance verifying (default $WERF_PROVENANCE_STRATEGY).
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--release`

  Use specified Helm release name (default [[project]]-[[env]] template or deploy.helmRelease custom template from werf.yaml or $WERF_RELEASE)
- `--release-storage`

  How releases should be stored (default $WERF_RELEASE_STORAGE)
- `--release-storage-sql-connection`

  SQL Connection String for Helm SQL Storage (default $WERF_RELEASE_STORAGE_SQL_CONNECTION)
- `--releases-history-max`

  Max releases to keep in release storage ($WERF_RELEASES_HISTORY_MAX or 5 by default)
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)

- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--secret-key`

  Secret key (default $WERF_SECRET_KEY)
- `--secret-values`

  Specify helm secret values in a YAML file (can specify multiple). Also, can be defined with $WERF_SECRET_VALUES_* (e.g. $WERF_SECRET_VALUES_ENV=.helm/secret_values_test.yaml, $WERF_SECRET_VALUES_DB=.helm/secret_values_db.yaml)
- `--set`

  Set helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_* (e.g. $WERF_SET_1=key1=val1, $WERF_SET_2=key2=val2)
- `--set-docker-config-json-value`

  Shortcut to set current docker config into the .Values.global.werf.dockerconfigjson
- `--set-file`

  Set values from respective files specified via the command line (can specify multiple or separate values with commas: key1=path1,key2=path2).
  Also, can be defined with $WERF_SET_FILE_* (e.g. $WERF_SET_FILE_1=key1=path1, $WERF_SET_FILE_2=key2=val2)
- `--set-json`

  Set new values, where the key is the value path and the value is JSON (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_JSON_* (e.g. $WERF_SET_JSON_1=key1=val1, $WERF_SET_JSON_2=key2=val2)
- `--set-literal`

  Set new values, where the key is the value path and the value is the value. The value will always become a literal string (can specify multiple or separate values with commas: key1=val1,key2=val2).)
  Also, can be defined with $WERF_SET_LITERAL_* (e.g. $WERF_SET_LITERAL_1=key1=val1, $WERF_SET_LITERAL_2=key2=val2)
- `--set-root-json`

  Set new keys in arbitrary things in the global root context ("$"), where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you REALLY know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_ROOT_JSON_* (e.g. $WERF_SET_ROOT_JSON_1=key1=val1, $WERF_SET_ROOT_JSON_2=key2=val2)
- `--set-runtime-json`

  Set new keys in $.Runtime, where the key is the value path and the value is JSON. This is meant to be generated inside the program, so use --set-json instead, unless you know what you are doing. Can specify multiple or separate values with commas: key1=val1,key2=val2.
  Also, can be defined with $WERF_SET_RUNTIME_JSON_* (e.g. $WERF_SET_RUNTIME_JSON_1=key1=val1, $WERF_SET_RUNTIME_JSON_2=key2=val2)
- `--set-string`

  Set STRING helm values on the command line (can specify multiple or separate values with commas: key1=val1,key2=val2).
  Also, can be defined with $WERF_SET_STRING_* (e.g. $WERF_SET_STRING_1=key1=val1, $WERF_SET_STRING_2=key2=val2)
- `--show-only`, `-s`

only show manifests rendered from the given templates

- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-dependencies-repo-refresh`, `-L`

  Do not refresh helm chart repositories locally cached index
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-helm-dependencies`

  Skip TLS certificate validation when accessing a Helm charts repository (default $WERF_SKIP_TLS_VERIFY_HELM_DEPENDENCIES)
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--status-progress-period`

  No-op
- `--stub-tags`

  Use stubs instead of real tags (default $WERF_STUB_TAGS)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--templates-allow-dns`

  Allow performing DNS requests in templating (default $WERF_TEMPLATES_ALLOW_DNS)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--use-custom-tag`

  Use a tag alias in helm templates instead of an image content-based tag (NOT RECOMMENDED).
  The alias may contain the following shortcuts:

- %image%, %image_slug% or %image_safe_slug% to use the image name (necessary if there is more than one image in the werf config);
- %image_content_based_tag% to use a content-based tag.

For cleaning custom tags and associated content-based tag are treated as one.
Also, can be defined with $WERF_USE_CUSTOM_TAG (e.g. $WERF_USE_CUSTOM_TAG="%image%-tag")

- `--validate`

  Validate your manifests against the Kubernetes cluster you are currently pointing at (default $WERF_VALIDATE)
- `--values`

  Specify helm values in a YAML file or a URL (can specify multiple). Also, can be defined with $WERF_VALUES_* (e.g. $WERF_VALUES_1=.helm/values_1.yaml, $WERF_VALUES_2=.helm/values_2.yaml)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)
- `--without-images`

  Disable building of images defined in the werf.yaml (if any) and usage of such images in the .helm/templates ($WERF_WITHOUT_IMAGES or false by default — e.g. enable all images defined in the werf.yaml by default)

d8 delivery-kit rollback

Usage:

```
d8 delivery-kit rollback [options]
```

Rollback the Helm release

Show more...

Rollback the Helm release.

Rollback to the previous revision by default. Use --revision to specify the revision to rollback to. Should be run inside of a werf project directory, otherwise --namespace and --release must be specified.

The result of rollback command is an application deployed into Kubernetes. Command will create the new release based on the one we rollback to and wait until all resources of the release will become ready.

Options

- `--add-annotation`

  Add annotation to deploying resources (can specify multiple).
  Format: annoName=annoValue.
  Also, can be specified with $WERF_ADD_ANNOTATION_* (e.g. $WERF_ADD_ANNOTATION_1=annoName1=annoValue1, $WERF_ADD_ANNOTATION_2=annoName2=annoValue2)
- `--add-label`

  Add label to deploying resources (can specify multiple).
  Format: labelName=labelValue.
  Also, can be specified with $WERF_ADD_LABEL_* (e.g. $WERF_ADD_LABEL_1=labelName1=labelValue1, $WERF_ADD_LABEL_2=labelName2=labelValue2)
- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--debug`

  Enable debug (default $WERF_DEBUG).

- `--delete-propagation`

  Set default delete propagation strategy (default $WERF_DELETE_PROPAGATION or Foreground).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--force-adoption`

  Always adopt resources, even if they belong to a different Helm release (default $WERF_FORCE_ADOPTION or false)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--hooks-status-progress-period`

  No-op
- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

  Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)
- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

  Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)
- `--kube-key-data`

  Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)
- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--namespace`

  Use specified Kubernetes namespace (default [[project]]-[[env]] template or deploy.namespace custom template from werf.yaml or $WERF_NAMESPACE)
- `--network-parallelism`

  Parallelize some network operations (default $WERF_NETWORK_PARALLELISM or 30)

- `--no-final-tracking`

  By default disable tracking operations that have no create/update/delete resource operations after them, which are most tracking operations, to speed up the release (default $WERF_NO_FINAL_TRACKING)
- `--no-notes`

  Don't show release notes at the end of the release (default $WERF_NO_NOTES)
- `--no-pod-logs`

  Disable Pod logs collection and printing (default $WERF_NO_POD_LOGS or false)
- `--no-remove-manual-changes`

  Don't remove fields added manually to the resource in the cluster if fields aren't present in the manifest (default $WERF_NO_REMOVE_MANUAL_CHANGES)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--release`

  Use specified Helm release name (default [[project]]-[[env]] template or deploy.helmRelease custom template from werf.yaml or $WERF_RELEASE)
- `--release-info-annotations`

  Add annotations to release metadata (default $WERF_RELEASE_INFO_ANNOTATIONS)
- `--release-label`

  Add Helm release labels (can specify multiple). Kind of labels depends or release storage driver. Format: labelName=labelValue.
  Also, can be specified with $WERF_RELEASE_LABEL_* (e.g. $WERF_RELEASE_LABEL_1=labelName1=labelValue1, $WERF_RELEASE_LABEL_2=labelName2=labelValue2)
- `--release-storage`

  How releases should be stored (default $WERF_RELEASE_STORAGE)
- `--release-storage-sql-connection`

  SQL Connection String for Helm SQL Storage (default $WERF_RELEASE_STORAGE_SQL_CONNECTION)
- `--releases-history-max`

  Max releases to keep in release storage ($WERF_RELEASES_HISTORY_MAX or 5 by default)
- `--revision`

  Revision number to rollback to (if not specified, rolls back to previous revision)
- `--rollback-graph-path`

  Save rollback graph path to the specified file (by default $WERF_ROLLBACK_GRAPH_PATH). Extension must be .dot or not specified. If extension not specified, then .dot is used
- `--rollback-report-path`

  Change rollback report path and format (by default $WERF_ROLLBACK_REPORT_PATH or ".werf-rollback-report.json" if not set). Extension must be .json for JSON format. If extension not specified, then .json is used
- `--runtime-annotations`

  Add annotations which will not trigger resource updates to all resources (default $WERF_RUNTIME_ANNOTATIONS)
- `--runtime-labels`

  Add labels which will not trigger resource updates to all resources (default $WERF_RUNTIME_LABELS)
- `--save-rollback-report`

  Save rollback report (by default $WERF_SAVE_ROLLBACK_REPORT or false). Its path and format configured with --rollback-report-path
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--status-progress-period`

  Status progress period in seconds. Set -1 to stop showing status progress. Defaults to $WERF_STATUS_PROGRESS_PERIOD_SECONDS or 5 seconds
- `--timeout`, `-t`

  Resources tracking timeout in seconds ($WERF_TIMEOUT by default)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit run

Usage:

```
d8 delivery-kit run [options] [IMAGE_NAME] [-- COMMAND ARG...]
```

Run container for project image

Show more...

Run container for specified project image from werf.yaml (build if needed).

Options

- `--allow-includes-update`

  Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)
- `--annotate-layers-with-dm-verity-root-hash`

  Enable annotation of image layers with dm-verity root hash (default $WERF_ANNOTATE_LAYERS_WITH_DM_VERITY_ROOT_HASH)
- `--backend-network`

  Network mode for the build containers ($WERF_BACKEND_NETWORK or nothing by default)
- `--bash`

  Use predefined docker options and command for debug
- `--bsign-elf-files`

  Enable ELF files signing with bsign (default $WERF_BSIGN_ELF_FILES).
  When enabled, the private elf key must be specified with --elf-pgp-private-key-base64 or --elf-pgp-private-key-fingerprint option
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
Command needs granted permissions to read and pull images from the specified repo

- `--docker-options`
  Define docker run options (default $WERF_DOCKER_OPTIONS)
- `--dry-run`
  Indicate what the command would do without actually doing that (default $WERF_DRY_RUN)
- `--elf-pgp-private-key-base64`
  Base64-encoded PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_BASE64)
- `--elf-pgp-private-key-fingerprint`
  PGP private key fingerprint (default $WERF_ELF_PGP_PRIVATE_KEY_FINGERPRINT)
- `--elf-pgp-private-key-passphrase`
  Passphrase for the PGP private key (default $WERF_ELF_PGP_PRIVATE_KEY_PASSPHRASE)
- `--env`
  Use specified environment (default $WERF_ENV)
- `--final-repo`
  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`
  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`
  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`
  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`
  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`
  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`
  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`
  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`
  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--follow`
  Enable follow mode (default $WERF_FOLLOW).
  The mode allows restarting the command on a new commit.
  In development mode (--dev), werf restarts the command on any changes (including untracked files) in the git repository worktree
- `--git-work-tree`
  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`
  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`
  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-helm-dependencies`
  No-op
- `--insecure-registry`
  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--kube-config`
  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`
  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or

$WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)

- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--require-built-images`, `-Z`

  Requires all used images to be previously built and exist in repo. Exits with error if needed images are not cached and so require to run build instructions (default $WERF_REQUIRE_BUILT_IMAGES)
- `--secondary-repo`

Specify one or multiple secondary read-only repos with images that will be used as a cache.
Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)

- `--shell`

  Use predefined docker options and command for debug
- `--sign-cert`

  The leaf certificate as path to PEM file or base64-encoded PEM (default $WERF_SIGN_CERT)
- `--sign-elf-files`

  Enable ELF files signing (default $WERF_SIGN_ELF_FILES).
  When enabled, the private signing key must be specified with --sign-key option and the certificate must be specified with --sign-cert option
- `--sign-intermediates`

  The intermediate certificates as path to PEM file or base64-encoded PEM (default $WERF_SIGN_INTERMEDIATES)
- `--sign-key`

  The private signing key as path to PEM file, base64-encoded PEM or hashivault://[KEY] (default $WERF_SIGN_KEY)
- `--sign-manifest`

  Enable image manifest signing (default $WERF_SIGN_MANIFEST).
  When enabled,
  the private signing key must be specified with --sign-key option and
  the certificate must be specified with --sign-cert option
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).
- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)

d8 delivery-kit sbom

Usage:

```
d8 delivery-kit sbom [options]
```

Work with SBOM artifacts

d8 delivery-kit sbom get

Usage:

```
d8 delivery-kit sbom get [IMAGE_NAME] [options]
```

Get SBOM of an image

Show more...

Get SBOM of an image that is described in werf.yaml and prints the result to stdout.

SBOM is stored as an OCI artifact attached to the container image in the container registry, so --repo is required.
If SBOM is not found, the command triggers werf build to generate one.

A specific version of the image may be selected with --tag or --digest; these flags are mutually exclusive.

Options

- `--allowed-backend-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE)
- `--allowed-backend-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_BACKEND_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-docker-storage-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of backend (Docker or Buildah) storage volume usage which will cause cleanup of least recently used local backend images (default 70% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE)
- `--allowed-docker-storage-volume-usage-margin`

  During cleanup of least recently used local backend (Docker or Buildah) images werf would delete images until volume usage becomes below "allowed-backend-storage-volume-usage - allowed-backend-storage-volume-usage-margin" level (default 5% or $WERF_ALLOWED_DOCKER_STORAGE_VOLUME_USAGE_MARGIN)
- `--allowed-local-cache-volume-usage`

  Set allowed percentage or absolute value (e.g. 10GB) of local cache (~/.werf/local_cache by default) volume usage which will cause cleanup of least recently used data from the local cache (default 70% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE)
- `--allowed-local-cache-volume-usage-margin`

  During cleanup of local cache werf would delete local cache data until volume usage becomes below "allowed-local-cache-volume-usage - allowed-local-cache-volume-usage-margin" level (default 5% or $WERF_ALLOWED_LOCAL_CACHE_VOLUME_USAGE_MARGIN)
- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=...,

$WERF_CACHE_REPO_2=...)

- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--digest`

  Digest of the image to get SBOM for (mutually exclusive with --tag)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--disable-auto-host-cleanup`

  Disable auto host cleanup procedure in main werf commands like werf-build, werf-converge and other (default disabled or WERF_DISABLE_AUTO_HOST_CLEANUP)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo and to pull base images
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-repo`

  Container registry storage address (default $WERF_FINAL_REPO)
- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)

- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

  Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--kube-api-server`

  Kubernetes API server address (default $WERF_KUBE_API_SERVER)
- `--kube-auth-password`

  Basic auth password for Kubernetes API (default $WERF_KUBE_AUTH_PASSWORD)
- `--kube-auth-provider`

  Auth provider name for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER)
- `--kube-auth-provider-config`

  Auth provider config for authentication in Kubernetes API (default $WERF_KUBE_AUTH_PROVIDER_CONFIG)
- `--kube-auth-username`

  Basic auth username for Kubernetes API (default $WERF_KUBE_AUTH_USERNAME)
- `--kube-burst-limit`

  Kubernetes client burst limit (default $WERF_KUBE_BURST_LIMIT or 100)
- `--kube-ca-data`

  Pass Kubernetes API server TLS CA data (default $WERF_KUBE_CA_DATA)
- `--kube-ca-path`

  Kubernetes API server CA path (default $WERF_KUBE_CA_PATH)
- `--kube-cert`

  Path to PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT
- `--kube-cert-data`

  Pass PEM-encoded TLS client cert for connecting to Kubernetes API (default $WERF_KUBE_CERT_DATA)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kube-context-cluster`

  Use cluster from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_CLUSTER)
- `--kube-context-user`

  Use user from Kubeconfig for current context (default $WERF_KUBE_CONTEXT_USER)

- `--kube-impersonate-group`

  Sets Impersonate-Group headers when authenticating in Kubernetes. Can be also set with $WERF_KUBE_IMPERSONATE_GROUP_* environment variables
- `--kube-impersonate-uid`

  Sets Impersonate-Uid header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_UID)
- `--kube-impersonate-user`

  Sets Impersonate-User header when authenticating in Kubernetes (default $WERF_KUBE_IMPERSONATE_USER)
- `--kube-key`

  Path to PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY)
- `--kube-key-data`

  Pass PEM-encoded TLS client key for connecting to Kubernetes API (default $WERF_KUBE_KEY_DATA)
- `--kube-proxy-url`

  Proxy URL to use for proxying all requests to Kubernetes API (default $WERF_KUBE_PROXY_URL)
- `--kube-qps-limit`

  Kubernetes client QPS limit (default $WERF_KUBE_QPS_LIMIT or 30)
- `--kube-request-timeout`

  Timeout for all requests to Kubernetes API (default $WERF_KUBE_REQUEST_TIMEOUT)
- `--kube-tls-server`

  Server name to use for Kubernetes API server certificate validation. If it is not provided, the hostname used to contact the server is used (default $WERF_KUBE_TLS_SERVER)
- `--kube-token`

  Kubernetes bearer token used for authentication (default $WERF_KUBE_TOKEN)
- `--kube-token-path`

  Path to file with bearer token for authentication in Kubernetes (default $WERF_KUBE_TOKEN_PATH)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

Set a specific project name (default $WERF_PROJECT_NAME)

- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-image-spec-stage`

  Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)
- `--skip-tls-verify-kube`

  Skip TLS certificate validation when accessing a Kubernetes cluster (default $WERF_SKIP_TLS_VERIFY_KUBE)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--ssh-key`

  Use only specific ssh key(s).
  Can be specified with $WERF_SSH_KEY_* (e.g. $WERF_SSH_KEY_REPO=~/.ssh/repo_rsa, $WERF_SSH_KEY_NODEJS=~/.ssh/nodejs_rsa).
  Defaults to $WERF_SSH_KEY_*, system ssh-agent or ~/.ssh/{id_rsa|id_dsa}
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tag`

  Content-based tag of the image to get SBOM for (mutually exclusive with --digest)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

- `--virtual-merge`

  Enable virtual/ephemeral merge commit mode when building current application state ($WERF_VIRTUAL_MERGE by default)

d8 delivery-kit sbom merge

Usage:

```
d8 delivery-kit sbom merge [options]
```

Merge per-image SBOMs into a product-level SBOM

Show more...

Merge per-image CycloneDX 1.6 SBOMs into a single product/module-level SBOM.

Takes a JSON mapping file (image name -> sha256 digest) as input, pulls per-image SBOMs from the container registry, and produces an aggregated SBOM with preserved dependency graphs.

Two ISPRAS-defined output formats are supported:
- "container": hierarchical — each image becomes a top-level container component with nested packages.
- "oss": flat — all packages from all images are merged into a deduplicated flat list.

GOST properties (attack_surface, security_function) are aggregated bottom-up using the "yes > indirect > no" precedence rule.

The flags --input, --ispras-format, --app-name, --app-version and --manufacturer are required. The merged SBOM is written to stdout unless --output is given.

Options

- `--app-name`

  Application/product name for the merged SBOM metadata
- `--app-version`

  Application/product version for the merged SBOM metadata
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)

  Command needs granted permissions to pull SBOM artifacts from the specified repo
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--input`

  Path to JSON mapping file (image name -> sha256:digest)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--ispras-format`

  ISPRAS SBOM format: "oss" or "container"
- `--log-color-mode`

  Set log color mode.

  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.

  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.

  Defaults to:

  * $WERF_LOG_TERMINAL_WIDTH

  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--manufacturer`

  Manufacturer name for the merged SBOM metadata
- `--output`, `-o`

  Output file path (defaults to stdout)
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.

  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.

  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit sbom validate

Usage:

```
d8 delivery-kit sbom validate [options]
```

Validate SBOM file against ISPRAS schemas

Show more...

Validate CycloneDX JSON SBOM files against ISPRAS schemas using sbom-checker.

The command runs sbom-checker inside a Docker container and reports validation results. Supports both OSS and container SBOM types.

The flags --path and --ispras-format are required. Repeat --path to validate several files in one run. Pass --check-vcs to additionally validate VCS URLs.

Options

- `--check-vcs`

  Enable VCS URL validation
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to pull the ISPRAS SBOM checker image
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--ispras-format`

  ISPRAS SBOM format: oss or container
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--path`

  Path to CycloneDX JSON SBOM file (repeatable)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit slugify

Usage:

```
d8 delivery-kit slugify STRING [options]
```

Print slugged string by specified format.

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).

- `--format`, `-f`

  r|helm-release: suitable for Helm Release
  ns|kubernetes-namespace: suitable for Kubernetes Namespace
  tag|docker-tag: suitable for Docker Tag
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit stages

Usage:

```
d8 delivery-kit stages [options]
```

Work with werf stages

d8 delivery-kit stages copy

Usage:

```
d8 delivery-kit stages copy [options]
```

Copy stages between container registry and archive

Show more...

Copy project stages between storages.

Supported copy scenarios:
• Container registry to container registry
• Container registry to archive
• Archive to container registry

By default copies all project stages. Use --all=false to copy only stages relevant for the current git commit. This requires a working directory with git repository and performs build to identify current stages.

Note: this flag is ignored when copying from archive to container registry.

Options

- `--all`

  Copy all project stages (default: true). Use --all=false to copy stages for current build only. Note: this flag is ignored when copying from archive to container registry.
- `--allow-includes-update`

Allow use includes latest versions (default $WERF_ALLOW_INCLUDES_UPDATE or false)

- `--backend-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_BACKEND_STORAGE_PATH)
- `--build-report-operations`

  Collect low-level operations statistics: add Operations and StageCache sections to the build report and print operations summary after the build (by default $WERF_BUILD_REPORT_OPERATIONS or false). Also enabled by --log-debug
- `--build-report-path`

  Change build report path and format (by default $WERF_BUILD_REPORT_PATH or ".werf-build-report.json" if not set). Extension must be either .json for JSON format or .env for env-file format. If extension not specified, then .json is used
- `--cache-repo`

  Specify one or multiple cache repos with images that will be used as a cache. Cache will be populated when pushing newly built images into the primary repo and when pulling existing images from the primary repo. Cache repo will be used to pull images and to get manifests before making requests to the primary repo. Also, can be specified with $WERF_CACHE_REPO_* (e.g. $WERF_CACHE_REPO_1=..., $WERF_CACHE_REPO_2=...)
- `--config`

  Use custom configuration file (default $WERF_CONFIG or werf.yaml in the project directory)
- `--config-render-path`

  Custom path for storing rendered configuration file
- `--config-templates-dir`

  Custom configuration templates directory (default $WERF_CONFIG_TEMPLATES_DIR or .werf in working directory)
- `--container-registry-mirror`

  (Buildah-only) Use specified mirrors for docker.io
- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--debug-templates`

  Enable debug mode for Go templates (default $WERF_DEBUG_TEMPLATES or false)
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--dir`

  Use specified project directory where project’s werf.yaml and other configuration files should reside (default $WERF_DIR or current working directory)
- `--docker-config`

  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repos
- `--docker-server-storage-path`

  Use specified path to the local backend (Docker or Buildah) storage to check backend storage volume usage while performing garbage collection of local backend images (detect local backend storage path by default or use $WERF_DOCKER_SERVER_STORAGE_PATH)
- `--env`

  Use specified environment (default $WERF_ENV)
- `--final-images-only`

  Process final images only ($WERF_FINAL_IMAGES_ONLY or false by default)
- `--final-repo`

Container registry storage address (default $WERF_FINAL_REPO)

- `--final-repo-container-registry`

  Choose final-repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_FINAL_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--final-repo-docker-hub-password`

  final-repo Docker Hub password (default $WERF_FINAL_REPO_DOCKER_HUB_PASSWORD)
- `--final-repo-docker-hub-token`

  final-repo Docker Hub token (default $WERF_FINAL_REPO_DOCKER_HUB_TOKEN)
- `--final-repo-docker-hub-username`

  final-repo Docker Hub username (default $WERF_FINAL_REPO_DOCKER_HUB_USERNAME)
- `--final-repo-github-token`

  final-repo GitHub token (default $WERF_FINAL_REPO_GITHUB_TOKEN)
- `--final-repo-harbor-password`

  final-repo Harbor password (default $WERF_FINAL_REPO_HARBOR_PASSWORD)
- `--final-repo-harbor-username`

  final-repo Harbor username (default $WERF_FINAL_REPO_HARBOR_USERNAME)
- `--final-repo-quay-token`

  final-repo quay.io token (default $WERF_FINAL_REPO_QUAY_TOKEN)
- `--from`

  Source address to copy stages from. Use archive:PATH for stage archive or [docker://]REPO for container registry.
- `--git-work-tree`

  Use specified git work tree dir (default $WERF_WORK_TREE or lookup for directory that contains .git in the current or parent directories)
- `--giterminism-config`

  Custom path to the giterminism configuration file relative to working directory (default $WERF_GITERMINISM_CONFIG or werf-giterminism.yaml in working directory)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--insecure-registry`

  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--introspect-before-error`

  Introspect failed stage in the clean state, before running all assembly instructions of the stage
- `--introspect-error`

  Introspect failed stage in the state, right after running failed assembly instruction
- `--introspect-stage`

  Introspect a specific stage. The option can be used multiple times to introspect several stages.

  There are the following formats to use:
  * specify IMAGE_NAME/STAGE_NAME to introspect stage STAGE_NAME of either image or artifact IMAGE_NAME
  * specify STAGE_NAME or */STAGE_NAME for the introspection of all existing stages with name STAGE_NAME

  IMAGE_NAME is the name of an image or artifact described in werf.yaml, the nameless image specified with ~.
  STAGE_NAME should be one of the following: from, beforeInstall, dependenciesBeforeInstall, gitArchive, install, dependenciesAfterInstall, beforeSetup, dependenciesBeforeSetup, setup, dependenciesAfterSetup, gitCache, gitLatestPatch, dockerInstructions, dockerfile, imageSpec
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).

- `--log-project-dir`

  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--parallel`, `-p`

  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`

  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--platform`

  Enable platform emulation when building images with werf, format: OS/ARCH[/VARIANT] ($WERF_PLATFORM or $DOCKER_DEFAULT_PLATFORM by default)
- `--project-name`, `-N`

  Set a specific project name (default $WERF_PROJECT_NAME)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--repo`

  Container registry storage address (default $WERF_REPO)
- `--repo-container-registry`

  Choose repo container registry implementation.
  The following container registries are supported: ecr, acr, default, dockerhub, gcr, github, gitlab, harbor, quay.
  Default $WERF_REPO_CONTAINER_REGISTRY or auto mode (detect container registry by repo address).
- `--repo-docker-hub-password`

  repo Docker Hub password (default $WERF_REPO_DOCKER_HUB_PASSWORD)
- `--repo-docker-hub-token`

  repo Docker Hub token (default $WERF_REPO_DOCKER_HUB_TOKEN)
- `--repo-docker-hub-username`

  repo Docker Hub username (default $WERF_REPO_DOCKER_HUB_USERNAME)
- `--repo-github-token`

  repo GitHub token (default $WERF_REPO_GITHUB_TOKEN)
- `--repo-harbor-password`

  repo Harbor password (default $WERF_REPO_HARBOR_PASSWORD)
- `--repo-harbor-username`

  repo Harbor username (default $WERF_REPO_HARBOR_USERNAME)
- `--repo-quay-token`

  repo quay.io token (default $WERF_REPO_QUAY_TOKEN)
- `--save-build-report`

  Save build report (by default $WERF_SAVE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--secondary-repo`

  Specify one or multiple secondary read-only repos with images that will be used as a cache.
  Also, can be specified with $WERF_SECONDARY_REPO_* (e.g. $WERF_SECONDARY_REPO_1=..., $WERF_SECONDARY_REPO_2=...)
- `--skip-image-spec-stage`

Force skipping "imageSpec" build stage (default $WERF_SKIP_IMAGE_SPEC_STAGE or false)

- `--skip-tls-verify-registry`

  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--synchronization`, `-S`

  Address of synchronizer for multiple werf processes to work with a single repo.

  Default:
  - $WERF_SYNCHRONIZATION, or
  - :local if --repo is not specified, or
  - https://delivery-sync.deckhouse.ru if --repo has been specified.

  The same address should be specified for all werf processes that work with a single repo. :local address allows execution of werf processes from a single host only
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--to`

  Destination address to copy stages to. Use archive:PATH for stage archive or [docker://]REPO for container registry.
- `--use-build-report`

  Use build report, previously saved with --save-build-report (by default $WERF_USE_BUILD_REPORT or false). Its path and format configured with --build-report-path
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit synchronization

Usage:

```
d8 delivery-kit synchronization [options]
```

Run synchronization server

Show more...

Run synchronization server

Options

- `--debug`

  Enable debug (default $WERF_DEBUG).
- `--dev`

  Enable development mode (default $WERF_DEV).
  The mode allows working with project files without doing redundant commits during debugging and development
- `--dev-branch`

  Set dev git branch name (default $WERF_DEV_BRANCH or "_werf-dev")
- `--dev-ignore`

  Add rules to ignore tracked and untracked changes in development mode (can specify multiple).
  Also, can be specified with $WERF_DEV_IGNORE_* (e.g. $WERF_DEV_IGNORE_TESTS=*_test.go, $WERF_DEV_IGNORE_DOCS=path/to/docs)
- `--home-dir`

  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--host`

  Bind synchronization server to the specified host (default localhost or $WERF_HOST)
- `--kube-config`

  Kubernetes config file path (default $WERF_KUBE_CONFIG, or $WERF_KUBECONFIG, or $KUBECONFIG)
- `--kube-config-base64`

  Kubernetes config data as base64 string (default $WERF_KUBE_CONFIG_BASE64 or $WERF_KUBECONFIG_BASE64 or $KUBECONFIG_BASE64)
- `--kube-context`

  Kubernetes config context (default $WERF_KUBE_CONTEXT)
- `--kubernetes`

Use kubernetes lock-manager stages-storage-cache (default $WERF_KUBERNETES)

- `--kubernetes-namespace-prefix`

  Use specified prefix for namespaces created for lock-manager and stages-storage-cache (defaults to 'werf-synchronization-' when --kubernetes option is used or $WERF_KUBERNETES_NAMESPACE_PREFIX)
- `--local`

  Use file lock-manager and file stages-storage-cache (true by default or $WERF_LOCAL)
- `--local-lock-manager-base-dir`

  Use specified directory as base for file lock-manager (~/.werf/synchronization_server/lock_manager by default or $WERF_LOCAL_LOCK_MANAGER_BASE_DIR)
- `--local-stages-storage-cache-base-dir`

  Use specified directory as base for file stages-storage-cache (~/.werf/synchronization_server/stages_storage_cache by default or $WERF_LOCAL_STAGES_STORAGE_CACHE_BASE_DIR)
- `--log-color-mode`

  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`

  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`

  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-quiet`

  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`

  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`

  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`

  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`

  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--loose-giterminism`

  Loose werf giterminism mode restrictions
- `--port`

  Bind synchronization server to the specified port (default 55581 or $WERF_PORT)
- `--quiet`

  Disable explanatory output (default $WERF_QUIET).
- `--tmp-dir`

  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--ttl`

  Time to live for lock-manager locks and stages-storage-cache records (default $WERF_TTL)
- `--verbose`

  Enable verbose output (default $WERF_VERBOSE).

d8 delivery-kit verify

Usage:

```
d8 delivery-kit verify --image-ref <image-ref> [--image-ref <image-ref>...] --verify-roots=<root-ca.pem> [--verify-manifest] [--verify-elf-files] [options]
```

Verify images

Show more...

Verify the integrity of built images by checking signatures of manifests and ELF files using specific image references.

The command outputs detailed logs about the verification process.

Options

- `--container-registry-mirror`
  (Buildah-only) Use specified mirrors for docker.io
- `--debug`
  Enable debug (default $WERF_DEBUG).
- `--docker-config`
  Specify docker config directory path. Default $WERF_DOCKER_CONFIG or $DOCKER_CONFIG or ~/.docker (in the order of priority)
  Command needs granted permissions to read, pull and push images into the specified repo, to pull base images
- `--home-dir`
  Use specified dir to store werf cache files and dirs (default $WERF_HOME or ~/.werf)
- `--image-ref`
  Verify only passed references (default $WERF_IMAGE_REF separated by comma)
- `--insecure-registry`
  Use plain HTTP requests when accessing a registry (default $WERF_INSECURE_REGISTRY)
- `--log-color-mode`
  Set log color mode.
  Supported on, off and auto (based on the stdout’s file descriptor referring to a terminal) modes.
  Default $WERF_LOG_COLOR_MODE or auto mode.
- `--log-debug`
  Enable debug (default $WERF_LOG_DEBUG).
- `--log-pretty`
  Enable emojis, auto line wrapping and log process border (default $WERF_LOG_PRETTY or true).
- `--log-project-dir`
  Print current project directory path (default $WERF_LOG_PROJECT_DIR)
- `--log-quiet`
  Disable explanatory output (default $WERF_LOG_QUIET).
- `--log-terminal-width`
  Set log terminal width.
  Defaults to:
  * $WERF_LOG_TERMINAL_WIDTH
  * interactive terminal width or 140
- `--log-time`
  Add time to log entries for precise event time tracking (default $WERF_LOG_TIME or false).
- `--log-time-format`
  Specify custom log time format (default $WERF_LOG_TIME_FORMAT or RFC3339 format).
- `--log-verbose`
  Enable verbose output (default $WERF_LOG_VERBOSE).
- `--parallel, -p`
  Run in parallel (default $WERF_PARALLEL or true)
- `--parallel-tasks-limit`
  Parallel tasks limit, set -1 to remove the limitation (default $WERF_PARALLEL_TASKS_LIMIT or 5)
- `--quiet`
  Disable explanatory output (default $WERF_QUIET).
- `--skip-tls-verify-registry`
  Skip TLS certificate validation when accessing a registry (default $WERF_SKIP_TLS_VERIFY_REGISTRY)
- `--tmp-dir`
  Use specified dir to store tmp files and dirs (default $WERF_TMP_DIR or system tmp dir)
- `--verbose`
  Enable verbose output (default $WERF_VERBOSE).
- `--verify-bsign-elf-files`
  Enable ELF files verification for bsign signed files (default $WERF_VERIFY_BSIGN_ELF_FILES).
- `--verify-elf-files`
  Enable ELF files verification (default $WERF_VERIFY_ELF_FILES).
  When enabled, the root certificates must be specified with --verify-roots option
- `--verify-manifest`
  Enable image manifest verification (default $WERF_VERIFY_MANIFEST).

When enabled,
the root certificates must be specified with --verify-roots option

- `--verify-roots`

  The root certificates as path to PEM file or base64-encoded PEM (default $WERF_VERIFY_ROOTS separated by comma)

d8 delivery-kit version

Usage:

```
d8 delivery-kit version [options]
```

Print version

d8 dist

Manage the d8 distribution: the deckhouse-cli binary and its plugins

Show more...

Manage the d8 distribution - the deckhouse-cli binary and its plugins.

See the state of the distribution with 'd8 dist status': the d8 version, installed
plugins, and what is outdated.

Versions are served by the in-cluster registry-packages-proxy, authenticated by the
current kubeconfig identity.

Update the binary with 'd8 dist update'; manage plugins under 'd8 dist plugins'.

Environment variables:
D8_RPP_ENDPOINT registry-packages-proxy base URL (otherwise discovered from the cluster)
D8_RPP_CA_FILE PEM CA bundle to verify the proxy TLS certificate
KUBECONFIG path to the kubeconfig file

Options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 dist check

Usage:

```
d8 dist check [options]
```

Report whether a newer deckhouse-cli version is available

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.

- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 dist plugins

Usage:

```
d8 dist plugins [options]
```

Manage Deckhouse CLI plugins

Show more...

Manage Deckhouse CLI plugins.

Plugins are pulled from the in-cluster registry-packages-proxy, authenticated by the
current kubeconfig identity.

Installing a plugin that is already present updates it: 'd8 dist plugins install <name>',
or 'd8 dist plugins install --all' for every installed plugin at once.

Environment variables:
  D8_PLUGINS_SKIP_CLUSTER_CHECKS=1 skip cluster-side plugin requirement checks
  DECKHOUSE_CLI_PATH   plugins directory (same as --plugins-dir)
  D8_RPP_ENDPOINT   registry-packages-proxy base URL
  D8_RPP_CA_FILE   PEM CA bundle for proxy TLS verification
  KUBECONFIG   path to the kubeconfig file

Options

- `--insecure`

  Interact with the source registry over HTTP.
- `--license`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.
- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--rpp-ca-file`

Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.

- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 dist plugins contract

Usage:

```
d8 dist plugins contract <plugin-name> [options]
```

Show a plugin's contract

Show more...

Show the latest published contract of a plugin: version, description and requirements.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure`

  Interact with the source registry over HTTP.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--license`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.
- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

d8 dist plugins install

Usage:

```
d8 dist plugins install <plugin-name> | --all [options]
```

Install or update Deckhouse CLI plugins

Show more...

Install a plugin: the newest version compatible with this cluster by default,

an exact one with --version.

Installing a plugin that is already present updates it, so this is also how a
plugin is brought up to date; --all does that for every installed plugin at once,
each within its own current major.

Plugins this one depends on are installed/upgraded automatically. With --use-major
dependencies may also cross their own major to satisfy a constraint.

A version already on disk is activated by repointing the 'current' symlink -
no download. Plugin requirements are always checked before the switch.

Options

- `--all`

  Update every installed plugin instead of naming one, each within its own current major.
- `--force`

  Reinstall even if the selected version is already installed (re-pull + re-verify).
- `--use-major`

  Pin to a specific major version. By default an install stays within the installed plugin's major; pass this to cross majors (dependencies may cross theirs too).
- `--version`

  Exact version to install. Skips compatibility selection and may install a pre-release.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure`

  Interact with the source registry over HTTP.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--license`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.
- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

d8 dist plugins list

Usage:

```
d8 dist plugins list [options]
```

List Deckhouse CLI plugins

Show more...

Show the plugins installed locally and, when the transport can enumerate them, the plugins published in the registry and ready to install.

The published set is read from the tags of the plugins repository, where each plugin has an image tagged with its name. Only direct registry access (--source) reaches that repository: the registry-packages-proxy addresses plugins by exact name and does not serve the plugins path, so over the proxy this half is reported as unsupported rather than attempted.

Whatever cannot be resolved is reported in place rather than dropped: a plugin whose versions cannot be read is still listed by name, and an unreachable registry leaves the installed list intact.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure`

  Interact with the source registry over HTTP.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--license`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.
- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

d8 dist plugins remove

Aliases: `uninstall`, `delete`

Usage:

```
d8 dist plugins remove <plugin-name> [options]
```

Remove an installed plugin

Show more...

Remove an installed plugin from disk.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure`

  Interact with the source registry over HTTP.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--license`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.
- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

d8 dist plugins remove all

Usage:

```
d8 dist plugins remove <plugin-name> all [options]
```

Remove all installed plugins

Show more...

Remove all plugins from the Deckhouse CLI at once

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure`

  Interact with the source registry over HTTP.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--license`

Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.

- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

d8 dist plugins versions

Usage:

```
d8 dist plugins versions <plugin-name> [options]
```

List all versions of a plugin

Show more...

List all published versions of a plugin, newest first. The installed version is marked, versions newer than it are highlighted.

A plugin is published one image per platform, so a release reaches the registry as several tags. They are collapsed into one line per version, listing the platforms that version was built for.

Versions are fetched by the plugin's name through the registry-packages-proxy, so no catalog access is needed. Install a specific version with 'd8 dist plugins install <name> --version X' - a version already on disk is switched to instantly, without a download.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure`

  Interact with the source registry over HTTP.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--license`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=. Defaults to $D8_MIRROR_LICENSE_TOKEN.
- `--plugins-dir`

  Path to the d8 plugins directory. Defaults to $DECKHOUSE_CLI_PATH.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.

- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.
- `--skip-cluster-checks`

  Skip enforcement of cluster-side plugin requirements (Kubernetes/Deckhouse/module versions) when the cluster is unreachable. Defaults to $D8_PLUGINS_SKIP_CLUSTER_CHECKS.
- `--source`

  Pull plugins directly from this registry repo instead of the registry-packages-proxy (bypasses the cluster).
- `--source-login`

  Source registry login. Defaults to $D8_MIRROR_SOURCE_LOGIN.
- `--source-password`

  Source registry password. Defaults to $D8_MIRROR_SOURCE_PASSWORD.
- `--tls-skip-verify`

  Disable TLS certificate validation for the source registry.

d8 dist status

Usage:

```
d8 dist status [options]
```

Show the distribution status: the d8 version, plugins, what is outdated

Show more...

Show the state of the d8 distribution: the running deckhouse-cli version and the
installed plugins, with update status from the registry-packages-proxy.

When the cluster is unreachable, prints the local data and a warning instead of failing.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 dist update

Usage:

```
d8 dist update [options]
```

Update deckhouse-cli to the latest version

Options

- `--version`

  Exact version to install; downgrades are allowed (default: the latest).

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.

- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 dist use

Usage:

```
d8 dist use <version> [options]
```

Switch to a specific deckhouse-cli version (no download when it is installed locally)

Show more...

Switch the d8 binary to the given version.

Versions live in the local store (~/.deckhouse-cli/cli/versions) and the active one is
selected by the store's 'current' symlink - the same layout plugins use. Switching to an
installed version repoints that symlink: instant, offline, no elevated privileges.
A version missing from the store is downloaded through the registry-packages-proxy first
(kubeconfig required) and stays installed afterwards.

The first switch migrates a plain-file install to the symlink layout; the original binary
is kept with a ".old" suffix.

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 dist versions

Alias: `list`

Usage:

```
d8 dist versions [options]
```

List deckhouse-cli versions available in the cluster registry

Global options

- `--context`

  Kubeconfig context to use. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements.
- `--insecure-skip-tls-verify`

  Skip TLS verification of both the Kubernetes API server and registry-packages-proxy certificates. For

debugging only.
- `--kubeconfig`, `-k`

  Path to the kubeconfig file. Used to reach registry-packages-proxy and to enforce cluster-side plugin requirements. Defaults to $KUBECONFIG.
- `--rpp-ca-file`

  Path to a PEM CA bundle used to verify the registry-packages-proxy TLS certificate. Defaults to $D8_RPP_CA_FILE.
- `--rpp-endpoint`

  registry-packages-proxy base URL (e.g. https://master:4219). Discovered from the cluster when empty. Defaults to $D8_RPP_ENDPOINT.

d8 help

Help about any command

Show more...

Help provides help for any command in the application.
Simply type d8 help [path to command] for full details.

d8 iam

Manage Deckhouse users, groups, and access grants

Show more...

Manage Deckhouse identity and access: users, groups, and access grants.

Subcommands: user — local users (user-authn Dex): create/delete/reset-password/ reset2fa/lock/unlock. group — local groups: create/delete and add-member/remove-member. access — grant and revoke (current authz model). get — show one user/group/rule with effective access and warnings. list — list users/groups/rules with effective access.

All subcommands accept the standard --kubeconfig / --context flags.

© Flant JSC 2026

d8 iam access

Usage:

```
d8 iam access [options]
```

Grant or revoke access (current authz model)

Show more...

Grant and revoke access in Deckhouse (current authz model).

For inspecting existing rules and effective access (warnings, group cycles, manual rules), use the top-level "d8 iam get" / "d8 iam list".

© Flant JSC 2026

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam access grant

Usage:

```
d8 iam access grant (user|group) NAME --access-level LEVEL [scope] [options]
```

Grant access to a user or group (current authz model)

Show more...

Grant access to a user or group using the current authorization model.

For users, the subject is resolved by reading User.spec.email from the cluster, because the current authz model requires email as the subject name when user-authn is used.

Specify the scope via -n/--namespace OR --scope (mutually exclusive):

-n/--namespace NS AuthorizationRule per namespace. Repeat to target several namespaces. User, PrivilegedUser, Editor, Admin levels only. --scope cluster ClusterAuthorizationRule, every namespace EXCEPT system ones (d8-*, kube-system). --scope all-namespaces ClusterAuthorizationRule with matchAny: true. Covers ALL namespaces, including system ones. --scope labels=K=V[,...] ClusterAuthorizationRule with namespaceSelector.labelSelector.matchLabels.

--allow-scale and --port-forwarding add capabilities to any scope.

© Flant JSC 2026

Options

- `--access-level`

  Access level: User, PrivilegedUser, Editor, Admin, ClusterEditor, ClusterAdmin, SuperAdmin
- `--allow-scale`

  Allow scaling workloads
- `--dry-run`

  Print the resource(s) that would be created without applying
- `--namespace`, `-n`

  Target namespace(s) for namespaced grants (repeatable). Mutually exclusive with --scope
- `--output`, `-o`

  Output format: name|yaml|json
- `--port-forwarding`

  Allow port-forwarding
- `--scope`

  Cluster-wide scope: cluster | all-namespaces | labels=K=V[,K2=V2,...]. Mutually exclusive with -n/--namespace

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam access revoke

Usage:

```
d8 iam access revoke (user|group) NAME --access-level LEVEL [scope] [options]
```

Revoke a d8-managed access grant

Show more...

Revoke access previously granted with "d8 iam access grant".

The flags must match the original grant's scope/level — the d8-managed object name is derived from the canonical spec, so a mismatch yields a "not found" error rather than removing an unrelated rule.

Only d8-managed objects (label app.kubernetes.io/managed-by=d8-cli) are affected. Manually maintained AuthorizationRules and ClusterAuthorizationRules are never touched; edit them with kubectl.

© Flant JSC 2026

Options

- `--access-level`

  Access level to revoke
- `--allow-scale`

  Match grants with allow-scale enabled
- `--dry-run`

  Resolve and print the object(s) that would be deleted without touching the cluster
- `--namespace`, `-n`

Target namespace(s). Mutually exclusive with --scope

- `--output`, `-o`

  Output format: name|yaml|json
- `--port-forwarding`

  Match grants with port-forwarding enabled
- `--scope`

  Cluster-wide scope: cluster | all-namespaces | labels=K=V[,K2=V2,...]. Mutually exclusive with -n/--namespace

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam get

Usage:

```
d8 iam get (user|group|rule) NAME [options]
```

Show a single Deckhouse IAM object

Show more...

Show a single Deckhouse IAM object with its effective context.

Subcommands: user<name> show effective access for a user (groups, grants, summary) group<name> show effective access for a group (members, grants, summary) rule REF show one ClusterAuthorizationRule or AuthorizationRule

Aliases users / groups / rules are accepted for symmetry with "d8 iam list".

© Flant JSC 2026

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam get group

Alias: `groups`

Usage:

```
d8 iam get (user|group|rule) NAME group <name> [options]
```

Show detailed access for a specific group

Options

- `--output`, `-o`

  Output format: table|json|yaml

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam get rule

Alias: `rules`

Usage:

```
d8 iam get (user|group|rule) NAME rule REF [options]
```

Show a single CAR or AR with subjects, scope and reverse CR lookup

Options

- `--output`, `-o`

  Output format: text|json|yaml

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam get user

Alias: `users`

Usage:

```
d8 iam get (user|group|rule) NAME user <name> [options]
```

Show detailed access for a specific user

Options

- `--output`, `-o`

  Output format: table|json|yaml

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam group

Alias: `groups`

Usage:

```
d8 iam group [options]
```

Manage Deckhouse local groups (user-authn)

Show more...

Manage Deckhouse local groups (user-authn).

This command provides lifecycle operations for local Group CRs: Create, Delete, and membership management via add-member / remove-member.

For viewing groups (single or list with effective access), use the top-level commands:

d8 iam get group <name>
d8 iam list groups

© Flant JSC 2026

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam group add-member

Usage:

```
d8 iam group add-member GROUP [user|group] MEMBER [options]
```

Add a member (user or group) to a local group

Options

- `--create-group`
  Create the target group if it does not exist

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam group create

Usage:

```
d8 iam group create <name> [options]
```

Create a local group in Deckhouse

Options

- `--dry-run`
  Print the resource that would be created without applying
- `--output`, `-o`
  Output format: name|yaml|json

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam group delete

Usage:

```
d8 iam group delete <name> [options]
```

Delete a local group

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam group remove-member

Usage:

```
d8 iam group remove-member GROUP [user|group] MEMBER [options]
```

Remove a member (user or group) from a local group

Global options

- `--context`

The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam list

Usage:

```
d8 iam list (users|groups|rules) [options]
```

List Deckhouse IAM objects

Show more...

List Deckhouse IAM objects with their effective context.

Subcommands: users list every user with effective-access summary (groups, grants count, level) groups list every group with effective-access summary (members, grants count, level) rules list every ClusterAuthorizationRule and AuthorizationRule

Aliases user / group / rule are accepted so both forms work as muscle memory.

© Flant JSC 2026

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam list groups

Alias: `group`

Usage:

```
d8 iam list (users|groups|rules) groups [options]
```

List all groups with their effective access

Options

- `--output`, `-o`

  Output format: table|json

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam list rules

Alias: `rule`

Usage:

```
d8 iam list (users|groups|rules) rules [options]
```

List ClusterAuthorizationRules and AuthorizationRules

Options

- `--cluster`

  Only ClusterAuthorizationRules
- `--managed-only`

  Only rules managed by d8-cli (label app.kubernetes.io/managed-by=d8-cli)

- `--manual-only`

  Only rules NOT managed by d8-cli
- `--namespace`, `-n`

  Restrict to AuthorizationRules in these namespaces (repeatable). Implicitly disables CARs unless --cluster is also set.
- `--output`, `-o`

  Output format: table|json|yaml

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam list users

Alias: `user`

Usage:

```
d8 iam list (users|groups|rules) users [options]
```

List all users with their effective access

Options

- `--output`, `-o`

  Output format: table|json

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user

Alias: `userop`

Usage:

```
d8 iam user [options]
```

Manage Deckhouse users (user-authn)

Show more...

Manage Deckhouse local static users (user-authn).

This command provides lifecycle operations for Dex local users: Create, Delete, ResetPassword, Reset2FA, Lock, Unlock.

For viewing users (single or list with effective access), use the top-level commands:

d8 iam get user <name>
d8 iam list users

© Flant JSC 2026

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user create

Usage:

```
d8 iam user create <name> --email <email> [flags] [options]
```

Create a local static user in Deckhouse

Show more...

Create a local static user in Deckhouse (User CR).

The password can be provided interactively (--password-prompt), piped from stdin (--password-stdin), auto-generated (--generate-password), or supplied as a pre-computed bcrypt hash (--password-hash). If no password flag is given and stdin is a terminal, the command prompts interactively.

When --generate-password is used, the password is shown exactly once on stderr.

If the cluster has a password policy enabled, the user may be required to change the password on first login. If staticUsers2FA is enabled, the user will also need to enroll TOTP on first login.

© Flant JSC 2026

Options

- `--create-groups`

  Create groups specified by --member-of if they do not exist
- `--dry-run`

  Print the resource that would be created without applying
- `--email`

  User email address (required, must be lowercase)
- `--generate-password`

  Auto-generate a strong password (shown once on stderr)
- `--member-of`

  Add user to these groups (repeatable)
- `--output`, `-o`

  Output format: name|yaml|json
- `--password-hash`

  Use a pre-computed bcrypt hash directly (must start with $2 and be a valid bcrypt cost)
- `--password-prompt`

  Read password interactively with hidden input
- `--password-stdin`

  Read password from stdin (for CI/pipelines)
- `--ttl`

  User time-to-live (e.g. 24h, 30m). Can only be set once; expireAt will not update on change.

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user delete

Usage:

```
d8 iam user delete <name> [options]
```

Delete a local static user

Show more...

Delete a local static user from Deckhouse.

The User CR is removed and, by default, the user is also removed from every local Group CR that lists them under spec.members. Pass --keep-memberships to leave the membership references in place (e.g. for audit retention or to re-create the user with the same memberships later).

© Flant JSC 2026

Options

- `--keep-memberships`

  Do not remove the user from local Group spec.members; only delete the User CR

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user lock

Usage:

```
d8 iam user lock <username> <lockDuration> [options]
```

Lock local user in Dex for a period of time

Show more...

Lock local user in Dex for a period of time.

The lockDuration argument must be a duration string (e.g. 30s, 10m, 1h).

Options

- `--timeout`

  How long to wait for completion when --wait is enabled.
- `--wait`

  Wait for UserOperation completion and print result.

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user reset-password

Alias: `resetpass`

Usage:

```
d8 iam user reset-password <username> [options]
```

Reset local user's password in Dex

Show more...

Reset a local static user's password in Dex.

The new password is read from one of:

--password-prompt (default if stdin is a terminal) --password-stdin (echo "newpw" | d8 iam user reset-password ...) --generate-password (auto-generate, shown once on stderr) --password-hash STRING (pre-computed bcrypt hash, must start with $2)

This is the same flag layout as 'd8 iam user create', so muscle memory and shell autocompletion transfer between the two commands.

Internally a UserOperation of type ResetPassword is created with the raw bcrypt hash in spec.resetPassword.newPasswordHash. The user-authn hook validates the prefix and bcrypt.Cost, base64-encodes the hash, and applies it to the Dex Password CR. We never write the plaintext to the API.

© Flant JSC 2026

Options

- `--generate-password`

  Auto-generate a strong password (shown once on stderr)
- `--password-hash`

  Use a pre-computed bcrypt hash directly (must start with $2 and be a valid bcrypt cost)
- `--password-prompt`

  Read password interactively with hidden input
- `--password-stdin`

  Read password from stdin (for CI/pipelines)
- `--timeout`

  How long to wait for completion when --wait is enabled.
- `--wait`

  Wait for UserOperation completion and print result.

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user reset2fa

Usage:

```
d8 iam user reset2fa <username> [options]
```

Reset local user's 2FA (TOTP) in Dex

Show more...

Reset local user's 2FA (TOTP) in Dex.

This requests a UserOperation of type Reset2FA and waits for completion by default.

Options

- `--timeout`

  How long to wait for completion when --wait is enabled.
- `--wait`

  Wait for UserOperation completion and print result.

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 iam user unlock

Usage:

```
d8 iam user unlock <username> [options]
```

Unlock local user in Dex

Show more...

Unlock local user in Dex.

This requests a UserOperation of type Unlock and waits for completion by default.

Options

- `--timeout`

  How long to wait for completion when --wait is enabled.
- `--wait`

  Wait for UserOperation completion and print result.

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 k

Alias: `kubectl`

kubectl controls the Kubernetes cluster manager

Show more...

kubectl controls the Kubernetes cluster manager.

Find more information at: https://kubernetes.io/docs/reference/kubectl/

Options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`

Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k alpha

Usage:

```
d8 k alpha [options]
```

Commands for features in alpha

Show more...

These commands correspond to alpha features that are not enabled in Kubernetes clusters by default.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k alpha kuberc

Usage:

```
d8 k alpha kuberc SUBCOMMAND [options]
```

Manage kuberc configuration files

Show more...

Manage user preferences (kuberc) file.

The kuberc file allows you to customize your kubectl experience.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.

- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log

format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k alpha kuberc set

Usage:

```
d8 k alpha kuberc SUBCOMMAND set --section (defaults|aliases) --command COMMAND [options]
```

Set values in the kuberc configuration

Show more...

Set values in the kuberc configuration file.

Use --section to specify whether to set defaults or aliases.

For defaults: Sets default flag values for kubectl commands. The --command flag should specify only the command (e.g., "get", "create", "set env"), not resources.

For aliases: Creates command aliases with optional default flag values and arguments. Use --prependarg and --appendarg to include resources or other arguments.

Options

- `--appendarg`

  Argument to append to the command (can be specified multiple times, for aliases only)
- `--command`

  Command to configure (e.g., 'get', 'create', 'set env')
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--name`

  Alias name (required for --section=aliases)
- `--option`

  Flag option in the form flag=value (can be specified multiple times)
- `--overwrite`

  Allow overwriting existing entries
- `--prependarg`

  Argument to prepend to the command (can be specified multiple times, for aliases only)
- `--section`

  Section to modify: 'defaults' or 'aliases'

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use

- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k alpha kuberc view

Usage:

```
d8 k alpha kuberc SUBCOMMAND view [options]
```

Display the current kuberc configuration

Show more...

Display the contents of the kuberc file in the specified output format.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false

feature gate or turning off the feature KUBERC=off.

- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k annotate

Usage:

```
d8 k annotate [--overwrite] (-f FILENAME | TYPE NAME) KEY_1=VAL_1 ... KEY_N=VAL_N [--resource-version=version]
[options]
```

Update the annotations on a resource

Show more...

Update the annotations on one or more resources.

All Kubernetes objects support the ability to store additional data with the object as annotations. Annotations are key/value pairs that can be larger than labels and include arbitrary string values such as structured JSON. Tools and system extensions may use annotations to store their own data.

Attempting to set an annotation that already exists will fail unless --overwrite is set. If --resource-version is specified and does not match the current resource version on the server the command will fail.

Use "kubectl api-resources" for a complete list of supported resources.

Options

- `--all`

  Select all resources, in the namespace of the specified resource types.
- `--all-namespaces`, `-A`

  If true, check the specified action in all namespaces.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--field-selector`

  Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to update the annotation
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--list`

  If true, display the annotations for a given resource.
- `--local`

  If true, annotation will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile,

jsonpath, jsonpath-as-json, jsonpath-file).

- `--overwrite`

  If true, allow annotations to be overwritten, otherwise reject annotation updates that overwrite existing annotations.
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--resource-version`

  If non-empty, the annotation update will only succeed if this is the current resource-version for the object. Only valid when specifying a single resource.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes

- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k api-resources

Usage:

```
d8 k api-resources [options]
```

Print the supported API resources on the server

Show more...

Print the supported API resources on the server.

Options

- `--api-group`

  Limit to resources in the specified API group.
- `--cached`

  Use the cached list of resources if available.
- `--categories`

  Limit to resources that belong to the specified categories.
- `--namespaced`

  If false, non-namespaced resources will be returned, otherwise returning namespaced resources by default.
- `--no-headers`

  When using the default or custom-column output format, don't print headers (default print headers).
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, wide).
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--sort-by`

  If non-empty, sort list of resources using specified field. The field can be either 'name' or 'kind'.

- `--verbs`

  Limit to resources that support the specified verbs.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server

- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k api-versions

Usage:

```
d8 k api-versions [options]
```

Print the supported API versions on the server, in the form of "group/version"

Show more...

Print the supported API versions on the server, in the form of "group/version".

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version

- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k apply

Usage:

```
d8 k apply (-f FILENAME | -k DIRECTORY) [options]
```

Apply a configuration to a resource by file name or stdin

Show more...

Apply a configuration to a resource by file name or stdin. The resource name must be specified. This resource will be created if it doesn't exist yet. To use 'apply', always create the resource initially with either 'apply' or 'create --save-config'.

JSON and YAML formats are accepted.

Alpha Disclaimer: the --prune functionality is not yet complete. Do not use unless you are aware of what the current state is. See https://issues.k8s.io/34274.

Options

- `--all`

  Select all resources in the namespace of the specified resource types.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--cascade`

  Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.

- `--filename`, `-f`

  The files that contain the configurations to apply.
- `--force`

  If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.
- `--force-conflicts`

  If true, server-side apply will force the changes against conflicts.
- `--grace-period`

  Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when --force is true (force deletion).
- `--kustomize`, `-k`

  Process a kustomization directory. This flag can't be used together with -f or -R.
- `--openapi-patch`

  If true, use openapi to calculate diff when the openapi presents and the resource can be found in the openapi spec. Otherwise, fall back to use baked-in types.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--overwrite`

  Automatically resolve conflicts between the modified and live configuration by using values from the modified configuration
- `--prune`

  Automatically delete resource objects, that do not appear in the configs and are created by either apply or create --save-config. Should be used with either -l or --all.
- `--prune-allowlist`

  Overwrite the default allowlist with for --prune
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--server-side`

  If true, apply runs in the server instead of the client.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--subresource`

  If specified, apply will operate on the subresource of the requested object. Only allowed when using --server-side.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--timeout`

  The length of time to wait before giving up on a delete, zero means determine a timeout from the size of the object
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--wait`

  If true, wait for resources to be gone before returning. This waits for finalizers.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

Username for basic authentication to the API server

- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k apply edit-last-applied

Usage:

```
d8 k apply (-f FILENAME | -k DIRECTORY) edit-last-applied (RESOURCE/NAME | -f FILENAME) [options]
```

Edit latest last-applied-configuration annotations of a resource/object

Show more...

Edit the latest last-applied-configuration annotations of resources from the default editor.

The edit-last-applied command allows you to directly edit any API resource you can retrieve via the command-line tools. It will open the editor defined by your KUBE_EDITOR, or EDITOR environment variables, or fall back to 'vi' for Linux or 'notepad' for Windows. You can edit multiple objects, although changes are applied one at a time. The command accepts file names as well as command-line arguments, although the files you point to must be previously saved versions of resources.

The default format is YAML. To edit in JSON, specify "-o json".

The flag --windows-line-endings can be used to force Windows line endings, otherwise the default for your operating system will be used.

In the event an error occurs while updating, a temporary file will be created on disk that contains your unapplied changes. The most common error when updating a resource is another editor changing the resource on the server. When this occurs, you will have to apply your changes to the newer version of the resource, or update your temporary saved copy to include the latest resource version.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files to use to edit the resource
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn

about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

- `--windows-line-endings`

  Defaults to the line ending native to your platform.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the

server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k apply set-last-applied

Usage:

```
d8 k apply (-f FILENAME | -k DIRECTORY) set-last-applied -f FILENAME [options]
```

Set the last-applied-configuration annotation on a live object to match the contents of a file

Show more...

Set the latest last-applied-configuration annotations by setting it to match the contents of a file. This results in the last-applied-configuration being updated as though 'kubectl apply -f<file> ' was run, without updating any other parts of the object.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--create-annotation`

  Will create 'last-applied-configuration' annotations if current objects doesn't have one
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--filename`, `-f`

  Filename, directory, or URL to files that contains the last-applied-configuration annotations
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory

- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k apply view-last-applied

Usage:

```
d8 k apply (-f FILENAME | -k DIRECTORY) view-last-applied (TYPE [NAME | -l label] | TYPE/NAME | -f FILENAME)
[options]
```

View the latest last-applied-configuration annotations of a resource/object

Show more...

View the latest last-applied-configuration annotations by type/name or file.

The default output will be printed to stdout in YAML format. You can use the -o option to change the output format.

Options

- `--all`

  Select all resources in the namespace of the specified resource types
- `--filename`, `-f`

  Filename, directory, or URL to files that contains the last-applied-configuration annotations
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. Must be one of (yaml, json)
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k attach

Usage:

```
d8 k attach (POD | TYPE/NAME) -c CONTAINER [options]
```

Attach to a running container

Show more...

Attach to a process that is already running inside an existing container.

Options

- `--container`, `-c`

  Container name. If omitted, use the kubectl.kubernetes.io/default-container annotation for selecting the container to be attached or the first container in the pod will be chosen
- `--pod-running-timeout`

  The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running
- `--quiet`, `-q`

  Only print output from the remote session
- `--stdin`, `-i`

  Pass stdin to the container
- `--tty`, `-t`

  Stdin is a TTY

Global options

- `--as`

Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k auth

Usage:

```
d8 k auth [options]
```

Inspect authorization

Show more...

Inspect authorization.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k auth can-i

Usage:

```
d8 k auth can-i VERB [TYPE | TYPE/NAME | NONRESOURCEURL] [options]
```

Check whether an action is allowed

Show more...

Check whether an action is allowed.

VERB is a logical Kubernetes API verb like 'get', 'list', 'watch', 'delete', etc. TYPE is a Kubernetes resource. Shortcuts and groups will be resolved. NONRESOURCEURL is a partial URL that starts with "/". NAME is the name of a particular Kubernetes resource. This command pairs nicely with impersonation. See --as global flag.

Options

- `--all-namespaces`, `-A`

  If true, check the specified action in all namespaces.
- `--list`

  If true, prints all allowed actions.
- `--no-headers`

  If true, prints allowed actions without headers
- `--quiet`, `-q`

  If true, suppress output and just return the exit code.
- `--subresource`

  SubResource such as pod/log or deployment/scale

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.

- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k auth reconcile

Usage:

```
d8 k auth reconcile -f FILENAME [options]
```

Reconciles rules for RBAC role, role binding, cluster role, and cluster role binding objects

Show more...

Reconciles rules for RBAC role, role binding, cluster role, and cluster role binding objects.

Missing objects are created, and the containing namespace is created for namespaced objects, if required.

Existing roles are updated to include the permissions in the input objects, and remove extra permissions if --remove-extra-permissions is specified.

Existing bindings are updated to include the subjects in the input objects, and remove extra subjects if --remove-extra-subjects is specified.

This is preferred to 'apply' for RBAC resources so that semantically-aware merging of rules and subjects is done.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to reconcile.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--remove-extra-permissions`

  If true, removes extra permissions added to roles
- `--remove-extra-subjects`

  If true, removes extra subjects added to rolebindings
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority

- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k auth whoami

Usage:

```
d8 k auth whoami [options]
```

Experimental: Check self subject attributes

Show more...

Experimental: Check who you are and your attributes (groups, extra).

This command is helpful to get yourself aware of the current user attributes,
especially when dynamic authentication, e.g., token webhook, auth proxy, or OIDC provider,
is enabled in the Kubernetes cluster.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request

- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k autoscale

Usage:

```
d8 k autoscale (-f FILENAME | TYPE NAME | TYPE/NAME) [--min=MINPODS] --max=MAXPODS [--cpu=CPU] [--memory=MEMORY]
[options]
```

Auto-scale a deployment, replica set, stateful set, or replication controller

Show more...

Creates an autoscaler that automatically chooses and sets the number of pods that run in a Kubernetes cluster. The command will attempt to use the autoscaling/v2 API first, in case of an error, it will fall back to autoscaling/v1 API.

Looks up a deployment, replica set, stateful set, or replication controller by name and creates an autoscaler that uses the given resource as a reference. An autoscaler can automatically increase or decrease number of pods deployed within the system as needed.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--cpu`

  Target CPU utilization over all the pods. When specified as a percentage (e.g."70%" for 70% of requested CPU) it will target average utilization. When specified as quantity (e.g."500m" for 500 milliCPU) it will target average value. Value without units is treated as a quantity with miliCPU being the unit (e.g."500" is "500m").
- `--cpu-percent`

  The target average CPU utilization (represented as a percent of requested CPU) over all the pods. If it's not specified or negative, a default autoscaling policy will be used.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

Name of the manager used to track field ownership.

- `--filename, -f`

  Filename, directory, or URL to files identifying the resource to autoscale.
- `--kustomize, -k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--max`

  The upper limit for the number of pods that can be set by the autoscaler. Required.
- `--memory`

  Target memory utilization over all the pods. When specified as a percentage (e.g."60%" for 60% of requested memory) it will target average utilization. When specified as quantity (e.g."200Mi" for 200 MiB, "1Gi" for 1 GiB) it will target average value. Value without units is treated as a quantity with mebibytes being the unit (e.g."200" is "200Mi").
- `--min`

  The lower limit for the number of pods that can be set by the autoscaler. If it's not specified or negative, the server will apply a default value.
- `--name`

  The name for the newly created object. If not specified, the name of the input resource will be used.
- `--output, -o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive, -R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k certificate

Usage:

```
d8 k certificate SUBCOMMAND [options]
```

Modify certificate resources

Show more...

Modify certificate resources.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k certificate approve

Usage:

```
d8 k certificate SUBCOMMAND approve (-f FILENAME | NAME) [options]
```

Approve a certificate signing request

Show more...

Approve a certificate signing request.

kubectl certificate approve allows a cluster admin to approve a certificate signing request (CSR). This action tells a certificate signing controller to issue a certificate to the requester with the attributes requested in the CSR.

SECURITY NOTICE: Depending on the requested attributes, the issued certificate can potentially grant a requester access to cluster resources or to authenticate as a requested identity. Before approving a CSR, ensure you understand what the signed certificate can do.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to update
- `--force`

  Update the CSR even if it is already approved.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS

- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k certificate deny

Usage:

```
d8 k certificate SUBCOMMAND deny (-f FILENAME | NAME) [options]
```

Deny a certificate signing request

Show more...

Deny a certificate signing request.

kubectl certificate deny allows a cluster admin to deny a certificate signing request (CSR). This action tells a certificate signing controller to not to issue a certificate to the requester.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to update
- `--force`

  Update the CSR even if it is already denied.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k cluster-info

Usage:

```
d8 k cluster-info [options]
```

Display cluster information

Show more...

Display addresses of the control plane and services with label kubernetes.io/cluster-service=true. To further debug and diagnose cluster problems, use 'kubectl cluster-info dump'.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k cluster-info dump

Usage:

```
d8 k cluster-info dump [options]
```

Dump relevant information for debugging and diagnosis

Show more...

Dump cluster information out suitable for debugging and diagnosing cluster problems. By default, dumps everything to stdout. You can optionally specify a directory with --output-directory. If you specify a directory, Kubernetes will build a set of files in that directory. By default, only dumps things in the current namespace and 'kube-system' namespace, but you can switch to a different namespace with the --namespaces flag, or specify --all-namespaces to dump all namespaces.

The command also dumps the logs of all of the pods in the cluster; these logs are dumped into different directories based on namespace and pod name.

Options

- `--all-namespaces`, `-A`

  If true, dump all namespaces. If true, --namespaces is ignored.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--namespaces`

  A comma separated list of namespaces to dump.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--output-directory`

  Where to output the files. If empty or '-' uses stdout, otherwise creates a directory hierarchy in that directory
- `--pod-running-timeout`

  The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure

- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k completion

Usage:

```
d8 k completion SHELL [options]
```

Output shell completion code for the specified shell (bash, zsh, fish, or powershell)

Show more...

Output shell completion code for the specified shell (bash, zsh, fish, or powershell). The shell code must be evaluated to provide interactive completion of kubectl commands. This can be done by sourcing it from the .bash_profile.

Detailed instructions on how to do this are available here:

for macOS:
https://kubernetes.io/docs/tasks/tools/install-kubectl-macos/#enable-shell-autocompletion

for linux:
https://kubernetes.io/docs/tasks/tools/install-kubectl-linux/#enable-shell-autocompletion

for windows:
https://kubernetes.io/docs/tasks/tools/install-kubectl-windows/#enable-shell-autocompletion

Note for zsh users: [1] zsh completions are only supported in versions of zsh >= 5.2.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

Username for basic authentication to the API server

- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config

Usage:

```
d8 k config SUBCOMMAND [options]
```

Modify kubeconfig files

Show more...

Modify kubeconfig files using subcommands like "kubectl config set current-context my-context".

The loading order follows these rules:

1. If the --kubeconfig flag is set, then only that file is loaded. The flag may only be set once and no merging takes place.
2. If $KUBECONFIG environment variable is set, then it is used as a list of paths (normal path delimiting rules for your system). These paths are merged. When a value is modified, it is modified in the file that defines the stanza. When a value is created, it is created in the first file that exists. If no files in the chain exist, then it creates the last file in the list.
3. Otherwise, ${HOME}/.kube/config is used and no merging takes place.

Options

- `--kubeconfig`

  use a particular kubeconfig file

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kuberc`

Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config current-context

Usage:

```
d8 k config SUBCOMMAND current-context [options]
```

Display the current-context

Show more...

Display the current-context.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory

- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config delete-cluster

Usage:

```
d8 k config SUBCOMMAND delete-cluster NAME [options]
```

Delete the specified cluster from the kubeconfig

Show more...

Delete the specified cluster from the kubeconfig.

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  use a particular kubeconfig file
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`
  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`
  Name of the file to write the profile to
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`
  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

Bearer token for authentication to the API server

- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config delete-context

Usage:

```
d8 k config SUBCOMMAND delete-context NAME [options]
```

Delete the specified context from the kubeconfig

Show more...

Delete the specified context from the kubeconfig.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config delete-user

Usage:

```
d8 k config SUBCOMMAND delete-user NAME [options]
```

Delete the specified user from the kubeconfig

Show more...

Delete the specified user from the kubeconfig.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config get-clusters

Usage:

```
d8 k config SUBCOMMAND get-clusters [options]
```

Display clusters defined in the kubeconfig

Show more...

Display clusters defined in the kubeconfig.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server

- `--v`, `-v`
  number for the log level verbosity
- `--vmodule`
  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`
  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config get-contexts

Usage:

```
d8 k config SUBCOMMAND get-contexts [(-o|--output=)name)] [options]
```

Describe one or many contexts

Show more...

Display one or many contexts from the kubeconfig file.

Options

- `--no-headers`
  When using the default or custom-column output format, don't print headers (default print headers).
- `--output`, `-o`
  Output format. One of: (name).

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  use a particular kubeconfig file
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes

- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config get-users

Usage:

```
d8 k config SUBCOMMAND get-users [options]
```

Display users defined in the kubeconfig

Show more...

Display users defined in the kubeconfig.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS

- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config rename-context

Usage:

```
d8 k config SUBCOMMAND rename-context CONTEXT_NAME NEW_NAME [options]
```

Rename a context from the kubeconfig file

Show more...

Renames a context from the kubeconfig file.

CONTEXT_NAME is the context name that you want to change.

NEW_NAME is the new name you want to set.

Note: If the context being renamed is the 'current-context', this field will also be updated.

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  use a particular kubeconfig file
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`
  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`
  Name of the file to write the profile to
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`
  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config set

Usage:

```
d8 k config SUBCOMMAND set PROPERTY_NAME PROPERTY_VALUE [options]
```

Set an individual value in a kubeconfig file

Show more...

Set an individual value in a kubeconfig file.

PROPERTY_NAME is a dot delimited name where each token represents either an attribute name or a map key. Map keys may not contain dots.

PROPERTY_VALUE is the new value you want to set. Binary fields such as 'certificate-authority-data' expect a base64 encoded string unless the --set-raw-bytes flag is used.

Specifying an attribute name that already exists will merge new fields on top of existing values.

Options

- `--set-raw-bytes`

  When writing a []byte PROPERTY_VALUE, write the given string directly without base64 decoding.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server

- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config set-cluster

Usage:

```
d8 k config SUBCOMMAND set-cluster NAME [--server=server] [--certificate-authority=path/to/certificate/authority]
[--insecure-skip-tls-verify=true] [--tls-server-name=example.com] [options]
```

Set a cluster entry in kubeconfig

Show more...

Set a cluster entry in kubeconfig.

Specifying a name that already exists will merge new fields on top of existing values for those fields.

Options

- `--certificate-authority`

  Path to certificate-authority file for the cluster entry in kubeconfig
- `--embed-certs`

  embed-certs for the cluster entry in kubeconfig

- `--insecure-skip-tls-verify`

  insecure-skip-tls-verify for the cluster entry in kubeconfig
- `--proxy-url`

  proxy-url for the cluster entry in kubeconfig
- `--server`

  server for the cluster entry in kubeconfig
- `--tls-server-name`

  tls-server-name for the cluster entry in kubeconfig

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server

- `--v`, `-v`
  number for the log level verbosity
- `--vmodule`
  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`
  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config set-context

Usage:

```
d8 k config SUBCOMMAND set-context [NAME | --current] [--cluster=cluster_nickname] [--user=user_nickname] [--
namespace=namespace] [options]
```

Set a context entry in kubeconfig

Show more...

Set a context entry in kubeconfig.

Specifying a name that already exists will merge new fields on top of existing values for those fields.

Options

- `--cluster`
  cluster for the context entry in kubeconfig
- `--current`
  Modify the current context
- `--namespace`, `-n`
  namespace for the context entry in kubeconfig
- `--user`
  user for the context entry in kubeconfig

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  use a particular kubeconfig file
- `--kuberc`

Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config set-credentials

Usage:

```
d8 k config SUBCOMMAND set-credentials NAME [--client-certificate=path/to/certfile] [--client-key=path/to/keyfile]
[--token=bearer_token] [--username=basic_user] [--password=basic_password] [--auth-provider=provider_name] [--auth-
provider-arg=key=value] [--exec-command=exec_command] [--exec-api-version=exec_api_version] [--exec-arg=arg] [--
exec-env=key=value] [options]
```

Set a user entry in kubeconfig

Show more...

Set a user entry in kubeconfig.

Specifying a name that already exists will merge new fields on top of existing values.

Client-certificate flags:
--client-certificate=certfile --client-key=keyfile

Bearer token flags:
--token=bearer_token

Basic auth flags:
--username=basic_user --password=basic_password

Bearer token and basic auth are mutually exclusive.

Options

- `--auth-provider`

  Auth provider for the user entry in kubeconfig
- `--auth-provider-arg`

  'key=value' arguments for the auth provider
- `--client-certificate`

Path to client-certificate file for the user entry in kubeconfig
- `--client-key`

  Path to client-key file for the user entry in kubeconfig
- `--embed-certs`

  Embed client cert/key for the user entry in kubeconfig
- `--exec-api-version`

  API version of the exec credential plugin for the user entry in kubeconfig
- `--exec-arg`

  New arguments for the exec credential plugin command for the user entry in kubeconfig
- `--exec-command`

  Command for the exec credential plugin for the user entry in kubeconfig
- `--exec-env`

  'key=value' environment values for the exec credential plugin
- `--exec-interactive-mode`

  InteractiveMode of the exec credentials plugin for the user entry in kubeconfig
- `--exec-provide-cluster-info`

  ProvideClusterInfo of the exec credentials plugin for the user entry in kubeconfig
- `--password`

  password for the user entry in kubeconfig
- `--token`

  token for the user entry in kubeconfig
- `--username`

  username for the user entry in kubeconfig

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

If present, the namespace scope for this CLI request
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--user`

  The name of the kubeconfig user to use
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config unset

Usage:

```
d8 k config SUBCOMMAND unset PROPERTY_NAME [options]
```

Unset an individual value in a kubeconfig file

Show more...

Unset an individual value in a kubeconfig file.

PROPERTY_NAME is a dot delimited name where each token represents either an attribute name or a map key. Map keys may not contain dots.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config use-context

Alias: `use`

Usage:

```
d8 k config SUBCOMMAND use-context CONTEXT_NAME [options]
```

Set the current-context in a kubeconfig file

Show more...

Set the current-context in a kubeconfig file.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log

format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k config view

Usage:

```
d8 k config SUBCOMMAND view [options]
```

Display merged kubeconfig settings or a specified kubeconfig file

Show more...

Display merged kubeconfig settings or a specified kubeconfig file.

You can use --output jsonpath={...} to extract specific values using a jsonpath expression.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--flatten`

  Flatten the resulting kubeconfig file into self-contained output (useful for creating portable kubeconfig files)
- `--merge`

  Merge the full hierarchy of kubeconfig files
- `--minify`

  Remove all information not used by current-context from the output
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--raw`

  Display raw byte data and sensitive data
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use

- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  use a particular kubeconfig file
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k cordon

Usage:

```
d8 k cordon NODE [options]
```

Mark node as unschedulable

Show more...

Mark node as unschedulable.

Options

- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--selector`, `-l`

Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server

- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k cp

Usage:

```
d8 k cp <file-spec-src> <file-spec-dest> [options]
```

Copy files and directories to and from containers

Show more...

Copy files and directories to and from containers.

Options

- `--container`, `-c`

  Container name. If omitted, use the kubectl.kubernetes.io/default-container annotation for selecting the container to be attached or the first container in the pod will be chosen
- `--no-preserve`

  The copied file/directory's ownership and permissions will not be preserved in the container
- `--retries`

  Set number of retries to complete a copy operation from a container. Specify 0 to disable or any negative value for infinite retrying. The default is 0 (no retry).

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections

insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create

Usage:

```
d8 k create -f FILENAME [options]
```

Create a resource from a file or from stdin

Show more...

Create a resource from a file or from stdin.

JSON and YAML formats are accepted.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--edit`

Edit the API resource before creating
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename, -f`

  Filename, directory, or URL to files to use to create the resource
- `--kustomize, -k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output, -o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--raw`

  Raw URI to POST to the server. Uses the transport specified by the kubeconfig file.
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive, -R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--selector, -l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--windows-line-endings`

  Only relevant if --edit=true. Defaults to the line ending native to your platform.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create clusterrole

Usage:

```
d8 k create -f FILENAME clusterrole NAME --verb=verb --resource=resource.group [--resource-name=resourcename] [--
dry-run=server|client|none] [options]
```

Create a cluster role

Show more...

Create a cluster role.

Options

- `--aggregation-rule`

  An aggregation label selector for combining ClusterRoles.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--non-resource-url`

  A partial url that user should have access to.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--resource`

  Resource that the rule applies to
- `--resource-name`

  Resource in the white list that the rule applies to, repeat this flag for multiple items
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--verb`

  Verb that applies to the resources contained in the rule

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create clusterrolebinding

Usage:

```
d8 k create -f FILENAME clusterrolebinding NAME --clusterrole=NAME [--user=username] [--group=groupname] [--
serviceaccount=namespace:serviceaccountname] [--dry-run=server|client|none] [options]
```

Create a cluster role binding for a particular cluster role

Show more...

Create a cluster role binding for a particular cluster role.

Options

- `--allow-missing-template-keys`

If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.

- `--clusterrole`

  ClusterRole this ClusterRoleBinding should reference
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--group`

  Groups to bind to the clusterrole. The flag can be repeated to add multiple groups.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--serviceaccount`

  Service accounts to bind to the clusterrole, in the format :. The flag can be repeated to add multiple service accounts.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--user`

  Usernames to bind to the clusterrole. The flag can be repeated to add multiple users.
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use

- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create configmap

Alias: `cm`

Usage:

```
d8 k create -f FILENAME configmap NAME [--from-file=[key=]source] [--from-literal=key1=value1] [--dry-
run=server|client|none] [options]
```

Create a config map from a local file, directory or literal value

Show more...

Create a config map based on a file, directory, or specified literal value.

A single config map may package one or more key/value pairs.

When creating a config map based on a file, the key will default to the basename of the file, and the value will default to the file content. If the basename is an invalid key, you may specify an alternate key.

When creating a config map based on a directory, each file whose basename is a valid key in the directory will be packaged into the config map. Any directory entries except regular files are ignored (e.g. subdirectories,

symlinks, devices, pipes, etc).

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--append-hash`

  Append a hash of the configmap to its name.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--from-env-file`

  Specify the path to a file to read lines of key=val pairs to create a configmap.
- `--from-file`

  Key file can be specified using its file path, in which case file basename will be used as configmap key, or optionally with a key and file path, in which case the given key will be used. Specifying a directory will iterate each named file in the directory whose basename is a valid configmap key.
- `--from-literal`

  Specify a key and literal value to insert in configmap (i.e. mykey=somevalue)
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS

- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create cronjob

Alias: `cj`

Usage:

```
d8 k create -f FILENAME cronjob NAME --image=image --schedule='0/5 * * * ?' -- [COMMAND] [args...] [options]
```

Create a cron job with the specified name

Show more...

Create a cron job with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--image`

  Image name to run.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--restart`

  job's restart policy. supported values: OnFailure, Never
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--schedule`

  A schedule in the Cron format the job should be run with.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create deployment

Alias: `deploy`

Usage:

```
d8 k create -f FILENAME deployment NAME --image=image -- [COMMAND] [args...] [options]
```

Create a deployment with the specified name

Show more...

Create a deployment with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.

- `--field-manager`

  Name of the manager used to track field ownership.
- `--image`

  Image names to run. A deployment can have multiple images set for multi-container pod.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--port`

  The containerPort that this deployment exposes.
- `--replicas`, `-r`

  Number of replicas to create. Default is 1.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

Path to the kubeconfig file to use for CLI requests.

- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create ingress

Alias: `ing`

Usage:

```
d8 k create -f FILENAME ingress NAME --rule=host/path=service:port[,tls[=secret]]  [options]
```

Create an ingress with the specified name

Show more...

Create an ingress with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--annotation`

  Annotation to insert in the ingress object, in the format annotation=value
- `--class`

  Ingress Class to be used
- `--default-backend`

  Default service for backend, in format of svcname:port

- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--rule`

  Rule in format host/path=service:port[,tls=secretname]. Paths containing the leading character '*' are considered pathType=Prefix. tls argument is optional.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create job

Usage:

```
d8 k create -f FILENAME job NAME --image=image [--from=cronjob/name] -- [COMMAND] [args...] [options]
```

Create a job with the specified name

Show more...

Create a job with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--from`

  The name of the resource to create a Job from (only CronJob is supported).
- `--image`

  Image name to run.

- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request

- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create namespace

Alias: `ns`

Usage:

```
d8 k create -f FILENAME namespace NAME [--dry-run=server|client|none] [options]
```

Create a namespace with the specified name

Show more...

Create a namespace with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server

- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create poddisruptionbudget

Alias: `pdb`

Usage:

```
d8 k create -f FILENAME poddisruptionbudget NAME --selector=SELECTOR --min-available=N [--dry-
run=server|client|none] [options]
```

Create a pod disruption budget with the specified name

Show more...

Create a pod disruption budget with the specified name, selector, and desired minimum available pods.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--max-unavailable`

  The maximum number or percentage of unavailable pods this budget requires.
- `--min-available`

  The minimum number or percentage of available pods this budget requires.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--selector`

  A label selector to use for this budget. Only equality-based selector requirements are supported.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn

about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`
  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`
  Name of the file to write the profile to
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`
  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

Bearer token for authentication to the API server

- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create priorityclass

Alias: `pc`

Usage:

```
d8 k create -f FILENAME priorityclass NAME --value=VALUE --global-default=BOOL [--dry-run=server|client|none]
[options]
```

Create a priority class with the specified name

Show more...

Create a priority class with the specified name, value, globalDefault and description.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--description`

  description is an arbitrary string that usually provides guidelines on when this priority class should be used.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--global-default`

  global-default specifies whether this PriorityClass should be considered as the default priority.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--preemption-policy`

  preemption-policy is the policy for preempting pods with lower priority.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--value`

the value of this priority class.

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`
  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`
  Name of the file to write the profile to
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`
  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`
  Bearer token for authentication to the API server
- `--user`

The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create quota

Alias: `resourcequota`

Usage:

```
d8 k create -f FILENAME quota NAME [--hard=key1=value1,key2=value2] [--scopes=Scope1,Scope2] [--dry-
run=server|client|none] [options]
```

Create a quota with the specified name

Show more...

Create a resource quota with the specified name, hard limits, and optional scopes.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--hard`

  A comma-delimited set of resource=quantity pairs that define a hard limit.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--scopes`

  A comma-delimited set of quota scopes that must all match each object tracked by the quota.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log

format)

- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create role

Usage:

```
d8 k create -f FILENAME role NAME --verb=verb --resource=resource.group/subresource [--resource-name=resourcename]
[--dry-run=server|client|none] [options]
```

Create a role with single rule

Show more...

Create a role with single rule.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--resource`

  Resource that the rule applies to
- `--resource-name`

  Resource in the white list that the rule applies to, repeat this flag for multiple items
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--verb`

  Verb that applies to the resources contained in the rule

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.

- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create rolebinding

Usage:

```
d8 k create -f FILENAME rolebinding NAME --clusterrole=NAME|--role=NAME [--user=username] [--group=groupname] [--
serviceaccount=namespace:serviceaccountname] [--dry-run=server|client|none] [options]
```

Create a role binding for a particular role or cluster role

Show more...

Create a role binding for a particular role or cluster role.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--clusterrole`

  ClusterRole this RoleBinding should reference
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--group`

  Groups to bind to the role. The flag can be repeated to add multiple groups.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--role`

  Role this RoleBinding should reference
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--serviceaccount`

  Service accounts to bind to the role, in the format :. The flag can be repeated to add multiple service accounts.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--user`

  Usernames to bind to the role. The flag can be repeated to add multiple users.
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create secret

Usage:

```
d8 k create -f FILENAME secret (docker-registry | generic | tls) [options]
```

Create a secret using a specified subcommand

Show more...

Create a secret with specified type.

A docker-registry type secret is for accessing a container registry.

A generic type secret indicate an Opaque secret type.

A tls type secret holds TLS certificate and its associated key.

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`
  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`
  Name of the file to write the profile to
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`

Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create secret docker-registry

Usage:

```
d8 k create -f FILENAME secret (docker-registry | generic | tls) docker-registry NAME --docker-username=user --docker-password=password --docker-email=email [--docker-server=string] [--from-file=[key=]source] [--dry-run=server|client|none] [options]
```

Create a secret for use with a Docker registry

Show more...

Create a new secret for use with Docker registries.

Dockercfg secrets are used to authenticate against Docker registries.

When using the Docker command line to push images, you can authenticate to a given registry by running: '$ docker login DOCKER_REGISTRY_SERVER --username=DOCKER_USER --password=DOCKER_PASSWORD --email=DOCKER_EMAIL'.

That produces a ~/.dockercfg file that is used by subsequent 'docker push' and 'docker pull' commands to authenticate to the registry. The email address is optional.

When creating applications, you may have a Docker registry that requires authentication. In order for the nodes to pull images on your behalf, they must have the credentials. You can provide this information by creating a dockercfg secret and attaching it to your service account.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--append-hash`

  Append a hash of the secret to its name.
- `--docker-email`

  Email for Docker registry
- `--docker-password`

  Password for Docker registry authentication
- `--docker-server`

  Server location for Docker registry
- `--docker-username`

  Username for Docker registry authentication
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--from-file`

  Key files can be specified using their file path, in which case a default name of .dockerconfigjson will be given to them, or optionally with a name and file path, in which case the given name will be used.

Specifying a directory will iterate each named file in the directory that is a valid secret key. For this command, the key should always be .dockerconfigjson.

- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

If present, the namespace scope for this CLI request

- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create secret generic

Usage:

```
d8 k create -f FILENAME secret (docker-registry | generic | tls) generic NAME [--type=string] [--from-file=
[key=]source] [--from-literal=key1=value1] [--dry-run=server|client|none] [options]
```

Create a secret from a local file, directory, or literal value

Show more...

Create a secret based on a file, directory, or specified literal value.

A single secret may package one or more key/value pairs.

When creating a secret based on a file, the key will default to the basename of the file, and the value will default to the file content. If the basename is an invalid key or you wish to chose your own, you may specify an alternate key.

When creating a secret based on a directory, each file whose basename is a valid key in the directory will be packaged into the secret. Any directory entries except regular files are ignored (e.g. subdirectories, symlinks, devices, pipes, etc).

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--append-hash`

  Append a hash of the secret to its name.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--from-env-file`

Specify the path to a file to read lines of key=val pairs to create a secret.

- `--from-file`

  Key files can be specified using their file path, in which case a default name will be given to them, or optionally with a name and file path, in which case the given name will be used. Specifying a directory will iterate each named file in the directory that is a valid secret key.
- `--from-literal`

  Specify a key and literal value to insert in secret (i.e. mykey=somevalue)
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--type`

  The type of secret to create
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.

- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create secret tls

Usage:

```
d8 k create -f FILENAME secret (docker-registry | generic | tls) tls NAME --cert=path/to/cert/file --
key=path/to/key/file [--dry-run=server|client|none] [options]
```

Create a TLS secret

Show more...

Create a TLS secret from the given public/private key pair.

The public/private key pair must exist beforehand. The public key certificate must be .PEM encoded and match the given private key.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--append-hash`

  Append a hash of the secret to its name.
- `--cert`

  Path to PEM encoded public key certificate.
- `--dry-run`

Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.

- `--field-manager`

  Name of the manager used to track field ownership.
- `--key`

  Path to private key associated with given certificate.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create service

Alias: `svc`

Usage:

```
d8 k create -f FILENAME service [options]
```

Create a service using a specified subcommand

Show more...

Create a service using a specified subcommand.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create service clusterip

Usage:

```
d8 k create -f FILENAME service clusterip NAME [--tcp=<port>:<targetPort>] [--dry-run=server|client|none] [options]
```

Create a ClusterIP service

Show more...

Create a ClusterIP service with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--clusterip`

  Assign your own ClusterIP or set to 'None' for a 'headless' service (no loadbalancing).
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--tcp`

  Port pairs can be specified as ':'.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use

- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create service externalname

Usage:

```
d8 k create -f FILENAME service externalname NAME --external-name external.name [--dry-run=server|client|none]
[options]
```

Create an ExternalName service

Show more...

Create an ExternalName service with the specified name.

ExternalName service references to an external DNS address instead of only pods, which will allow application authors to reference services that exist off platform, on other clusters, or locally.

Options

- `--allow-missing-template-keys`

If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.

- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--external-name`

  External name of service
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--tcp`

  Port pairs can be specified as ':'.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure

- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create service loadbalancer

Usage:

```
d8 k create -f FILENAME service loadbalancer NAME [--tcp=port:targetPort] [--dry-run=server|client|none] [options]
```

Create a LoadBalancer service

Show more...

Create a LoadBalancer service with the specified name.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).

- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--tcp`

  Port pairs can be specified as ':'.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. - `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k create token

Usage:

```
d8 k create -f FILENAME token SERVICE_ACCOUNT_NAME [options]
```

Request a service account token

Show more...

Request a service account token.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--audience`

  Audience of the requested token. If unset, defaults to requesting a token for use with the Kubernetes API server. May be repeated to request a token valid for multiple audiences.
- `--bound-object-kind`

  Kind of an object to bind the token to. Supported kinds are Node, Pod, Secret. If set, --bound-object-name must be provided.
- `--bound-object-name`

  Name of an object to bind the token to. The token will expire when the object is deleted. Requires --bound-object-kind.
- `--bound-object-uid`

  UID of an object to bind the token to. Requires --bound-object-kind and --bound-object-name. If unset, the UID of the existing object is used.
- `--duration`

  Requested lifetime of the issued token. If not set or if set to 0, the lifetime will be determined by the server automatically. The server may return a token with a longer or shorter lifetime.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k debug

Usage:

```
d8 k debug (POD | TYPE[[.VERSION].GROUP]/NAME) [ -- COMMAND [args...] ] [options]
```

Create debugging sessions for troubleshooting workloads and nodes

Show more...

Debug cluster resources using interactive debugging containers.

'debug' provides automation for common debugging tasks for cluster objects identified by resource and name. Pods will be used by default if no resource is specified.

The action taken by 'debug' varies depending on what resource is specified. Supported actions include:

* Workload: Create a copy of an existing pod with certain attributes changed, for example changing the image tag to a new version.
* Workload: Add an ephemeral container to an already running pod, for example to add debugging utilities without restarting the pod.
* Node: Create a new pod that runs in the node's host namespaces and can access the node's filesystem.

Note: When a non-root user is configured for the entire target Pod, some capabilities granted by debug profile may not work.

Options

- `--arguments-only`

  If specified, everything after -- will be passed to the new container as Args instead of Command.
- `--attach`

  If true, wait for the container to start running, and then attach as if 'kubectl attach ...' were called. Default false, unless '-i/--stdin' is set, in which case the default is true.
- `--container`, `-c`

  Container name to use for debug container.
- `--copy-to`

  Create a copy of the target Pod with this name.
- `--custom`

  Path to a JSON or YAML file containing a partial container spec to customize built-in debug profiles.
- `--env`

  Environment variables to set in the container.
- `--filename`, `-f`

  identifying the resource to debug
- `--image`

  Container image to use for debug container. If not specified, the platform's recommended image will be used.
- `--image-pull-policy`

  The image pull policy for the container. If left empty, this value will not be specified by the client and defaulted by the server.
- `--keep-annotations`

  If true, keep the original pod annotations.(This flag only works when used with '--copy-to')
- `--keep-init-containers`

  Run the init containers for the pod. Defaults to true.(This flag only works when used with '--copy-to')
- `--keep-labels`

  If true, keep the original pod labels.(This flag only works when used with '--copy-to')
- `--keep-liveness`

  If true, keep the original pod liveness probes.(This flag only works when used with '--copy-to')
- `--keep-readiness`

  If true, keep the original pod readiness probes.(This flag only works when used with '--copy-to')
- `--keep-startup`

  If true, keep the original startup probes.(This flag only works when used with '--copy-to')
- `--profile`

  Options are "legacy", "general", "baseline", "netadmin", "restricted" or "sysadmin".
- `--quiet`, `-q`

  If true, suppress informational messages.
- `--replace`

  When used with '--copy-to', delete the original Pod.
- `--same-node`

When used with '--copy-to', schedule the copy of target Pod on the same node.

- `--set-image`

  When used with '--copy-to', a list of name=image pairs for changing container images, similar to how 'kubectl set image' works.
- `--share-processes`

  When used with '--copy-to', enable process namespace sharing in the copy.
- `--stdin`, `-i`

  Keep stdin open on the container(s) in the pod, even if nothing is attached.
- `--target`

  When using an ephemeral container, target processes in this container name.
- `--tty`, `-t`

  Allocate a TTY for the debugging container.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a

corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.

- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k delete

Usage:

```
d8 k delete ([-f FILENAME] | [-k DIRECTORY] | TYPE [(NAME | -l label | --all)]) [options]
```

Delete resources by file names, stdin, resources and names, or by resources and label selector

Show more...

Delete resources by file names, stdin, resources and names, or by resources and label selector.

JSON and YAML formats are accepted. Only one type of argument may be specified: file names, resources and names, or resources and label selector.

Some resources, such as pods, support graceful deletion. These resources define a default period before they are forcibly terminated (the grace period) but you may override that value with the --grace-period flag, or pass --now to set a grace-period of 1. Because these resources often represent entities in the cluster, deletion may not be acknowledged immediately. If the node hosting a pod is down or cannot reach the API server, termination may take significantly longer than the grace period. To force delete a resource, you must specify the --force flag. Note: only a subset of resources support graceful deletion. In absence of the support, the --grace-period flag is ignored.

IMPORTANT: Force deleting pods does not wait for confirmation that the pod's processes have been terminated, which can leave those processes running until the node detects the deletion and completes graceful deletion. If your processes use shared storage or talk to a remote API and depend on the name of the pod to identify themselves, force deleting those pods may result in multiple processes running on different machines using the same identification which may lead to data corruption or inconsistency. Only force delete pods when you are sure the pod is terminated, or if your application can tolerate multiple copies of the same pod running at once. Also, if you force delete pods, the scheduler may place new pods on those nodes before the node has released those resources and causing those pods to be evicted immediately.

Note that the delete command does NOT do resource version checks, so if someone submits an update to a resource right when you submit a delete, their update will be lost along with the rest of the resource.

After a CustomResourceDefinition is deleted, invalidation of discovery cache may take up to 6 hours. If you don't want to wait, you might want to run "kubectl api-resources" to refresh the discovery cache.

Options

- `--all`

  Delete all resources, in the namespace of the specified resource types.
- `--all-namespaces`, `-A`

  If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.
- `--cascade`

  Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without

sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-selector`

  Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.
- `--filename`, `-f`

  containing the resource to delete.
- `--force`

  If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.
- `--grace-period`

  Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when --force is true (force deletion).
- `--ignore-not-found`

  Treat "resource not found" as a successful delete. Defaults to "true" when --all is specified.
- `--interactive`, `-i`

  If true, delete resource only when user confirms.
- `--kustomize`, `-k`

  Process a kustomization directory. This flag can't be used together with -f or -R.
- `--now`

  If true, resources are signaled for immediate shutdown (same as --grace-period=1).
- `--output`, `-o`

  Output mode. Use "-o name" for shorter output (resource/name).
- `--raw`

  Raw URI to DELETE to the server. Uses the transport specified by the kubeconfig file.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--timeout`

  The length of time to wait before giving up on a delete, zero means determine a timeout from the size of the object
- `--wait`

  If true, wait for resources to be gone before returning. This waits for finalizers.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k describe

Usage:

```
d8 k describe (-f FILENAME | TYPE [NAME_PREFIX | -l label] | TYPE/NAME) [options]
```

Show details of a specific resource or group of resources

Show more...

Show details of a specific resource or group of resources.

Print a detailed description of the selected resources, including related resources such as events or controllers. You may select a single object by name, all objects of that type, provide a name prefix, or label selector. For example:

$ kubectl describe TYPE NAME_PREFIX

will first check for an exact match on TYPE and NAME_PREFIX. If no such resource exists, it will output details for every resource that has a name prefixed with NAME_PREFIX.

Use "kubectl api-resources" for a complete list of supported resources.

Options

- `--all-namespaces`, `-A`

  If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.
- `--chunk-size`

  Return large lists in chunks rather than all at once. Pass 0 to disable.
- `--filename`, `-f`

  Filename, directory, or URL to files containing the resource to describe
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-events`

  If true, display events related to the described object.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes

- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k diff

Usage:

```
d8 k diff -f FILENAME [options]
```

Diff the live version against a would-be applied version

Show more...

Diff configurations specified by file name or stdin between the current online configuration, and the configuration as it would be if applied.

The output is always YAML.

KUBECTL_EXTERNAL_DIFF environment variable can be used to select your own diff command. Users can use external commands with params too, example: KUBECTL_EXTERNAL_DIFF="colordiff -N -u"

By default, the "diff" command available in your path will be run with the "-u" (unified diff) and "-N" (treat absent files as empty) options.

Exit status: 0 No differences were found. 1 Differences were found. >1 Kubectl or diff failed with an error.

Note: KUBECTL_EXTERNAL_DIFF, if used, is expected to follow that convention.

Options

- `--concurrency`

  Number of objects to process in parallel when diffing against the live version. Larger number = faster, but more memory, I/O and CPU over that shorter period of time.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files contains the configuration to diff

- `--force-conflicts`

  If true, server-side apply will force the changes against conflicts.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--prune`

  Include resources that would be deleted by pruning. Can be used with -l and default shows all resources would be pruned
- `--prune-allowlist`

  Overwrite the default allowlist with for --prune
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--server-side`

  If true, apply runs in the server instead of the client.
- `--show-managed-fields`

  If true, include managed fields in the diff.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k drain

Usage:

```
d8 k drain NODE [options]
```

Drain node in preparation for maintenance

Show more...

Drain node in preparation for maintenance.

The given node will be marked unschedulable to prevent new pods from arriving. 'drain' evicts the pods if the API server supports https://kubernetes.io/docs/concepts/workloads/pods/disruptions/ eviction https://kubernetes.io/docs/concepts/workloads/pods/disruptions/ . Otherwise, it will use normal DELETE to delete the pods. The 'drain' evicts or deletes all pods except mirror pods (which cannot be deleted through the API server). If there are daemon set-managed pods, drain will not proceed without --ignore-daemonsets, and regardless it will not delete any daemon set-managed pods, because those pods would be immediately replaced by the daemon set controller, which ignores unschedulable markings. If there are any pods that are neither mirror pods nor managed by a replication controller, replica set, daemon set, stateful set, or job, then drain will not delete any pods unless you use --force. --force will also allow deletion to proceed if the managing resource of one or more pods is missing.

'drain' waits for graceful termination. You should not operate on the machine until the command completes.

When you are ready to put the node back into service, use kubectl uncordon, which will make the node schedulable again.

https://kubernetes.io/images/docs/kubectl_drain.svg
Workflowhttps://kubernetes.io/images/docs/kubectl_drain.svg

Options

- `--chunk-size`

  Return large lists in chunks rather than all at once. Pass 0 to disable.
- `--delete-emptydir-data`

  Continue even if there are pods using emptyDir (local data that will be deleted when the node is drained).
- `--disable-eviction`

Force drain to use delete, even if eviction is supported. This will bypass checking PodDisruptionBudgets, use with caution.

- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--force`

  Continue even if there are pods that do not declare a controller.
- `--grace-period`

  Period of time in seconds given to each pod to terminate gracefully. If negative, the default value specified in the pod will be used.
- `--ignore-daemonsets`

  Ignore DaemonSet-managed pods.
- `--pod-selector`

  Label selector to filter pods on the node
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--skip-wait-for-delete-timeout`

  If pod DeletionTimestamp older than N seconds, skip waiting for the pod. Seconds must be greater than 0 to skip.
- `--timeout`

  The length of time to wait before giving up, zero means infinite

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes

- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k edit

Usage:

```
d8 k edit (RESOURCE/NAME | -f FILENAME) [options]
```

Edit a resource on the server

Show more...

Edit a resource from the default editor.

The edit command allows you to directly edit any API resource you can retrieve via the command-line tools. It will open the editor defined by your KUBE_EDITOR, or EDITOR environment variables, or fall back to 'vi' for Linux or 'notepad' for Windows. When attempting to open the editor, it will first attempt to use the shell that has been defined in the 'SHELL' environment variable. If this is not defined, the default shell will be used, which is '/bin/bash' for Linux or 'cmd' for Windows.

You can edit multiple objects, although changes are applied one at a time. The command accepts file names as well as command-line arguments, although the files you point to must be previously saved versions of resources.

Editing is done with the API version used to fetch the resource. To edit using a specific API version, fully-qualify the resource, version, and group.

The default format is YAML. To edit in JSON, specify "-o json".

The flag --windows-line-endings can be used to force Windows line endings, otherwise the default for your operating system will be used.

In the event an error occurs while updating, a temporary file will be created on disk that contains your unapplied changes. The most common error when updating a resource is another editor changing the resource on the server. When this occurs, you will have to apply your changes to the newer version of the resource, or update your temporary saved copy to include the latest resource version.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files to use to edit the resource
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--output-patch`

  Output the patch if the resource is edited.
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--subresource`

  If specified, edit will operate on the subresource of the requested object.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--windows-line-endings`

  Defaults to the line ending native to your platform.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS

- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k events

Usage:

```
d8 k events [(-o|--output=)json|yaml|kyaml|name|go-template|go-template-
file|template|templatefile|jsonpath|jsonpath-as-json|jsonpath-file] [--for TYPE/NAME] [--watch] [--
types=Normal,Warning] [options]
```

List events

Show more...

Display events.

Prints a table of the most important information about events. You can request events for a namespace, for all namespace, or filtered to only those pertaining to a specified resource.

Options

- `--all-namespaces`, `-A`

  If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--chunk-size`

  Return large lists in chunks rather than all at once. Pass 0 to disable.
- `--for`

  Filter events to only those pertaining to the specified resource.
- `--no-headers`

  When using the default output format, don't print headers.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--types`

  Output only events of given types.
- `--watch`, `-w`

  After listing the requested events, watch for more events.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure

- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k exec

Usage:

```
d8 k exec (POD | TYPE/NAME) [-c CONTAINER] [flags] -- COMMAND [args...] [options]
```

Execute a command in a container

Show more...

Execute a command in a container.

Options

- `--container`, `-c`

  Container name. If omitted, use the kubectl.kubernetes.io/default-container annotation for selecting the container to be attached or the first container in the pod will be chosen
- `--filename`, `-f`

  to use to exec into the resource
- `--pod-running-timeout`

  The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running
- `--quiet`, `-q`

  Only print output from the remote session

- `--stdin`, `-i`

  Pass stdin to the container
- `--tty`, `-t`

  Stdin is a TTY

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k explain

Usage:

```
d8 k explain TYPE [--recursive=FALSE|TRUE] [--api-version=api-version-group] [-o|--output=plaintext|plaintext-openapiv2] [options]
```

Get documentation for a resource

Show more...

Describe fields and structure of various resources.

This command describes the fields associated with each supported API resource. Fields are identified via a simple JSONPath identifier:

<type>.<fieldName>[.<fieldName>]

Information about each field is retrieved from the server in OpenAPI format.

Use "kubectl api-resources" for a complete list of supported resources.

Options

- `--api-version`

  Get different explanations for particular API version (API group/version)
- `--output`, `-o`

  Format in which to render the schema (plaintext, plaintext-openapiv2)
- `--recursive`

  Print the fields of fields (Currently only 1 level deep)

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k expose

Usage:

```
d8 k expose (-f FILENAME | TYPE NAME) [--port=port] [--protocol=TCP|UDP|SCTP] [--target-port=number-or-name] [--
name=name] [--external-ip=external-ip-of-service] [--type=type] [options]
```

Take a replication controller, service, deployment or pod and expose it as a new Kubernetes service

Show more...

Expose a resource as a new Kubernetes service.

Looks up a deployment, service, replica set, replication controller or pod by name and uses the selector for that resource as the selector for a new service on the specified port. A deployment or replica set will be exposed as a

service only if its selector is convertible to a selector that service supports, i.e. when the selector contains only the matchLabels component. Note that if no port is specified via --port and the exposed resource has multiple ports, all will be re-used by the new service. Also if no labels are specified, the new service will re-use the labels from the resource it exposes.

Possible resources include (case insensitive):

pod (po), service (svc), replicationcontroller (rc), deployment (deploy), replicaset (rs)

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--cluster-ip`

  ClusterIP to be assigned to the service. Leave empty to auto-allocate, or set to 'None' to create a headless service.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--external-ip`

  Additional external IP address (not managed by Kubernetes) to accept for the service. If this IP is routed to a node, the service can be accessed by this IP in addition to its generated service IP.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to expose a service
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--labels`, `-l`

  Labels to apply to the service created by this call.
- `--load-balancer-ip`

  IP to assign to the LoadBalancer. If empty, an ephemeral IP will be created and used (cloud-provider specific).
- `--name`

  The name for the newly created object.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--override-type`

  The method used to override the generated object: json, merge, or strategic.
- `--overrides`

  An inline JSON override for the generated object. If this is non-empty, it is used to override the generated object. Requires that the object supply a valid apiVersion field.
- `--port`

  The port that the service should serve on. Copied from the resource being exposed, if unspecified
- `--protocol`

  The network protocol for the service to be created. Default is 'TCP'.
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--selector`

  A label selector to use for this service. Only equality-based selector requirements are supported. If empty (the default) infer the selector from the resource being exposed.

- `--session-affinity`

  If non-empty, set the session affinity for the service to this; legal values: 'None', 'ClientIP'
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--target-port`

  Name or number for the port on the container that the service should direct traffic to. Optional.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--type`

  Type for this service: ClusterIP, NodePort, LoadBalancer, or ExternalName. Default is 'ClusterIP'.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.

- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k get

Usage:

```
d8 k get [(-o|--output=)json|yaml|kyaml|name|go-template|go-template-file|template|templatefile|jsonpath|jsonpath-as-json|jsonpath-file|custom-columns|custom-columns-file|wide] (TYPE[.VERSION][.GROUP] [NAME | -l label] | TYPE[.VERSION][.GROUP]/NAME ...) [flags] [options]
```

Display one or many resources

Show more...

Display one or many resources.

Prints a table of the most important information about the specified resources. You can filter the list using a label selector and the --selector flag. If the desired resource type is namespaced you will only see results in the current namespace if you don't specify any namespace.

By specifying the output as 'template' and providing a Go template as the value of the --template flag, you can filter the attributes of the fetched resources.

Use "kubectl api-resources" for a complete list of supported resources.

Options

- `--all-namespaces`, `-A`

  If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--chunk-size`

  Return large lists in chunks rather than all at once. Pass 0 to disable.
- `--field-selector`

  Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--ignore-not-found`

  If set to true, suppresses NotFound error for specific objects that do not exist. Using this flag with commands that query for collections of resources has no effect when no resources are found.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--label-columns`, `-L`

Accepts a comma separated list of labels that are going to be presented as columns. Names are case-sensitive. You can also use multiple flag options like -L label1 -L label2...

- `--no-headers`

  When using the default or custom-column output format, don't print headers (default print headers).
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file, custom-columns, custom-columns-file, wide). See custom columns [https://kubernetes.io/docs/reference/kubectl/#custom-columns], golang template [http://golang.org/pkg/text/template/#pkg-overview] and jsonpath template [https://kubernetes.io/docs/reference/kubectl/jsonpath/].
- `--output-watch-events`

  Output watch event objects when --watch or --watch-only is used. Existing objects are output as initial ADDED events.
- `--raw`

  Raw URI to request from the server. Uses the transport specified by the kubeconfig file.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--scope`

  Cross-namespace listing scope for users without cluster-wide list/watch RBAC: accessible (everything RBAC grants you), projects, system, or project:. Requires -A/--all-namespaces and Deckhouse platform support on the server side.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--server-print`

  If true, have the server return the appropriate table output. Supports extension APIs and CRDs.
- `--show-kind`

  If present, list the resource type for the requested object(s).
- `--show-labels`

  When printing, show all labels as the last column (default hide labels column)
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--sort-by`

  If non-empty, sort list types using this field specification. The field specification is expressed as a JSONPath expression (e.g. '{.metadata.name}'). The field in the API resource specified by this JSONPath expression must be an integer or a string.
- `--subresource`

  If specified, gets the subresource of the requested object.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--watch`, `-w`

  After listing/getting the requested object, watch for changes.
- `--watch-only`

  Watch for changes to the requested object(s), without listing/getting first.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.

- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k kustomize

Usage:

```
d8 k kustomize DIR [options]
```

Build a kustomization target from a directory or URL

Show more...

Build a set of KRM resources using a 'kustomization.yaml' file. The DIR argument must be a path to a directory containing 'kustomization.yaml', or a git repository URL with a path suffix specifying same with respect to the repository root. If DIR is omitted, '.' is assumed.

Options

- `--as-current-user`

  use the uid and gid of the command executor to run the function in the container
- `--enable-alpha-plugins`

  enable kustomize plugins
- `--enable-helm`

  Enable use of the Helm chart inflator generator.
- `--enable-managedby-label`

  enable adding app.kubernetes.io/managed-by
- `--env`, `-e`

  a list of environment variables to be used by functions
- `--helm-api-versions`

  Kubernetes api versions used by Helm for Capabilities.APIVersions
- `--helm-command`

  helm command (path to executable)
- `--helm-debug`

  Enable debug output from the Helm chart inflator generator.
- `--helm-kube-version`

  Kubernetes version used by Helm for Capabilities.KubeVersion
- `--load-restrictor`

  if set to 'LoadRestrictionsNone', local kustomizations may load files from outside their root. This does, however, break the relocatability of the kustomization.
- `--mount`

  a list of storage options read from the filesystem
- `--network`

  enable network access for functions that declare it
- `--network-name`

  the docker network to run the container in
- `--output`, `-o`

  If specified, write output to this path.
- `--reorder`

  Reorder the resources just before output. Use 'legacy' to apply a legacy reordering (Namespaces first, Webhooks last, etc). Use 'none' to suppress a final reordering.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k label

Usage:

```
d8 k label [--overwrite] (-f FILENAME | TYPE NAME) KEY_1=VAL_1 ... KEY_N=VAL_N [--resource-version=version]
[options]
```

Update the labels on a resource

Show more...

Update the labels on a resource.

  * A label key and value must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 63 characters each.
  * Optionally, the key can begin with a DNS subdomain prefix and a single '/', like example.com/my-app.
  * If --overwrite is true, then existing labels can be overwritten, otherwise attempting to overwrite a label will result in an error.
  * If --resource-version is specified, then updates will use this resource version, otherwise the existing resource-version will be used.

Options

- `--all`

  Select all resources, in the namespace of the specified resource types
- `--all-namespaces`, `-A`

  If true, check the specified action in all namespaces.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--field-selector`

  Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to update the labels
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--list`

  If true, display the labels for a given resource.
- `--local`

  If true, label will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--overwrite`

  If true, allow labels to be overwritten, otherwise reject label updates that overwrite existing labels.
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--resource-version`

  If non-empty, the labels update will only succeed if this is the current resource-version for the object. Only valid when specifying a single resource.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a

namespace.

- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity

- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k logs

Usage:

```
d8 k logs [-f] [-p] (POD | TYPE/NAME) [-c CONTAINER] [options]
```

Print the logs for a container in a pod

Show more...

Print the logs for a container in a pod or specified resource. If the pod has only one container, the container name is optional.

Options

- `--all-containers`

  Get all containers' logs in the pod(s).
- `--all-pods`

  Get logs from all pod(s). Sets prefix to true.
- `--container`, `-c`

  Print the logs of this container
- `--follow`, `-f`

  Specify if the logs should be streamed.
- `--ignore-errors`

  If watching / following pod logs, allow for any errors that occur to be non-fatal
- `--insecure-skip-tls-verify-backend`

  Skip verifying the identity of the kubelet that logs are requested from. In theory, an attacker could provide invalid log content back. You might want to use this if your kubelet serving certificates have expired.
- `--limit-bytes`

  Maximum bytes of logs to return. Defaults to no limit.
- `--max-log-requests`

  Specify maximum number of concurrent logs to follow when using by a selector. Defaults to 5.
- `--pod-running-timeout`

  The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running
- `--prefix`

  Prefix each log line with the log source (pod name and container name)
- `--previous`, `-p`

  If true, print the logs for the previous instance of the container in a pod if it exists.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--since`

  Only return logs newer than a relative duration like 5s, 2m, or 3h. Defaults to all logs. Only one of since-time / since may be used.
- `--since-time`

  Only return logs after a specific date (RFC3339). Defaults to all logs. Only one of since-time / since may be used.
- `--tail`

  Lines of recent log file to display. Defaults to -1 with no selector, showing all log lines otherwise 10, if a selector is provided.
- `--timestamps`

  Include timestamps on each line in the log output

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k options

Usage:

```
d8 k options [options]
```

Print the list of flags inherited by all commands

Show more...

Print the list of flags inherited by all commands

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k patch

Usage:

```
d8 k patch (-f FILENAME | TYPE NAME) [-p PATCH|--patch-file FILE] [options]
```

Update fields of a resource

Show more...

Update fields of a resource using strategic merge patch, a JSON merge patch, or a JSON patch.

JSON and YAML formats are accepted.

Note: Strategic merge patch is not supported for custom resources.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to update
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--local`

  If true, patch will operate on the content of the file, not the server-side resource.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--patch`, `-p`

  The patch to be applied to the resource JSON file.
- `--patch-file`

  A file containing a patch to be applied to the resource.
- `--record`

Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.

- `--recursive, -R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--subresource`

  If specified, patch will operate on the subresource of the requested object.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--type`

  The type of patch being provided; one of [json merge strategic]

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace, -n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k plugin

Usage:

```
d8 k plugin [flags] [options]
```

Provides utilities for interacting with plugins

Show more...

Provides utilities for interacting with plugins.

Plugins provide extended functionality that is not part of the major command-line distribution. Please refer to the documentation and examples for more information about how write your own plugins.

The easiest way to discover and install plugins is via the kubernetes sub-project krew: [krew.sigs.k8s.io]. To install krew, visit https://krew.sigs.k8s.io/docs/user-guide/setup/install

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k plugin list

Usage:

```
d8 k plugin [flags] list [options]
```

List all visible plugin executables on a user's PATH

Show more...

List all available plugin files on a user's PATH. To see plugins binary names without the full path use --name-only flag.

Available plugin files are those that are: - executable - anywhere on the user's PATH - begin with "kubectl-"

Options

- `--name-only`

  If true, display only the binary name of each plugin, rather than its full path

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server

- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k port-forward

Usage:

```
d8 k port-forward TYPE/NAME [options] [LOCAL_PORT:]REMOTE_PORT [...[LOCAL_PORT_N:]REMOTE_PORT_N]
```

Forward one or more local ports to a pod

Show more...

Forward one or more local ports to a pod.

Use resource type/name such as deployment/mydeployment to select a pod. Resource type defaults to 'pod' if omitted.

If there are multiple pods matching the criteria, a pod will be selected automatically. The forwarding session ends when the selected pod terminates, and a rerun of the command is needed to resume forwarding.

Options

- `--address`

  Addresses to listen on (comma separated). Only accepts IP addresses or localhost as a value. When localhost is supplied, kubectl will try to bind on both 127.0.0.1 and ::1 and will fail if neither of these addresses are available to bind.
- `--pod-running-timeout`

  The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server

- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k proxy

Usage:

```
d8 k proxy [--port=PORT] [--www=static-dir] [--www-prefix=prefix] [--api-prefix=prefix] [options]
```

Run a proxy to the Kubernetes API server

Show more...

Creates a proxy server or application-level gateway between localhost and the Kubernetes API server. It also allows serving static content over specified HTTP path. All incoming data enters through one port and gets forwarded to the remote Kubernetes API server port, except for the path matching the static content path.

Options

- `--accept-hosts`

  Regular expression for hosts that the proxy should accept.
- `--accept-paths`

  Regular expression for paths that the proxy should accept.
- `--address`

The IP address on which to serve on.

- `--api-prefix`

  Prefix to serve the proxied API under.
- `--append-server-path`

  If true, enables automatic path appending of the kube context server path to each request.
- `--disable-filter`

  If true, disable request filtering in the proxy. This is dangerous, and can leave you vulnerable to XSRF attacks, when used with an accessible port.
- `--keepalive`

  keepalive specifies the keep-alive period for an active network connection. Set to 0 to disable keepalive.
- `--port`, `-p`

  The port on which to run the proxy. Set to 0 to pick a random port.
- `--reject-methods`

  Regular expression for HTTP methods that the proxy should reject (example --reject-methods='POST,PUT,PATCH').
- `--reject-paths`

  Regular expression for paths that the proxy should reject. Paths specified here will be rejected even accepted by --accept-paths.
- `--unix-socket`, `-u`

  Unix socket on which to run the proxy.
- `--www`, `-w`

  Also serve static files from the given directory under the specified prefix.
- `--www-prefix`, `-P`

  Prefix to serve static files under, if static file directory is specified.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k replace

Usage:

```
d8 k replace -f FILENAME [options]
```

Replace a resource by file name or stdin

Show more...

Replace a resource by file name or stdin.

JSON and YAML formats are accepted. If replacing an existing resource, the complete resource spec must be provided. This can be obtained by

    $ kubectl get TYPE NAME -o yaml

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--cascade`

  Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

Name of the manager used to track field ownership.

- `--filename, -f`

  The files that contain the configurations to replace.
- `--force`

  If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.
- `--grace-period`

  Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when --force is true (force deletion).
- `--kustomize, -k`

  Process a kustomization directory. This flag can't be used together with -f or -R.
- `--output, -o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--raw`

  Raw URI to PUT to the server. Uses the transport specified by the kubeconfig file.
- `--recursive, -R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--subresource`

  If specified, replace will operate on the subresource of the requested object.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--timeout`

  The length of time to wait before giving up on a delete, zero means determine a timeout from the size of the object
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.
- `--wait`

  If true, wait for resources to be gone before returning. This waits for finalizers.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout

Usage:

```
d8 k rollout SUBCOMMAND [options]
```

Manage the rollout of a resource

Show more...

Manage the rollout of one or many resources.

Valid resource types include:

* deployments
* daemonsets
* statefulsets

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`
  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--match-server-version`
  Require server version to match client version
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--profile`
  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`
  Name of the file to write the profile to
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`
  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the

server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout history

Usage:

```
d8 k rollout SUBCOMMAND history (TYPE NAME | TYPE/NAME) [flags] [options]
```

View rollout history

Show more...

View previous rollout revisions and configurations.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--revision`

  See the details, including podTemplate of the revision specified
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.

- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout pause

Usage:

```
d8 k rollout SUBCOMMAND pause RESOURCE [options]
```

Mark the provided resource as paused

Show more...

Mark the provided resource as paused.

Paused resources will not be reconciled by a controller. Use "kubectl rollout resume" to resume a paused resource. Currently only deployments support being paused.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout restart

Usage:

```
d8 k rollout SUBCOMMAND restart RESOURCE [options]
```

Restart a resource

Show more...

Restart a resource.

Resource rollout will be restarted.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to

golang and jsonpath output formats.

- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename, -f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize, -k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output, -o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive, -R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector, -l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout resume

Usage:

```
d8 k rollout SUBCOMMAND resume RESOURCE [options]
```

Resume a paused resource

Show more...

Resume a paused resource.

Paused resources will not be reconciled by a controller. By resuming a resource, we allow it to be reconciled again. Currently only deployments support being resumed.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.

- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout status

Usage:

```
d8 k rollout SUBCOMMAND status (TYPE NAME | TYPE/NAME) [flags] [options]
```

Show the status of the rollout

Show more...

Show the status of the rollout.

By default 'rollout status' will watch the status of the latest rollout until it's done. If you don't want to wait for the rollout to finish then you can use --watch=false. Note that if a new rollout starts in-between, then 'rollout status' will continue watching the latest revision. If you want to pin to a specific revision and abort if it is rolled over by another revision, use --revision=N where N is the revision you need to watch for.

Options

- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--revision`

  Pin to a specific revision for showing its status. Defaults to 0 (last revision).
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--timeout`

  The length of time to wait before ending watch, zero means never. Any other values should contain a corresponding time unit (e.g. 1s, 2m, 3h).
- `--watch`, `-w`

  Watch the status of the rollout until it's done.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.

- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k rollout undo

Usage:

```
d8 k rollout SUBCOMMAND undo (TYPE NAME | TYPE/NAME) [flags] [options]
```

Undo a previous rollout

Show more...

Roll back to a previous rollout.

Options

- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--to-revision`

  The revision to rollback to. Default to 0 (last revision).

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use

- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k run

Usage:

```
d8 k run NAME --image=image [--env="key=value"] [--port=port] [--dry-run=server|client] [--overrides=inline-json]
[--command] -- [COMMAND] [args...] [options]
```

Run a particular image on the cluster

Show more...

Create and run a particular image in a pod.

Options

- `--allow-missing-template-keys`

If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.

- `--annotations`

  Annotations to apply to the pod.
- `--attach`

  If true, wait for the Pod to start running, and then attach to the Pod as if 'kubectl attach ...' were called. Default false, unless '-i/--stdin' is set, in which case the default is true. With '--restart=Never' the exit code of the container process is returned.
- `--cascade`

  Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.
- `--command`

  If true and extra arguments are present, use them as the 'command' field in the container, rather than the 'args' field which is the default.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--env`

  Environment variables to set in the container.
- `--expose`

  If true, create a ClusterIP service associated with the pod. Requires `--port`.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  to use to replace the resource.
- `--force`

  If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.
- `--grace-period`

  Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when --force is true (force deletion).
- `--image`

  The image for the container to run.
- `--image-pull-policy`

  The image pull policy for the container. If left empty, this value will not be specified by the client and defaulted by the server.
- `--kustomize`, `-k`

  Process a kustomization directory. This flag can't be used together with -f or -R.
- `--labels`, `-l`

  Comma separated labels to apply to the pod. Will override previous values.
- `--leave-stdin-open`

  If the pod is started in interactive mode or with stdin, leave stdin open after the first attach completes. By default, stdin will be closed after the first attach completes.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--override-type`

  The method used to override the generated object: json, merge, or strategic.
- `--overrides`

  An inline JSON override for the generated object. If this is non-empty, it is used to override the generated object. Requires that the object supply a valid apiVersion field.
- `--pod-running-timeout`

  The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running
- `--port`

  The port that this container exposes.
- `--privileged`

  If true, run the container in privileged mode.
- `--quiet`, `-q`

If true, suppress prompt messages.

- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--restart`

  The restart policy for this Pod. Legal values [Always, OnFailure, Never].
- `--rm`

  If true, delete the pod after it exits. Only valid when attaching to the container, e.g. with '--attach' or with '-i/--stdin'.
- `--save-config`

  If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--stdin`, `-i`

  Keep stdin open on the container in the pod, even if nothing is attached.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--timeout`

  The length of time to wait before giving up on a delete, zero means determine a timeout from the size of the object
- `--tty`, `-t`

  Allocate a TTY for the container in the pod.
- `--wait`

  If true, wait for resources to be gone before returning. This waits for finalizers.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections

insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k scale

Usage:

```
d8 k scale [--resource-version=version] [--current-replicas=count] --replicas=COUNT (-f FILENAME | TYPE NAME)
[options]
```

Set a new size for a deployment, replica set, or replication controller

Show more...

Set a new size for a deployment, replica set, replication controller, or stateful set.

Scale also allows users to specify one or more preconditions for the scale action.

If --current-replicas or --resource-version is specified, it is validated before the scale is attempted, and it is guaranteed that the precondition holds true when the scale is sent to the server.

Options

- `--all`

  Select all resources in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to

golang and jsonpath output formats.

- `--current-replicas`

  Precondition for current size. Requires that the current size of the resource match this value in order to scale. -1 (default) for no condition.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to set a new size
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--replicas`

  The new desired number of replicas. Required.
- `--resource-version`

  Precondition for resource version. Requires that the current resource version match this value in order to scale.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--timeout`

  The length of time to wait before giving up on a scale operation, zero means don't wait. Any other values should contain a corresponding time unit (e.g. 1s, 2m, 3h).

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set

Usage:

```
d8 k set SUBCOMMAND [options]
```

Set specific features on objects

Show more...

Configure application resources.

These commands help you make changes to existing application resources.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server

- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set env

Usage:

```
d8 k set SUBCOMMAND env RESOURCE/NAME KEY_1=VAL_1 ... KEY_N=VAL_N [options]
```

Update environment variables on a pod template

Show more...

Update environment variables on a pod template.

List environment variable definitions in one or more pods, pod templates. Add, update, or remove container environment variable definitions in one or more pod templates (within replication controllers or deployment configurations). View or modify the environment variable definitions on all containers in the specified pods or pod templates, or just those that match a wildcard.

If "--env -" is passed, environment variables can be read from STDIN using the standard env syntax.

Possible resources include (case insensitive):

pod (po), replicationcontroller (rc), deployment (deploy), daemonset (ds), statefulset (sts), cronjob (cj), replicaset (rs)

Options

- `--all`

  If true, select all resources in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--containers`, `-c`

  The names of containers in the selected pod templates to change - may use wildcards
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--env`, `-e`

  Specify a key-value pair for an environment variable to set into each container.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files the resource to update the env
- `--from`

  The name of a resource from which to inject environment variables
- `--keys`

  Comma-separated list of keys to import from specified resource
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--list`

  If true, display the environment and any changes in the standard format. this flag will removed when we have kubectl view env.
- `--local`

  If true, set env will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--overwrite`

If true, allow environment to be overwritten, otherwise reject updates that overwrite existing environment.

- `--prefix`

  Prefix to append to variable names
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--resolve`

  If true, show secret or configmap references when listing variables
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server

- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set image

Usage:

```
d8 k set SUBCOMMAND image (-f FILENAME | TYPE NAME) CONTAINER_NAME_1=CONTAINER_IMAGE_1 ...
CONTAINER_NAME_N=CONTAINER_IMAGE_N [options]
```

Update the image of a pod template

Show more...

Update existing container image(s) of resources.

Possible resources include (case insensitive):

pod (po), replicationcontroller (rc), deployment (deploy), daemonset (ds), statefulset (sts), cronjob (cj), replicaset (rs)

Options

- `--all`

  Select all resources, in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--local`

  If true, set image will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile,

jsonpath, jsonpath-as-json, jsonpath-file).

- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server

- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set resources

Usage:

```
d8 k set SUBCOMMAND resources (-f FILENAME | TYPE NAME)  ([--limits=LIMITS & --requests=REQUESTS] [options]
```

Update resource requests/limits on objects with pod templates

Show more...

Specify compute resource requirements (CPU, memory) for any resource that defines a pod template. If a pod is successfully scheduled, it is guaranteed the amount of resource requested, but may burst up to its specified limits.

For each compute resource, if a limit is specified and a request is omitted, the request will default to the limit.

Possible resources include (case insensitive): Use "kubectl api-resources" for a complete list of supported resources..

Options

- `--all`

  Select all resources, in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--containers`, `-c`

  The names of containers in the selected pod templates to change, all containers are selected by default - may use wildcards
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files identifying the resource to get from a server.
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.

- `--limits`

  The resource requirement requests for this container. For example, 'cpu=100m,memory=256Mi'. Note that server side components may assign requests depending on the server configuration, such as limit ranges.
- `--local`

  If true, set resources will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--requests`

  The resource requirement requests for this container. For example, 'cpu=100m,memory=256Mi'. Note that server side components may assign requests depending on the server configuration, such as limit ranges.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set selector

Usage:

```
d8 k set SUBCOMMAND selector (-f FILENAME | TYPE NAME) EXPRESSIONS [--resource-version=version] [options]
```

Set the selector on a resource

Show more...

Set the selector on a resource. Note that the new selector will overwrite the old selector if the resource had one prior to the invocation of 'set selector'.

A selector must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 63 characters. If --resource-version is specified, then updates will use this resource version, otherwise the existing resource-version will be used. Note: currently selectors can only be set on Service objects.

Options

- `--all`

  Select all resources in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

Name of the manager used to track field ownership.

- `--filename, -f`

  identifying the resource.
- `--local`

  If true, annotation will NOT contact api-server but run locally.
- `--output, -o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive, -R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--resource-version`

  If non-empty, the selectors update will only succeed if this is the current resource-version for the object. Only valid when specifying a single resource.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set serviceaccount

Alias: `sa`

Usage:

```
d8 k set SUBCOMMAND serviceaccount (-f FILENAME | TYPE NAME) SERVICE_ACCOUNT [options]
```

Update the service account of a resource

Show more...

Update the service account of pod template resources.

Possible resources (case insensitive) can be:

replicationcontroller (rc), deployment (deploy), daemonset (ds), job, replicaset (rs), statefulset

Options

- `--all`

  Select all resources, in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

Filename, directory, or URL to files identifying the resource to get from a server.

- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--local`

  If true, set serviceaccount will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--record`

  Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists.
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version

- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k set subject

Usage:

```
d8 k set SUBCOMMAND subject (-f FILENAME | TYPE NAME) [--user=username] [--group=groupname] [--
serviceaccount=namespace:serviceaccountname] [--dry-run=server|client|none] [options]
```

Update the user, group, or service account in a role binding or cluster role binding

Show more...

Update the user, group, or service account in a role binding or cluster role binding.

Options

- `--all`

  Select all resources, in the namespace of the specified resource types
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--filename`, `-f`

  Filename, directory, or URL to files the resource to update the subjects
- `--group`

  Groups to bind to the role
- `--kustomize`, `-k`

  Process the kustomization directory. This flag can't be used together with -f or -R.
- `--local`

If true, set subject will NOT contact api-server but run locally.

- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--serviceaccount`

  Service accounts to bind to the role
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--user`

  Usernames to bind to the role

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k taint

Usage:

```
d8 k taint NODE NAME KEY_1=VAL_1:TAINT_EFFECT_1 ... KEY_N=VAL_N:TAINT_EFFECT_N [options]
```

Update the taints on one or more nodes

Show more...

Update the taints on one or more nodes.

  * A taint consists of a key, value, and effect. As an argument here, it is expressed as key=value:effect.
  * The key must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 253 characters.
  * Optionally, the key can begin with a DNS subdomain prefix and a single '/', like example.com/my-app.
  * The value is optional. If given, it must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 63 characters.
  * The effect must be NoSchedule, PreferNoSchedule or NoExecute.
  * Currently taint can only apply to node.

Options

- `--all`

  Select all nodes in the cluster
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--field-manager`

  Name of the manager used to track field ownership.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--overwrite`

  If true, allow taints to be overwritten, otherwise reject taint updates that overwrite existing taints.

- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--validate`

  Must be one of: strict (or true), warn, ignore (or false). "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k top

Usage:

```
d8 k top [options]
```

Display resource (CPU/memory) usage

Show more...

Display resource (CPU/memory) usage.

This command provides a view of recent resource consumption for nodes and pods. It fetches metrics from the Metrics Server, which aggregates this data from the kubelet on each node. The Metrics Server must be installed and running in the cluster for this command to work.

The metrics shown are specifically optimized for Kubernetes autoscaling decisions, such as those made by the Horizontal Pod Autoscaler (HPA) and Vertical Pod Autoscaler (VPA). Because of this, the values may not match those from standard OS tools like 'top', as the metrics are designed to provide a stable signal for autoscalers rather than for pinpoint accuracy.

When to use this command:

* For on-the-fly spot-checks of resource usage (e.g. identify which pods are consuming the most resources at a glance, or get a quick sense of the load on your nodes)
* Understand current resource consumption patterns
* Validate the behavior of your HPA or VPA configurations by seeing the metrics they use for scaling decisions.

It is not intended to be a replacement for full-featured monitoring solutions. Its primary design goal is to provide a low-overhead signal for autoscalers, not to be a perfectly accurate monitoring tool. For high-accuracy reporting, historical analysis, dashboarding, or alerting, you should use a dedicated monitoring solution.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.

- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k top node

Aliases: `nodes`, `no`

Usage:

```
d8 k top node [NAME | -l label] [options]
```

Display resource (CPU/memory) usage of nodes

Show more...

Display resource (CPU/memory) usage of nodes.

The top-node command allows you to see the resource consumption of nodes.

Options

- `--no-headers`
  If present, print output without headers
- `--selector`, `-l`
  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-capacity`
  Print node resources based on Capacity instead of Allocatable(default) of the nodes.
- `--show-swap`
  Print node resources related to swap memory.
- `--sort-by`
  If non-empty, sort nodes list using specified field. The field can be either 'cpu' or 'memory'.
- `--use-protocol-buffers`
  Enables using protocol-buffers to access Metrics API.

Global options

- `--as`
  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation.
- `--as-user-extra`
  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`
  Default cache directory
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.

- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k top pod

Aliases: `pods`, `po`

Usage:

```
d8 k top pod [NAME | -l label] [options]
```

Display resource (CPU/memory) usage of pods

Show more...

Display resource (CPU/memory) usage of pods.

The 'top pod' command allows you to see the resource consumption of pods.

Due to the metrics pipeline delay, they may be unavailable for a few minutes since pod creation.

Options

- `--all-namespaces`, `-A`

  If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.
- `--containers`

  If present, print usage of containers within a pod.
- `--field-selector`

  Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.

- `--no-headers`

  If present, print output without headers.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.
- `--show-swap`

  Print pod resources related to swap memory.
- `--sort-by`

  If non-empty, sort pods list using specified field. The field can be either 'cpu' or 'memory'.
- `--sum`

  Print the sum of the resource usage
- `--use-protocol-buffers`

  Enables using protocol-buffers to access Metrics API.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k uncordon

Usage:

```
d8 k uncordon NODE [options]
```

Mark node as schedulable

Show more...

Mark node as schedulable.

Options

- `--dry-run`

  Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', '!=', 'in', 'notin'.(e.g. -l key1=value1,key2=value2,key3 in (value3)). Matching objects must satisfy all of the specified label constraints.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k version

Usage:

```
d8 k version [options]
```

Print the client and server version information

Show more...

Print the client and server version information for the current context.

Options

- `--client`

  If true, shows client version only (no server required).
- `--output`, `-o`

  One of 'yaml' or 'json'.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 k wait

Usage:

```
d8 k wait ([-f FILENAME] | resource.group/resource.name | resource.group [(-l label | --all)]) [--for=create|--
for=delete|--for condition=available|--for=jsonpath='{}'[=value]] [options]
```

Wait for a specific condition on one or many resources

Show more...

Wait for a specific condition on one or many resources.

The command takes multiple resources and waits until the specified condition is seen in the Status field of every given resource.

Alternatively, the command can wait for the given set of resources to be created or deleted by providing the "create" or "delete" keyword as the value to the --for flag.

A successful message will be printed to stdout indicating when the specified condition has been met. You can use -o option to change to output destination.

Options

- `--all`

  Select all resources in the namespace of the specified resource types
- `--all-namespaces`, `-A`

  If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.
- `--allow-missing-template-keys`

  If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.
- `--field-selector`

  Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.
- `--filename`, `-f`

  identifying the resource.
- `--for`

  The condition to wait on: [create|delete|condition=condition-name[=condition-value]|jsonpath='{JSONPath expression}'=[JSONPath value]]. The default condition-value is true. Condition values are compared after Unicode simple case folding, which is a more general form of case-insensitivity.
- `--local`

  If true, annotation will NOT contact api-server but run locally.
- `--output`, `-o`

  Output format. One of: (json, yaml, kyaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).
- `--recursive`, `-R`

  Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.
- `--selector`, `-l`

  Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2)

- `--show-managed-fields`

  If true, keep the managedFields when printing objects in JSON or YAML format.
- `--template`

  Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [http://golang.org/pkg/text/template/#pkg-overview].
- `--timeout`

  The length of time to wait before giving up. Zero means check once and don't wait, negative means wait for a week.

Global options

- `--as`

  Username to impersonate for the operation. User could be a regular user or a service account in a namespace.
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation.
- `--as-user-extra`

  User extras to impersonate for the operation, this flag can be repeated to specify multiple values for the same key.
- `--cache-dir`

  Default cache directory
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--kuberc`

  Path to the kuberc file to use for preferences. This can be disabled by exporting KUBECTL_KUBERC=false feature gate or turning off the feature KUBERC=off.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--match-server-version`

  Require server version to match client version
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--profile`

  Name of profile to capture. One of (none|cpu|heap|goroutine|threadcreate|block|mutex|trace)
- `--profile-output`

  Name of the file to write the profile to
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

The address and port of the Kubernetes API server
- `--tls-server-name`

  Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)
- `--warnings-as-errors`

  Treat warnings received from the server as errors and exit with a non-zero exit code

d8 mirror

Copy Deckhouse Kubernetes Platform distribution to the local filesystem or third-party registry

Show more...

Copy Deckhouse Kubernetes Platform distribution to the local filesystem or the air-gapped registries.

For more information on how to use it, consult the docs at https://deckhouse.io/products/kubernetes-platform/documentation/latest/installing/#manual-loading-of-dkp-images-and-vulnerability-db-into-a-private-registry

LICENSE NOTE: The d8 mirror functionality is exclusively available to users holding a valid license for any commercial version of the Deckhouse Kubernetes Platform.

© Flant JSC 2025

d8 mirror pull

Usage:

```
d8 mirror pull <images-bundle-path> [options]
```

Copy Deckhouse Kubernetes Platform distribution to the local filesystem

Show more...

Download Deckhouse Kubernetes Platform distribution to the local filesystem.

This command downloads the Deckhouse Kubernetes Platform distribution bundle
containing specific platform releases and it's modules,
to be pushed into the air-gapped container registry at a later time.

For more information on how to use it, consult the docs at
https://deckhouse.io/products/kubernetes-platform/documentation/latest/installing/#manual-loading-of-dkp-images-and-vulnerability-db-into-a-private-registry

Additional configuration options for the d8 mirror family of commands are available as environment variables:

 * $SSL_CERT_FILE — Path to the SSL certificate. If the variable is set, system certificates are not used;
 * $SSL_CERT_DIR — List of directories to search for SSL certificate files, separated by a colon.
If set, system certificates are not used. More info at
https://docs.openssl.org/1.0.2/man1/c_rehash/;
 * $HTTP_PROXY/$HTTPS_PROXY — URL of the proxy server for HTTP(S) requests to hosts that are not listed in the $NO_PROXY;
 * $NO_PROXY — Comma-separated list of hosts to exclude from proxying.
Supported value formats include IP's', CIDR notations (1.2.3.4/8), domains, and asterisk sign (*).
The IP addresses and domain names can also include a literal port number (1.2.3.4:80).
The domain name matches that name and all the subdomains.
The domain name with a leading . matches subdomains only.
For example, foo.com matches foo.com and bar.foo.com; .y.com matches x.y.com but does not match y.com.
A single asterisk * indicates that no proxying should be done;

Options

- `--deckhouse-cli-tag`

  Specific d8 CLI version to mirror, e.g. "v0.13.1". Without this flag the newest published stable version is mirrored.

  The CLI binary lives at the deckhouse-cli registry segment, next to the plugins catalog; a registry that publishes no such repository is reported in the summary instead of failing the pull, unless this flag asked for a version.
- `--deckhouse-tag`

  Specific Deckhouse build tag to pull. Conflicts with --since-version and --include-platform. If registry contains release channel image for specified tag, all release channels in the bundle will be pointed to it.
- `--dry-run`

  Print what would be pulled without downloading any images. Useful for fast validation of flags and filters.
- `--exclude-module`, `-e`

  Blacklist specific modules from downloading. Format is "module-name[@constraint]", the same dialect as --include-module, quoting included. Use one flag per each module. Overridden by use of --include-module.
- `--exclude-package`

  Blacklist specific packages from downloading. Format is "package-name[@constraint]", the same dialect as --include-module, quoting included. Use one flag per each package. Overridden by use of --include-package.
- `--force`

  Overwrite existing bundle packages if they are conflicting with current pull operation.
- `--gost-digest`

  Calculate GOST R 34.11-2012 STREEBOG digest for downloaded bundle
- `--ignore-suspend`

  Ignore suspended release channels and continue mirroring. Use with caution.
- `--images-bundle-chunk-size`, `-c`

  Split resulting bundle file into chunks of at most N gigabytes
- `--include-module`, `-i`

  Whitelist specific modules for downloading. Format is "module-name[@constraint]". Use one flag per each module. Disables blacklisting by --exclude-module.

  Quote the whole value when the constraint uses >= or <=: --include-module "module-name@>=1.3.0". Unquoted, the shell takes > as a redirection and d8 receives a module with no version.

  A constraint keeps the latest patch in each minor it covers. Versions named with >= or <= are kept as well. An exact tag (=) pins one tag and publishes it to the release channels.

  All other constraints also pull the versions the release channels point at. These are added on top of the range without being checked against it, so the upper bound does not apply to them: "module-name@>=1.3.0 <=1.4.0" still pulls v1.4.1 if a release channel points at it. The examples below leave them out.

  Given v1.0.0, v1.1.0, v1.2.0, v1.3.0, v1.3.3, v1.4.0, v1.4.1:
  module-name only what the release channels point at, like a pull with no filters
  module-name@1.3.0 >=1.3.0 <2.0.0, same major line: v1.3.3, v1.4.1
  module-name@~1.3.0 >=1.3.0 <1.4.0: v1.3.3
  module-name@^1.3.0 >=1.3.0 <2.0.0: v1.3.3, v1.4.1
  "module-name@>=1.3.0" the same, plus the named v1.3.0
  "module-name@>=1.3.0 <=1.4.0" v1.3.0, v1.3.3, v1.4.0
  module-name@=v1.3.0 only v1.3.0, published to every release channel
  module-name@=v1.3.0+stable only v1.3.0, published to stable
  module-name@=bobV1 only the bobV1 tag, published to every release channel

  For a 0.x module the bare form spans the whole 0.x line (0.4.0 means >=0.4.0 <1.0.0) while the caret locks

the minor (^0.4.0 means >=0.4.0 <0.5.0).

- `--include-package`

  Whitelist specific packages for downloading. Format is "package-name[@constraint]", the same dialect as --include-module, quoting included. Use one flag per each package. Disables blacklisting by --exclude-package.

  Packages live under the packages/ registry segment, with release metadata under packages//version.
- `--include-platform`

  Select platform releases to download by a semver constraint. Same dialect as the version part of --include-module.
  Conflicts with --since-version and --deckhouse-tag.

  Always quote the value: > and < are shell redirections.

  A constraint keeps the latest patch in each minor it covers. Versions named with >= or <= are kept as well. An exact tag (=) pins one release and propagates it to the release channels, just like --deckhouse-tag.

  Given platform releases v1.63.x .. v1.71.x:
  ">=1.64 <=1.68" latest patch per minor in v1.64..v1.68, plus v1.64.0 and v1.68.0
  "~1.65.0" latest v1.65.x patch
  "^1.65.0" latest patch per minor from v1.65.x up
  "1.65.0" same as ^1.65.0 here: platform majors are always >= 1
  "=v1.65.3" only v1.65.3, published to every release channel
  "=v1.65.3+stable" only v1.65.3; the +channel suffix is accepted but changes nothing here
- `--include-plugin`

  Mirror a specific d8 CLI plugin in addition to the automatic selection. Format is "plugin-name[@constraint]", the same dialect as --include-module, quoting included. Use one flag per each plugin.

  Plugins live under the deckhouse-cli/plugins registry segment. Without this flag, plugins required by the mirrored modules (and their plugin dependencies) are selected automatically.
- `--insecure`

  Interact with registries over HTTP.
- `--installer-tag`

  Specific Deckhouse installer build tag to pull. If not specified, the latest tag for the installer will be pulled from the registry path.
- `--license, -l`

  Deckhouse license key. Shortcut for --source-login=license-token --source-password=<>.
- `--modules-path-suffix`

  Registry path suffix to read modules from, relative to the source repo. Use "/" to read modules from the repo root.
- `--no-installer`

  Do not pull Deckhouse installer into bundle.
- `--no-modules`

  Do not pull Deckhouse modules into bundle.
- `--no-packages`

  Do not pull Deckhouse packages into bundle.
- `--no-platform`

  Do not pull Deckhouse Kubernetes Platform into bundle.
- `--no-pull-resume`

  Do not continue last unfinished pull operation and start from scratch.
- `--no-security-db`

  Do not pull security databases into bundle.
- `--only-extra-images`

  Pull only extra images for modules (additional images like security databases, scanners, etc.) without pulling main module images.
- `--proxy-registry`

  Pull from a proxy/caching registry that does not implement the registry catalog API.

  Instead of calling the registry's "list tags" endpoint (which proxy registries typically return empty), this mode

probes individual tags by incrementing patch -> minor -> major from the version explicitly named via --include-platform / --include-module. The probe stops once both a new patch and a new minor of the current major fail to resolve, then attempts the next major; if that also fails the probe terminates and downloads what was discovered.

Requires --include-platform when platform is not skipped via --no-platform, and at least one --include-module when modules are not skipped via --no-modules. --exclude-module and --no-platform are respected.

Cannot be combined with --deckhouse-tag or --since-version (use --include-platform's lower bound instead).

- `--since-version`

  Minimal Deckhouse release to pull. Ignored if above current Rock Solid release. Conflicts with --deckhouse-tag.
- `--skip-vex-images`

  Do not pull VEX images.
- `--source`

  Source registry to pull Deckhouse images from (format: registry-host[:port]/path).
- `--source-login`

  Source registry login.
- `--source-password`

  Source registry password.
- `--tls-skip-verify`

  Disable TLS certificate validation.
- `--tmp-dir`

  Path to a temporary directory to use for image pulling and pushing. All processing is done in this directory, so make sure there is enough free disk space to accommodate the entire bundle you are downloading;
- `--verbose-summary`

  List every module and package in the end-of-pull summary with its resolved versions (and VEX count, when present), instead of just the totals. Output only - it does not change what is pulled.

d8 mirror push

Usage:

```
d8 mirror push [images-bundle-path] <registry> [options]
```

Copy Deckhouse Kubernetes Platform distribution to the third-party registry

Show more...

Upload Deckhouse Kubernetes Platform distribution bundle to the third-party registry.

This command pushes the Deckhouse Kubernetes Platform distribution into the specified container registry.

When the registry path ends with an edition (ce, be, se, se-plus, ee, fe, cse), e.g. registry.example.com/deckhouse/ee, the edition-independent installer and d8 CLI (with its plugins) are pushed one level up, outside the edition: registry.example.com/deckhouse/installer and registry.example.com/deckhouse/deckhouse-cli. That is where the Deckhouse registry keeps them, once for all editions. Everything else is pushed under the given path.

For more information on how to use it, consult the docs at https://deckhouse.io/products/kubernetes-platform/documentation/latest/installing/#manual-loading-of-dkp-images-and-vulnerability-db-into-a-private-registry

Additional configuration options for the d8 mirror family of commands are available as environment variables:

 * $SSL_CERT_FILE — Path to the SSL certificate. If the variable is set, system certificates are not used;
 * $SSL_CERT_DIR — List of directories to search for SSL certificate files, separated by a colon. If set, system certificates are not used. More info at https://docs.openssl.org/1.0.2/man1/c_rehash/;
 * $HTTP_PROXY/$HTTPS_PROXY — URL of the proxy server for HTTP(S) requests to hosts that are not listed in the $NO_PROXY;
 * $NO_PROXY — Comma-separated list of hosts to exclude from proxying.
Supported value formats include IP's', CIDR notations (1.2.3.4/8), domains, and asterisk sign (*).
The IP addresses and domain names can also include a literal port number (1.2.3.4:80).
The domain name matches that name and all the subdomains.
The domain name with a leading . matches subdomains only.
For example, foo.com matches foo.com and bar.foo.com; .y.com matches x.y.com but does not match y.com.

A single asterisk * indicates that no proxying should be done;

LICENSE NOTE:
The d8 mirror functionality is exclusively available to users holding a
valid license for any commercial version of the Deckhouse Kubernetes Platform.

© Flant JSC 2025

Options

- `--file`

  `Path` to a tar or chunked package to push. May be repeated to push multiple packages. Can be used instead of the bundle directory argument or combined with it.
- `--insecure`

  Interact with registries over HTTP.
- `--modules-path-suffix`

  Registry path suffix to push modules to, relative to the target repo. Use "/" to push modules to the repo root.
- `--registry-login`, `-u`

  Username to log into the target registry.
- `--registry-password`, `-p`

  Password to log into the target registry.
- `--tls-skip-verify`

  Disable TLS certificate validation.
- `--tmp-dir`

  Path to a temporary directory to use for image pulling and pushing. All processing is done in this directory, so make sure there is enough free disk space to accommodate the entire bundle you are downloading;

d8 network

Alias: `n`

A group of commands to operate network related tasks in The Deckhouse Ecosystem.

Show more...

A group of commands to operate network related tasks in The Deckhouse Ecosystem.

© Flant JSC 2025

d8 network cni-migration

Usage:

```
d8 network cni-migration [options]
```

A group of commands to switch CNI in the cluster

Show more...

A group of commands to switch the CNI (Container Network Interface) provider in the DKP.

The migration process is handled automatically by an in-cluster controller.
This CLI tool is used to trigger the migration and monitor its status.

Workflow:

1. 'd8 network cni-migration switch --to-cni <CNI>' - Initiates the migration.
   This creates a CNIMigration resource, which triggers the deployment of the migration agent.
   The agent then performs all necessary steps (validation, node checks, CNI switching).

2. 'd8 network cni-migration watch' - (Optional) Monitors the progress of the migration.
   Since the process is automated, this command simply watches the status.

3. 'd8 network cni-migration cleanup' - Cleans up the migration resources after completion.

d8 network cni-migration cleanup

Usage:

```
d8 network cni-migration cleanup [options]
```

Cleans up resources created during CNI switching

d8 network cni-migration switch

Usage:

```
d8 network cni-migration switch [options]
```

Initiates the CNI switching

Options

- `--to-cni`

  Target CNI provider to switch to. Supported values: cilium, flannel, simple-bridge

d8 network cni-migration watch

Usage:

```
d8 network cni-migration watch [options]
```

Monitors the CNI switching progress

d8 network istio

Usage:

```
d8 network istio [options]
```

Run an interactive istioctl debug container

Show more...

Start an interactive debug container with istioctl and the RBAC needed to inspect pods in a target namespace (get/list pods and create pods/portforward).

The ServiceAccount is created in --namespace. Roles and RoleBindings are created in --target-namespace (workload pods) and --istio-namespace (default d8-istio): pods get/list, pods/portforward create, and in the Istio namespace also serviceaccounts get plus serviceaccounts/token create for istiod RPC auth (istioctl proxy-status). No Istio config mutations. The debug image is taken from ConfigMap d8-system/debug-container unless --image is set.

The pod is deleted when the session ends. RBAC objects are left in place so the next run can reuse them.

© Flant JSC 2026

Options

- `--context`

  The name of the kubeconfig context to use
- `--image`

  Debug container image (default: ConfigMap d8-system/debug-container)
- `--istio-namespace`

  Istio control-plane namespace for read-only access (istioctl proxy-status)
- `--kubeconfig`, `-k`

  Path to kubeconfig file
- `--namespace`, `-n`

  Namespace for the ServiceAccount and debug pod (default: current kubeconfig namespace)
- `--target-namespace`

  Namespace whose workload pods istioctl should inspect (default: --namespace)

d8 package

Package build and bootstrap tool for containerized packages

Show more...

A plugin for building and bootstrapping packages.

This plugin helps you:
• Bootstrap new packages from templates with registry configuration
• Build containerized packages and push them to container registries
• Manage package lifecycle with semantic versioning

d8 package bootstrap

Usage:

```
d8 package bootstrap [options]
```

Bootstrap a new package (module or application)

Show more...

Bootstrap a new package from templates.

Use 'bootstrap module <name>' for a module (with hooks, CRDs).
Use 'bootstrap app <name>' for an application package (per-instance resources).

d8 package bootstrap app

Alias: `application`

Usage:

```
d8 package bootstrap app <name> [options]
```

Bootstrap a new application package

Show more...

Bootstrap a new application package from templates.

- Creates a package with type Application in package.yaml
- Includes hooks
- Initializes a git repository with an initial commit

Options

- `--extended`

  Generate extended files in the package
- `--hooks`

  Generate hooks in the package
- `--output`, `-o`

  Custom path for the package (default: /)
- `--werf`

  Use werf file for images

d8 package bootstrap module

Usage:

```
d8 package bootstrap module <name> [options]
```

Bootstrap a new module package

Show more...

Bootstrap a new module package from templates.

- Creates a package with type Module in package.yaml
- Includes hooks and CRDs; templates use package name
- Initializes a git repository with an initial commit

Options

- `--extended`

  Generate extended files in the package
- `--hooks`

  Generate hooks in the package
- `--output`, `-o`

  Custom path for the package (default: /)
- `--werf`

  Use werf file for images

d8 package build

Usage:

```
d8 package build --version <version> [--repository <repository>] [--force] [options]
```

Build and push a package to a container registry

Show more...

Build a package using Werf and push it to a container registry.

This command:
- Validates the package structure (package.yaml)
- Builds container images using Werf in a Docker container
- Pushes the built images to the specified registry
- Tags images with semantic version

Environment Variables:
```
PACKAGE_BUILD_REPOSITORY              Registry URL for build command
PACKAGE_BUILD_REPOSITORY_USER         Registry username for authentication
PACKAGE_BUILD_REPOSITORY_TOKEN        Registry token for authentication
PACKAGE_BUILD_FINAL_REPOSITORY        Final registry URL for the published artifact
PACKAGE_BUILD_FINAL_REPOSITORY_USER   Final registry username for authentication
PACKAGE_BUILD_FINAL_REPOSITORY_TOKEN  Final registry token for authentication
PACKAGE_BUILD_INSECURE                Allow plain HTTP and skip TLS verification
```

Options

- `--debug`

  enable debug logging
- `--final-repo`

  Final repository (env: PACKAGE_BUILD_FINAL_REPOSITORY)
- `--final-token`

  Final registry token (env: PACKAGE_BUILD_FINAL_REPOSITORY_TOKEN)
- `--final-user`

  Final registry user (env: PACKAGE_BUILD_FINAL_REPOSITORY_USER)
- `--force`, `-f`

  force update version in registry
- `--insecure`

  Allow plain HTTP and skip TLS verification for every registry used by the build, including the final repository and base-image pulls (env: PACKAGE_BUILD_INSECURE)
- `--repo`, `-r`

  Repository (env: PACKAGE_BUILD_REPOSITORY)
- `--sign`

  sign package with certificate and key. --sign-cert and --sign-key are required
- `--sign-cert`

  sign certificate path or base64 string (env: PACKAGE_BUILD_SIGN_CERT)
- `--sign-key`

  sign key path or base64 string or vault url (env: PACKAGE_BUILD_SIGN_KEY)
- `--token`, `-t`

  Registry token (env: PACKAGE_BUILD_REPOSITORY_TOKEN)
- `--user`, `-u`

  Registry user (env: PACKAGE_BUILD_REPOSITORY_USER)
- `--version`, `-v`

  Package version

d8 package doc

Usage:

```
d8 package doc [linter] [options]
```

Show documentation for verify linters and rules

Show more...

Show documentation for the linters run by 'package verify'.

Use 'package doc' to list every linter.

Use 'package doc <linter>' to see what a linter checks, the rules it runs with
their default severities, and the .pkglint.yaml keys that configure it.

Use 'package doc <linter> --rule <rule>' to see what makes a single rule report a finding and how to satisfy it.

A rule's impact caps the severity of its findings: ignored hides them, warn reports them without failing, error fails verification.

Options

- `--rule`

  Show documentation for a single rule of the linter

d8 package render

Usage:

```
d8 package render [options]
```

Render package templates to Kubernetes manifests

Show more...

Render a package's templates to Kubernetes manifests using stubbed runtime values.

Use 'package render' in a package directory to preview the manifests that would be installed in a cluster. Image digests, registry and credentials are stubbed, so the output is a smoke-check preview, not a faithful representation of a real cluster.

Use 'package render --remote <registry-path>/<package>:<version>' to render a published bundle image instead of the current directory. The image must exist and must carry an explicit tag or digest. Only the bundle image is renderable: the release image ships without a templates directory.

Registry credentials default to the ambient Docker keychain. Pass --remote-user and --remote-password to authenticate explicitly, or set them in the environment:

```
PACKAGE_REMOTE_USER      fallback for --remote-user
PACKAGE_REMOTE_PASSWORD  fallback for --remote-password
```

Use --file to print only the manifests rendered from the template with that file name, and --render-file to write a clean render (without '# Source:' headers) to a file.

Options

- `--file`

  Show only manifests rendered from the template with this file name
- `--remote`, `-r`

  Render a published bundle image by its reference, /:
- `--remote-password`

  Registry password or token for --remote (env: PACKAGE_REMOTE_PASSWORD)
- `--remote-user`

  Registry user for --remote (env: PACKAGE_REMOTE_USER)
- `--render-file`

  Write the clean render (without '# Source:' headers) to this file path

d8 package verify

Usage:

```
d8 package verify [options]
```

Verify a package structure and configuration

Show more...

Verify a package structure and configuration.

Use 'package verify' to verify the current package directory against the 'static' linter settings.

Use 'package verify remote <registry-path> <package>' to verify a published package instead.

Linter configuration can be customized via .pkglint.yaml in the package root.

Options

- `--hide-warnings`

  Hide warning-level messages
- `--lint-config`

  Path to lint config file
- `--show-ignored`

  Show ignored-level messages

d8 package verify remote

Usage:

```
d8 package verify remote <registry-path> <package> [options]
```

Verify a published package from a registry

Show more...

Verify a published package.

The arguments are the registry path the package is published under and the package name. Build publishes two images per version, both tagged with that version:

```
  bundle   <registry-path>/<package>:<version>
         checked against the 'remote.bundle' linter settings
  release  <registry-path>/<package>/version:<version>
         checked against the 'remote.release' linter settings
```

Without --version the latest published version is verified, chosen by comparing the repository tags as semver. The bundle image carries the package itself and is always verified; add --release to verify the release image alongside it, in which case both are verified concurrently and each must exist.

Lint settings are read from the working directory, not from the image: published images do not carry a .pkglint.yaml.

Options

- `--release`

  Also verify the release image published for the version
- `--version`

  Version to verify (default: the latest published version)

Global options

- `--hide-warnings`

  Hide warning-level messages
- `--lint-config`

  Path to lint config file
- `--show-ignored`

  Show ignored-level messages

d8 snapshot

Snapshot operations (create, delete, download, restore, upload, get)

d8 snapshot create

Usage:

```
d8 snapshot create <name> [options]
```

Create a Snapshot of a namespace

Show more...

Create a Snapshot object that captures a namespace's state/configuration.

The Snapshot is created in the target namespace (defaults to the kubeconfig context namespace). An empty selector captures the whole namespace; pass --selector to capture only the objects matching the given labels (sets spec.resourceSelector.matchLabels).

The Snapshot is reconciled asynchronously by the state-snapshotter controller. Use --wait

to block until it reports Ready, after which it can be listed, downloaded, and imported.

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--namespace`, `-n`

  namespace to create the Snapshot in (defaults to the kubeconfig context namespace)
- `--output`, `-o`

  Output format: name|json|yaml
- `--selector`, `-l`

  capture only objects matching this label selector (e.g. app=demo,tier=db); sets spec.resourceSelector.matchLabels
- `--timeout`

  timeout for --wait
- `--wait`

  wait until the Snapshot reports Ready

d8 snapshot delete

Usage:

```
d8 snapshot delete [name...] [options]
```

Delete one or more Snapshots

Show more...

Delete Snapshot objects in a namespace.

Targets are selected in exactly one of three ways:
 - by name: d8 snapshot delete snap-a snap-b -n demo
 - by selector: d8 snapshot delete -l app=demo -n demo
 - all: d8 snapshot delete --all -n demo

Deleting a Snapshot lets the state-snapshotter controller garbage-collect the associated SnapshotContent and data artifacts. Use --wait to block until the Snapshot objects are fully removed from the API server.

Options

- `--all`

  delete all Snapshots in the namespace
- `--context`

  The name of the kubeconfig context to use
- `--ignore-not-found`

  do not error if a named Snapshot does not exist
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--namespace`, `-n`

  namespace of the Snapshots (defaults to the kubeconfig context namespace)
- `--selector`, `-l`

  delete Snapshots matching this label selector (e.g. app=demo,tier=db)
- `--timeout`

  timeout for --wait
- `--wait`

  wait until the Snapshots are fully deleted

d8 snapshot describe

Usage:

```
d8 snapshot describe [flags] <name> [options]
```

Show the snapshot hierarchy as a tree

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--namespace`, `-n`

  snapshot namespace (defaults to the kubeconfig context namespace)

d8 snapshot download

Usage:

```
d8 snapshot download [flags] <snapshot> [options]
```

Download a snapshot to a local directory tree

Show more...

Download a Snapshot CR's manifest tree and volume data into a local directory tree
(consumed by 'd8 snapshot upload' or 'd8 snapshot restore').

--publish selects how each data leaf's volume bytes are streamed from its DataExport
exporter pod. With --publish=false (or when autodetection picks it), bytes come straight
from the exporter's in-cluster service, trusting only its internal CA (status.ca). With
--publish=true, bytes come through the storage-foundation-published Ingress endpoint
(status.publicURL) instead, so a kubeconfig without direct network access to the cluster's
internal service network can still download. If --publish is not given, the command probes
whether the in-cluster exporter endpoint is reachable and picks accordingly. Reusing an
existing DataExport upgrades its spec.publish from false to true when --publish=true is
requested, but never downgrades it back to false, so a concurrent run streaming through the
public endpoint is never torn down. IMPORTANT: the publish path works only with a kubeconfig
authenticated by a bearer token. Ingress terminates TLS with its own certificate and does not
forward the client's TLS certificate to the exporter pod, so a certificate-based kubeconfig
receives a 401 when --publish=true.

Options

- `--cleanup`

  delete the per-volume DataExport (and its server-side export chain) after each volume completes; --cleanup=false leaves them in the cluster for debugging
- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--max-parallel-downloads`

  global cap on concurrent whole-volume-stream downloads across all nodes (independent of --workers and --per-volume-concurrency)
- `--namespace`, `-n`

  snapshot namespace (required)
- `--node`

  restrict download to a single node subtree; format '/' (e.g. --node DemoVirtualDisk/bk-disk-a, --node Snapshot/my-snap); the generated snapshot CR name form (e.g. DemoVirtualDiskSnapshot/nss-child-abc) is still accepted
- `--output`, `-o`

  root output directory (required)
- `--per-volume-concurrency`

  maximum parallel chunk/file downloads per volume; lower to 1 on a distant or flaky link if long-lived streams keep breaking
- `--publish`

  download volume data through the published (ingress) exporter endpoint instead of the in-cluster service; if unset, the in-cluster endpoint's reachability is auto-detected
- `--ttl`

  DataExport TTL (e.g. 2h, 30m)

- `--volume-compression`

  volume compression codec (none, zstd); block volumes: data.bin[.]; filesystem volumes: per-file compressed entries inside an uncompressed data.tar container
- `--volume-compression-level`

  compression level for the selected codec (0 = codec default; ignored when --volume-compression=none)
- `--workers`

  maximum number of nodes downloaded concurrently

d8 snapshot get

Aliases: `list`, `ls`

Usage:

```
d8 snapshot get [options]
```

List Snapshot resources in the cluster

Options

- `--all-namespaces`, `-A`

  list Snapshots across all namespaces
- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--namespace`, `-n`

  namespace to list Snapshots from (defaults to the kubeconfig context namespace)
- `--output`, `-o`

  Output format: table|json|yaml

d8 snapshot local

Usage:

```
d8 snapshot local [options]
```

Operate on a locally downloaded snapshot archive (no kubeconfig required)

d8 snapshot local describe

Usage:

```
d8 snapshot local describe <DIR> [options]
```

Show the structure of a locally downloaded snapshot archive as a tree

Show more...

Show the structure of a locally downloaded snapshot archive as a tree.

By default, every node's content checksum and authenticated snapshot.yaml metadata are verified before any output is rendered. Legacy archives without formatVersion and metadataChecksum are rejected because their identity and volume metadata are unauthenticated. Use --allow-unauthenticated-legacy only to inspect a trusted pre-version archive; the command emits a warning because compatibility mode cannot distinguish a genuine legacy archive from a downgraded and tampered current archive.

Options

- `--allow-unauthenticated-legacy`

  allow trusted pre-version archives with unauthenticated snapshot.yaml metadata (unsafe compatibility mode)

d8 snapshot local get

Usage:

```
d8 snapshot local get <DIR> [options]
```

Print a one-line summary of a locally downloaded snapshot archive

Show more...

Print a one-line summary of a locally downloaded snapshot archive.

By default, every node's content checksum and authenticated snapshot.yaml metadata are verified before any output is rendered. Legacy archives without formatVersion and metadataChecksum are rejected because their identity and volume metadata are unauthenticated. Use --allow-unauthenticated-legacy only to inspect a trusted pre-version archive; the command emits a warning because compatibility mode cannot distinguish a genuine legacy archive from a downgraded and tampered current archive.

Options

- `--allow-unauthenticated-legacy`

  allow trusted pre-version archives with unauthenticated snapshot.yaml metadata (unsafe compatibility mode)

d8 snapshot restore

Usage:

```
d8 snapshot restore [flags] <snapshot> [options]
```

Restore a snapshot in-place into its namespace

Show more...

Restore a snapshot tree in-namespace.

The snapshot is restored into the same namespace it lives in: -n/--namespace is both the source Snapshot namespace and the restore target. The required VolumeSnapshot / VirtualDiskSnapshot leaves must already be present in that namespace (they exist after the original snapshot, or after the snapshot is re-created in this namespace).

Cross-namespace restore is not a single command: it is a separate procedure that downloads the snapshot from the source namespace, re-creates the Snapshot and its volume-snapshot leaves in the target namespace, and then runs restore there.

The client walks the selected namespaced snapshot hierarchy and asks the server to compile one node at a time. Every node response is independently size-bounded, and the complete child-before-parent result is staged and validated before the first apply. PersistentVolumeClaims already carry spec.dataSourceRef pointing at the VolumeSnapshot (or VirtualDiskSnapshot for domain disks) present in the namespace, so CSI provisions the data.

--node restricts the restore to a single node subtree. The positional Snapshot always anchors the hierarchy and must exist; the selection may use either the generated snapshot-CR Kind/name or the original captured source Kind/name. A Ready child selected by its generated identity remains restorable when the root is DEGRADED because an unrelated sibling CR was deleted. Selecting that deleted generated child reports that it belongs to the tree but is missing. Original-source selection fails closed while any child ref is unresolved, because a missing child's original identity cannot be inspected; retry with the live match's generated Kind/name and --node-api-version shown in the error.

--node-api-version disambiguates nodes whose selected Kind/name is shared across API groups or versions. Use "v1" for the Kubernetes core group, or "<group>/<version>" for a named group. It requires --node and must match the generated or original identity used by that selection.

--scope narrows how much of the addressed node (the root, or --node's selection) the server compiles: "subtree" (default) compiles the node and its whole subtree, recursively; "node" compiles only the addressed node itself, with no descendants. --scope node with no --node selects the root Snapshot node alone.

--object restricts a --scope node restore to a single captured object within that node, by "<Kind>/<name>"; it requires --scope node and fails fast, before any network call, otherwise.

--dry-run sends every apply with DryRunAll so the API server validates and admits objects (schema validation, webhooks, immutable-field checks) without persisting them. Use it to preflight a restore before committing. The --wait loop is skipped in dry-run mode because no objects are actually created.

Without --edit or --dry-run, an interactive restore automatically opens one editor session when the pre-mutation DryRunAll pass returns Kubernetes Invalid (HTTP 422), including schema, webhook, and immutable-field Invalid responses. Both stdin and stdout must be terminals. Use --no-auto-edit to opt out. Conflict (HTTP 409), AlreadyExists, conflicting duplicate manifests, and an existing Bound PVC never trigger automatic editing. A generic Invalid response does not imply that the object already exists or that an immutable field differs.

After an automatic edit, restore restages and validates the complete manifest set and retries the full DryRunAll pass once; a repeated Invalid is returned without reopening the editor. Explicit --edit opens before preflight and suppresses later automatic editing. Explicit --dry-run never opens the automatic editor. In non-interactive use, Invalid is returned with the original API response preserved as its cause and without invoking an editor. Editor selection is $KUBE_EDITOR, then $EDITOR, falling back to vi; a blank selected command, failed editor, unchanged file, or empty file aborts instead of applying.

Before any dry-run or real apply, restore reads every target PersistentVolumeClaim. If a same-named claim is already Bound, restore refuses to reuse it because that status may describe stale data from an earlier operation. Restore never deletes or replaces the claim.

--wait only tracks PersistentVolumeClaims that appear in the restored manifest set, and it reports when this command's own wait is over, not when a workload can use the restored data. Disk-backed PVCs for domain objects are recreated asynchronously by the domain controller (not part of this output), so they are not awaited; the command may return before such volumes finish provisioning. A Pending PVC on a WaitForFirstConsumer StorageClass is not awaited while it has no selected node, live Pod consumer, active provisioning event, or terminal provisioning failure: every such claim is listed once, by namespace/name and StorageClass, as a claim this command does not wait to become Bound. Once selected, consumed, or provisioning, it is polled until Bound or --timeout; an observed provisioning failure is returned with its cause. An expired --timeout means only that the wait could not be confirmed within that period: the objects were already applied and are not rolled back. Success revalidates the post-apply PVC UID, restore source, and bound PersistentVolume identity; it does not promise that every restored PVC is Bound.

Options

- `--context`

  The name of the kubeconfig context to use
- `--dry-run`

  validate objects via DryRunAll without persisting; skips --wait (use to preflight a restore)
- `--edit`

  open resolved manifests in $KUBE_EDITOR/$EDITOR (falling back to vi) before applying; aborts on non-zero exit, unchanged, or empty content
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--namespace`, `-n`

  snapshot namespace; also the restore target namespace (required)
- `--no-auto-edit`

  disable the one automatic editor session for interactive Kubernetes Invalid (HTTP 422) preflight responses
- `--node`

  restrict restore to a single node subtree; format '/' (e.g. --node DemoVirtualDisk/bk-disk-a); the generated snapshot CR name form (e.g. DemoVirtualDiskSnapshot/nss-child-abc123) is still accepted
- `--node-api-version`

  disambiguate --node by exact API version: 'v1' for core resources or '/' for named groups (requires --node)
- `--object`

  restrict a --scope node restore to a single captured object; format '/' (requires --scope node)
- `--scope`

  restore scope: 'subtree' (default) compiles the addressed node and its whole subtree; 'node' compiles only the addressed node itself
- `--timeout`

  bounds the --wait Bound check only; an expired timeout does not roll back the applied objects
- `--wait`

  wait for applicable manifest PVCs to become Bound; a dormant WaitForFirstConsumer PVC with no selected node, live consumer, or provisioning signal is listed by name and is not awaited

d8 snapshot upload

Alias: `import`

Usage:

```
d8 snapshot upload [flags] [options]
```

Upload a downloaded snapshot archive into a namespace

Show more...

Upload a local snapshot archive (produced by 'd8 snapshot download') into a namespace.

The archive tree is reconstructed in stages: first every import-mode CR is created top-down (parents before children) so each child carries a child->parent ownerRef the state-snapshotter binders use to attach it to its parent; then every node's manifests plus direct child refs are uploaded to the state-snapshotter aggregated API; only after all manifests are uploaded are the data-leaf volume bytes uploaded via a DataImport. Manifests are uploaded before any volume data because a leaf's DataImport stays pending until the leaf VolumeSnapshot is bound, which requires its ancestors' manifests to already be present. After the whole tree is uploaded it waits for the root Snapshot and its bound SnapshotContent to become Ready, leaving the namespace ready for 'd8 snapshot restore'.

--node restricts the upload to a single node and its descendants. The selected node becomes the upload root; it must be a core Snapshot, a CSI VolumeSnapshot data leaf, or a domain data leaf (e.g. DemoVirtualDiskSnapshot). Domain aggregator nodes (a DemoVirtualMachineSnapshot that references child snapshots) and manifest-only domain nodes cannot be selected as the upload root (they have no parent SnapshotContent to attach to when uploaded standalone); they are uploaded only as part of a full-archive upload (omit --node) or by selecting an ancestor Snapshot.

Scope and limitations:
- Full Snapshot trees are uploaded as-is, including domain aggregator nodes (a DemoVirtualMachineSnapshot that aggregates child DemoVirtualDiskSnapshot nodes): the CLI creates each node's unified import marker and uploads its manifests + child refs, and the server-side genericbinder reconstructs the aggregator's content from its children's SnapshotContents. The aggregator is a non-root node in this case, so no DataImport is created for it (only its data-leaf descendants stream volume bytes).
- Manifest-only domain nodes (e.g. a disk-less DemoVirtualMachineSnapshot, which carries only manifests) are uploaded as part of their parent tree (the server materialises their content from the uploaded manifests alone, with no data leg).
- A domain aggregator can be reconstructed only within a tree, never as a standalone --node root. To upload an individual disk snapshot from such a tree on its own, use --node <DomainDataLeafKind>/<name> (e.g. --node DemoVirtualDiskSnapshot/dvd-1).
- Both block-volume and filesystem-volume data leaves are supported.
- Filesystem archives can upload regular files only. Symlink, hardlink, device, FIFO, and socket entries, plus empty directories other than well-known filesystem-reserved names (for example lost+found), cannot be uploaded: the protocol supports only regular-file PUTs, and creates directories only as a side effect of a file PUT inside them.
- --skip-unsupported-fs-entries uploads the supported regular files instead of failing, but causes data loss for each skipped path; review the bounded post-upload summary.
- Legacy archives without formatVersion and metadataChecksum are rejected by default because their snapshot.yaml identity and volume metadata are unauthenticated. Use --allow-unauthenticated-legacy only for deliberate migration or inspection of trusted pre-version archives; this mode cannot distinguish a genuine legacy archive from a downgraded and tampered current archive.
- Uploading requires RBAC to create DataImport (storage-volume-data-manager) and to call the manifests-and-children-refs-upload subresource (e.g. an admin kubeconfig); the read-only snapshot admin role is not sufficient.

--publish selects how each data leaf's bytes are streamed to its DataImport importer pod. With --publish=false (or when autodetection picks it), bytes go straight to the importer's in-cluster service, trusting only its internal CA (status.ca). With --publish=true, bytes go through the storage-foundation-published Ingress endpoint (status.publicURL) instead, so a kubeconfig without direct network access to the cluster's internal service network can still upload. If --publish is not given, the command probes whether the in-cluster importer endpoint is reachable and picks accordingly. IMPORTANT: the publish path works only with a kubeconfig authenticated by a bearer token. Ingress terminates TLS with its own certificate and does not forward the client's TLS certificate to the importer pod, so a certificate-based kubeconfig receives a 401 when --publish=true.

Options

- `--allow-existing`

  downgrade namespace preflight conflict check to a warning (import-mode markers from a prior run are never conflicts regardless of this flag)
- `--allow-unauthenticated-legacy`

  allow trusted pre-version archives whose snapshot.yaml metadata is unauthenticated (unsafe; explicit compatibility mode)
- `--context`

  The name of the kubeconfig context to use
- `--input`, `-i`

  root archive directory produced by 'd8 snapshot download' (required)
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

- `--namespace`, `-n`

  target namespace to import into (required)
- `--node`

  restrict import to a single node subtree; format '/' (e.g. --node VolumeSnapshot/pvc-1)
- `--publish`

  upload volume data through the published (ingress) importer endpoint instead of the in-cluster service; if unset, the in-cluster endpoint's reachability is auto-detected
- `--skip-unsupported-fs-entries`

  skip unsupported filesystem entries and report them after upload (causes data loss for skipped paths)
- `--timeout`

  timeout for per-node readiness/completion waits
- `--ttl`

  idle TTL for each data-leaf DataImport (e.g. 2h, 30m); must exceed the importer's provisioning and post-upload completion time
- `--workers`

  maximum number of data-leaf volume uploads to run in parallel (fixed cap via errgroup.SetLimit; default 5)

Options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 stronghold

Deckhouse Stronghold commands

d8 stronghold audit

Usage:

```
d8 stronghold [command] [args...] audit [options]
```

Interact with audit devices

d8 stronghold audit disable

Usage:

```
d8 stronghold [command] [args...] audit disable [options]
```

Disables an audit device

d8 stronghold audit enable

Usage:

```
d8 stronghold [command] [args...] audit enable [options]
```

Enables an audit device

d8 stronghold audit list

Usage:

```
d8 stronghold [command] [args...] audit list [options]
```

Lists enabled audit devices

d8 stronghold auth

Usage:

```
d8 stronghold [command] [args...] auth [options]
```

Interact with auth methods

d8 stronghold auth disable

Usage:

```
d8 stronghold [command] [args...] auth disable [options]
```

Disables an auth method

d8 stronghold auth enable

Usage:

```
d8 stronghold [command] [args...] auth enable [options]
```

Enables a new auth method

d8 stronghold auth help

Usage:

```
d8 stronghold [command] [args...] auth help [options]
```

Prints usage for an auth method

d8 stronghold auth list

Usage:

```
d8 stronghold [command] [args...] auth list [options]
```

Lists enabled auth methods

d8 stronghold auth move

Usage:

```
d8 stronghold [command] [args...] auth move [options]
```

Move an auth method to a new path

d8 stronghold auth tune

Usage:

```
d8 stronghold [command] [args...] auth tune [options]
```

Tunes an auth method configuration

d8 stronghold debug

Usage:

```
d8 stronghold [command] [args...] debug [options]
```

Runs the debug command

d8 stronghold delete

Usage:

```
d8 stronghold [command] [args...] delete [options]
```

Delete secrets and configuration

d8 stronghold events

Usage:

```
d8 stronghold [command] [args...] events [options]
```

d8 stronghold events subscribe

Usage:

```
d8 stronghold [command] [args...] events subscribe [options]
```

Subscribe to events

d8 stronghold kv

Usage:

```
d8 stronghold [command] [args...] kv [options]
```

Interact with Stronghold's Key-Value storage

d8 stronghold kv delete

Usage:

```
d8 stronghold [command] [args...] kv delete [options]
```

Deletes versions in the KV store

d8 stronghold kv destroy

Usage:

```
d8 stronghold [command] [args...] kv destroy [options]
```

Permanently removes one or more versions in the KV store

d8 stronghold kv enable-versioning

Usage:

```
d8 stronghold [command] [args...] kv enable-versioning [options]
```

Turns on versioning for a KV store

d8 stronghold kv get

Usage:

```
d8 stronghold [command] [args...] kv get [options]
```

Retrieves data from the KV store

d8 stronghold kv list

Usage:

```
d8 stronghold [command] [args...] kv list [options]
```

List data or secrets

d8 stronghold kv metadata

Usage:

```
d8 stronghold [command] [args...] kv metadata [options]
```

Interact with Stronghold's Key-Value storage

d8 stronghold kv metadata delete

Usage:

```
d8 stronghold [command] [args...] kv metadata delete [options]
```

Deletes all versions and metadata for a key in the KV store

d8 stronghold kv metadata get

Usage:

```
d8 stronghold [command] [args...] kv metadata get [options]
```

Retrieves key metadata from the KV store

d8 stronghold kv metadata patch

Usage:

```
d8 stronghold [command] [args...] kv metadata patch [options]
```

Patches key settings in the KV store

d8 stronghold kv metadata put

Usage:

```
d8 stronghold [command] [args...] kv metadata put [options]
```

Sets or updates key settings in the KV store

d8 stronghold kv patch

Usage:

```
d8 stronghold [command] [args...] kv patch [options]
```

Sets or updates data in the KV store without overwriting

d8 stronghold kv put

Usage:

```
d8 stronghold [command] [args...] kv put [options]
```

Sets or updates data in the KV store

d8 stronghold kv rollback

Usage:

```
d8 stronghold [command] [args...] kv rollback [options]
```

Rolls back to a previous version of data

d8 stronghold kv undelete

Usage:

```
d8 stronghold [command] [args...] kv undelete [options]
```

Undeletes versions in the KV store

d8 stronghold lease

Usage:

```
d8 stronghold [command] [args...] lease [options]
```

Interact with leases

d8 stronghold lease lookup

Usage:

```
d8 stronghold [command] [args...] lease lookup [options]
```

Lookup the lease of a secret

d8 stronghold lease renew

Usage:

```
d8 stronghold [command] [args...] lease renew [options]
```

Renews the lease of a secret

d8 stronghold lease revoke

Usage:

```
d8 stronghold [command] [args...] lease revoke [options]
```

Revokes leases and secrets

d8 stronghold list

Usage:

```
d8 stronghold [command] [args...] list [options]
```

List data or secrets

d8 stronghold login

Usage:

```
d8 stronghold [command] [args...] login [options]
```

Authenticate locally

d8 stronghold monitor

Usage:

```
d8 stronghold [command] [args...] monitor [options]
```

Stream log messages from a Stronghold server

d8 stronghold namespace

Usage:

```
d8 stronghold [command] [args...] namespace [options]
```

Interact with namespaces

d8 stronghold namespace create

Usage:

```
d8 stronghold [command] [args...] namespace create [options]
```

Create a new namespace

d8 stronghold namespace delete

Usage:

```
d8 stronghold [command] [args...] namespace delete [options]
```

Delete an existing namespace

d8 stronghold namespace list

Usage:

```
d8 stronghold [command] [args...] namespace list [options]
```

List child namespaces

d8 stronghold namespace lock

Usage:

```
d8 stronghold [command] [args...] namespace lock [options]
```

Lock the API for particular namespaces

d8 stronghold namespace lookup

Usage:

```
d8 stronghold [command] [args...] namespace lookup [options]
```

Look up an existing namespace

d8 stronghold namespace patch

Usage:

```
d8 stronghold [command] [args...] namespace patch [options]
```

Patch an existing namespace

d8 stronghold namespace unlock

Usage:

```
d8 stronghold [command] [args...] namespace unlock [options]
```

Unlock the API for particular namespaces

d8 stronghold operator

Usage:

```
d8 stronghold [command] [args...] operator [options]
```

Perform operator-specific tasks

d8 stronghold operator generate-root

Usage:

```
d8 stronghold [command] [args...] operator generate-root [options]
```

Generates a new root, DR operation, or recovery token

d8 stronghold operator init

Usage:

```
d8 stronghold [command] [args...] operator init [options]
```

Initializes a server

d8 stronghold operator key-status

Usage:

```
d8 stronghold [command] [args...] operator key-status [options]
```

Provides information about the active encryption key

d8 stronghold operator members

Usage:

```
d8 stronghold [command] [args...] operator members [options]
```

Returns the list of nodes in the cluster

d8 stronghold operator raft

Usage:

```
d8 stronghold [command] [args...] operator raft [options]
```

Interact with Vault's raft storage backend

d8 stronghold operator raft autopilot

Usage:

```
d8 stronghold [command] [args...] operator raft autopilot [options]
```

d8 stronghold operator raft autopilot get-config

Usage:

```
d8 stronghold [command] [args...] operator raft autopilot get-config [options]
```

Returns the configuration of the autopilot subsystem under integrated storage

d8 stronghold operator raft autopilot set-config

Usage:

```
d8 stronghold [command] [args...] operator raft autopilot set-config [options]
```

Modify the configuration of the autopilot subsystem under integrated storage

d8 stronghold operator raft autopilot state

Usage:

```
d8 stronghold [command] [args...] operator raft autopilot state [options]
```

Displays the state of the raft cluster under integrated storage as seen by autopilot

d8 stronghold operator raft demote

Usage:

```
d8 stronghold [command] [args...] operator raft demote [options]
```

Demotes a voter to a permanent non-voter

d8 stronghold operator raft join

Usage:

```
d8 stronghold [command] [args...] operator raft join [options]
```

Joins a node to the Raft cluster

d8 stronghold operator raft list-peers

Usage:

```
d8 stronghold [command] [args...] operator raft list-peers [options]
```

Returns the Raft peer set

d8 stronghold operator raft promote

Usage:

```
d8 stronghold [command] [args...] operator raft promote [options]
```

Promotes a permanent non-voter to a voter

d8 stronghold operator raft remove-peer

Usage:

```
d8 stronghold [command] [args...] operator raft remove-peer [options]
```

Removes a node from the Raft cluster

d8 stronghold operator raft snapshot

Usage:

```
d8 stronghold [command] [args...] operator raft snapshot [options]
```

Restores, saves and inspects snapshots from the Raft cluster

d8 stronghold operator raft snapshot inspect

Usage:

```
d8 stronghold [command] [args...] operator raft snapshot inspect [options]
```

Inspects a Raft snapshot

d8 stronghold operator raft snapshot restore

Usage:

```
d8 stronghold [command] [args...] operator raft snapshot restore [options]
```

Installs the provided snapshot, returning the cluster to the state defined in it

d8 stronghold operator raft snapshot save

Usage:

```
d8 stronghold [command] [args...] operator raft snapshot save [options]
```

Saves a snapshot of the current state of the Raft cluster into a file

d8 stronghold operator rekey

Usage:

```
d8 stronghold [command] [args...] operator rekey [options]
```

Generates new unseal keys

d8 stronghold operator rotate

Usage:

```
d8 stronghold [command] [args...] operator rotate [options]
```

Rotates the underlying encryption key

d8 stronghold operator seal

Usage:

```
d8 stronghold [command] [args...] operator seal [options]
```

Seals the Stronghold server

d8 stronghold operator step-down

Usage:

```
d8 stronghold [command] [args...] operator step-down [options]
```

Forces Stronghold to resign active duty

d8 stronghold operator unseal

Usage:

```
d8 stronghold [command] [args...] operator unseal [options]
```

Unseals the Stronghold server

d8 stronghold operator usage

Usage:

```
d8 stronghold [command] [args...] operator usage [options]
```

Lists historical client counts

d8 stronghold patch

Usage:

```
d8 stronghold [command] [args...] patch [options]
```

Patch data, configuration, and secrets

d8 stronghold path-help

Usage:

```
d8 stronghold [command] [args...] path-help [options]
```

Retrieve API help for paths

d8 stronghold pki

Usage:

```
d8 stronghold [command] [args...] pki [options]
```

Interact with Stronghold's PKI Secrets Engine

d8 stronghold pki health-check

Usage:

```
d8 stronghold [command] [args...] pki health-check [options]
```

Check a PKI Secrets Engine mount's health and operational status

d8 stronghold pki issue

Usage:

```
d8 stronghold [command] [args...] pki issue [options]
```

Given a parent certificate, and a list of generation parameters, creates an issuer on a specified mount

d8 stronghold pki list-intermediates

Usage:

```
d8 stronghold [command] [args...] pki list-intermediates [options]
```

Determine which of a list of certificates, were issued by a given parent certificate

d8 stronghold pki reissue

Usage:

```
d8 stronghold [command] [args...] pki reissue [options]
```

Uses a parent certificate and a template certificate to create a new issuer on a child mount

d8 stronghold pki verify-sign

Usage:

```
d8 stronghold [command] [args...] pki verify-sign [options]
```

Check whether one certificate validates another specified certificate

d8 stronghold plugin

Usage:

```
d8 stronghold [command] [args...] plugin [options]
```

Interact with Stronghold plugins and catalog

d8 stronghold plugin deregister

Usage:

```
d8 stronghold [command] [args...] plugin deregister [options]
```

Deregister an existing plugin in the catalog

d8 stronghold plugin info

Usage:

```
d8 stronghold [command] [args...] plugin info [options]
```

Read information about a plugin in the catalog

d8 stronghold plugin list

Usage:

```
d8 stronghold [command] [args...] plugin list [options]
```

Lists available plugins

d8 stronghold plugin register

Usage:

```
d8 stronghold [command] [args...] plugin register [options]
```

Registers a new plugin in the catalog

d8 stronghold plugin reload

Usage:

```
d8 stronghold [command] [args...] plugin reload [options]
```

Reload mounted plugin backend

d8 stronghold plugin reload-status

Usage:

```
d8 stronghold [command] [args...] plugin reload-status [options]
```

Get the status of an active or recently completed global plugin reload

d8 stronghold policy

Usage:

```
d8 stronghold [command] [args...] policy [options]
```

Interact with policies

d8 stronghold policy delete

Usage:

```
d8 stronghold [command] [args...] policy delete [options]
```

Deletes a policy by name

d8 stronghold policy list

Usage:

```
d8 stronghold [command] [args...] policy list [options]
```

Lists the installed policies

d8 stronghold policy read

Usage:

```
d8 stronghold [command] [args...] policy read [options]
```

Prints the contents of a policy

d8 stronghold policy write

Usage:

```
d8 stronghold [command] [args...] policy write [options]
```

Uploads a named policy from a file

d8 stronghold print

Usage:

```
d8 stronghold [command] [args...] print [options]
```

Prints runtime configurations

d8 stronghold print token

Usage:

```
d8 stronghold [command] [args...] print token [options]
```

Prints token currently in use

d8 stronghold read

Usage:

```
d8 stronghold [command] [args...] read [options]
```

Read data and retrieves secrets

d8 stronghold secrets

Usage:

```
d8 stronghold [command] [args...] secrets [options]
```

Interact with secrets engines

d8 stronghold secrets disable

Usage:

```
d8 stronghold [command] [args...] secrets disable [options]
```

Disable a secret engine

d8 stronghold secrets enable

Usage:

```
d8 stronghold [command] [args...] secrets enable [options]
```

Enable a secrets engine

d8 stronghold secrets list

Usage:

```
d8 stronghold [command] [args...] secrets list [options]
```

List enabled secrets engines

d8 stronghold secrets move

Usage:

```
d8 stronghold [command] [args...] secrets move [options]
```

Move a secrets engine to a new path

d8 stronghold secrets tune

Usage:

```
d8 stronghold [command] [args...] secrets tune [options]
```

Tune a secrets engine configuration

d8 stronghold ssh

Usage:

```
d8 stronghold [command] [args...] ssh [options]
```

Initiate an SSH session

d8 stronghold status

Usage:

```
d8 stronghold [command] [args...] status [options]
```

Print seal and HA status

d8 stronghold token

Usage:

```
d8 stronghold [command] [args...] token [options]
```

Interact with tokens

d8 stronghold token capabilities

Usage:

```
d8 stronghold [command] [args...] token capabilities [options]
```

Print capabilities of a token on a path

d8 stronghold token create

Usage:

```
d8 stronghold [command] [args...] token create [options]
```

Create a new token

d8 stronghold token lookup

Usage:

```
d8 stronghold [command] [args...] token lookup [options]
```

Display information about a token

d8 stronghold token renew

Usage:

```
d8 stronghold [command] [args...] token renew [options]
```

Renew a token lease

d8 stronghold token revoke

Usage:

```
d8 stronghold [command] [args...] token revoke [options]
```

Revoke a token and its children

d8 stronghold transit

Usage:

```
d8 stronghold [command] [args...] transit [options]
```

Interact with Stronghold's Transit Secrets Engine

d8 stronghold transit import

Usage:

```
d8 stronghold [command] [args...] transit import [options]
```

Import a key into the Transit secrets engines.

d8 stronghold transit import-version

Usage:

```
d8 stronghold [command] [args...] transit import-version [options]
```

Import key material into a new key version in the Transit secrets engines.

d8 stronghold unwrap

Usage:

```
d8 stronghold [command] [args...] unwrap [options]
```

Unwrap a wrapped secret

d8 stronghold version

Usage:

```
d8 stronghold [command] [args...] version [options]
```

Prints the Stronghold CLI version

d8 stronghold version-history

Usage:

```
d8 stronghold [command] [args...] version-history [options]
```

Prints the version history of the target Stronghold server

d8 stronghold write

Usage:

```
d8 stronghold [command] [args...] write [options]
```

Write data, configuration, and secrets

d8 system

Aliases: `s`, `p`, `platform`

Operate system options. Aliases: s, p, platform

Show more...

Operate system options in DKP.

© Flant JSC 2025

Options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system collect-debug-info

Usage:

```
d8 system collect-debug-info [flags] > deckhouse-debug-$(date +"%Y_%m_%d").tar.gz [options]
```

Collect debug info.

Show more...

Collect debug info from Deckhouse Kubernetes Platform.

© Flant JSC 2025

Options

- `--command-timeout`
  Timeout for each individual debug command execution
- `--exclude`
  Exclude specific files from the debug archive. Use comma-separated names as printed by --list-exclude; the file extension is optional. An unknown name is an error
- `--list-exclude`, `-l`
  List all files that can be excluded from the debug archive, then exit
- `--request-interval`
  Minimum interval between debug command executions to avoid overloading the cluster (e.g. 200ms, 500ms, 1s). Zero disables rate limiting (default 0s)

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system collect-debug-info virtualization

Usage:

```
d8 system collect-debug-info [flags] > deckhouse-debug-$(date +"%Y_%m_%d").tar.gz virtualization [flags] >
deckhouse-debug-virtualization-$(date +"%Y_%m_%d").tar.gz [options]
```

Collect a separate virtualization debug archive.

Show more...

Collect a separate debug archive with detailed data from the d8-virtualization namespace.

Options

- `--command-timeout`

  Timeout for each individual debug command execution
- `--request-interval`

  Minimum interval between debug command executions to avoid overloading the cluster (e.g. 200ms, 500ms, 1s). Zero disables rate limiting (default 0s)
- `--skip-ds-logs`

  Skip collecting logs from pods managed by a DaemonSet (virt-handler, virtualization-dra, vm-route-forge, ...) to reduce archive size on clusters with many nodes

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

Inspect deckhouse-controller logs from Deckhouse Kubernetes Platform.

© Flant JSC 2025

Options

- `--follow`, `-f`
  Specify if the logs should be streamed.
- `--since`
  Show logs newer than a relative duration like 5s, 2m, or 1h. Only one of since-time / since may be used.
- `--since-time`
  Show logs after a specific timestamp, e.g. --since-time='2025-05-19 12:00:00'. Only one of since-time / since may be used.
- `--tail`
  Limit the number of lines in the output to the last N lines. Defaults to -1 with no limit.

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module

Usage:

```
d8 system module [options]
```

Operate the Deckhouse Kubernetes Platform modules

Show more...

Operate the Deckhouse Kubernetes Platform modules.

© Flant JSC 2025

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module apply-now

Usage:

```
d8 system module apply-now <module-name> <version> [options]
```

Apply a module release immediately, bypassing update windows.

Show more...

Apply a module release immediately, bypassing update windows.

This command adds the annotation 'modules.deckhouse.io/apply-now="true"' to the specified ModuleRelease resource, forcing immediate deployment regardless of configured update windows or applyAfter schedules.

This command is used for modules with Auto update policy that have update windows configured or releases scheduled for future deployment.

© Flant JSC 2025

Global options

- `--context`

The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module approve

Usage:

```
d8 system module approve <module-name> <version> [options]
```

Approve a pending module release for Manual update policy.

Show more...

Approve a pending module release for installation.

This command adds the annotation 'modules.deckhouse.io/approved="true"' to the specified ModuleRelease resource, allowing it to be deployed according to the update policy.

This command is used for modules with Manual update policy that require explicit approval before deployment.

© Flant JSC 2025

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module disable

Usage:

```
d8 system module disable [options]
```

Disable module.

Show more...

Disable module using the ModuleConfig resource.

© Flant JSC 2025

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module enable

Usage:

```
d8 system module enable [options]
```

Enable module.

Show more...

Enable module using the ModuleConfig resource.

© Flant JSC 2025

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module list

Usage:

```
d8 system module list [options]
```

List enabled modules.

Show more...

List enabled Deckhouse Kubernetes Platform modules.

© Flant JSC 2025

Options

- `--output`, `-o`
  Output format: yaml|json

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module maintenance

Usage:

```
d8 system module maintenance [options]
```

Enable or disable module maintenance mode.

Show more...

Enable or disable maintenance mode for a module via its ModuleConfig resource.

While maintenance mode is enabled, Deckhouse stops reconciling the module's resources (it sets 'spec.maintenance="NoResourceReconciliation"' on the ModuleConfig). This lets you develop or tweak the module's resources.

Disabling maintenance mode removes the 'spec.maintenance' field and lets Deckhouse resume normal reconciliation.

The module's ModuleConfig must already exist. If it does not enable it first.

© Flant JSC 2026

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module maintenance disable

Usage:

```
d8 system module maintenance disable <module-name> [options]
```

Disable maintenance mode for a module using ModuleConfig resource.

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module maintenance enable

Usage:

```
d8 system module maintenance enable <module-name> [options]
```

Enable maintenance mode for a module using ModuleConfig resource.

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system module snapshots

Usage:

```
d8 system module snapshots [options]
```

Dump shapshots.

Show more...

Dump module hooks snapshots.

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system package scan

Usage:

```
d8 system package scan <repository-name> [options]
```

Create a scan task for a PackageRepository

Show more...

Create a scan task for a PackageRepository.

This command creates a PackageRepositoryOperation resource that triggers a full scan of the specified package repository.

© Flant JSC 2026

Options

- `--dry-run`
  Preview the operation without creating it
- `--name`
  Custom name for the PackageRepositoryOperation (auto-generated if not specified)
- `--timeout`
  Timeout for the scan operation

Global options

- `--context`
  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`
  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system queue

Usage:

```
d8 system queue [options]
```

Dump queues.

Show more...

Dump queues from Deckhouse Kubernetes Platform.

© Flant JSC 2025

Global options

- `--context`
  The name of the kubeconfig context to use

- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system queue list

Usage:

```
d8 system queue list [options]
```

Dump all queues.

Show more...

Dump all Deckhouse Kubernetes Platform queues.

© Flant JSC 2025

Options

- `--http`

  Query the Deckhouse debug server through a Kubernetes API port-forward instead of exec into the pod. Needs pods/portforward, not pods/exec.
- `--output`, `-o`

  Output format: json|yaml|text.
- `--show-empty`, `-e`

  Show empty queues.
- `--watch`, `-w`

  Watch for changes to the queue list.

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 system queue main

Usage:

```
d8 system queue main [options]
```

Dump main queue.

Show more...

Dump main Deckhouse Kubernetes Platform queues.

© Flant JSC 2025

Options

- `--http`

  Query the Deckhouse debug server through a Kubernetes API port-forward instead of exec into the pod. Needs pods/portforward, not pods/exec.
- `--output`, `-o`

  Output format: json|yaml|text.

Global options

- `--context`

  The name of the kubeconfig context to use
- `--kubeconfig`, `-k`

  Path to kubeconfig file. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)

d8 tools

Alias: `t`

Various useful tools for operating in The Deckhouse Ecosystem.

Show more...

Various useful tools for operating in The Deckhouse Ecosystem.

© Flant JSC 2025

d8 tools cosign

Usage:

```
d8 tools cosign [options]
```

Sign and verify container images with cosign v2

Show more...

Built-in cosign v2 for signing and verifying container images.

Deckhouse image signature verification (admission-policy-engine) supports cosign v2 signatures only, cosign v3 is not supported.

Run "d8 tools cosign --help" for the full list of cosign commands.

© Flant JSC 2026

d8 tools far-convert

Usage:

```
d8 tools far-convert [options]
```

Converts files with Falco rules to FalcoAuditRules CRD format

Show more...

Converts files with Falco rules to FalcoAuditRules CRD format.

© Flant JSC 2025

d8 tools gostsum

Usage:

```
d8 tools gostsum [options]
```

Calculate Streebog checksum of the data according to the RFC 6986 (GOST R 34.11-2012) specifications

Show more...

Calculate Streebog checksum of the data according to the RFC 6986 (GOST R 34.11-2012) specifications.

Data for checksumming is provided as a list of filepaths in the command-line arguments. If no filepaths are provided, data is assumed to be available from stdin.

© Flant JSC 2025

Options

- `--hash-length`, `-l`

  Bit-length variant of the algorithm to use. Only 256 (default) and 512 bit lengths are supported.

d8 tools htpasswd

Usage:

```
d8 tools htpasswd [flags] [passwordfile] [username] [password] [options]
```

Manage password files and hash passwords (Apache htpasswd analog)

Show more...

Manage password files and hash passwords, a self-contained analog of Apache htpasswd. No external htpasswd binary is required.

Usage mirrors htpasswd:

```
d8 tools htpasswd [-cbdps... -C cost -r rounds] passwordfile username
d8 tools htpasswd -b [...] passwordfile username password
d8 tools htpasswd -n [-bmBdps...] [username]
d8 tools htpasswd -D passwordfile username
d8 tools htpasswd -v passwordfile username
```

Algorithms (choose one; default bcrypt):

```
-B  bcrypt        secure, the default
-m  apr1 MD5      Apache MD5, legacy htpasswd default
-2  SHA-256 crypt  secure
-5  SHA-512 crypt  secure
-d  CRYPT (DES)    INSECURE, only first 8 chars used
-s  SHA-1          INSECURE, unsalted
-p  plaintext      INSECURE, no hashing
```

Unlike Apache htpasswd (apr1 at cost 5 by default), d8 defaults to bcrypt at cost 10, so 'd8 tools htpasswd -n <username>' produces a strong hash ready for 'd8 iam user create/reset-password --password-hash'. With -n and no username the bare hash is printed, which is exactly what --password-hash expects. The -2 and -5 SHA-crypt algorithms and the -r rounds flag are d8 extensions; Apache htpasswd has no -2, -5, or -r flag.

© Flant JSC 2026

Options

- `--batch`, `-b`

  Batch mode: take the password from the command line.
- `--bcrypt`, `-B`

  Use bcrypt (secure; the default).
- `--cost`, `-C`

  bcrypt cost/work factor (4-31); only with -B.
- `--create`, `-c`

  Create a new password file, overwriting any existing one.
- `--delete`, `-D`

  Delete the given user from the password file.
- `--des`, `-d`

  Use CRYPT (DES; INSECURE, 8-char limit).
- `--md5`, `-m`

  Use Apache MD5 (apr1).
- `--plaintext`, `-p`

  Store the password in plaintext (INSECURE).
- `--rounds`, `-r`

  SHA-256/512 rounds (1000-999999999); only with -2/-5.
- `--sha1`, `-s`

  Use SHA-1 (INSECURE, unsalted).
- `--sha256`, `-2`

  Use SHA-256 crypt (secure).
- `--sha512`, `-5`

  Use SHA-512 crypt (secure).
- `--stdin`, `-i`

  Read the password from stdin without verification.
- `--stdout`, `-n`

  Do not update a file; print the result to stdout.
- `--verify`, `-v`

  Verify the given password for the user.

d8 tools imagedigest

Usage:

```
d8 tools imagedigest [options]
```

Options

- `--debug`, `-d`

Enable debug logging
- `--insecure`, `-i`

  Allow insecure connections to registries (skip TLS verification)
- `--json`

  Use JSON formatter for output logs

d8 tools imagedigest add

Usage:

```
d8 tools imagedigest add <image> [options]
```

Calculating and adding the image digest to the image metadata according to the GOST standard Streebog (GOST R 34.11-2012)

Show more...

Calculating and adding the image digest to the image metadata according to the GOST standard Streebog (GOST R 34.11-2012)

Global options

- `--debug`, `-d`

  Enable debug logging
- `--insecure`, `-i`

  Allow insecure connections to registries (skip TLS verification)
- `--json`

  Use JSON formatter for output logs

d8 tools imagedigest calculate

Usage:

```
d8 tools imagedigest calculate <image> [options]
```

Calculating the image digest according to the GOST standard Streebog (GOST R 34.11-2012)

Show more...

Calculating the image digest according to the GOST standard Streebog (GOST R 34.11-2012)

Global options

- `--debug`, `-d`

  Enable debug logging
- `--insecure`, `-i`

  Allow insecure connections to registries (skip TLS verification)
- `--json`

  Use JSON formatter for output logs

d8 tools imagedigest calculate-from-file

Usage:

```
d8 tools imagedigest calculate-from-file <file> [options]
```

Calculating the file digest according to the GOST standard Streebog (GOST R 34.11-2012). For stdin use '-'

Show more...

Calculating the file digest according to the GOST standard Streebog (GOST R 34.11-2012)

Global options

- `--debug`, `-d`

  Enable debug logging
- `--insecure`, `-i`

  Allow insecure connections to registries (skip TLS verification)
- `--json`

  Use JSON formatter for output logs

d8 tools imagedigest validate

Usage:

```
d8 tools imagedigest validate <image> [options]
```

Validating the image digest in the image metadata calculated according to the GOST standard Streebog (GOST R 34.11-2012)

Show more...

Validating the image digest in the image metadata calculated according to the GOST standard Streebog (GOST R 34.11-2012)

Options

- `--fix`

  Fix GOST Image Digest if it is incorrect

Global options

- `--debug`, `-d`

  Enable debug logging
- `--insecure`, `-i`

  Allow insecure connections to registries (skip TLS verification)
- `--json`

  Use JSON formatter for output logs

d8 tools pki

Usage:

```
d8 tools pki [options]
```

Tools for working with control-plane PKI

Show more...

Tools for working with control-plane PKI.

© Flant JSC 2026

d8 tools pki certs

Usage:

```
d8 tools pki certs [options]
```

Manage and inspect control-plane TLS certificates

Show more...

Manage and inspect control-plane TLS certificates.

© Flant JSC 2026

d8 tools pki certs check

Usage:

```
d8 tools pki certs check [PATH] [options]
```

Check expiration of control-plane certificates

Show more...

Check expiration of control-plane certificates and kubeconfig client certificates.

Without arguments, all known control-plane certificates under --path and the kubeconfig files under --kubeconfig-dir are checked. Output is split into two sections – leaf certificates and certificate authorities – similar to "kubeadm certs check-expiration".

Missing known files are skipped in full-scan mode, so on worker or arbiter nodes the command prints the artifacts that are actually present locally.

--kubeconfig-dir defaults to the parent directory of --path, which matches the standard Kubernetes layout

(/etc/kubernetes/pki → /etc/kubernetes). Set it explicitly when using a non-default directory layout.

With a single PATH argument, only that file is inspected. The command auto-detects whether the file is a kubeconfig or a PEM certificate.

© Flant JSC 2026

Options

- `--kubeconfig-dir`

  Directory containing kubeconfig files (full-scan mode only; defaults to the parent of --path)
- `--path`

  Directory containing the PKI certificates (used in full-scan mode only)

d8 tools pki certs renew

Usage:

```
d8 tools pki certs renew (all | PATH) [options]
```

Renew control-plane certificates and kubeconfig client certificates

Show more...

Renew control-plane certificates and kubeconfig client certificates.

Renewal is unconditional — certificates are re-signed regardless of their current expiration date.

All Subject/SAN/Usage fields are read from the existing certificate on disk. No cluster configuration is required — this command is designed for emergency recovery when the Kubernetes API is unavailable.

The signing CA must be present on disk and must not be expired. If the CA private key is absent (external CA), or the CA certificate has expired, the certificate is skipped; renewing leaf certificates against an expired CA is pointless because chain validation will fail. The command exits non-zero if any certificate was skipped.

After renewal, restart kube-apiserver, kube-controller-manager, kube-scheduler and etcd so that the new certificates take effect or reboot the node/kubelet.

© Flant JSC 2026

Options

- `--dry-run`

  Run all without writing any files
- `--kubeconfig-dir`

  Directory containing kubeconfig files (defaults to the parent of --path)
- `--path`

  Directory containing the PKI certificates and CA files

d8 tools pki certs renew all

Usage:

```
d8 tools pki certs renew (all | PATH) all [options]
```

Renew all control-plane certificates and kubeconfig client certificates

Options

- `--dry-run`

  Run all without writing any files
- `--kubeconfig-dir`

  Directory containing kubeconfig files (defaults to the parent of --path)
- `--path`

  Directory containing the PKI certificates and CA files
- `--san`

  New IP SAN to add to serving certificates (e.g. the new master IP)

d8 tools sig-migrate

Usage:

```
d8 tools sig-migrate [options]
```

Migrate Kubernetes resources by adding and removing migration annotations

Show more...

Migrate Kubernetes resources by adding and removing migration annotations.

This command collects all Kubernetes resources (both namespaced and cluster-wide), adds a migration annotation (d8-migration=<timestamp>), and then removes the d8-migration- annotation prefix. This is useful for triggering reconciliation in Deckhouse controllers.

The command supports: - Retrying failed annotations from previous runs - Using different service accounts via impersonation - Configurable log levels (INFO, DEBUG, TRACE)

© Flant JSC 2025

Options

- `--as`

  Specify a Kubernetes service account for the kubectl operations (impersonation).
- `--context`

  The name of the kubeconfig context to use.
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests. (default is $KUBECONFIG when it is set, otherwise the default kubeconfig path for the current OS user)
- `--log-level`

  Set the log level (INFO, DEBUG, TRACE). Defaults to DEBUG.
- `--measure-stages`

  Print execution time for major migration stages.
- `--object`

  Process objects by identifier in format //. Use 'clusterwide' namespace for cluster-scoped resources. Resource name must match kubectl api-resources output.
- `--retry`

  Retry annotation for previously failed objects.
- `--threads`

  Number of worker threads for resource discovery and migration. Values <=0 use default.

d8 v

Alias: `virtualization`

Commands to work with Deckhouse Virtualization Platform.

Options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections

insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v ansible-inventory

Usage:

```
d8 v [command] [args...] ansible-inventory [options]
```

Generate ansible inventory from virtual machines (ansible inventory script compatible).

Show more...

Generate ansible inventory from virtual machines.

When called without arguments, returns all hosts (same as --list).

Only virtual machines with assigned IP addresses are included in the inventory.

Arguments:
  --list   Return all hosts (default behavior if no arguments)
  --host <hostname>   Show variables for a particular host; output format matches inventory entries
  --output, -o <format> Output format: json, ini, or yaml (default: json)
  --namespace, -n <ns>   Namespace to list virtual machines from
                        (overrides kubeconfig context namespace)

Host names format: <vmname>.<namespace> (e.g., myvm.default)

VM annotations:
  - Annotations with prefix 'vars.ansible.deckhouse.io/' are included
    as host variables (prefix is stripped from variable name)
  - Use 'ansible.deckhouse.io/groups' annotation to add VMs to groups
    (comma-separated list of group names)

Network access:
  - For VM access, the Default network interface is used
  - The 'ansible_ssh_common_args' variable is automatically set for port-forwarding
    through kubectl using 'd8 v port-forward' command; the --context, --server and
    --kubeconfig flags of this command are carried over into it
  - Additional network interfaces are not currently supported

Options

- `--host`

  Return variables for specific host
- `--list`

  Return all hosts (default behavior if no arguments)
- `--namespace`, `-n`

  Namespace to list virtual machines from (overrides kubeconfig context namespace)
- `--output`, `-o`

  Output format: json, ini, or yaml (default: json)

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log

format)

d8 v collect-debug-info

Usage:

```
d8 v [command] [args...] collect-debug-info (VirtualMachine) [options]
```

Collect debug information for VM: configuration, events, and logs. Output is written as compressed archive to stdout.

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v console

Usage:

```
d8 v [command] [args...] console (VirtualMachine) [options]
```

Connect to a console of a virtual machine.

Options

- `--force`
  Connect without asking, even when somebody else is using the console.
- `--timeout`
  Duration to wait until console is successfully connected (e.g., 1s, 5m, 300s).

Global options

- `--as`
  Username to impersonate for the operation
- `--as-group`
  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`
  UID to impersonate for the operation
- `--certificate-authority`
  Path to a cert file for the certificate authority
- `--client-certificate`
  Path to a client certificate file for TLS
- `--client-key`
  Path to a client key file for TLS
- `--cluster`
  The name of the kubeconfig cluster to use
- `--context`
  The name of the kubeconfig context to use
- `--disable-compression`
  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`
  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`
  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`
  Maximum number of seconds between log flushes
- `--namespace`, `-n`
  If present, the namespace scope for this CLI request
- `--password`
  Password for basic authentication to the API server
- `--proxy-url`
  If provided, this URL will be used to connect via proxy
- `--request-timeout`
  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`
  The address and port of the Kubernetes API server
- `--tls-server-name`
  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`
  Bearer token for authentication to the API server
- `--user`

The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v evict

Usage:

```
d8 v [command] [args...] evict (VirtualMachine) [options]
```

Evict a virtual machine.

Options

- `--all`

  Set this flag to apply the action to all VMs.
- `--create-only`, `-c`

  Set this flag to only create the action without status warnings or notifications.
- `--force`, `-f`

  Set this flag to force the operation.
- `--label-selector`, `-l`

  Set this flag to apply the action to VMs with the specified labels.
- `--timeout`, `-t`

  Set this flag to change the timeout.
- `--wait`, `-w`

  Set this flag to wait for the operation to complete.
- `--yes`, `-y`

  Set this flag to confirm the action without prompting for confirmation.

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v migrate

Usage:

```
d8 v [command] [args...] migrate (VirtualMachine) [options]
```

Migrate a virtual machine.

Options

- `--all`

  Set this flag to apply the action to all VMs.
- `--create-only`, `-c`

  Set this flag to only create the action without status warnings or notifications.
- `--force`, `-f`

  Set this flag to force the operation.
- `--label-selector`, `-l`

  Set this flag to apply the action to VMs with the specified labels.
- `--target-node-name`

  Set the target node name for virtual machine migration.
- `--timeout`, `-t`

  Set this flag to change the timeout.
- `--wait`, `-w`

  Set this flag to wait for the operation to complete.
- `--yes`, `-y`

  Set this flag to confirm the action without prompting for confirmation.

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority

- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v port-forward

Usage:

```
d8 v [command] [args...] port-forward name[.namespace] [protocol/]localPort[:targetPort]... [options]
```

Forward local ports to a virtual machine

Show more...

Forward local ports to a virtualmachine.
The port argument supports the syntax protocol/localPort:targetPort with protocol/ and :targetPort as optional fields.
Protocol supports TCP (default) and UDP.

Portforwards get established over the Kubernetes control-plane using websocket streams.
Usage can be restricted by the cluster administrator through the /portforward subresource.

Options

- `--address`

--address=: Set this to the address the local ports should be opened on

- `--stdio`

  --stdio=true: Set this to true to forward the tunnel to stdout/stdin; Only works with a single port

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v restart

Usage:

```
d8 v [command] [args...] restart (VirtualMachine) [options]
```

Restart a virtual machine.

Options

- `--all`

  Set this flag to apply the action to all VMs.
- `--create-only`, `-c`

  Set this flag to only create the action without status warnings or notifications.
- `--force`, `-f`

  Set this flag to force the operation.
- `--label-selector`, `-l`

  Set this flag to apply the action to VMs with the specified labels.
- `--timeout`, `-t`

  Set this flag to change the timeout.
- `--wait`, `-w`

  Set this flag to wait for the operation to complete.
- `--yes`, `-y`

  Set this flag to confirm the action without prompting for confirmation.

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v scp

Usage:

```
d8 v [command] [args...] scp [flags] SOURCE TARGET [options]
```

Secure file CoPy from/to a virtual machine.

Options

- `--identity-file`, `-i`

  Specify a path to a private key passed to the local SSH/SCP client as -i; If not provided, OpenSSH default identity selection applies
- `--known-hosts`

  Set a path to the known_hosts file passed to the local SSH/SCP client as UserKnownHostsFile.
- `--local-ssh`

  Deprecated: local SSH/SCP client is always used
- `--local-ssh-opts`

  Deprecated: use --ssh-args instead
- `--port`, `-p`

  Specify a port to connect to
- `--preserve`

  Preserves modification times, access times, and modes from the original file.
- `--recursive`, `-r`

  Recursively copy entire directories
- `--ssh-args`

  Additional options to be passed to the local SSH/SCP client. May be repeated, or a single value may contain several options separated by spaces (e.g. --ssh-args='-o X -o Y').

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v spice

Usage:

```
d8 v [command] [args...] spice VirtualMachine [options]
```

Open a spice connection to a virtual machine.

Options

- `--address`

  --address=127.0.0.1: Setting this will change the listening address of the SPICE proxy. Example: --address=0.0.0.0 will make the proxy listen on all interfaces.
- `--force`

  Connect without asking, even when somebody else is using the SPICE display.
- `--port`

  --port=0: Assigning a port value to this will try to run the proxy on the given port if the port is accessible; If unassigned, the proxy will run on a random port
- `--preferred-compression`

  --preferred-compression=glz: Ask the server for this image codec: auto-glz, auto-lz, quic, glz, lz, off. Overrides what the VM is configured with, so codecs can be compared without restarting it.
- `--proxy-only`

  --proxy-only=false: Setting this true will run only the spice proxy and show the port where SPICE viewers can connect

Global options

- `--as`

Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v ssh

Usage:

```
d8 v [command] [args...] ssh [-n|--namespace NAMESPACE] VIRTUAL-MACHINE-NAME [-- COMMAND [ARGS]...] [options]
```

Open a SSH connection to a virtual machine.

Options

- `--command`, `-c`

Specify a command to execute in the VM. Equivalent to passing the command after --.

- `--identity-file`, `-i`

  Specify a path to a private key passed to the local SSH/SCP client as -i; If not provided, OpenSSH default identity selection applies
- `--known-hosts`

  Set a path to the known_hosts file passed to the local SSH/SCP client as UserKnownHostsFile.
- `--local-ssh`

  Deprecated: local SSH/SCP client is always used
- `--local-ssh-opts`

  Deprecated: use --ssh-args instead
- `--port`, `-p`

  Specify a port to connect to
- `--ssh-args`

  Additional options to be passed to the local SSH/SCP client. May be repeated, or a single value may contain several options separated by spaces (e.g. --ssh-args='-o X -o Y').
- `--username`, `-l`

  Specify user to log into virtual machine; If unassigned, this will be empty and the SSH default will apply

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.

- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v start

Usage:

```
d8 v [command] [args...] start (VirtualMachine) [options]
```

Start a virtual machine.

Options

- `--all`

  Set this flag to apply the action to all VMs.
- `--create-only`, `-c`

  Set this flag to only create the action without status warnings or notifications.
- `--force`, `-f`

  Set this flag to force the operation.
- `--label-selector`, `-l`

  Set this flag to apply the action to VMs with the specified labels.
- `--timeout`, `-t`

  Set this flag to change the timeout.
- `--wait`, `-w`

  Set this flag to wait for the operation to complete.
- `--yes`, `-y`

  Set this flag to confirm the action without prompting for confirmation.

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes

- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v stop

Usage:

```
d8 v [command] [args...] stop (VirtualMachine) [options]
```

Stop a virtual machine.

Options

- `--all`

  Set this flag to apply the action to all VMs.
- `--create-only`, `-c`

  Set this flag to only create the action without status warnings or notifications.
- `--force`, `-f`

  Set this flag to force the operation.
- `--label-selector`, `-l`

  Set this flag to apply the action to VMs with the specified labels.
- `--timeout`, `-t`

  Set this flag to change the timeout.
- `--wait`, `-w`

  Set this flag to wait for the operation to complete.
- `--yes`, `-y`

  Set this flag to confirm the action without prompting for confirmation.

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

  comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

d8 v vnc

Usage:

```
d8 v [command] [args...] vnc VirtualMachine [options]
```

Open a vnc connection to a virtual machine.

Options

- `--address`

  --address=127.0.0.1: Setting this will change the listening address of the VNC server. Example: --address=0.0.0.0 will make the server listen on all interfaces.
- `--compress`

  --compress=6: Compression effort from 0 to 9. Higher spends more CPU on both ends; above 6 the gain is negligible
- `--force`

  Connect without asking, even when somebody else is using the VNC.
- `--port`

--port=0: Assigning a port value to this will try to run the proxy on the given port if the port is accessible; If unassigned, the proxy will run on a random port

- `--proxy-only`

  --proxy-only=false: Setting this true will run only the vnc proxy and show the port where VNC viewers can connect
- `--quality`

  --quality=6: Image quality from 0 to 9. Up to 7 the server encodes smooth areas as JPEG, 8 and 9 stay lossless at the cost of bandwidth

Global options

- `--as`

  Username to impersonate for the operation
- `--as-group`

  Group to impersonate for the operation, this flag can be repeated to specify multiple groups.
- `--as-uid`

  UID to impersonate for the operation
- `--certificate-authority`

  Path to a cert file for the certificate authority
- `--client-certificate`

  Path to a client certificate file for TLS
- `--client-key`

  Path to a client key file for TLS
- `--cluster`

  The name of the kubeconfig cluster to use
- `--context`

  The name of the kubeconfig context to use
- `--disable-compression`

  If true, opt-out of response compression for all requests to the server
- `--insecure-skip-tls-verify`

  If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure
- `--kubeconfig`

  Path to the kubeconfig file to use for CLI requests.
- `--log-flush-frequency`

  Maximum number of seconds between log flushes
- `--namespace`, `-n`

  If present, the namespace scope for this CLI request
- `--password`

  Password for basic authentication to the API server
- `--proxy-url`

  If provided, this URL will be used to connect via proxy
- `--request-timeout`

  The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.
- `--server`, `-s`

  The address and port of the Kubernetes API server
- `--tls-server-name`

  If provided, this name will be used to validate server certificate. If this is not provided, hostname used to contact the server is used.
- `--token`

  Bearer token for authentication to the API server
- `--user`

  The name of the kubeconfig user to use
- `--username`

  Username for basic authentication to the API server
- `--v`, `-v`

  number for the log level verbosity
- `--vmodule`

comma-separated list of pattern=N settings for file-filtered logging (only works for the default text log format)

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Glossary

The glossary lists the terms used in the Deckhouse Platform documentation and explains what each of them means. Technical details and implementation details are described in the Architecture section.

Active-active balancing

A scheme of balancing incoming traffic in a multicluster in which the external load balancer distributes traffic across several active clusters at once, for example by geographic proximity or current load.

In the active-active scheme all clusters of the multicluster process traffic simultaneously. Traffic goes to the nearest or least loaded cluster, or follows other defined rules. Shared data is replicated between the clusters. When one cluster fails, traffic is automatically rerouted to the others. The balancing is configured by the cluster administrator as part of geo-reserving. The alternative scheme is active-standby.

For details, see Geo-reserving.

Active-standby balancing

A scheme of balancing incoming traffic in a multicluster in which the external load balancer routes all traffic to the currently active cluster, and the standby cluster receives traffic only when the active one becomes unavailable.

In the active-standby scheme the active cluster of the multicluster receives all traffic, and the standby cluster stays idle until the active one fails. Traffic failover to the standby cluster happens automatically when problems are detected. The balancing is configured by the cluster administrator as part of geo-reserving. The alternative scheme is active-active.

For details, see Geo-reserving.

Additional network

A software-defined network for pods and virtual machines on top of the main cluster network, provided by the sdn module. Additional networks are cluster networks or project networks.

A cluster network is publicly available in every project and is managed by the administrator. A project network is available within one namespace and is created by the user. Pods are connected to additional networks with a pod annotation, virtual machines with the list of networks in the machine specification. IP addresses on the additional interfaces are assigned by the IPAM of the `sdn` module.

For details, see Additional networks for use in application pods.

Additional project namespace

A user namespace created within a project in addition to the main one. It is used only to run the workload.

Additional namespaces let you divide the workload of a project logically and apply separate access policies to each part. Like the main project namespace, an additional project namespace is a user namespace.

Addon-operator queue

A task queue of the Deckhouse controller that processes built-in modules and modules from a source. Each queue is a separate pipeline with one worker that executes tasks from the head until they succeed.

The Deckhouse controller creates three kinds of queues:

- the `main` queue, which runs global hooks at startup, installs critical modules and configures or deletes modules;
- several parallel queues `parallel_queue_0..N` for module runs with dependencies taken into

account;
- hook queues named in the configuration of a hook.

A task that fails and has no `allowFailure` blocks its queue, and it is restarted with an exponential delay starting at 5 seconds. Queues do not block each other. The queues can be inspected with `d8 system queue list`.

For details, see Queuing mechanism.

Admission policy

A rule that is applied to objects such as pods and Services when they are created or modified in the cluster, based on their manifests, and not while they run.

Admission policies formalize the parameters that are allowed or prohibited in object manifests. Deckhouse Platform implements them with the `admission-policy-engine` module and divides them into three categories: Pod Security Standards, operational policies (OperationPolicy) that validate parameters not related to security, such as allowed image registries, and security policies (SecurityPolicy) that validate security-related parameters, such as privileged mode or host namespaces.

The policies complement each other: if several apply to a namespace, an object must satisfy all of them. When a policy changes, existing pods are validated on the next restart, and Deckhouse Platform raises an alert for running objects that violate a policy. SecurityPolicyException allows fine-grained exceptions for individual pods or containers.

For details, see Security policies.

Advanced load balancer

A load balancer of the `service-with-healthchecks` module that runs active probes for individual TCP ports instead of relying on container readiness probes, so that each balancer serving the same pod works independently.

The advanced load balancer is built on ServiceWithHealthchecks objects. It consists of a controller that runs on the master nodes and manages these objects, and agents on every node that run the probes and publish only verified addresses. The standard load balancer, a Kubernetes Service, remains available for workloads that need no separate probes.

For details, see Intra-cluster communication.

Air-gapped cluster

A cluster without access to an external container image registry. The only source of images for it is the in-cluster cache.

In the `Managed` registry mode the cluster is considered isolated when the `primary.upstream` parameter is not set. The in-cluster cache is then filled with the `d8 mirror push` command and serves as the registry of Deckhouse Platform components.

For details, see Managing the registry in DP-managed clusters.

ALB (application load balancing)

Load balancing at the application level. HTTP(S) headers, paths and domains are analysed, SSL termination and content-based routing are supported.

Deckhouse Platform provides three ALB implementations: Ingress NGINX Controller (the `ingress-nginx` module), Kubernetes Gateway API (the `alb` module) and Istio (the `istio` module). Balancing at the network level is NLB.

For the criteria of choosing an implementation, see Incoming traffic balancing.

Alert

A notification of the Deckhouse Platform monitoring system about an event in the cluster or its components.

The standard delivery includes a set of basic alerts that cover the state of the cluster and its components. Custom alerts can be added. Alerts are sent to external systems through Alertmanager: by SMTP, to PagerDuty, Slack, Telegram or by webhook.

The list of all alerts of the monitoring system is given in the Alerts reference.

Alert notification channel

A delivery channel through which the monitoring system of Deckhouse Platform sends alerts to recipients, such as Telegram, email or a webhook.

Notification channels, notification policies and silences are configured in the `observability` module. Alerts are delivered by Alertmanager, which in Deckhouse Platform supports multitenancy: alerts are divided into system (cluster) and project ones, and channels and delivery policies can be configured separately in every project.

For details, see Observability module.

Alert severity

The Severity (S) parameter of an alert that indicates its level of criticality, from S1 for a critical failure that requires immediate action to S4–S9 for a low-level problem that does not impair overall performance.

Every alert description contains the Severity parameter with a value from `S1` to `S9`:

- `S1` is the maximum level, a critical failure that requires immediate action;
- `S2` is a high level close to the maximum, a possible accident that requires rapid response;
- `S3` is a medium level, a potentially serious problem that requires verification;
- `S4` to `S9` are low levels, a problem that does not impair overall performance.

The severity of every alert is shown in the list of alerts.

Application endpoints

The addresses of the Ingresses of an application that Deckhouse Platform publishes in the `status.urls` field of the Application. The web interface shows them as links to the application.

To publish an endpoint, the package adds the `packages.deckhouse.io/application-endpoint-description` annotation to the Ingress: its value is the endpoint description, `"true"` adds the endpoint without a description, `"false"` excludes the Ingress. Deckhouse Platform builds a URL for every `host` and `path` pair of the Ingress rules, with the `https` scheme if the host is listed in `spec.tls`, and updates `status.urls` of the application instance after every successful apply of the templates.

For details, see Templates.

Application instance

An application installed from a Marketplace package as an Application object in a namespace. The same package can be installed several times with separate names and settings, and the instance name is a part of the names of all application objects.

Each instance is fully independent: two Redis instances, one for caching and one for sessions, can live in the same namespace. Deckhouse Platform processes every instance in a separate queue. The objects of an instance are named `d8a-<INSTANCE_NAME>-<SUFFIX>`, so the instance name is limited to 24 characters, and every rendered object carries the `packages.deckhouse.io/instance` label.

For details, see Installing and managing applications.

Application reconciliation run

The configuration, hook initialization and apply steps that Deckhouse Platform performs for an application instance. A new run starts when the settings change.

Deckhouse Platform processes each application instance in a separate queue: it downloads the package bundle, loads it, waits until the package requirements are met, validates and applies the settings, enables the hook bindings and runs the `onStartup` hooks, then runs `beforeHelm` hooks, renders the templates and applies them with Nelm, and runs `afterHelm` hooks. The last three steps form a reconciliation run. The Helm release is upgraded only when needed: on the first installation, if the rendered manifests have changed, or if some resources are missing in the cluster.

A new run starts when `spec.settings` or `spec.maintenance` of the Application changes or when a `schedule` or Kubernetes hook changes values.

For details, see Lifecycle and debugging.

Application suspension

The state of an installed application whose package requirements have stopped being met, for example a mandatory module was disabled. Deckhouse Platform uninstalls the Helm release but keeps the Application in the Suspended state.

Deckhouse Platform checks the package requirements all the time, not only on admission. When they stop being met, it runs the `beforeDeleteHelm` hooks, uninstalls the Helm release, which deletes the resources of the application instance, and runs the `afterDeleteHelm` hooks. The orphan resources are not deleted. When the requirements are met again, the application is installed again with the same settings.

The resources are deleted together with the Helm release, including PersistentVolumeClaims. To keep the data, add the `helm.sh/resource-policy: keep` annotation to them.

For details, see Lifecycle and debugging.

Arbiter node

A node that holds only etcd, without the other control plane components, to provide the etcd quorum in HA mode with two master nodes.

HA mode with two master nodes and an arbiter node meets the high availability requirements with limited resources. The arbiter node must have the label `node.deckhouse.io/etcd-arbiter: ""` and a taint that keeps user workloads off it. It needs at least 2 CPU cores, 4 GB of RAM and 8 GB of disk space for etcd, and the same network latency as the master nodes.

For details, see Managing HA mode.

Automatic certificate issuance

Obtaining TLS certificates automatically with the `cert-manager` module, either through a Certificate object that references a ClusterIssuer or through the tls-acme annotation on an Ingress.

With a Certificate object, `cert-manager` runs the domain ownership challenge by the method defined in the ClusterIssuer, for example `HTTP-01` or `DNS-01`, creates a temporary Ingress for the challenge if needed and stores the certificate in the Secret. The `tls-acme` annotation on an Ingress requests a certificate without a separate Certificate object. Deckhouse Platform supports certificates from Let’s Encrypt, HashiCorp Vault and Venafi, self-signed certificates, automatic renewal and expiration monitoring.

For details, see Configuration of using TLS certificates.

Availability probe

A check that the upmeter module runs regularly to calculate the availability of Deckhouse Platform components. Probes are grouped, and groups or individual probes can be disabled.

The upmeter-agent component runs on master nodes and executes probe groups: control-plane (API server availability and controller health), deckhouse (cluster health and the deckhouse controller), extensions, load-balancing, monitoring-and-autoscaling, nginx (every Ingress controller has a `Ready` pod), nodegroups and synthetic (network connectivity between nodes). For example, the control-plane group creates a namespace, a pod and a StatefulSet and checks that Kubernetes processes them.

Probe results are stored by the upmeter controller excluding the downtime intervals defined in Downtime objects, shown on the status page and the availability dashboard, and used for SLA monitoring. Probes or probe groups are disabled with the `disabledProbes` parameter of the module.

For details, see Upmeter module.

Availability zone

The basic unit of a disaster-resilient architecture: a logical group of one or several data centers located within a few kilometers of each other and viewed as an isolated unit. Availability zones are part of regions.

An availability zone (AZ) is physically distributed infrastructure that can be treated as a virtual data center. The data centers of one zone are separated far enough (usually 10 km or less) to survive local incidents such as floods or fires, keep low network latency between each other, have independent power supply and use different network providers and routes. Several zones form a region.

Deckhouse Platform lets you distribute cluster nodes across availability zones (Multi-AZ) so that applications keep running when one zone of a data center or cloud becomes unavailable. With most cloud providers the zone distribution happens automatically. Outside clouds the administrator labels nodes with their zone. This is one form of geo-distribution.

For details, see Geo-distribution.

bashible

The service that runs on every cluster node and executes the bash scripts, also called bashible, that configure the node according to its node group.

The scripts are Go templates grouped into bundles. An individual script is called a step. They are written so that they can be re-run safely. The service re-runs the steps when the configuration checksum of the node group changes. The steps are stored on the node in `/var/lib/bashible/bundle_steps/`. NodeGroupConfiguration adds custom steps to the bashible configuration of a group.

bashible is part of the Cluster & Infrastructure subsystem. It runs at the operating system level as a system service and is not part of the `node-manager` module.

For details, see Bashible.

Bashible bundle

A collection of bashible scripts. Four bundles exist, bashible installation scripts, bootstrap scripts for the first node, node configuration scripts of a cloud provider and common scripts. An individual script of a bundle is a step.

bashible scripts are Go templates, so a bundle is rendered for a specific node group, and every step must be safe to run again after a failure. Rendered bundles are served by bashible-api-server. The steps cover the main node configuration stages: access for NodeUser, CA certificates, binaries in `/opt/deckhouse/bin`, packages, containerd, kubernetes-api-proxy, kubelet and the bashible service itself.

For details, see Bashible.

bashible-api-server

A Kubernetes extension API server on the master nodes that generates bashible scripts from templates stored in custom resources.

Storing every variant of the scripts for all supported operating systems in etcd is not feasible because of the key size limit and the load, so kube-apiserver forwards requests for resources with bashible bundles to bashible-api-server and returns the generated result. It serves the second phase of the bootstrap script, the `bashible.sh` script and the rendered bundle of a node group.

For details, see Bashible.

Bastion host

A host through which the master node is reached over SSH when the cluster nodes have no public IP addresses.

A bastion host is needed in layouts where nodes are created without public IP addresses. The installer connects through it when run with the `--ssh-bastion-host`, `--ssh-bastion-user` and, if needed, `--ssh-bastion-port` parameters.

Bootstrap script

The bootstrap.sh script that Deckhouse Platform generates for every NodeGroup to connect a server to the cluster as a node of that group.

The script is stored in the `manual-bootstrap-for-<NODE-GROUP>` secret in the `d8-cloud-instance-manager` namespace and is also available in the Deckhouse web interface. For manual connection of a static node, copy the script to the server and run it as `root`. CAPS runs it over SSH itself. The script installs and configures the operating system settings, containerd, kubelet and the `kubernetes-api-proxy` component, then registers the node in the cluster.

For details, see Adding and managing bare-metal nodes.

bpfLB

The BPF Load Balancer mode of the `cni-cilium` module that processes external traffic for Services of the NodePort and LoadBalancer types. The mode is set by the bpfLBMode parameter.

In the `SNAT` mode, the BPF load balancer fully replicates the logic of `kube-proxy`: the source IP address of packets sent to pods on other nodes is replaced with the InternalIP of the node. In the DSR

mode, incoming traffic passes through the load balancer and outgoing traffic goes directly from the node of the target pod, which increases the overall throughput.

For details, see BpfLB operation modes.

Built-in module

A module included in Deckhouse Platform. Its release cycle is tied to the release cycle of the platform.

Built-in modules are delivered together with a Deckhouse Platform release and are updated with it. Which of them are enabled by default depends on the module bundle and the edition. The other kind of modules are modules from a source, whose releases do not depend on the platform releases.

For details, see Deckhouse Platform module development.

Caching DNS server

A DNS server that the `node-local-dns` module runs on every cluster node. It caches DNS responses and removes the network round trip to the cluster DNS for repeated requests.

On each node the module configures an interface with the IP address of the `kube-dns` service, starts a caching CoreDNS on that address and adds an iptables rule that redirects DNS traffic to it while its socket is open. Otherwise the standard routing through the cluster DNS is used. External requests that are not cached yet are still resolved through the chain of internal zones first, but under load the cache alone improves resolution performance noticeably.

For details, see Caching DNS server in a cluster.

Canary deployment

An application deployment strategy that rolls out a new version to a small portion of traffic first and shifts more traffic to it as confidence grows, with a quick rollback to the old version if issues arise.

In Deckhouse Platform a canary deployment is implemented with the `ingress-nginx` module through Ingress annotations or with the `istio` module through VirtualService and DestinationRule objects (the Istio way is recommended). The new version runs as a separate Deployment and Service next to the stable one.

For details, see Configuring Canary deployment.

Chaos engineering

Deliberate or random disruption of cluster components to test its resilience. In Deckhouse Platform it is enabled per node group with the spec.chaos parameter, only for CloudEphemeral nodes.

The `spec.chaos` parameter of a node group of CloudEphemeral nodes sets the mode and the period. In `DrainAndDelete` mode Chaos Monkey drains and deletes a node of the group once per `period`. The `Disabled` mode skips the group. The mode can also be enabled in the web interface in the node group settings.

For details, see Chaos engineering.

CIS compliance check

A check that Deckhouse Platform runs automatically in every cluster against the CIS Kubernetes Benchmark recommendations. The results are available as reports and on the Security / CIS Kubernetes Benchmark dashboard.

Deckhouse Platform follows the CIS Kubernetes Benchmark both at the level of individual components and for the platform as a whole. Access to the reports, like access to vulnerability scanning results, is granted through the role model of the `operator-trivy` module.

For details, see Configuration of container image vulnerability scanning.

Cloud cluster

A cluster with the clusterType: Cloud. Deckhouse Platform has access to the API of the cloud infrastructure and creates and manages the virtual machines of the nodes.

The installer creates all the required resources, such as virtual machines and networks, from the `<PROVIDER>ClusterConfiguration` of the cloud provider. The master nodes of a cloud cluster are CloudPermanent nodes, worker nodes are usually CloudEphemeral nodes.

For details, see Platform installation.

Cloud provider

A cloud platform or virtualization system that Deckhouse Platform integrates with through a cloud-provider-* module to create virtual machines, connect them to the cluster as nodes and create base infrastructure resources.

The workflow is the same for all providers, only the preparation steps, such as creating a service account, and the configuration files differ. The integration enables CloudEphemeral nodes, which Deckhouse Platform creates and deletes through the provider API, and the choice of a layout.

For details, see Integration with IaaS.

CloudEphemeral node

A temporary cloud node that Deckhouse Platform orders, creates and deletes automatically through the cloud provider API. It is described by a NodeGroup with the CloudEphemeral node type.

The parameters of the virtual machines are taken from an instance class, the number of nodes and their zones from the `cloudInstances` section of the node group. The nodes are created by Machine Controller Manager or Cluster API, which are part of the `node-manager` module.

CloudEphemeral groups support node group autoscaling, standby nodes and chaos engineering.

For details, see Adding and managing cloud nodes.

CloudPermanent node

A permanent cloud node whose configuration is taken from the provider cluster configuration rather than from a NodeGroup. The master nodes of a cloud cluster are CloudPermanent nodes.

CloudPermanent nodes are described in the `nodeGroups` section of the `<PROVIDER>ClusterConfiguration` structure, and their number is set by `replicas`. The nodes are managed by Terraform built into Deckhouse Platform, and configuration changes are applied by running the installer with `dhctl converge`.

For details, see Adding and managing cloud nodes.

CloudStatic node

A node created manually or by external tools in the cloud for which the provider integration is configured, and connected to the cluster with the bootstrap script. CSI runs on it, and cloud-controller-manager manages its Node object.

The Node object of a CloudStatic node automatically receives the zone and region from the provider data. If the machine is deleted from the cloud, its Node object is deleted from the cluster. Like a static node, a CloudStatic node does not support automatic scaling and updates.

For details, see Adding and managing cloud nodes.

Cluster

A group of interconnected nodes managed by Deckhouse Platform that provides a single environment for deploying, scaling and operating workloads.

A cluster consists of the system, which keeps the cluster running, and the workload, which runs in the cluster.

Cluster API Provider Static (CAPS)

The mechanism that connects, configures and, when needed, cleans up static nodes automatically, based on StaticInstance and SSHCredentials objects.

CAPS is enabled by the `staticInstances` section of a node group with the Static type: `count` sets how many nodes the group must have, `labelSelector` selects the StaticInstance objects to use. CAPS keeps the number of nodes equal to `count`: it connects to a server over SSH, runs the bootstrap script and adds the node to the cluster, and when a node is removed it cleans the server up and returns its StaticInstance to the `Pending` state for reuse.

For details, see Adding and managing bare-metal nodes.

Cluster configuration (ClusterConfiguration)

The structure that holds the general parameters of the cluster, such as the Kubernetes version, network settings, CRI parameters and the cluster type.

The cluster configuration is defined at installation and edited in a running cluster with the `d8 system edit cluster-configuration` command. After the change is saved, Deckhouse Platform reconciles the cluster state with the new configuration. Some of its parameters are protected and cannot be changed in a running cluster by default.

The `clusterType` parameter defines whether the cluster is static or cloud.

For details, see Deckhouse Platform configuration.

Cluster managed by Deckhouse Platform

A cluster in which Deckhouse Platform manages both the control plane and the nodes. The opposite is a Managed Kubernetes cluster, where the control plane is managed by a cloud provider.

Deckhouse Platform can also be installed into an existing Managed Kubernetes cluster, such as GKE, EKS or AKS. In this case Deckhouse Platform does not manage the control plane, and some features are limited by the API of the cloud provider: for example, node management and the `registry` module are available only in clusters fully managed by Deckhouse Platform.

For details, see Platform installation.

Cluster network

An additional software-defined network that is publicly available in every project of the cluster and is configured and managed by the administrator.

Examples of a cluster network are a public WAN network or a shared network for traffic exchange between projects. The administrator creates it with a ClusterNetwork object of the `sdn` module and, if needed, enables IPAM for it with a cluster-wide address pool. To use such a network in application pods, contact the cluster administrator. The other kind of additional network is the project network.

For details, see Software-defined networking (SDN).

ColdStandby

A mechanism that returns a virtual machine to service on another node after the failure of the node it was running on.

The mechanism requires the `runPolicy` of the virtual machine to be `AlwaysOnUnlessStoppedManually` or `AlwaysOn`, and Fencing to be enabled on the nodes that run virtual machines. Without Fencing, an unavailable machine does not move: it stays on the failed node and resumes together with it.

For details, see Virtual machine fault tolerance and balancing.

Conditional module dependency

A dependency on another module that applies only if that module is enabled. The module works on its own, but if the other module is present its version must match the constraint.

A conditional dependency is a kind of module dependency and is available in Deckhouse Platform starting with version 1.73. It may affect the ability to enable, disable and update both modules: the dependent one and the one it depends on. A Marketplace package lists such modules in `requirements.modules.conditional`.

For details, see Dependencies of the Deckhouse Platform modules.

Consistent snapshot

A snapshot of a virtual machine disk that captures a coherent and integral state of its data. It is created when the disk is not attached to any machine, the machine is powered off, or the guest OS agent freezes the file system while the snapshot is taken.

Whether a consistent snapshot is required is set by the `requiredConsistency` parameter, which is `true` by default. With a running machine the file system is frozen by the guest OS agent. Its hook scripts can also prepare applications for the snapshot without stopping services.

An inconsistent snapshot is created when the machine is running and the agent is not installed or not running. Recovery from such a snapshot can lead to file system integrity problems.

For details, see Snapshots of disks and virtual machines.

Control plane

The Kubernetes components that manage the cluster, such as kube-apiserver and etcd. In Deckhouse Platform they run on master nodes, and in HA mode with two master nodes the etcd quorum is provided by an arbiter node.

Deckhouse Platform manages the certificates of the control plane, generates the configuration and manifests of its components, upgrades and downgrades their versions, manages the etcd cluster and its members, runs etcd defragmentation and maintains the kubeconfig files. The `control-plane-manager` module runs on all master nodes.

The control plane works in the single-master or multi-master mode. In HA mode with two master nodes, the third etcd member runs on an arbiter node: it holds only etcd, without the other control plane components, so that the etcd cluster keeps its quorum.

For details, see General management and configuration of the control plane.

Core fraction

The guaranteed share of the power of each virtual core of a virtual machine, set by the coreFraction parameter. Without it every virtual core gets 100% of a physical one.

A machine with `cores: 2` and `coreFraction: 20%` is guaranteed 0.4 cores in total regardless of the node load and can take both cores in full when the node has free resources. Such a reserve keeps more machines on a node than it has physical cores. This is how CPU oversubscription works. The guaranteed share is taken into account when a node is selected, so a machine does not start where the node cannot provide the guarantees to all machines placed on it.

An administrator can restrict the allowed values in the sizing policy of the VM class. In commercial editions `coreFraction: Auto` lets Deckhouse Platform pick the share by the actual consumption of the machine.

For details, see Virtual machine CPU and memory.

CPU oversubscription

Giving the virtual machines on a node more virtual cores than the node physically has. The degree of oversubscription is controlled by the core fraction guaranteed to a virtual machine.

The `coreFraction` parameter of a virtual machine defines the share of a core’s capacity guaranteed to it. The allowed values are set in the sizing policy of the class. With `coreFraction: 20%`, a machine always gets a fifth of a core and can take a whole core when the node has spare resources. When placing a machine, Deckhouse Platform sums the guaranteed shares of all machines on the node, and if the sum exceeds the number of physical cores, the machine does not start on that node.

For details, see CPU oversubscription for virtual machines.

Critical module

A module marked with critical set to true in module.yaml. It starts during the initial cluster bootstrap, before the cluster is considered fully ready. Other modules start only after that.

The Deckhouse controller puts the tasks of critical modules into the `main` queue in ascending order of module weight. Non-critical modules are processed in the parallel queues without regard to weight. If critical modules can be processed in parallel, the controller runs them as a batch and waits for completion before continuing the `main` queue.

For details, see Queuing mechanism.

CSI driver

A plugin that manages persistent storage volumes in Deckhouse Platform. It is part of the cloud-provider-* and csi-* modules, and all implementations share one reference architecture.

Container Storage Interface (CSI) is a standard interface that unifies access to storage systems. Every cloud provider and external storage system has its own implementation of the specification. The implementations differ in the supported capabilities and components, but not in architecture.

For details, see CSI driver.

Dashboard

A collection of charts and tables with data about the state of the cluster and the applications running in

it. Deckhouse Platform ships preinstalled dashboards and lets users create custom ones.

Dashboards show CPU usage, memory consumption, disk and network activity, and the status of pods, controllers, nodes and namespaces. They are available in the Deckhouse web UI under “Monitoring” → “Dashboards”.

Preinstalled dashboards are shipped with Deckhouse Platform and cannot be edited. Custom dashboards are created with an ObservabilityDashboard object of the `observability` module at the namespace level with access control, or with a GrafanaDashboardDefinition object at the cluster level, which is a legacy approach.

For details, see Monitoring dashboards.

Deckhouse CLI (d8)

The command-line interface for working with the products of the Deckhouse ecosystem. It combines commands for Kubernetes, Deckhouse Platform administration, application delivery, image copying, backups, diagnostics, virtualization and other tasks.

Starting from release 1.59, `d8` is installed on all Deckhouse Platform cluster nodes. It can also be installed on an administrator machine with trdl (an open-source tool for securely delivering and updating binary files) or from the executable file. Commands are grouped by purpose: `d8 k` is equivalent to `kubectl`, `d8 system` works with platform settings, modules, queues and packages, `d8 mirror` copies platform images, `d8 v` manages virtual machines, `d8 backup` creates backups.

For details, see Deckhouse CLI overview and installation.

Deckhouse controller

The controller of the deckhouse module that implements platform management operations and coordinates them through the queueing mechanism. The deckhouse module is the only module without which Deckhouse Platform cannot run.

The Deckhouse controller manages modules: it runs their hooks, applies module settings and installs module releases. Tasks are processed in the addon-operator queues. In HA mode several controller instances run and elect a leader through the `deckhouse-leader-election` Lease. The leader performs all management operations.

The controller can run in standard mode or in hook isolation mode, in which shell hooks and module enable scripts run in a chroot environment with a limited set of mounted directories.

For details, see Deckhouse module.

Deckhouse Platform API

The interface through which users and Deckhouse Platform components interact with the cluster. It is fully compatible with the Kubernetes API.

All operations in Deckhouse Platform are performed through the API, which keeps the interaction uniform. The API of every module, its custom resources and parameters, are described in the module documentation.

Deckhouse Platform component registry

The container image registry from which the cluster pulls the images of Deckhouse Platform components.

The registry is specified during cluster bootstrap in the `deckhouse` parameter of InitConfiguration. How its configuration is managed in a running cluster depends on how the cluster is managed: in a cluster fully managed by Deckhouse Platform, the `registry` module is used and the registry management mode is set in its ModuleConfig. In a Managed Kubernetes cluster, the `helper change-registry` is used.

For details, see DP components registry.

Deckhouse Platform image bundle

An archive of Deckhouse Platform container images produced by d8 mirror pull and loaded into a private container registry with d8 mirror push. It is the way to deliver platform images into a private environment.

The bundle is downloaded from the public Deckhouse Platform registry with a license key, usually on the bastion host, and brought into the perimeter by any permitted means, for example on removable

media. Its size after `d8 mirror push` guides the disk capacity of the private registry. The `d8 mirror` commands are not available in the Community Edition and Basic Edition editions.

For details, see Installing DP in a private environment.

Deckhouse Platform release

Any published version of Deckhouse Platform. Releases are distributed through release channels with defined delays and are of two types, a patch version and a minor version.

A patch version includes bug fixes, a minor version includes new features. Each new release first appears on the Alpha release channel and then moves to the more stable channels. In the cluster a release is represented by a DeckhouseRelease object, which is applied according to the update mode and update windows. Minor releases cannot be skipped, because they contain migrations that must be applied in order.

For details, see Updating.

Deckhouse web UI

The web interface of Deckhouse Platform for cluster management, including monitoring, parameter configuration, node and module management, security and network configuration.

Most operations available from the command line through Deckhouse CLI or `kubectl` can also be performed in the web UI. It opens at `console.<CLUSTER_NAME_TEMPLATE>`, where the template is the DNS name template of the cluster, and contains the sections Deckhouse, node management, multitenancy, access, network, storage, security, monitoring and logging.

For details, see Deckhouse Platform web UI.

Deletion confirmation

A confirmation that the user must give in the web interface before an application is deleted or a module is disabled. It is declared in the disable section of package.yaml or module.yaml together with the message shown to the user.

For a Marketplace package the `disable` section sets `confirmation: true` and localized messages, for example a warning that deleting the application deletes the data stored in its volumes. Deckhouse Platform publishes the section in the `status.packageMetadata.disableOptions` field of the package version, and the Deckhouse web UI shows the message in the language of the user. The confirmation is not checked when an Application is deleted through the Kubernetes API.

For a module the `disable.confirmation` and `disable.message` parameters of `module.yaml` work the same way when the module is disabled.

For details, see Application development.

Deployment option

A cluster configuration that defines the number of nodes, the distribution of roles between them, and whether the cluster tolerates a node failure.

The deployment option is chosen before the installation. Examples of options: a single-node cluster, a single-master cluster, a high-availability cluster with three master nodes, and a cluster with role separation, where system, frontend and monitoring nodes are dedicated to the platform components and incoming traffic. The node resource requirements depend on the deployment option.

For details, see the Deployment options section of the “System requirements” page.

Device passthrough

Giving a virtual machine a device of the node it runs on, such as a USB device, a GPU or a PCI device.

Each device type has its own node requirements and its own preparation order.

For details, see Virtualization.

Disaster resilience

The ability of infrastructure based on Deckhouse Platform to remain operational in the event of large-scale failures. It is achieved through distributed deployment, automatic traffic switching and replication of critical components.

Deckhouse Platform implements two approaches to disaster resilience. Geo-distribution spreads the components of one cluster across several availability zones or regions. Geo-reserving combines several independent clusters into a multicluster and redirects traffic to another cluster when one becomes unavailable.

Both approaches require network connectivity between nodes and regions, traffic balancing and a suitable storage organization. The choice of an architecture depends on the applications and the constraints of the infrastructure. Within one cluster, the redundancy of critical components is provided by the HA mode.

For details, see Disaster resilience.

Disruptive update

A node update that requires node downtime and may briefly interrupt system components, for example upgrading containerd or kubelet across several versions. The approval mode is set by the disruptions.approvalMode parameter of the NodeGroup.

Regular node updates are always applied automatically and cause no downtime or reboot. The `disruptions` section governs only disruptive updates, such as a kernel or containerd update or a significant kubelet version change. Only one node per group is updated at a time.

Three approval modes are available in a node group. In `Manual` mode the `NodeRequiresDisruptionApprovalForUpdate` alert is raised, and the update starts after the `update.node.deckhouse.io/disruption-approved=` annotation is added to the node. The node is not drained automatically. In `Automatic` mode the node is drained and updated without confirmation. In `RollingUpdate` mode a new node with the updated settings is created and the old one is removed. This mode applies to cloud nodes only.

Use `Manual` mode for the groups of master nodes.

For details, see Node management basics.

DNS name template

The cluster DNS name template from the modules.publicDomainTemplate parameter of the global ModuleConfig. Deckhouse Platform modules substitute a reserved name for the `%s` placeholder to build the DNS names of their service web interfaces.

If the template is not set, the modules do not create Ingress resources. The domain in the template must not match or be a subdomain of the cluster domain from `clusterDomain`. With a wildcard DNS record one record covers all names. With a non-wildcard template, for example `%s-kube.company.my`, an A or CNAME record is needed for each reserved name, pointing to the public IP address of the Ingress controller. The template is a part of the global settings.

For details, see List of reserved Deckhouse Platform DNS names.

DSR (Direct Server Return)

A traffic processing method in which incoming packets pass through the load balancer and outgoing packets go directly from the servers that handle the request.

Responses are usually much larger than requests, so DSR unloads the balancer and increases the overall throughput. In Deckhouse Platform, DSR is one of the bpfLB modes of the `cni-cilium` module and is used instead of SNAT.

For details, see BpfLB operation modes.

DVCR

The internal container image storage in which Deckhouse Platform keeps virtual machine images. It resides on a persistent volume of the cluster.

Images travel from DVCR to virtual machine disks, so the size of the volume determines how many images fit into the cluster. The volume size and storage class are set in the `dvcr.storage` block of the `virtualization` ModuleConfig. After the volume is created, its size cannot be reduced and its storage class cannot be changed. Stale data of deleted images and disks is removed by garbage collection on a schedule, daily at 02:00 by default.

For details, see Virtual machine image storage.

Edition

A Deckhouse Platform distribution, such as Open, Core, Ultimate, or CSE Pro, that defines the set of available modules and features.

The edition is selected when the cluster is installed. A running cluster can be switched to another edition.

For details, see Switching between DP editions.

Egress gateway

Centralized management and control of outgoing traffic from the cluster, including encryption, routing and monitoring.

The egress gateway is provided by the `cni-cilium` module and is configured with two custom resources. EgressGateway describes a group of nodes, one of which is selected as the active gateway while the others stay in standby mode. EgressGatewayPolicy describes which traffic of cluster pods is routed through that gateway.

Two modes are available: the basic mode with pre-configured IP addresses on the egress nodes and the Virtual IP mode, in which additional IP addresses are assigned to nodes dynamically. For details, see Egress Gateway configuration.

End-to-end authentication

Authentication implemented in Deckhouse Platform so that a user is verified when accessing any interface of the platform or any cluster resource. Users can also enable it for their own applications.

Depending on the configuration, authentication uses either the internal user database (static users) or external authentication providers such as LDAP, GitLab or GitHub. An external provider lets users keep their existing credentials and use them in several Deckhouse Platform clusters. For a cluster user or an application developer the interface and the authentication methods for applications stay the same whichever way the administrator configured authentication.

For details, see Configuring authentication for applications.

Extended monitoring

A monitoring mode of the `extended-monitoring` module that adds monitoring of secrets and TLS certificate expiration, collection of cluster events as metrics, checks of image availability in the registry and monitoring of objects in labelled namespaces.

Objects are monitored in the namespaces that carry the label `extended-monitoring.deckhouse.io/enabled=""`. Image availability is checked for the images used by Deployments, StatefulSets, DaemonSets and CronJobs.

For details, see Monitoring in Deckhouse Platform.

External storage

Storage systems outside the cluster nodes, Ceph, NFS, S3, SCSI and vendor storage systems, connected to Deckhouse Platform through csi-* modules, as opposed to software-defined storage.

Deckhouse Platform ships ready-to-use integrations with distributed Ceph storage, HPE, Huawei and TATLIN.UNIFIED (Yadro) storage systems, NFS, S3 object storage and SCSI-based storage. Each integration is a module with a CSI driver. The second group of storage types is software-defined storage on the disks of cluster nodes.

For details, see Storage.

Federation

An inter-cluster communication model that connects independent clusters. Each cluster keeps its own namespaces and services, and access between clusters is configured explicitly.

In a federation, the administrator defines which services are accessible from outside the cluster. The model is implemented with Istio through the `istio` module and is built on the service mesh. The model for tightly connected clusters is multicluster.

For details, see Inter-cluster cooperation.

Fencing

A mechanism that isolates a node that has lost connectivity with the cluster. The node is shut down

and, if needed, its Node object is deleted, so that no workload keeps running on it in an undefined state.

Fencing works in two stages: the node is first marked as suspicious at the gossip protocol level, then isolated. It is enabled per node group with the `spec.fencing.mode` parameter of the NodeGroup. Fencing is required for ColdStandby: without it an unavailable virtual machine stays on the failed node and resumes together with it.

For details, see Virtual machine reliability.

Frontend node

A node that balances incoming traffic. Ingress controllers run on frontend nodes.

A cluster needs more than one frontend node, and the nodes must handle the traffic when at least one of them fails. With two frontend nodes each must carry the full load, with three each must withstand a load increase of at least 150%. Frontend nodes usually form the `front` node group and run the Ingress controllers.

For details, see Recommendations for configuring cluster nodes.

Geo-distribution

An approach to disaster resilience in which the components of a cluster are distributed across several availability zones (Multi-AZ) or regions (Multi-Region) so that the cluster keeps running when a zone or region fails.

Geo-distribution reduces the impact of infrastructure failures on application availability. Distributing nodes across availability zones protects applications from the failure of one zone in a data center or cloud. Distributing them across regions lets applications survive the outage of a whole data center or cloud provider, provided that the application can work independently in each region.

The platform administrator is responsible for the network connectivity between cluster nodes, for the balancing of incoming traffic by the cloud provider or an internal load balancer, and for the organization of storage. Geo-distribution is one of the two approaches to disaster resilience in Deckhouse Platform. The other is geo-reserving.

For details, see Geo-distribution.

Geo-reserving

A method of increasing fault tolerance in which several independent Kubernetes clusters in different geographic locations are combined into a multicluster, and traffic is automatically redirected to a cluster that has an available copy of the application.

Geo-reserving requires one Deckhouse Platform cluster per region, connected with a declarative API into a multicluster: either through the built-in service mesh based on Istio or through the networking features of the platform based on Cilium. The application must be able to run in parallel in different regions, and a stable network channel must exist between the regions. A properly configured system keeps the application running even when a whole region or cloud becomes unavailable.

Incoming traffic in a multicluster is balanced by an external load balancer in one of two schemes, active-active or active-standby. The balancing and the storage organization are configured by the cluster administrator. Geo-reserving is one of the two approaches to disaster resilience. The other is geo-distribution.

For details, see Geo-reserving.

Global settings

Deckhouse Platform settings that apply to the whole cluster. They are stored in the ModuleConfig named global.

Global settings can be thought of as a special `global` module that cannot be disabled. The settings of other modules are stored in separate ModuleConfig objects named after the module.

For details, see Global settings.

Grantable cluster-wide resource

A cluster-wide resource, for example a StorageClass, that the `multitenancy-manager` module makes available to a project through a grant. Application settings bound to such a resource get the project default and are validated against the resources available to the project.

A `settings` field of type `string` is bound to a grantable resource with the `x-deckhouse-grantable-resource` extension, which names the resource available to the project, for example `storageclasses`. When the user leaves the field empty, the resource name configured as the project default is injected into the values. A value that is not in the list of resources available to the project is rejected. The group, version and kind of the resource are defined by the grant.

For details, see Application settings.

Guest OS agent

QEMU Guest Agent installed in the guest system so that Deckhouse Platform can interact with the operating system inside the virtual machine.

The agent is needed for three things: it makes consistent snapshots of disks and machines possible, it reports information about the running system to the `.status.guestOSInfo` block, and it shows that the operating system has actually booted rather than just the virtual machine having started. The `AgentReady` condition of a running machine means that the agent is working.

Deckhouse Platform works with `qemu-guest-agent` version 5.2.0 and later. The agent can be installed and enabled by the VM provisioning script.

For details, see Initial provisioning and the guest OS agent.

HA mode

A mode in which critical Deckhouse Platform components run with redundancy, so that the failure of a single instance does not stop the service.

HA mode is enabled automatically when the cluster has more than one master node, both at the initial deployment and when nodes are added later. It can also be managed manually.

For details, see High reliability and availability.

High-level role

A role of the basic role model of Deckhouse Platform, provided by the `user-authz` module on top of Kubernetes RBAC. User, PrivilegedUser, Editor, Admin, ClusterEditor, ClusterAdmin and SuperAdmin.

High-level roles belong to the basic role model. The `user-authz` module creates them as a set of ClusterRole objects and grants them to users and groups with ClusterAuthorizationRule and AuthorizationRule. Each role extends the previous one: `User` can view pods, logs and Deployments, `Admin` manages RBAC in a namespace, `ClusterAdmin` has full access to cluster-wide resources.

The recommended granular role model uses use roles and manage roles instead of high-level roles. The models are not compatible, automatic conversion is impossible, but they can be used at the same time: the permissions of both models are summed up.

For details, see Basic authorization model.

Hook binding

An event on which a hook runs, specified in the hook configuration. A hook can run on Kubernetes events, on schedule, at startup, before or after the Helm templates are applied.

Bindings of a module hook are `onStartup`, `beforeHelm`, `afterHelm`, `kubernetes` and `schedule`. Global hooks also have `beforeAll` and `afterAll`. The hooks of a Marketplace package use the same kinds of bindings, with the `Queue` field that sets a separate queue for the `Schedule` and `Kubernetes` bindings. Hooks with the same binding run in the order of their `Order` value.

For details, see Hooks.

Host firewall

A Cilium mode in which network policies apply to the cluster nodes themselves rather than to pods.

A host firewall is configured with CiliumClusterwideNetworkPolicy and the `nodeSelector` field. Such a policy applies to the host endpoint with the label `reserved:host` and filters the traffic entering and leaving the node, including `hostNetwork` pods. It is available only in clusters with the `cni-cilium` module.

Host policies add a filter layer inside the cluster and do not replace infrastructure-level protection such as physical firewalls or cloud security groups. A mistake in them can break SSH access, the control plane, kubelet or etcd, so they are rolled out through the audit mode first. For details, see Host firewall on nodes.

Hybrid cluster

A static Deckhouse Platform cluster extended with nodes placed in the infrastructure of a supported cloud provider.

The control plane and the initial nodes remain part of the static cluster. Additional nodes are added through the cloud provider module: either created automatically through the provider API as CloudEphemeral nodes, or created in advance and connected with the bootstrap script as CloudStatic nodes.

A hybrid cluster requires L3 connectivity between the data center and the cloud.

For details, see Hybrid clusters.

Hybrid node group

A node group that includes both Static nodes deployed in the cloud and servers in the on-premises data centre, bare metal or virtual machines.

In a hybrid node group the primary workload can run on bare-metal servers while cloud instances serve as a scalable addition during peak loads. All nodes are static nodes, so the `node-manager` module works as for static nodes. The only requirement is L3 connectivity between the data centre and the cloud. A hybrid node group differs from a hybrid cluster, which combines static nodes with CloudEphemeral nodes.

For details, see Hybrid node groups and clusters.

Image signature verification

Verification of the integrity and authenticity of user application images during Kubernetes API request validation, before a pod is created, against Cosign signatures and the public keys listed in a SecurityPolicy.

At the build stage the image is signed with a private key using Cosign. The signature is published in the registry as a separate tag and does not change the image. In the cluster a SecurityPolicy with the `verifyImageSignatures` parameter lists the public keys, and the `admission-policy-engine` module with Ratify verifies the signature of every image when the pod is created. This is the part of integrity control available in all editions. Verification at the container runtime level exists only in Certified Core and Certified Pro.

For details, see Integrity control.

In-cluster image cache

A container image registry deployed on the master nodes of the cluster, from which all nodes pull the images of Deckhouse Platform components.

The cache is enabled by the `storage.cache` parameter of the `registry` ModuleConfig in the `Managed` registry management mode. While the cache is being filled, the upstream registry stays a fallback path. In an isolated cluster, the cache is the only source of images and is filled with the `d8 mirror push` command.

Infrastructure node

A collective name for the master, frontend, system and monitoring nodes of a cluster, as opposed to worker nodes that run user applications.

Infrastructure nodes run the cluster control plane and Deckhouse Platform components. The recommended resource minimums depend on the role: master nodes and monitoring nodes need fast disks, frontend nodes need the least resources, and the size of system nodes depends on whether the cluster has dedicated monitoring nodes.

For details, see Going to production.

Ingress controller

A controller that routes user requests to applications and services by the rules defined in Ingress resources.

In Deckhouse Platform, the Ingress controller is Ingress NGINX Controller, managed by the `ingress-nginx` module through IngressNginxController resources. Several Ingress NGINX Controllers can run in one cluster at the same time, one of them is the primary one. Kubernetes Gateway API (the `alb` module) and Istio Ingress Gateway also balance traffic at the application level, but they work not with

Ingress resources but with Gateway API routes and Gateway and VirtualService resources. All three solutions are implementations of ALB.

Ingress controllers are usually placed on frontend nodes. The way traffic reaches a controller is defined by its inlet. For details, see Incoming traffic balancing.

Inlet

The way incoming traffic reaches an application-level load balancer — Ingress NGINX Controller or a gateway of the `alb` module. It is set in the inlet field of IngressNginxController, ClusterALBInstance and ALBInstance resources.

For the Ingress controller, the inlet takes one of the values `LoadBalancer`, `LoadBalancerWithProxyProtocol`, `HostPort` or `HostWithFailover`. The `LoadBalancer` and `LoadBalancerWithProxyProtocol` inlets use a load balancer of the cloud provider or the built-in `metallb` module. The `HostPort` inlet exposes the controller on node ports, for example behind an external load balancer. The `HostWithFailover` inlet is used on bare metal, where the controller runs on frontend nodes.

For gateways of the `alb` module, the inlet takes one of the values `LoadBalancer`, `HostPort` or `ClusterIP`. ClusterALBInstance supports `LoadBalancer` and `HostPort`, ALBInstance supports `LoadBalancer` and `ClusterIP`. The `ClusterIP` inlet accepts traffic through a service of the `ClusterIP` type, without an external entry point.

For examples of each inlet, see ALB with Ingress NGINX Controller and the Inlets section of the “ALB with Kubernetes Gateway API” page.

Installation configuration file

A set of YAML documents with Deckhouse Platform settings and manifests of the cluster objects to be created after installation. It is passed to the CLI installer with the –config parameter.

The file contains InitConfiguration (required), ClusterConfiguration (required unless Deckhouse Platform is installed into an existing cluster), StaticClusterConfiguration or the provider cluster configuration, and optionally ModuleConfig, NodeGroup and other objects. The CLI installer reads it during preflight checks and the cluster bootstrap.

For details, see Installation.

Installation into an existing cluster

An installation mode in which Deckhouse Platform runs on top of an existing Kubernetes cluster and installs and updates platform modules, but does not manage the operating system, control plane or node lifecycle.

In this mode the existing infrastructure keeps managing the operating system, kubelet, containerd, etcd, the control plane and Kubernetes updates, the existing CNI provides pod networking, and machines are created and deleted by an external provisioner or the user. The module bundle `Managed` is selected during installation and cannot be changed afterwards. ClusterConfiguration is not required in the installation configuration file.

For details, see Installing Deckhouse Platform in an existing Talos cluster.

Installer

The tool that deploys a Kubernetes cluster and installs Deckhouse Platform in it. It is available as the `dhctl` CLI installer in a container image and as the graphical installer.

The `dhctl` CLI installer deploys a cluster in a supported cloud, on bare-metal servers, including hybrid clusters, or installs Deckhouse Platform into an existing Kubernetes cluster. In a cloud cluster it creates the required infrastructure: virtual machines, networks and other resources. In a running cluster the `dhctl converge` command applies configuration changes of CloudPermanent nodes and changes of protected parameters.

The second form is the graphical installer available on the Deckhouse Platform website.

For details, see Platform installation.

Instance class

A provider-specific resource, such as OpenStackInstanceClass or AWSInstanceClass, that describes the parameters of the virtual machines Deckhouse Platform creates for a node group.

A node group of CloudEphemeral nodes refers to an instance class in `cloudInstances.classReference`. The instance class defines the machine type, the image, disks and other provider-specific parameters, while the number of nodes and their zones are defined by the node group.

For details, see Adding and managing cloud nodes.

Integrity control

A set of mechanisms that verify containers to ensure their security and compliance with the specified configuration, including image signature verification at startup, runtime audit of running containers and immutable images of platform modules.

Deckhouse Platform provides three mechanisms: image signature verification of user workloads during Kubernetes API request validation, runtime audit of running containers, and integrity protection of Deckhouse Platform modules. Cryptographic verification of image signatures at the container runtime (CRI) level with DM-Verity protection of unpacked layers is available only in the certified editions.

Starting with version 1.74, modules are installed as read-only EROFS images mounted through DM-Verity, which protects an installed module from being replaced or modified on the node. This mechanism is enabled automatically when the node OS supports the `erofs` kernel module. Without it Deckhouse Platform keeps working and raises an alert.

For details, see Integrity control.

IPAM

An IP address management mechanism that allocates addresses to the network interfaces of pods and virtual machines and ensures that no address is assigned twice. In Deckhouse Platform the CNI modules, the sdn module and the virtualization module each have their own IPAM.

The `cni-cilium`, `cni-flannel` and `cni-simple-bridge` modules assign pod addresses from the pod address range allocated to the node. This IPAM is not configurable.

In the `sdn` module, IPAM allocates IPv4 addresses from pools to the additional network interfaces of pods and virtual machines. It is enabled for each network separately by an address pool reference in Network or ClusterNetwork. For cluster networks the pools are created by the administrator, for project networks by users. If a pod is connected to multiple networks that use IPAM, specify the address objects for each interface explicitly.

The addresses of virtual machines in the main cluster network are managed by default by the `virtualization` module through the VirtualMachineIPAddress and VirtualMachineIPAddressLease. When a pool is configured for the main network in the `sdn` module, the addresses of virtual machines are managed by the shared IPAM of that module: the address is requested automatically, and existing virtual machines are brought under its management without changing their addresses or restarting.

For details, see Additional networks for use in application pods and IP addresses of virtual machines.

Istio Ingress Gateway

The entry point of an application load balancer built on Istio. The administrator deploys it with IngressIstioController, and application developers publish applications with Gateway and VirtualService objects.

Publishing with Istio has two layers: the cluster administrator deploys the IngressIstioController and the related infrastructure, and developers create Gateway and VirtualService objects in their namespace. This is one of the ALB implementations in Deckhouse Platform, next to Ingress NGINX and the Gateway API with its managed Gateway.

For details, see Publishing applications using Istio.

Kubernetes API audit

Logging of requests to the Kubernetes API server according to an audit policy. By default the log is written to the `/var/log/kube-audit/audit.log` file on master nodes.

Kubernetes API audit tracks requests to the API server and helps to investigate unexpected behaviour and to meet security requirements. Deckhouse Platform configures a basic audit policy by default: it skips frequent service updates such as Endpoints, Events and leader election and logs changes of pods, nodes, ServiceAccount objects and operations in system namespaces. The policy can be extended with custom rules.

The audit log is a source for runtime audit and for security events.

For details, see Kubernetes API event audit.

Kubernetes conformance

Testing of Deckhouse Platform against the conformance test suite of the CNCF Certified Kubernetes Conformance Program. The tests are run for every supported Kubernetes minor version.

The tests are run with Sonobuoy in the `certified-conformance` mode, and the JUnit reports are published in the reference. The results are valid only when the `multitenancy-manager` module is disabled.

For details, see Kubernetes conformance test results.

kubernetes-api-proxy

An NGINX-based proxy on every cluster node that serves requests to the Kubernetes API sent to localhost and forwards them to the master nodes, providing high availability and load balancing of the API.

bashible installs and configures the proxy and keeps its list of upstream master nodes up to date. On master nodes it runs as a static pod: by default it proxies requests to the local kube-apiserver and, if that is unavailable, queries the remaining instances in turn. Requests from kubelet to `localhost` go through it.

For details, see Control plane management.

Layout

The scheme of node placement in the infrastructure of a cloud provider. It affects networking, availability of public IP addresses, outgoing traffic routing and the way nodes are accessed.

The layout is set in the `layout` parameter of the ModuleConfig of the cloud provider module. The available layouts depend on the provider, for example `Standard`, `WithoutNAT` and `WithNATInstance` in Yandex Cloud.

In some layouts nodes have no public IP addresses, and the master node is reached through a bastion host.

For details, see Integration with cloud providers.

License key

The credential required for using the commercial editions of Deckhouse Platform.

The license key is required to pull images of the commercial editions from `registry.deckhouse.io`, for example when updating a cluster in a private environment with `d8 mirror pull`.

For details, see Updating DP in air-gapped environment.

Live migration

Moving a running virtual machine from one node to another without shutting it down.

Live migration is used for load balancing, to free a node for maintenance or update, and for a virtual machine firmware update that would otherwise require a restart. A node sends the memory of one virtual machine at a time and accepts one incoming migration at a time, and the transfer rate of a single migration is limited to 640 MiB/s. VM rebalancing also moves machines with live migration.

For details, see Maintenance of nodes running virtual machines.

Local storage

Storage on the local disks of a node. It reduces network latency and gives higher performance than storage accessed over the network.

Local storage is one of the software-defined storage types and is provided by the `sds-local-volume` module, which supports the LVM and LVMThin modes. It is effective in test environments and EDGE clusters.

For details, see Setting up local storage based on LVM.

Log buffering

Temporary accumulation of logs in a buffer before they are sent to the storage system.

Buffering keeps logs during temporary connection issues with the storage and sends them when the connection is restored, smooths load spikes on the storage and reduces the number of network requests by sending logs in batches. It is configured with the `buffer` parameter of ClusterLogDestination in the log pipeline.

For details, see Log collection and delivery.

Log pipeline

The chain of log collection, filtering and delivery that the `log-shipper` module builds from ClusterLoggingConfig, PodLoggingConfig and ClusterLogDestination.

ClusterLoggingConfig describes log sources at the cluster level, PodLoggingConfig describes sources within one namespace, and ClusterLogDestination defines the parameters of the log storage. Along the pipeline, logs can be filtered by labels and message content, enriched with Kubernetes metadata, buffered and sent to several storages at once, for example to the short-term log storage and to Elasticsearch.

For details, see Log collection and delivery.

Long-term metrics storage

A separate storage, for example VictoriaMetrics, to which Prometheus sends metrics with the remote_write mechanism.

In Deckhouse Platform, sending metrics to a long-term storage is configured with a PrometheusRemoteWrite object.

For details, see Writing Prometheus data to longterm storage.

Main cluster network

The network in which every virtual machine gets an IP address. It is bound to the main network interface of the pod that runs the machine.

In the list of networks of a virtual machine the main cluster network has the type `Main`. It does not have to be listed, but if it is, it must come first. Adding or removing the main network requires a reboot of the machine, unlike additional networks, because it cannot be changed on a running pod. The subnets that machines get addresses from are set in `virtualMachineCIDRs` of the `virtualization` module. When an address pool is configured for the main network in the `sdn` module, the addresses are managed by the shared IPAM.

For details, see IP addresses of virtual machines.

Main project namespace

The user namespace that is created together with the project. It is used to manage additional project namespaces and to run the workload.

The main project namespace is a user namespace created as part of a project. Additional project namespaces are managed from it.

Maintenance mode of a module or application

A mode in which Deckhouse Platform stops applying templates and restoring the resources of a module or an application, so that they can be changed manually. It is enabled with spec.maintenance: NoResourceReconciliation and is not related to the node maintenance mode.

In this mode changes of settings and values are not reflected in the resources, deleted resources are not restored, and hooks keep running. The resources rendered from the templates get the `maintenance.deckhouse.io/no-resource-reconciliation` label, and the admission policies stop protecting them. For an application instance the `Managed` condition becomes `False` and the `ApplicationIsInMaintenanceMode` alert fires. To return to normal operation, remove the `spec.maintenance` field.

The field is set in ModuleConfig for a module and in Application for an application. The mode is intended for debugging and development, not for production clusters. The node maintenance mode is a different mechanism.

For details, see Lifecycle and debugging.

Manage role

A role of the granular role model for administering Deckhouse Platform or one of its subsystems, that is, cluster-wide resources, the modules of the subsystem and their system namespaces.

Manage roles belong to the granular role model. A manage role grants access to cluster-wide Kubernetes resources, to the ModuleConfig and cluster-wide resources of the modules of its subsystem, and to the system namespaces in which these modules run. It does not grant access to the namespaces of user applications.

The name of a manage role has the form `d8:manage:<SUBSYSTEM>:<ACCESS_LEVEL>`, for example `d8:manage:networking:manager`. The subsystem `all` covers all modules. Permissions within a namespace are granted with use roles.

For details, see Granular authorization model.

Managed cluster

A Deckhouse Platform cluster with the `commander-agent` module installed. Its configuration and lifecycle are managed from a managing cluster.

The `commander-agent` module connects the cluster to the `commander` module of the managing cluster. Not to be confused with a Managed Kubernetes cluster, in which the control plane is provided by a cloud provider: see cluster managed by Deckhouse Platform.

For details, see Cluster management.

Managed Gateway

The Gateway object that the `alb` module creates from a ClusterALBInstance or an ALBInstance. Applications are published through it with ListenerSet and route resources of the Kubernetes Gateway API.

A cluster-wide gateway is created by the cluster administrator from a ClusterALBInstance, usually in the `d8-alb` namespace. A dedicated gateway in the application namespace is created from an ALBInstance. The name of the managed Gateway is published in the `status.gateway` field of the instance. The namespace administrator attaches ListenerSets with hostnames, TLS and ports, and developers attach HTTPRoute and other routes. The listeners `d8-http` and `d8-https` serve service tasks such as availability checks and are not meant for application routes.

For details, see Publishing applications using the Kubernetes Gateway API.

Managed service

A ready-to-use application service in the cluster, such as a database or a message queue, whose lifecycle is handled by Deckhouse Platform.

Each managed service adds its own Kubernetes resources and controllers to the cluster. A user describes the desired state of the service in a namespaced resource, and the controller creates and updates the related objects: workload instances, Services, secrets and snapshots. The administrator manages cluster-wide resources, such as service classes, that define the allowed configurations and default values for user resources. Deckhouse Platform handles administration, scaling, backup and updates of the service.

For details, see Managed services.

Managing cluster

A Deckhouse Platform cluster with the `commander` module installed. It creates standardised Deckhouse Platform clusters and manages their configuration and lifecycle.

The `commander` module implements a web application for cluster management and needs a PostgreSQL instance, deployed inside or outside the cluster. Clusters under its management run the `commander-agent` module and are called managed clusters.

For details, see Cluster management.

Marketplace

The package management system of Deckhouse Platform. Administrators connect package repositories, and users install applications from the packages in their namespaces.

A cluster administrator connects a package repository with PackageRepository, monitors the scanning

operations in which Marketplace discovers the available packages, and grants users the permissions to view package versions and to create Application objects. An installed application is an Application object in the namespace of the user.

Marketplace is available in Deckhouse Platform starting from version 1.76.

For details, see Marketplace.

Marketplace package

An abstract unit of Marketplace: either an application, a user workload deployed into a namespace, or a module that extends the capabilities of the cluster.

Packages are published in container registries connected to Marketplace as package repositories. For every discovered package version Deckhouse Platform stores its metadata: description, lifecycle stage, requirements, deletion confirmation, changelog and the OpenAPI schemas of settings and values.

For details, see Concepts.

Master node

A node that runs the control plane components. Master nodes carry the label `node-role.kubernetes.io/control-plane`, and the `control-plane-manager` module runs on them.

Deckhouse Platform manages the control plane on master nodes: certificates, component configuration, versions, the etcd cluster and kubeconfig files. In a cloud cluster, master nodes are CloudPermanent nodes.

The number of master nodes defines whether the cluster is single-master or multi-master. With more than one master node, HA mode is enabled automatically.

For details, see General management and configuration of the control plane.

Minor version

A Deckhouse Platform release that includes new features.

A minor version is one of the two types of a Deckhouse Platform release, the other being a patch version. Minor versions are installed sequentially: if the cluster lags behind the release channel by several minor versions, Deckhouse Platform reconstructs the intermediate releases, because they contain migrations that must be applied in order. In the `Manual` update mode a minor version needs approval.

For details, see Updating.

Module

A set of resources and applications that adds new capabilities to Deckhouse Platform.

Modules perform related functions, for example collecting metrics, balancing traffic or working with secrets. The documentation of a module and its API is available in the module library.

Module accessibility

The accessibility settings of module.yaml that define in which Deckhouse Platform editions a module is available and in which module bundles it is enabled by default.

Settings are given per edition with a `_default` block for editions without their own settings: `available` says whether the module can be used in the edition, `enabledInBundles` lists the module bundles (`Default`, `Managed`, `Minimal`) in which the module is enabled without a ModuleConfig.

For details, see Module structure.

Module artifacts

The three kinds of artifacts a module build pushes to the container registry, images of application containers, the module image and the release. Deckhouse Platform pulls and updates a module from them.

Images of application containers are tagged with content-based tags and referenced from the templates. The module image is built by `werf.yaml` and tagged with the semantic version. The release is the artifact of a module version: it carries a semantic version tag and a tag of the release channel, and Deckhouse Platform decides whether to update the module in the cluster by its data. The registry

with the artifacts serves as a module source.

For details, see Build and publish.

Module bundle

A named set of built-in Deckhouse Platform modules that are enabled by default. Default, Minimal or Managed.

The bundle is set in the `bundle` parameter of the `deckhouse` module and cannot be changed in a deployed cluster. `Default` is the recommended set for cluster operation, including monitoring, authorization, networking and other basic modules. `Managed` is the set for managed clusters of cloud providers. `Minimal` is the minimal set.

Regardless of the bundle, a module can be enabled or disabled explicitly in its ModuleConfig.

For details, see Deckhouse Platform configuration.

Module dependencies

A set of conditions (requirements) that must be met for Deckhouse Platform to run a module. They are declared in the requirements section of module.yaml.

A module can depend on the Deckhouse Platform version, on the Kubernetes version and on the versions of other modules. Dependencies on other modules affect the module startup order together with the module weight, and a dependency may be conditional. A Marketplace package declares the same kind of requirements in `package.yaml`, including groups of alternative and incompatible modules.

For details, see Dependencies of the Deckhouse Platform modules.

Module exclusive group

A group of modules that share one value of the exclusiveGroup parameter in module.yaml. Only one module of the group can be active in the cluster at a time.

Exclusive groups prevent conflicts between modules that perform similar or incompatible functions. Enabling a second module of the same group is not possible while the first one is active.

For details, see Module structure.

Module from a source

A module that Deckhouse Platform gets from a module source instead of its own distribution. Its release cycle is not tied to the release cycle of the platform.

The list of available modules is defined by the module sources tracked by Deckhouse Platform. Such a module is updated by its own update policy: it has its own release channels, lifecycle stage and dependencies. Alerts of modules from a source are not included in the alerts reference of the platform.

For details, see Updating DP in air-gapped environment.

Module hook

An executable file of a module or a Marketplace package that Deckhouse Platform runs in response to an event. Hooks prepare values for templates, create and change objects in the cluster and validate settings.

A hook runs when one of its bindings fires: at startup, before or after the Helm templates are applied, on schedule or when watched Kubernetes objects change. The hooks of a module are located in the `/hooks/batch` directory. The hooks of a Marketplace package are written in Go with module-sdk and compiled into a single binary. Module hooks and global hooks exist. The Deckhouse controller runs them as tasks of the addon-operator queues.

For details, see Module structure.

Module lifecycle stage

The maturity stage of a module or a Marketplace package, Experimental, Preview, General Availability or Deprecated. It is declared in module.yaml or package.yaml and, together with the release channel, defines how stable a version is.

- `Experimental`: the functionality may change significantly and compatibility with future versions is

not guaranteed; such modules cannot be enabled unless the `allowExperimentalModules` parameter of the `deckhouse` module is set to `true`.
- `Preview`: a preliminary version; the basic features are preserved, compatibility is ensured but may require migration.
- `General Availability`: ready for production environments.
- `Deprecated`: development and support are discontinued.

The stage of a Marketplace package is published in the package metadata when Deckhouse Platform scans the repository.

For details, see Versioning modules.

Module settings conversion

A rule in the `openapi/conversions` directory of a module that converts module parameters from one version of the OpenAPI specification to the next, for example when a parameter is renamed or moved.

Each conversion works between two consecutive versions and is stored in a `v<N>.yaml` file with its tests. The chain of conversions must cover all versions of the parameter specification without gaps, so that Deckhouse Platform can convert the settings of a module automatically when the version of its settings schema changes.

For details, see Module structure.

Module source

The container registry from which Deckhouse Platform fetches information about modules that are not built into the platform. It is set by ModuleSource with the registry address and authentication parameters.

Modules from a source are published to the registry as module artifacts. Deckhouse Platform synchronizes with the source and creates module releases according to the module update policy. A module is then enabled with ModuleConfig. In an air-gapped cluster the source points to the in-cluster or private registry.

For details, see How to run and verify a module in the DP cluster.

Module update policy

The rules by which Deckhouse Platform updates a module from a source in the cluster. It is set by ModuleUpdatePolicy and defines the update mode, the release channel and the update windows of the module.

A policy sets the update mode (automatic, manual or updates disabled), the release channel used for updates and the update windows in which automatic updates are allowed. If no policy is defined for a module, the module follows the update settings of the platform from the `update` parameter of the `deckhouse` module. A module release in the `Pending` status waits for manual approval.

For details, see How to run and verify a module in the DP cluster.

Module weight

A number from the weight parameter of module.yaml that defines the module startup order. Modules with a lower weight start earlier, the default is 900.

If `module.yaml` is missing, the weight is taken from the numeric prefix of the module directory, for example `040-node-manager` means 40. If it cannot be obtained, 100 is used. The Deckhouse controller considers the weight only for critical modules, whose tasks go to the `main` queue in ascending order of weight. The startup order is also affected by module dependencies.

For details, see Queuing mechanism.

Monitoring node

A dedicated node for Grafana, Prometheus and other monitoring components. Without such nodes the monitoring components run on system nodes.

Dedicated monitoring nodes are recommended in heavily loaded clusters with many alerts and large volumes of metrics. They need fast disks, at least 400 IOPS. Monitoring nodes usually form the `monitoring` node group.

For details, see Recommendations for configuring cluster nodes.

Multi-master cluster

A control plane operation mode with several master nodes. kube-apiserver interacts with all etcd instances, and requests are forwarded to other nodes if the local kube-apiserver is unavailable.

The multi-master mode provides high availability of the control plane and supports scaling of master nodes. When the cluster has more than one master node, HA mode is enabled automatically. In a configuration with two master nodes, an arbiter node provides the etcd quorum.

For details, see Scaling and changing master nodes.

Multicluster

An inter-cluster communication model that tightly connects clusters. The clusters share namespaces, and the services of one cluster are available to the others as local ones.

Access to services from other clusters can be restricted by authorization policies. The model is implemented with Istio through the `istio` module and is built on the service mesh. The model for independent clusters is federation.

For details, see Inter-cluster cooperation.

Namespace

A Kubernetes mechanism for grouping objects logically.

Examples of Kubernetes objects that can be grouped by a namespace: Pod, Deployment, Service, Ingress, ConfigMap.

Namespaces are often used for isolation, but without additional configuration they do not provide it, unlike projects in Deckhouse Platform.

Namespaces are divided into system and user namespaces.

Network policy

Rules that restrict how pods communicate with each other, with external systems and with cluster nodes.

The implementation of network policies in Deckhouse Platform depends on the enabled CNI module. With `cni-cilium`, policies are enforced by Cilium in three formats: the standard NetworkPolicy at L3 and L4, Cilium network policies with L3–L7 rules within a namespace, and CiliumClusterwideNetworkPolicy for the whole cluster, which also protects nodes as a host firewall. With `cni-flannel` or another CNI without policy support, the `network-policy-engine` module enforces the standard NetworkPolicy at L3 and L4 through `iptables` and `ipset` rules on every node.

For details, see Network policies.

NLB (network load balancing)

Load balancing at the network level. Traffic is routed by IP addresses and ports without inspecting the contents of requests.

In Deckhouse Platform, NLB is implemented either by an external load balancer of the cloud provider or by the built-in `metallb` module, which works both in cloud and in bare-metal clusters. Balancing at the application level is ALB.

For details, see Incoming traffic balancing.

Node group

A set of cluster nodes with common parameters, described by a NodeGroup. The NodeGroup defines the node type, the number of nodes and their configuration, and Deckhouse Platform keeps the nodes in line with it.

Node groups divide the cluster infrastructure logically. Typical groups are `master` for the control plane, `front` for frontend nodes, `monitoring` for monitoring nodes, `system` for system nodes and `worker` for user applications.

Each group has centralized settings: the Kubernetes version, resources, taints, labels and kubelet parameters. When a NodeGroup is created or changed, the `node-manager` module brings the nodes of the group to the specified configuration. The node type is one of Static, CloudEphemeral, CloudPermanent or CloudStatic.

For details, see Node management basics.

Node group autoscaling

Automatic change of the number of nodes in a group by the Cluster Autoscaler component of the `node-manager` module, based on CPU and memory demand. It triggers only when Pending pods cannot be scheduled on the existing nodes.

Autoscaling is available for CloudEphemeral nodes. The limits are set in the `cloudInstances` section of the node group: `minPerZone` and `maxPerZone` bound the number of nodes per zone, `maxUnavailablePerZone` limits unavailable nodes during changes, `priority` defines which groups Cluster Autoscaler scales first. Autoscaling does not apply to static nodes: for them CAPS maintains the number set by `staticInstances.count`.

For details, see Adding and managing cloud nodes.

Node maintenance mode

A node state in which Deckhouse Platform moves the virtual machines to other nodes and does not start new ones on it, so that work on the node does not disrupt them.

A node is switched to maintenance mode with the `d8 k drain` command or with **Cordon + Drain** in the web interface, and returned to service with `d8 k uncordon`. Virtual machines that can be moved are moved by live migration. A machine that cannot be moved, for example one pinned to the node or using a passed-through device, keeps the node busy until it is restarted. The restart is allowed by the `virtualization.deckhouse.io/virtualmachines-restart-approved` annotation on the node.

For details, see Maintenance of nodes running virtual machines.

Orphan resources of an application

Objects that stay in the namespace after the Helm release of an application is uninstalled, for example objects created by workloads or hooks at runtime. Deckhouse Platform deletes the listed kinds together with the Application object.

The package declares the kinds of orphan resources in the `orphanResources` field of `openapi/values.yaml`. When the Application is deleted, Deckhouse Platform deletes the objects of these kinds in the namespace of the application instance that carry the `packages.deckhouse.io/instance: <INSTANCE_NAME>` label, after the Helm release is uninstalled and the hooks are stopped. Objects created by workloads and hooks do not get the label automatically.

Orphan resources are deleted only when the Application is deleted. On suspension and on a package version change they stay in the cluster.

For details, see Lifecycle and debugging.

Package bundle

The main image of a package version in the container registry. It contains the package manifest, image digests, OpenAPI schemas, Helm templates, the hooks binary, documentation and the changelog.

The bundle is published as `<REPOSITORY>/<PACKAGE_NAME>:<PACKAGE_VERSION>`, next to the container images of the application (referenced by digest), the version metadata image and the release channel images. Deckhouse Platform downloads the bundle of the requested version as the first step of installing an application instance, then reads `package.yaml`, the schemas and `images_digests.json` and discovers the hooks.

For details, see Application development.

Patch version

A Deckhouse Platform release that includes fixes. Patch versions are published when needed.

A patch version is one of the two types of a Deckhouse Platform release, the other being a minor version. In the `AutoPatch` update mode only patch versions are installed automatically. Starting from Deckhouse Platform 1.70 they are applied with update windows taken into account.

For details, see Updating.

Pod limit per node

The maximum number of pods that can be placed on a node. In Deckhouse Platform it is derived from the node subnet size set by the podSubnetNodeCIDRPrefix parameter when the cluster is deployed.

With a prefix of 24 or larger a node holds 120 pods, with 23 it holds 250, with 22 it holds 500, and with 21 or smaller it holds 1000. The parameter is part of the protected parameters of the cluster, so choose the value at deployment time if many pods per node are expected. The control plane components for high pod density are configured by Deckhouse Platform automatically.

For details, see High pod density.

Pod redistribution

Periodic eviction of pods that match the active scheduling strategies, so that they are scheduled again according to the current state of the cluster. Controlled by the descheduler module.

Deckhouse Platform analyzes the state of the cluster every 15 minutes and evicts the matching pods. The evicted pods go through the standard scheduling process again. The priority class of a pod defines the order of eviction, and the `priorityClassThreshold` parameter of a Descheduler limits eviction to pods with a priority below the threshold. VM rebalancing is built on the same mechanism.

For details, see Scheduler.

Pod Security Standards

Three levels of pod security policies, privileged, baseline and restricted, that Deckhouse Platform applies to namespaces with the `admission-policy-engine` module.

Pod Security Standards are one of the categories of admission policies. The level `privileged` imposes no restrictions, `baseline` prevents the most common privilege escalation techniques, `restricted` sets the strictest requirements for pods. Deckhouse Platform takes only the policy descriptions from Kubernetes and enforces them with Gatekeeper rather than with the Kubernetes Pod Security Admission controller.

The default level is `baseline`. It applies to namespaces without the `security.deckhouse.io/pod-policy` label, except the system ones. The label assigns a level to one namespace, the `admission-policy-engine` module setting changes the default.

For details, see Security policies.

Post-bootstrap script

A custom script that the installer runs on one of the master nodes after the cluster installation is complete.

The script is used for additional cluster configuration, collecting diagnostic information or integration with external systems. Its path is passed to the installer with the `--post-bootstrap-script-path` parameter.

For details, see Installation.

Preflight checks

Checks that the installer runs before installing Deckhouse Platform.

The checks are grouped into general checks, checks for static clusters and checks for cloud clusters. An individual check is skipped with the `--preflight-skip-check` flag and its name, `--preflight-skip-all-checks` skips all of them, and `dhctl preflight list` prints the full list. Cluster subnets and the DNS name template are validated when the installation configuration file is loaded and cannot be skipped.

For details, see Installation.

Priority class

One of the PriorityClass objects that Deckhouse Platform creates in the cluster and assigns to its components. When resources are insufficient, the scheduler preempts pods with a lower priority first.

Applications use a priority class through the `priorityClassName` field. A pod without it is treated as having the lowest priority. The classes range from `system-node-critical` and `system-cluster-critical`, reserved for critical cluster components, through `production-high`, `production-medium`, `production-low` and `staging` to `develop`, the default. Additional classes can be created with a name and a numeric priority value. Priority classes also define the order of eviction during pod redistribution.

For details, see Priority classes.

Private environment

An environment without direct access to the public container registry of Deckhouse Platform and to external package repositories. Access goes through a proxy server or through a container registry deployed inside the perimeter.

Proxy server parameters set in the cluster configuration during installation are propagated to the environment variables of cluster nodes and Deckhouse Platform components. User applications do not receive them automatically. Cluster nodes are usually reached through a bastion host, and the private registry runs on a separate machine in the internal network. When access to external resources is disabled completely, no proxy is used, the required artefacts are brought into the perimeter by other means, and the cluster is an air-gapped cluster.

For details, see Installing DP in a private environment.

Project

A mechanism for isolating and managing workloads in Deckhouse Platform. A project logically divides the cluster and gives a team its own area to deploy applications, configure resources and manage access within the granted rights.

Projects provide isolation, support creation from templates, control which platform capabilities are available to the team and are compatible with Kubernetes namespaces. A project includes the main project namespace and may include additional project namespaces.

For details, see Multitenancy.

Project features

The set of platform capabilities available within a project. Features define which APIs and resource kinds can be used in the project.

Project features are not a part of the role model. Examples of features: Kubernetes, Virtualization. The features of a single namespace within the project are limited by the project namespace features.

Project namespace features

A restriction of the project features at the level of a single user namespace within the project.

The set of features of a user namespace cannot exceed the set of features of its project.

Project network

An additional software-defined network available within one namespace. The user creates and manages it with the NetworkClass provided by the administrator. It is also called a user network.

The administrator defines in a NetworkClass the range of VLAN tags and the node network interfaces on which users may create their own networks. The user creates the network with the Network resource in the namespace of the project. Users can allocate an address pool for the project network and assign addresses to pod interfaces through IPAM. The other kind of additional network is the cluster network.

For details, see Additional networks for use in application pods.

Protected parameters

Cluster parameters that are critical for cluster operation and cannot be changed in a running cluster by default. podSubnetCIDR, podSubnetNodeCIDRPrefix and serviceSubnetCIDR.

The protected parameters are part of the cluster configuration. An attempt to change them is blocked by the admission webhook with an error message. The procedure for changing them, with the installer or manually, is described in the documentation.

For details, see Deckhouse Platform configuration.

Quorum

The majority of the members of a distributed system (more than half of their total number) that must be available for the system to keep working and accept changes.

In Deckhouse Platform, the quorum matters most for etcd, the storage of the control plane. The etcd cluster accepts changes only while the majority of its members (N/2 + 1) are available: a cluster of three members tolerates the failure of one member, a cluster of five tolerates the failure of two. An even number of members does not improve fault tolerance: with two members, the failure of either one loses the quorum. For this reason, use an odd number of master nodes, usually three. In a configuration with two master nodes, the third etcd member may run on an arbiter node, which provides the quorum.

For details, see High availability in the control plane recovery guide.

Region

An independent geographic area that includes several, typically at least three, isolated availability zones united into a single logical infrastructure unit with shared management services.

A region is a key element of the global distributed architecture of cloud providers. Regions are widely dispersed geographically, placed outside seismically or politically unstable areas and connected to several power grids. Latency between the availability zones of one region is about 5 ms, between regions it is 50 to 200 ms.

Deckhouse Platform supports distributing cluster nodes across regions (Multi-Region) so that applications keep running even when a whole data center or cloud provider fails. Because of the latency between regions, this is appropriate only for applications that work independently in each region, for example CDN cache servers or distributed monitoring nodes. The administrator labels each node with its region and provides stable communication channels between regions.

For details, see Geo-distribution.

Registry management mode

The mode in which the registry module manages the pull paths of Deckhouse Platform component images, Unmanaged or Managed.

The mode is set by the `mode` parameter in the `registry` ModuleConfig:

- `Unmanaged` (the default). The `registry` module does not manage the pull paths: the cluster pulls images from the registry it was installed with.
- `Managed`. The `registry` module manages the pull paths. The `primary.upstream` parameter sets the upstream registry, and `storage.cache` enables the in-cluster image cache on the master nodes. Without `primary.upstream`, the cluster is considered isolated.

For details, see Managing the registry in DP-managed clusters.

Release channel

One of the five channels, from Alpha to Rock Solid, through which every new Deckhouse Platform version is rolled out gradually. The cluster receives the versions published on the channel it follows.

Each new version is first published to the Alpha channel and then moves to Beta, Early Access, Stable and Rock Solid. Versions appear on Early Access at least 7 days after the release, on Stable at least 14 days and on Rock Solid at least 30 days after the release.

The channel of the cluster is set in the `settings.releaseChannel` parameter of the `deckhouse` module. How a new version is applied depends on the update mode and update windows.

For details, see Updating.

Release channel image

The release-channel image in the Deckhouse Platform registry whose tag is the name of a release channel. The tag points to the image of a specific Deckhouse Platform version and is moved to a new image when a new version is released.

The image contains `version.json` with the current version of the release channel and `changelog.yaml`. When the version in the image changes, Deckhouse Platform creates a DeckhouseRelease object and starts the update. A rollout can be paused by patching the image with a `suspend` flag, which makes it a suspended release. In a private environment the image is copied to the private registry together with the image bundle.

For details, see Updating DP in air-gapped environment.

Replicated storage

Storage in which data is replicated across several nodes, so that it stays available when one of the nodes fails.

Replicated block StorageClass objects are created with the `sds-replicated-volume` module, which is based on Distributed Replicated Block Device (DRBD). Replicated storage is one of the software-defined storage types. Its pools are created on LVM volume groups as thick or thin pools.

For details, see Setting up replicated storage based on DRBD.

Role model

Role-based access control (RBAC), a mechanism that defines which users or services can perform specific actions within projects or the system.

Deckhouse Platform supports two role models: the granular one, which is recommended and is built on use roles and manage roles, and the basic one with high-level roles. Both models are supported by the `user-authz` module and can be used at the same time: the permissions they grant are summed up.

For details, see Authorization.

Runtime audit

Detection of security threats in a running cluster by analysing Linux kernel events and Kubernetes API audit events.

Runtime audit in Deckhouse Platform uses two sources of events: Linux kernel events, received through the eBPF driver of the Falco threat detection system, and Kubernetes API audit events, received through a webhook. It detects attempts to exploit known vulnerabilities, signs of cryptocurrency miners and Kubernetes-specific threats such as shells launched in containers, privileged containers, mounting of insecure paths and reading of sensitive files.

Capturing kernel events requires Linux kernel 5.8 or later with eBPF support.

For details, see Runtime audit.

Runtime audit rule

A rule of the runtime audit that describes a pattern of suspicious behaviour as a condition expression in the Falco syntax. Deckhouse Platform ships built-in rules and accepts custom ones.

Built-in rules include rules for the Kubernetes audit, which reveal problems with the security of Deckhouse Platform and of the audit mechanism itself, and the `fstec` regulatory rules that meet the requirements of FSTEC of Russia order No. 118 for containerization tools. Custom rules are defined with a FalcoAuditRules object of the `runtime-audit-engine` module. The runtime audit matches events against all rules and produces security events.

For details, see Runtime audit architecture.

Runtime profile

A behaviour model of an application or container at runtime, including system calls, executed processes, file access and network interactions, built by the node-agent of the `operator-trivy` module with eBPF programs.

The node-agent is an optional component that runs on all cluster nodes in privileged mode, observes container behaviour with eBPF programs and stores the profiles in the ApplicationProfile and NetworkNeighborhood objects. It works in profiling mode and does not detect attacks by rules. That is the task of the runtime audit. The profiles can be used to generate network policies from the observed traffic.

For details, see Module operator-trivy.

Scheduler extender

An extension of kube-scheduler provided by a Deckhouse Platform module that places pods according to the module’s own logic instead of the standard scheduler, for example by local volumes, node selectors of a storage class or network interfaces.

The `sds-local-volume` module places pods with local volumes by the free space on nodes and the space to reserve for the volumes. Its webhook sets `spec.schedulerName` of such pods to `sds-local-volume`. The `csi-nfs` module places pods by the node selectors of NFSStorageClass, and the `sdn` module suggests nodes according to the network interface settings of pods using software-defined networks. kube-scheduler sends scheduling requests for such pods to the extender’s webhook.

For details, see Storage architecture.

Secret distribution

Automatic copying of secrets from the default namespace that carry the `secret-copier.deckhouse.io/enabled` label to all namespaces of the cluster.

Deckhouse Platform copies the labelled secrets to every existing and every new namespace,

propagates updates of the original, overwrites manual changes of the copies and deletes the copies when the original is deleted. A nightly synchronization keeps the copies up to date. This removes manual copying of secrets in CI/CD pipelines, for example registry credentials.

The mechanism is not compatible with the multitenancy mode: a secret distributed to all namespaces can reach the isolated environment of a project. Shared secrets for projects are defined in the project template instead.

For details, see Automatic distribution of secrets across namespaces.

Secrets store

An external store compatible with the HashiCorp Vault API, or the built-in Deckhouse Stronghold, from which the `secrets-store-integration` module delivers secrets to applications without storing them in etcd.

The `secrets-store-integration` module delivers secrets to pods as mounted files or environment variables, refreshes mounted secrets every two minutes when the value in the store changes and injects an entrypoint for applications that cannot read secrets from the store themselves. It connects to an internal Deckhouse Stronghold instance automatically in the `DiscoverLocalStronghold` mode and works with any Vault-compatible store in the `Manual` mode.

For details, see Secrets-store-integration module.

Security event

A structured record of an action or fact that is significant from an information security perspective, extracted from the logs of applications and Kubernetes infrastructure components.

Deckhouse Platform collects security events from container sources, that is, application logs in pods, and from cluster sources, such as the Kubernetes API audit log and node authentication logs. The `log-shipper` module pre-selects log records, and the `security-events-manager` module parses them, brings them to a unified format with a mandatory set of attributes, enriches them with context and delivers them to storage and analytics systems such as Loki, Elasticsearch, Kafka or Splunk.

For details, see Security events.

Service mesh

An infrastructure layer that manages network communication between the services of an application. Encryption, access control, routing, request retries and metrics collection are configured centrally, without changing the code of the services.

The services of an application exchange requests over the network, and without a service mesh each of them has to implement encryption, authorization, retries and timeouts on its own. A service mesh takes over these tasks: traffic between services passes through proxies that are configured from a single place. Usually the proxy is added to the application pod as a sidecar container. In the experimental ambient mode the proxy runs at the node level, and pods need no sidecars.

In Deckhouse Platform the service mesh is provided by the `istio` module. Within a single cluster, it is used, for example, for canary deployment and for automatically cutting off a failing service (Circuit Breaker). It also forms the basis for federation and multicluster.

For details, see Inter-cluster cooperation.

Short-term log storage

The built-in in-cluster log storage of Deckhouse Platform based on Grafana Loki. It is integrated with log collection and added to Grafana as a data source.

The storage is provided by the `loki` module, whose settings define the disk size, the retention period, the StorageClass and the resources. Logs of system components flow into it after the log pipeline is configured. Log collection from user applications is configured separately. The storage does not support the high availability mode, so important logs are kept long-term in an external storage.

For details, see Short-term log storage.

Single-master cluster

A control plane operation mode with one master node. kube-apiserver uses only the local etcd instance and listens only on the address of the master node.

A proxy server on the node handles requests on `localhost`. When master nodes are added or

removed, Deckhouse Platform migrates the control plane between the single-master and multi-master modes.

For details, see Scaling and changing master nodes.

Single-node cluster

A cluster of one node that performs all node roles. It has no fault tolerance and is intended for familiarisation or workloads with low resource requirements.

After the taint is removed from the node, it runs all cluster components of the selected module bundle. The resource requirements for such a node depend on the workload type: containers, virtual machines or both. Do not use single-node clusters in production environments.

For details, see the Resource requirements section of the “System requirements” page.

Sizing policy

The block of a virtual machine class that defines which combinations of cores, core fraction and memory are allowed for virtual machines of this class.

A policy consists of a list of rules, each applying to its own range of cores. The ranges must not overlap. Changes to the policy affect existing virtual machines: a machine that no longer meets the requirements gets the `SizingPolicyMatched` condition with the `False` status. The allowed values of the core fraction set in the policy define the degree of CPU oversubscription.

For details, see Virtual machine sizing policy.

Skipping intermediate module releases

The from-to mechanism that lets Deckhouse Platform skip step-by-step module updates. If the installed module version falls into a from-to range declared in module.yaml, Deckhouse Platform installs the latest version within to.

Transition rules are listed in the `update.versions` section of `module.yaml`. A release that contains them is called a constrained release. The rule is read from the release to move to, and its `to` must match the version of that release. If the installed version is lower than `from`, the update proceeds sequentially. When several rules match, the one with the largest `to` is chosen.

For details, see Module development and debugging.

SLA monitoring

Collection of availability statistics of cluster components and Deckhouse Platform components by the upmeter module to evaluate SLA compliance.

Availability data is shown in the web interface and can be exported over the Prometheus Remote Write protocol with an UpmeterRemoteWrite object.

For details, see Cluster SLA monitoring.

Software-defined network (SDN)

An additional network segment for pods and virtual machines that the administrator describes declaratively in custom resources, while the `sdn` module configures the nodes.

Software-defined networks in Deckhouse Platform cover the configuration of network interfaces on nodes (port aggregation, bridges, VLAN interfaces), additional networks for workloads that are available in the whole cluster or within one namespace (project networks), IP address management for these networks, underlay networks for passing physical interfaces to applications, and system networks for service traffic at the node level.

For details, see Software-defined networking.

Software-defined storage

A group of storage types in Deckhouse Platform that run on the disks of the cluster nodes and are managed by the sds-* modules, as opposed to external storage systems.

Software-defined storage (SDS) includes managing logical volumes on cluster nodes, local storage based on Local Path Provisioner or LVM, and replicated storage based on DRBD. The other group is external storage: Ceph, NFS, S3 and storage systems of hardware vendors.

For details, see Storage.

Standby node

A pre-provisioned node kept in the cluster so that new application replicas start without waiting for node creation during horizontal scaling. The number of standby nodes is set by cloudInstances.standby.

Standby nodes are available for CloudEphemeral nodes. The number is set as an absolute value or as a percentage of the maximum number of nodes in the node group. At least one node of the group must already be running. The share of node resources taken by service components outside Deckhouse Platform is set by `standbyHolder.overprovisioningRate`. Standby nodes increase infrastructure costs.

For details, see Adding and managing cloud nodes.

Static cluster

A cluster with the clusterType: Static. Its nodes are physical servers or virtual machines that Deckhouse Platform does not create or manage through a cloud API.

The administrator prepares the servers, and the installer configures them, deploys Kubernetes and installs Deckhouse Platform. The nodes of such a cluster are static nodes. A static cluster can be extended with nodes of a cloud provider into a hybrid cluster.

For details, see Platform installation.

Static node

A node on a bare-metal server or a virtual machine that is created outside Deckhouse Platform automation and connected to the cluster manually or through CAPS. It is described by a NodeGroup with the Static node type.

Static nodes do not support automatic scaling and updates: kubelet updates, restarts and replacements are performed manually or by external tools. A node is connected either by running the bootstrap script on the server or automatically by CAPS. In a cloud environment, cloud-controller-manager does not manage a Static node even if a cloud provider module is enabled.

A node group can combine static nodes with CloudStatic nodes, which is the basis of a hybrid cluster.

For details, see Adding and managing bare-metal nodes.

Static pod

A pod that kubelet starts directly from a manifest in the `/etc/kubernetes/manifests` directory of the node, without the Kubernetes API. Control plane components and kubernetes-api-proxy run this way in Deckhouse Platform.

In Deckhouse Platform kubelet processes only files with the `.yaml` or `.yml` extension in this directory. Backup copies, editor swap files and other temporary files are ignored. The control plane components kube-apiserver, etcd, kube-controller-manager and kube-scheduler and the kubernetes-api-proxy are static pods.

For details, see Kubelet.

Static user

A user created in the cluster as a User object of local authentication, with an email and a hashed password, without an external authentication provider.

Static users and groups are the basis of local authentication in Deckhouse Platform. A User object stores the user information and the password hash, the password is not stored in plain text. A Group object defines a list of users. Local authentication supports password policies and temporary users with a TTL. Two-factor authentication is also available.

The recommended way to create a static user is the `d8 iam user create` command.

For details, see Local authentication.

Stronghold lease

Temporary access to secrets and resources in the Deckhouse Stronghold secrets store, identified by a lease ID.

Leases are managed in the “Leases” section of the Stronghold web interface, where a lease is found by its ID. Together with access control policies, authentication methods and entities, leases define who may use the secrets store and for how long.

For details, see Secret management web interface.

Stronghold sealing

The state of the Deckhouse Stronghold secrets store in which it can neither read nor write secrets. The store is sealed and unsealed in the Stronghold web interface.

The “Seal Stronghold” section of the web interface shows the current state of the secrets store and a button that seals or unseals it. While the store is sealed, the `stronghold` module does not serve requests to read or write secrets.

For details, see Secret management web interface.

Stronghold secrets engine

A component of the Deckhouse Stronghold secrets store that holds and serves secrets of one kind, for example key-value secrets (KV) or certificates (PKI).

Secrets engines are managed in the Stronghold web interface: each engine shows its list of secrets (roles, keys and others), its configuration and a button to add a new secret. The web interface is provided by the `stronghold` module and opens at `stronghold.<CLUSTER_NAME_TEMPLATE>`.

For details, see Secret management web interface.

Subsystem

A logical part of the system that groups related modules and their system components.

Subsystems group the components of the system and delimit access to them. A subsystem consists of modules and their system components.

Suspended release

A Deckhouse Platform release whose rollout on a release channel was paused after it had been published. The release channel image is patched with a suspend flag.

While a release is suspended, `d8 mirror pull` refuses to copy the release channel and reports that the source registry contains a suspended release channel. The platform images can still be downloaded by specifying a version explicitly with the `--deckhouse-tag` flag.

For details, see Updating DP in air-gapped environment.

System

The part of the cluster that keeps it operational, manages resources and automates processes.

The system consists of subsystems, which in turn consist of modules and system components.

The system runs mostly in system namespaces. The parts of the system that serve the workload of a specific project can run in user namespaces.

System component

A process or a group of processes that run in a container or as a systemd service on a node and keep the platform and its modules running.

Examples of system components are kubelet and containerd.

Some system components run in user namespaces. For example, when a user creates a virtual machine or a managed service, the pods that support this object start in the user namespace.

System namespace

A namespace in which the system runs, that is, modules and system components. Running the workload in system namespaces is prohibited.

System namespaces of Deckhouse Platform have the prefixes `d8-` and `kube-`. The system, its modules and system components run there.

System network

An additional service network on the cluster nodes, created by the `sdn` module on top of an existing underlay network for node-level service traffic.

A system network is created with a SystemNetwork object. Interfaces connected to a system network get cluster-scoped addresses through ClusterIPAddress, like interfaces of cluster networks. It belongs to the node-level functions of software-defined networks, together with the configuration of node interfaces and underlay networks.

For details, see Software-defined networking (SDN).

System node

A node dedicated to running Deckhouse Platform modules so that they do not interfere with user applications.

System nodes are isolated with labels and taints so that user pods are not scheduled on them. Two system nodes are recommended. System nodes can be static or cloud nodes and usually form the `system` node group. Without dedicated monitoring nodes, the monitoring components also run on system nodes.

For details, see Recommendations for configuring cluster nodes.

The deckhouse system user

The local user and group with UID and GID 64535 that Deckhouse Platform components use to run unprivileged processes on nodes. The name and identifiers are reserved and not configurable.

If the account does not exist, bashible creates it without a password, `sudo` privileges or a login shell. The account must not be provided through AD or LDAP. Processes owned by `deckhouse` in `ps` or `top` output belong to Deckhouse Platform components. The preflight check accepts an absent user and group or an existing pair with the reserved identifiers and no `sudo` privileges. The installation fails if the name is used with other identifiers or the identifiers belong to another account.

For details, see Installation.

Thick volume

An LVM volume in a thick pool, that is, a pool of the LVM type: the space for such a volume is allocated in full at creation. A thick pool gives performance comparable to the storage device but does not allow snapshots.

Thick volumes are created in thick pools of local and replicated storage: the LVM mode of the `sds-local-volume` module and LVM volume groups without a thin pool definition in the `sds-replicated-volume` module. For volumes that need snapshots, use a thin volume.

Thin volume

An LVM volume in a thin pool, that is, a pool of the LVMThin type: the space for such a volume is allocated as it fills up. A thin pool allows snapshots but has lower performance.

Thin volumes are created in thin pools of local and replicated storage: the LVMThin mode of the `sds-local-volume` module and LVM volume groups with a thin pool definition in the `sds-replicated-volume` module. Where snapshots are not needed, a thick volume gives higher performance.

Underlay network

Direct connection of physical functions (PF) and virtual functions (VF) of the network interfaces of a node to pods through Kubernetes Dynamic Resource Allocation. It serves workloads that need direct access to hardware, such as DPDK applications.

Physical network interfaces are connected to pods in one of two modes: `Shared`, where Virtual Functions are created from a Physical Function with SR-IOV and several pods share the hardware, or `Dedicated`, where a pod gets the whole Physical Function. The administrator creates an UnderlayNetwork object of the `sdn` module and marks the namespace that may use it. The pod requests a device with an annotation.

DPDK, Data Plane Development Kit, is a set of libraries for processing network packets in user space, bypassing the kernel network stack.

For details, see Connecting physical network interfaces to DPDK application pods.

Update mode

The setting that defines how Deckhouse Platform applies new versions.

In the `Auto` mode both patch and minor versions are applied automatically, in the `AutoPatch` mode only patch versions within the current minor version. In the `Manual` mode a version is applied only after the administrator approves the corresponding DeckhouseRelease.

The mode is set in the `settings.update.mode` parameter of the `deckhouse` module. In the automatic modes updates are applied with regard to update windows.

For details, see Configuring updates.

Update window

A time interval during which Deckhouse Platform is allowed to install updates automatically. Outside the windows new versions are not installed.

Update windows are set in the `update.windows` parameter of the `deckhouse` module. If no windows are configured, an update is applied as soon as a new version appears on the release channel.

Disruptive updates of nodes have separate windows in the NodeGroup parameters `disruptions.automatic.windows` and `disruptions.rollingUpdate.windows`.

For details, see Configuring updates.

Use role

A role of the granular role model for granting users permissions within one namespace, that is, access to namespaced module resources and standard namespaced Kubernetes resources.

Use roles belong to the granular role model. They are intended for users, typically application developers, who do not manage the cluster or its modules but need to create Ingress resources, configure authentication for applications or collect logs in their namespace.

The `user-authz` module creates the roles `d8:use:role:viewer`, `d8:use:role:user`, `d8:use:role:manager` and `d8:use:role:admin`. A use role is granted only with RoleBinding. Administrator permissions are granted with manage roles.

For details, see Granular authorization model.

User namespace

A namespace in which the workload runs. It always belongs to one project.

A user namespace always belongs to one project and cannot have the prefix of a system namespace.

The namespaces of a project are divided into the main project namespace and additional project namespaces.

Virtual machine (VM)

A machine that Deckhouse Platform creates and manages declaratively through the virtualization module. It runs in a pod on a cluster node under QEMU/KVM, managed by KubeVirt.

A machine is described by VirtualMachine in a project or namespace. Its disks and images are attached as block devices, its CPU is set by the number of cores and the core fraction within the limits of the VM class, and its state is kept by the run policy. The guest system is configured on the first boot by provisioning, after which Deckhouse Platform communicates with it through the guest OS agent.

The module core is based on KubeVirt: the QEMU process started by libvirtd in the `compute` container of the machine pod is the running machine. Machines move between nodes by live migration, are grouped into pools, and go through the phases of the virtual machine lifecycle.

For details, see Virtualization subsystem.

Virtual machine block device

A disk or an image attached to a virtual machine. Images are attached read-only or as a CD-ROM for ISO images, disks are attached read-write.

Devices are attached in two ways. The `blockDeviceRefs` list of the virtual machine specification sets the boot order by position or by the `bootOrder` field and is used for manual configuration, for example an ISO for OS installation. A VirtualMachineBlockDeviceAttachment attaches a disk as a separate

resource that does not take part in the boot order, over the `virtio-scsi` bus, and is used for automation and when the user has no rights to edit the machine.

With paravirtualization enabled, both ways attach and detach disks on a running machine without a reboot, if the storage is available on the node where the machine runs. While a live migration prepares the target node, devices can be neither attached nor detached.

For details, see Attaching disks and images to a virtual machine.

Virtual machine clone

A copy of a virtual machine created from an existing machine or from its snapshot. The clone gets a new IP address and new MAC addresses, and labels are not copied to it.

Because a clone copies the machine, the resources of the new machine need unique names: `nameReplacements` replaces the names of specific resources, and `customization` adds a prefix or a suffix to the names of all cloned resources, such as disks and IP addresses.

The clone gets a new IP address in the cluster network and new MAC addresses for additional interfaces, so the network settings of the guest OS have to be reconfigured. Labels are not copied, so the clone does not receive Service traffic until the needed labels are added. A snapshot of the machine can be the source of the clone.

For details, see Cloning virtual machines.

Virtual machine disk

Storage of virtual machine data, including the operating system and application files. A disk is described by its storage parameters, the StorageClass and the size, and by a data source, which can be an image, another disk or a snapshot.

A disk is described by VirtualDisk. Without a data source an empty disk of the given size is created. With a source, Deckhouse Platform takes the size from the source and picks the storage class by it. Disk behaviour depends on the storage behind the StorageClass: on file system volumes the disk is created in the `qcow2` format, on block devices data is written directly, and the volume binding mode defines whether the disk is created right away or only after it is attached to a virtual machine.

For a ready disk only the size and the storage class can be changed. A disk is attached to a machine read-write as a block device. Its data can be captured in a snapshot or written to a file by disk data export.

For details, see Virtual machine disks.

Virtual machine image

The contents of a disk from which virtual machine disks are created. A project image is available only in the project or namespace where it was created, and a virtual machine accesses an attached image read-only.

An image is described by VirtualImage. Its source can be an HTTP server with the image file, a container image registry, a file uploaded from the command line, another image, a virtual machine disk or a disk snapshot. The downloaded image is stored either in DVCR or in a PVC. An image stored in a PVC can be used to create disks only in the same storage class.

To make an image available to every project of the cluster, an administrator creates a cluster image, ClusterVirtualImage. Images are attached to a virtual machine as block devices: read-only or as a CD-ROM for ISO images.

For details, see Virtual machine images.

Virtual machine lifecycle

The phases a virtual machine goes through from creation to deletion, shown in its status. Conditions explain why the machine is in its current phase.

In the `Pending` phase the machine waits for its dependent resources to become ready: disks, images, the VM class and the secret with the provisioning script. In the `Starting` phase Deckhouse Platform starts the machine on one of the nodes, in `Running` it works, in `Migrating` it moves to another node by live migration, and the `Terminating` phase is irreversible.

The `.status.conditions` block answers why the machine is in its phase: the conditions ending in `Ready` show what blocks the startup, `Running` reports the reason from the scheduler, `Migratable` shows whether the machine can be moved, `EvictionRequired` warns about eviction from a node. The run policy defines how the machine is kept running.

For details, see Creating a virtual machine.

Virtual machine pool

A set of identical virtual machines, replicas created from one template, whose number Deckhouse Platform maintains. A pool can be scaled through the scale subresource, HPA or KEDA. Available in commercial editions.

A pool is described by VirtualMachinePool. Its template matches a regular virtual machine specification, so a replica is no different from a manually created virtual machine. Replica disks are described once in disk templates with a reclaim policy, a size and a data source, and the template references them in the boot order. Shared images, such as one ISO for all replicas, are attached read-only.

Replicas are differentiated by provisioning, so the `Legacy` OS type is not supported in a pool.

For details, see Virtual machine pools.

Virtual machine snapshot

The captured state of a disk or of a whole virtual machine at a point in time, kept for recovery or cloning. A disk snapshot saves only the data of the selected disk, a VM snapshot includes the VM parameters and the state of all its disks.

A disk snapshot is described by VirtualDiskSnapshot and serves as a source for new disks and images. A virtual machine snapshot is described by VirtualMachineSnapshot and is the saved state of the machine at a certain moment. Attached images are not saved with it, so they have to be present in the cluster at recovery.

Snapshots are consistent or inconsistent, see consistent snapshot. A snapshot of a machine can also be the source of a virtual machine clone.

For details, see Snapshots of disks and virtual machines.

VM CPU topology

The distribution of the processor cores of a virtual machine across sockets. The user sets only the total number of cores, and Deckhouse Platform calculates the number of sockets.

The more cores, the more sockets they are divided into and the larger the step in which their number can be changed: up to 16 cores use one socket, up to 32 two, up to 64 four and up to 248 eight. The total number of cores has to be a multiple of the number of sockets. The topology matters for applications sensitive to the processor configuration.

The number of cores of a running machine can be changed within the current topology by live migration when the corresponding feature is enabled. A change that requires a different topology needs a restart.

For details, see Virtual machine CPU and memory.

VM disk data export

Writing the contents of a virtual machine disk or of its snapshot to a file so that the data can be moved outside the cluster.

Export requires the enabled `storage-volume-data-manager` module and, from the command line, the `d8` utility version 0.20.7 or later. The export is performed by the `d8 data export download` command. The disk must not be in use at the moment of export, so a machine it is attached to is stopped first. A snapshot can be exported instead of the disk.

A downloaded file is imported back into the cluster by uploading it as an image or as a disk.

For details, see Exporting virtual machine disk data.

VM eviction

Moving or restarting a virtual machine to free its node. It is triggered when the node is put into maintenance mode, and a machine that can be moved by live migration is not restarted.

The `EvictionRequired` condition appears when the node with the machine is put into node maintenance mode. A node that was only cordoned does not trigger it. The condition message says what will happen: a live migration without stopping the guest OS, a restart by Deckhouse Platform with the administrator’s permission, or waiting until the machine is restarted. Until the eviction starts, the condition is only a warning, because maintenance can be cancelled.

After a restart the machine starts on another suitable node, and without one it stays in the `Pending`

phase. A user can also evict a machine to another node with `d8 v evict` or a VirtualMachineOperation of the `Evict` type.

For details, see Creating a virtual machine.

VM migration policy

The policy that determines when a live migration of a virtual machine uses the AutoConverge mechanism, CPU throttling that guarantees the migration completes. Set by the liveMigrationPolicy parameter of the machine.

AutoConverge gradually lowers the CPU frequency of the source machine so that fewer dirty memory pages appear, and completes the live migration as soon as the transfer rate exceeds the memory change rate. It helps on a slow network at the cost of application performance in the machine.

The allowed values: `AlwaysSafe` (never throttle), `PreferSafe` (the default, no throttling, but a migration with `force=true` may throttle), `AlwaysForced` (always use AutoConverge) and `PreferForced` (use AutoConverge, but a migration with `force=false` runs without it).

For details, see Live migration of virtual machines.

VM placement rules

The rules that control on which node a virtual machine starts, from nodeSelector, node affinity, and affinity and anti-affinity to other machines and pods. Conditions are hard or soft.

A hard condition is mandatory: if no node satisfies it, the machine stays in the `Pending` phase. A soft condition is taken into account by the scheduler where possible. All rules, including the `nodeSelector` of the VM class, apply together. Nodes with taints need matching tolerations on the machine.

When the rules of a running machine change and its current node no longer meets them, commercial editions move the machine by live migration, and in Deckhouse Platform Open the change applies after a reboot. The placement rules of the machine, its disks and its class are also checked when a block device is attached. VM rebalancing restores the correct placement when the node stops meeting the rules.

For details, see Placing virtual machines on nodes.

VM pool disk reclaim policy

The reclaim policy of a disk template of a virtual machine pool. It sets what happens to a replica disk when the replica is removed from the pool.

The policy is set in the `virtualDiskTemplates` block of a virtual machine pool together with the size and the data source of the replica disk. With `Delete`, the default, the disk is deleted together with the replica. With `Retain`, the disk is kept and reused by the next replica.

For details, see Virtual machine pools.

VM provisioning

Initial configuration of the guest system of a virtual machine on its first boot by an initialization script, Cloud-Init for Linux or Sysprep for Windows.

The initialization script creates users, sets passwords and SSH keys, installs software, runs commands and enables services, for example the guest OS agent. The Cloud-Init configuration is written in YAML and starts with the `#cloud-config` header.

Replicas of a virtual machine pool are differentiated by provisioning, so operating systems without it, the `Legacy` OS type, are not supported in pools.

For details, see Initial provisioning and the guest OS agent.

VM rebalancing

Restoring an even distribution of virtual machines across nodes by moving them with live migration. Performed by the descheduler module.

Rebalancing evens out the load: when a node reserves more than 80% of CPU, some machines are moved to nodes that reserve less than 50%. It also restores correct placement when the current node no longer meets the machine requirements or the rules of mutual placement. With the `descheduler` module enabled, Deckhouse Platform creates a Descheduler named `virtualization` and selects in it only the machines that can be moved by live migration.

For details, see Virtual machine fault tolerance and balancing.

VM run policy

The policy that determines how Deckhouse Platform maintains the state of a virtual machine, set by the runPolicy parameter of the machine.

The allowed values: `AlwaysOnUnlessStoppedManually` (the default, the machine always runs and can be stopped only manually), `AlwaysOn` (the machine is started again even after a shutdown from the guest OS), `Manual` (the user manages the state) and `AlwaysOff` (the machine is always off and cannot be started).

The state of a virtual machine is managed by VirtualMachineOperation or by the `d8 v start`, `d8 v stop`, `d8 v restart` and `d8 v evict` commands, which create the same operation.

For details, see Connecting to a virtual machine.

Vulnerability database

Databases of known vulnerabilities used by image scanning with Trivy. The `operator-trivy` module downloads them from the registry every 6 hours. They take about 5 GB on the system nodes.

Scanning uses public vulnerability databases. The database images have fixed names and tags in the registry, so they can be copied into a private registry for an air-gapped cluster. The databases are stored on the system nodes. If a cluster has none, they are placed on a worker node. See also vulnerability scanning.

For details, see Disk layout and size.

Vulnerability scanning

Automatic detection of known vulnerabilities (CVE) and CIS compliance checks for the container images used by pods of the cluster, based on Trivy.

Deckhouse Platform scans the container images of all resources in namespaces labelled `security-scanning.deckhouse.io/enabled=""`. Without such labels only the `default` namespace is scanned. Scanning starts every 24 hours and when components with new images are deployed. The result of scanning each image is stored in the namespace of the scanned resource.

For details, see Container image vulnerability scanning.

Worker node

A node intended to run user applications. Its resources are dictated by the workload, with a part of them reserved for kubelet and system pods.

Worker nodes are present in every deployment option except the single-node cluster, where the only node takes their role. In a single-master cluster, some Deckhouse Platform components also run on worker nodes. The actual node size depends on the applications running on it.

For details, see the Resource requirements section of the “System requirements” page.

Workload

All projects together with the disk, network and other resources they use.

The workload runs in user namespaces. Running the workload in system namespaces is prohibited.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Frequently Asked Questions

The page contains frequently asked questions about configuring and using the Deckhouse Platform.

Common

How can I apply an update for a specific module immediately?

To apply an update for a specific module immediately, set the `modules.deckhouse.io/apply-now: "true"` annotation on the corresponding ModuleRelease resource.

This annotation applies the release immediately without waiting for the update window. The requirements from `spec.requirements` still apply. If they are not met, the release will not be applied.

Example of setting the annotation for the `console` module:

```
d8 k annotate mr console-v1.43.3 modules.deckhouse.io/apply-now="true"
```

This can also be done using the `d8` CLI for convenience (module names and versions are autocompleted):

```
d8 system module apply-now console v1.43.3
```

Example resource with the annotation set:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleRelease
metadata:
  name: console-v1.43.3
  annotations:
    modules.deckhouse.io/apply-now: "true"
...
```

How can I apply an update DP immediately, bypassing update windows, canary releases, and manual update mode?

To apply a Deckhouse Platform (DP) update immediately, add the annotation `release.deckhouse.io/apply-now: "true"` to the corresponding DeckhouseRelease resource.

This will bypass update windows, canary release settings, and the manual cluster update mode. The update will be applied immediately after the annotation is set.

Example command to set the annotation and skip update windows for version `v1.56.2`:

```
d8 k annotate deckhousereleases v1.56.2 release.deckhouse.io/apply-now="true"
```

Example of a resource with the annotation set:

```
apiVersion: deckhouse.io/v1alpha1
kind: DeckhouseRelease
metadata:
  annotations:
    release.deckhouse.io/apply-now: "true"
...
```

What to do if, with VPN enabled, the container with the installer cannot access the network?

If a VPN is installed on the computer from which the cluster bootstrap is performed, there may be a problem with the container with the installer (or graphical installer) accessing the network. Because of this, for example, the graphical installer may not be displayed in the browser.

The problem can be solved in one of the following ways:

- Disable VPN on your computer and restart the container with the installer.
- If you cannot disable VPN (for example, if the cluster bootstrap is running on a VPN network), use the `--network host` parameter when starting the container with the installer (**for Docker Desktop on Mac OS, the parameter is available starting with version 4.34.0**). This will allow the container to access the network.

  Example of launching a container with an installer with VPN enabled, using the `--network host`

parameter:

```
docker run --network host --pull=always -it -v "$PWD/config.yml:/config.yml" -v
"$HOME/.ssh/:/tmp/.ssh/" -v "$PWD/dhctl-tmp:/tmp/dhctl"
registry.deckhouse.ru/deckhouse/ce/install:early-access bash
```

Example of running the graphical installer with VPN enabled, using the `--network host` parameter:

```
docker run --network host --rm --pull always -v $HOME/.d8installer:$HOME/.d8installer -v
/var/run/docker.sock:/var/run/docker.sock -p 127.0.0.1:8080:8080
registry.deckhouse.ru/deckhouse/installer:latest -r $HOME/.d8installer
```

How do I change the release channel for a module?

A module can be built-in to DP or connected from a module source (defined using ModuleSource). Built-in modules have a common release cycle with DP and are updated together with DP. **The release channel of a built-in module always matches the DP release channel.** A module connected from a source has its own release cycle, which is independent of the DP release cycle. **The release channel of a module connected from a source can be changed.**

Below is the process of changing the release channel for a module connected from a source.

By default, the release channel for modules is inherited from the DP release channel (specified in the `releaseChannel` parameter of the `deckhouse` ModuleConfig). For more information about release channels, see the Release Channels section.

For modules from a source, the release channel is specified using ModuleUpdatePolicy, which is then *linked* to the module via the `updatePolicy` parameter in ModuleConfig.

To change the release channel for a module from a source, follow these steps:

1. Define the module update policy.

   Create a ModuleUpdatePolicy where you specify the release channel in the `releaseChannel` parameter.

   Example ModuleUpdatePolicy:

   ```
   apiVersion: deckhouse.io/v1alpha2
   kind: ModuleUpdatePolicy
   metadata:
     name: my-module-policy
   spec:
     releaseChannel: Alpha
     update:
       mode: Auto
   ```

   If necessary, change the update mode and configure update windows.

   Ensure that the policy has been created:

   ```
   d8 k get mup my-module-policy
   ```

   Output example:

   ```
   NAME               RELEASE CHANNEL   UPDATE MODE
   my-module-policy   Alpha             AutoPatch
   ```

2. Link the update policy to the module.

   Specify the name of the created update policy in the updatePolicy parameter of the corresponding module's ModuleConfig.

   To edit the ModuleConfig, use the command (specify the module name):

   ```
   d8 k edit mc my-module
   ```

Example ModuleConfig:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: my-module
spec:
  enabled: true
  # ModuleUpdatePolicy name.
  updatePolicy: my-module-policy
```

When you change the module's release channel, its version will change according to the configured update mode.

To view the current release channel of the module and other information about the module's state in the cluster, use the corresponding Module object.

Example command to get information about the module:

```
d8 k get module my-module -o yaml
```

The update policy used will be specified in the `properties.updatePolicy` field, and the current release channel in the `properties.releaseChannel` field. Example output:

```
apiVersion: deckhouse.io/v1alpha1
kind: Module
metadata:
  name: my-module
  # ...
properties:
  # ...
  releaseChannel: Alpha # Module release channel.
  updatePolicy: my-module-policy # Module update policy.
  version: v1.16.10  # Module version.
  # ...
```

How do I configure an external module to update to patch versions only?

By default, if a module has no dedicated update policy, the update mode and windows are inherited from the DP settings.

If DP is set to the `AutoPatch` mode, the external module will also automatically receive only patch versions within the current minor version. Moving to a new minor version will require manual approval. In this case, no additional configuration is needed.

For more information about DP update modes, see Configuring updates.

If you need to manage the module update mode independently of DP, create a ModuleUpdatePolicy with `update.mode: AutoPatch` and link it to the module via the `updatePolicy` parameter in ModuleConfig:

1. Create an update policy.

   Example ModuleUpdatePolicy:

   ```
   apiVersion: deckhouse.io/v1alpha2
   kind: ModuleUpdatePolicy
   metadata:
     name: my-update-policy
   spec:
     releaseChannel: Stable
     update:
       mode: AutoPatch
   ```

   Ensure that the policy has been created:

```
d8 k get mup my-update-policy
```

2. Link the policy to the module.

   Specify the policy name in the updatePolicy parameter of the module's ModuleConfig:

   ```
   d8 k edit mc module
   ```

   Example ModuleConfig:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: module
   spec:
     enabled: true
     updatePolicy: my-update-policy
   ```

In the `AutoPatch` mode, module patch versions (for example, from `v1.16.1` to `v1.16.2`) are applied automatically, taking update windows into account if they are configured. To move to a new minor version (for example, from `v1.16.*` to `v1.17.*`), approve the corresponding ModuleRelease:

```
d8 k annotate mr module-v1.17.0 modules.deckhouse.io/approved="true"
```

Or using the `d8` CLI:

```
d8 system module approve module v1.17.0
```

What should I do if the module image did not download and the module did not reinstall?

In some cases, there may be a problem with automatically downloading the image and reinstalling the module. These cases include:

- Damage to the file system or other problems that have rendered the module image invalid.
- Switching to a different registry.
- Switching from one DP edition to another.

In this case, the module may be in the `Ready` state. The error occurs in the module's pods. To find the problematic pod, use the command:

```
d8 k -n d8-<module-name> get pods
```

A problematic pod will have a status other than `Running`.

To view information about a pod, use the command:

```
d8 k -n d8-<module-name> describe pod <pod-name>
```

Example of an error message in the pod when there is a problem with downloading the image and reinstalling the module:

```
Failed to pull image
"registry.deckhouse.ru/deckhouse/ce/modules/console@sha256:a12b4f8de1d997005155d0ba0
a7c968a015dd8d18bb5d54645ddb040ddab1ef4": rpc error: code = NotFound desc = failed
to pull and unpack image
"registry.deckhouse.ru/deckhouse/ce/modules/console@sha256:a12b4f8de1d997005155d0ba0
a7c968a015dd8d18bb5d54645ddb040ddab1ef4": failed to resolve reference ...
```

To download the image and reinstall the module that caused the problem:

1. Get a list of module releases:

```
d8 k get mr -l module=my-module
```

Output example:

```
NAME                PHASE        UPDATE POLICY   TRANSITIONTIME   MESSAGE
my-module-v3.7.4    Superseded                   5d23h
my-module-v3.7.5    Deployed                     5d23h
```

Find the module release deployed in the cluster in the list (it should have the status `Deployed`).

2. Add the annotation `modules.deckhouse.io/reinstall=true` to the expanded release:

```
d8 k annotate mr my-module-v3.7.5 modules.deckhouse.io/reinstall=true
```

After adding the annotation, the module image is re-downloaded from the registry, the module is validated with the current settings from `ModuleConfig`, and installed in the cluster. After successful reinstallation, the annotation is automatically removed from `ModuleRelease`.

To verify that the module has been successfully reinstalled and all module pods are working, use the command:

```
d8 k -n d8-<module-name> get pods
```

All pods in the module must have the status `Running`. Example:

```
NAME                                READY   STATUS    RESTARTS   AGE
backend-567d6c6cdc-g5qgt            1/1     Running   0          2d2h
frontend-7c8b567759-h8jdf           1/1     Running   0          2d2h
observability-gw-86cf75f5d6-7xljh   1/1     Running   0          2d2h
```

Cluster and Infrastructure

What to do if you encounter problems updating Kubernetes components on cluster nodes, synchronizing nodes, or applying NodeGroup Configuration?

If Kubernetes components are not updated on the cluster node, the NodeGroup configuration is not applied, and not all NodeGroup nodes are synchronized (have the `UPTODATE` status), perform the following steps:

1. Check the bashible logs on the node where the problems are occurring. The bashible mechanism is used to keep cluster nodes up to date. It is started by the `bashible.timer` timer at regular intervals as a service on the cluster nodes. This involves restarting, synchronizing scripts, and executing them (if necessary).

   To check bashible logs, use the command:

   ```
   journalctl -u bashible
   ```

   If the response contains the message `Configuration is in sync, nothing to do`, the node is synchronized and there are no problems. The absence of this message or the presence of errors indicates a problem.

2. Check the synchronization status of cluster nodes using the command:

   ```
   d8 k get ng
   ```

   The number of nodes in the `UPTODATE` state must match the total number of nodes in each group.

   Example output:

```
NAME       TYPE     READY   NODES   UPTODATE   INSTANCES   DESIRED   MIN   MAX
  STANDBY   STATUS   AGE     SYNCED
frontend   Static   1       1       1
                    118d    True
master     Static   3       3       3
                    118d    True
system     Static   2       2       2
                    118d    True
worker     Static   2       2       2
                    118d    True
```

How to migrate node groups to Cluster API (CAPI)?

Deckhouse Platform is migrating CloudEphemeral node management from Machine Controller Manager (MCM) to Cluster API (CAPI).

At the moment, migration from MCM to CAPI is supported for the following cloud providers:

- Yandex Cloud
- OpenStack
- VMware vSphere

After CAPI support is introduced for a cloud provider, existing CloudEphemeral node groups continue to use MCM (`status.engine: MCM`). New node groups use CAPI by default (`status.engine: CAPI`).

To check which management mechanism is used for a node group, run the following command:

```
d8 k get nodegroup -o custom-columns=NAME:.metadata.name,ENGINE:.status.engine
```

To migrate a node group from MCM to CAPI:

1. Create a new NodeGroup of the CloudEphemeral type with the required configuration. Do not set the `node.deckhouse.io/use-mcm` annotation — otherwise the group will remain on MCM.
2. Make sure the new group is managed by CAPI (`status.engine: CAPI`):

   ```
   d8 k get nodegroup <NODE_GROUP_NAME> -o custom-columns=NAME:.metadata.name,ENGINE:.status.engine
   ```

3. Wait until the nodes in the new group become `Ready`:

   ```
   d8 k get nodes -l node.deckhouse.io/group=<NODE_GROUP_NAME>
   ```

4. Move workloads from the old group to the new one.

   For example, update application `nodeSelector` and `tolerations` so that pods are scheduled onto nodes of the new group, or use another workload placement method adopted in your infrastructure. For details on allocating nodes for workloads, see Allocating nodes for specific workloads.

5. Make sure the migrated workloads are running successfully on the new group nodes and that no required pods remain on the old group nodes.
6. Delete the old NodeGroup.

> ⚠ Deleting a NodeGroup deletes all nodes in that group. Before deleting the old group, make sure the required workloads have been moved on the new group nodes and are running correctly.

If necessary, you can force a node group to be created using MCM. To do this, add the `node.deckhouse.io/use-mcm` annotation before creating the NodeGroup (or before recreating it):

```
d8 k annotate nodegroup <NODE_GROUP_NAME> node.deckhouse.io/use-mcm="true"
```

For example:

```
d8 k annotate nodegroup worker node.deckhouse.io/use-mcm="true"
```

⚠ The `node.deckhouse.io/use-mcm` annotation is a temporary workaround and its use is not recommended. Migrating node groups to CAPI is the preferred approach.

What to do if problems adding a node to the cluster via Cluster API Provider Static are present?

If, when adding a node to the cluster via Cluster API Provider Static (CAPS), it remains in `Pending` or `Bootstrapping` status, perform the following steps:

1. Verify that the access keys specified in the SSHCredentials resource are correct. Ensure that the username and SSH key specified in SSHCredentials are correct.
2. On the node where the problem occurred, check that the public key corresponding to the private key from SSHCredentials is present in `authorized_keys`. Example command for checking:

   ```
   cat ~/.ssh/authorized_keys
   ```

3. Check the number of nodes specified in NodeGroup, which should include the node being added. Make sure that the maximum number of nodes is not exceeded.
4. Check the status of the `bashible.service` on the node that caused the problem:

   ```
   systemctl status bashible.service
   ```

   It must have the status `active (running)`. If the service has the status `inactive` or `failed`, the service has not started. This indicates a problem with the configuration process.
5. If the steps above did not resolve the issue, remove the problematic node and its StaticInstance resource from the cluster so that the system will attempt to recreate them. To do this:
   - Get a list of nodes and locate the problematic one:

     ```
     d8 k get nodes
     ```

   - Find the corresponding StaticInstance resource:

     ```
     kubectl get staticinstances -n <namespace-name>
     ```

   - Remove the problematic node:

     ```
     kubectl delete node <node-name>
     ```

   - Remove the corresponding StaticInstance resource:

     ```
     kubectl delete staticinstances -n <namespace-name> <static-instance-name>
     ```

How do I replace the OS image in a cloud cluster?

Deckhouse Platform creates `CloudEphemeral` and `CloudPermanent` nodes, including master nodes, based on an operating system (OS) image specified in the node group configuration. To move the nodes to a new image, specify it in this configuration instead of the previous one. Deckhouse Platform recreates the `CloudEphemeral` nodes from the new image automatically. The `CloudPermanent` nodes and master nodes are recreated when you apply the configuration with the `dhctl converge` command.

For `CloudStatic` nodes, the administrator creates and maintains the virtual machines. To replace the image of such a node, prepare a virtual machine with the required OS and connect it using the instructions for adding CloudStatic nodes.

The resource where the image is specified depends on the node type and the cloud provider configuration method:

Node type	Provider configuration method	Where to change the image
`CloudEphemeral`	Through ModuleConfig or `<PROVIDER>ClusterConfiguration`	In the `<PROVIDER>InstanceClass` resource referenced by the node group
`CloudPermanent` and master nodes	Through ModuleConfig	In the `<PROVIDER>InstanceClass` resource referenced by the node group
`CloudPermanent` and master nodes	Through `<PROVIDER>ClusterConfiguration`	In the `instanceClass` section of the required node group in that resource

> **i** Migration from `<PROVIDER>ClusterConfiguration` to the new ModuleConfig-based configuration model is supported only for built-in virtualization (DVP), Yandex Cloud, and zVirt.

The image parameters depend on the resource whose configuration you edit. Select the appropriate tab.

- InstanceClass
- ClusterConfiguration

For `CloudEphemeral` nodes, use the instance class parameters with either provider configuration method. With a ModuleConfig-based configuration, these parameters also define the image for `CloudPermanent` nodes and master nodes.

Cloud provider	Parameter in the `spec` section	Instance class resource
Amazon Web Services	`ami`	AWSInstanceClass
Microsoft Azure	`urn`	AzureInstanceClass
Google Cloud Platform	`image`	GCPInstanceClass
Yandex Cloud	`imageID`	YandexInstanceClass
OpenStack	`imageName`	OpenStackInstanceClass
Huawei Cloud	`imageName`	HuaweiCloudInstanceClass
Basis Dynamix	`imageName`	DynamixInstanceClass
VMware Cloud Director	`template`	VCDInstanceClass
VMware vSphere	`template`	VsphereInstanceClass
zVirt	`template`	ZvirtInstanceClass
Built-in virtualization	`rootDisk.image`	DVPInstanceClass

With a `<PROVIDER>ClusterConfiguration`-based provider configuration, the master node image is set in `masterNodeGroup.instanceClass`, and the image for other `CloudPermanent` nodes is set in `nodeGroups[].instanceClass`.

Cloud provider	Master nodes	`CloudPermanent` worker nodes
Amazon Web Services	`masterNodeGroup.instanceClass.ami`	`nodeGroups[].instanceClass.ami`
Microsoft Azure	`masterNodeGroup.instanceClass.urn`	`nodeGroups[].instanceClass.urn`
Google Cloud Platform	`masterNodeGroup.instanceClass.image`	`nodeGroups[].instanceClass.image`
Yandex Cloud	`masterNodeGroup.instanceClass.imageID`	`nodeGroups[].instanceClass.imageID`

Cloud provider	Master nodes	`CloudPermanent` worker nodes
OpenStack	`masterNodeGroup.instanceClass.imageName`	`nodeGroups[].instanceClass.imageName`
Huawei Cloud	`masterNodeGroup.instanceClass.imageName`	`nodeGroups[].instanceClass.imageName`
Basis Dynamix	`masterNodeGroup.instanceClass.imageName`	`nodeGroups[].instanceClass.imageName`
VMware Cloud Director	`masterNodeGroup.instanceClass.template`	`nodeGroups[].instanceClass.template`
VMware vSphere	`masterNodeGroup.instanceClass.template`	`nodeGroups[].instanceClass.template`
zVirt	`masterNodeGroup.instanceClass.template`	`nodeGroups[].instanceClass.template`
Built-in virtualization	`masterNodeGroup.instanceClass.rootDisk.image`	`nodeGroups[].instanceClass.rootDisk.image`

With cloud providers other than VMware Cloud Director, VMware vSphere, zVirt, and built-in virtualization, the parameter value is a string with the OS image name or ID. In VMware Cloud Director, VMware vSphere, and zVirt, the `template` parameter sets a virtual machine template prepared based on the OS image. To move the nodes of these providers to a new image, prepare a new virtual machine template based on it.

> **i** In built-in virtualization, the image is specified as an object. In the `rootDisk.image.kind` parameter, specify the type of the resource with the image (`ClusterVirtualImage`, `VirtualImage`, or `VirtualDisk`), and in the `rootDisk.image.name` parameter, specify the name of this resource.

Example of the image parameter in built-in virtualization

```
apiVersion: deckhouse.io/v1alpha1
kind: DVPInstanceClass
metadata:
  name: worker
spec:
  rootDisk:
    # The other instance class parameters are not shown.
    image:
      kind: ClusterVirtualImage
      name: ubuntu-24-04-20260204
```

Requirements for the new image

The OS image or the virtual machine template prepared from it must meet the requirements of the selected cloud provider module.

Before the replacement, make sure that the new image or virtual machine template meets the following general requirements:

- The image parameter value differs from the previous one. If the image or the template is set by name, include the version or the date in the name, for example `ubuntu-24-04-20260204`.
- The image or the template prepared based on it exists in the cloud by the time the nodes are recreated.
- The image contains `cloud-init` and an operating system supported by Deckhouse Platform. The list of supported systems is given in “Supported OS versions”.

For some providers, preparing the image or template involves additional steps. Follow the instructions in the corresponding module documentation:

- For OpenStack, refer to “How do I create an image in OpenStack?”.
- For Basis Dynamix, refer to “Prepare an operating system image”.
- For VMware Cloud Director, refer to “Virtual machine template”.

- For VMware vSphere, refer to “VM image requirements”, which includes instructions for preparing the image.
- For zVirt, refer to “Prepare an operating system image” and “Prepare a virtual machine template”.

⚠ Deckhouse Platform compares the parameter values in the configuration, not the image content in the cloud. If you replace the image or the template in the cloud keeping its previous name, the nodes are not recreated.

Changing the image in the configuration

Create a new image in the cloud that meets the requirements above. In VMware Cloud Director, VMware vSphere, and zVirt, prepare a new virtual machine template based on it. Then select the cloud provider configuration method.

⚠ In Yandex Cloud, `CloudEphemeral` groups whose instance classes do not specify `imageID` use the master node image by default. Changing the master node image does not recreate the existing nodes in these groups. New nodes may use the new image, so a group can contain nodes with different images.

To keep the previous group image, explicitly set its `imageID` in YandexInstanceClass. To recreate the entire group from the new image, explicitly set the new `imageID`.

For DVP, Yandex Cloud, and zVirt, check the master node group configuration before selecting a tab:

```
d8 k get nodegroup master -o yaml
```

If `spec.cloudInstances.classReference.kind` and `spec.cloudInstances.classReference.name` are set and migration is complete, select the “Through ModuleConfig” tab. Make sure the migration alert for your provider is not firing:

- For DVP, this is `D8CloudProviderDVPMigrationPending`.
- For Yandex Cloud, this is `D8CloudProviderYandexCloudMigrationPending`.
- For zVirt, this is `D8CloudProviderZvirtMigrationPending`.

If the alert is firing, complete the migration first. If the master node group has no `classReference`, or the cluster uses another provider, select the “Through ClusterConfiguration” tab.

i After completing the migration to ModuleConfig, change the image in the instance class referenced by the required node group.

The cluster may retain the `d8-provider-cluster-configuration` Secret with the old provider configuration. The `d8 system edit provider-cluster-configuration` command lets you edit this configuration, but the platform no longer applies image changes from it.

Select the appropriate tab depending on how the cloud provider is configured:

- Through ModuleConfig
- Through ClusterConfiguration

With a ModuleConfig-based provider configuration, the image for `CloudEphemeral` and `CloudPermanent` nodes, including master nodes, is specified in an instance class. To replace the image, edit the instance class referenced by the required node group:

1. Open the node group configuration:

   ```
   d8 k get nodegroup <NODE_GROUP_NAME> -o yaml
   ```

   Replace `<NODE_GROUP_NAME>` with the node group name. For master nodes, use `master`.

   Check `spec.nodeType` for the node type and `spec.cloudInstances.classReference.kind` and `spec.cloudInstances.classReference.name` for the instance class kind and name. If multiple groups use the instance class, changing the image affects all of them.

2. Specify the new image or virtual machine template in the instance class of the node group and save the file:

```
d8 k edit <PROVIDER>instanceclass <INSTANCE_CLASS_NAME>
```

Replace `<PROVIDER>` with the cloud provider name in lowercase, for example `yandex`, and `<INSTANCE_CLASS_NAME>` with the instance class name.

An example for Yandex Cloud:

```
apiVersion: deckhouse.io/v1
kind: YandexInstanceClass
metadata:
  name: worker
spec:
  cores: 4
  memory: 8192
  imageID: fd83ergat2e815oohe7o
```

Example of the master node configuration in built-in virtualization

```
apiVersion: deckhouse.io/v1alpha1
kind: DVPInstanceClass
metadata:
  name: master
spec:
  rootDisk:
    # The other instance class parameters are not shown.
    image:
      kind: ClusterVirtualImage
      name: ubuntu-24-04-20260204
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: master
spec:
  nodeType: CloudPermanent
  cloudInstances:
    classReference:
      kind: DVPInstanceClass
      name: master
    minPerZone: 1
    maxPerZone: 1
```

After changing the instance class, proceed to applying the changes.

With a `<PROVIDER>ClusterConfiguration`-based provider configuration, the resource to edit depends on the node type. Select the node type of the group.

- CloudEphemeral
- CloudPermanent
- Master nodes

For `CloudEphemeral` nodes, the image is specified in the instance class referenced by the node group:

1. Check `spec.cloudInstances.classReference.kind` and `spec.cloudInstances.classReference.name` in the NodeGroup resource for the instance class kind and name:

   ```
   d8 k get nodegroup <NODE_GROUP_NAME> -o yaml
   ```

   Replace `<NODE_GROUP_NAME>` with the node group name.

2. Open the instance class and change the image parameter listed in the table above:

   ```
   d8 k edit <PROVIDER>instanceclass <INSTANCE_CLASS_NAME>
   ```

Replace `<PROVIDER>` with the cloud provider name in lowercase, for example `yandex`, and `<INSTANCE_CLASS_NAME>` with the instance class name.

For `CloudPermanent` nodes, change the image in the provider configuration:

1. Open the cloud provider configuration:

   ```
   d8 system edit provider-cluster-configuration
   ```

2. Change the image parameter in the `instanceClass` section of the required group in the `nodeGroups` list and save the file. An example for Yandex Cloud:

   ```
   nodeGroups:
   - name: front
     replicas: 2
     instanceClass:
       cores: 4
       memory: 8192
       imageID: fd83ergat2e815oohe7o
   ```

For master nodes, change the image in the provider configuration:

1. Open the cloud provider configuration:

   ```
   d8 system edit provider-cluster-configuration
   ```

2. Change the image parameter in the `masterNodeGroup.instanceClass` section and save the file.

After saving the configuration, apply the changes according to the node type.

Applying the changes

The way to apply the changes depends on the node type and is the same for both provider configuration methods. Select the appropriate tab.

- CloudEphemeral
- CloudPermanent and master nodes

Deckhouse Platform automatically recreates `CloudEphemeral` nodes after the image in the instance class changes. To check that the replacement is complete, follow these steps:

1. Wait until Deckhouse Platform recreates the nodes of the group:

   ```
   d8 k get nodes -l node.deckhouse.io/group=<NODE_GROUP_NAME>
   ```

   Replace `<NODE_GROUP_NAME>` with the node group name.

   During the replacement, the list may contain both the previous and the new nodes. The new nodes have a smaller value in the `AGE` column. An example of the output during the replacement:

   ```
   NAME                                        STATUS     ROLES    AGE     VERSION
   cloud-demo-worker-92f9049e-gm2lw-6hkm2      NotReady   worker   37s     v1.34.1
   cloud-demo-worker-92f9049e-xn29v-66rm9      Ready      worker   8m21s   v1.34.1
   ```

   The replacement is complete when only the new nodes in the `Ready` status remain in the list.

To apply the new image to `CloudPermanent` nodes and master nodes, run `dhctl converge`. The command reads the current configuration from the cluster, including ModuleConfig, NodeGroup, and instance classes when the provider uses a ModuleConfig-based configuration.

Before replacing master nodes, back up etcd. Also back up the `/etc/kubernetes` directory and copy both backups outside the cluster. Master nodes are recreated one at a time. In a single-master cluster, the command may offer a temporary transition to three master nodes and a return to one master node after the replacement.

1. On the local machine, get the Deckhouse Platform edition and version in the cluster:

```
DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]'
'[:lower:]')
```

2. On the local machine, run the Deckhouse Platform installer container of the same edition and version:

   ```
   docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
     registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
   ```

   If the cluster uses a different container registry, specify its address instead of `registry.deckhouse.io`.

3. In the installer container, check which changes will be made in the cloud:

   ```
   dhctl terraform check --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> \
     --ssh-user=<USERNAME> --ssh-host=<MASTER_IP>
   ```

   Replace `<SSH_KEY_FILENAME>` with the name of the private SSH key file, `<USERNAME>` with the user for connecting to the master node, and `<MASTER_IP>` with the master node address.

   When replacing master nodes, specify all master node addresses by repeating `--ssh-host` for each address.

   In the `dhctl terraform check` output, verify that the changes to nodes and other cloud resources match your expectations. In the final `nodes` list, nodes that require recreation have the `destructively_changed` status. If multiple groups use the same instance class, check the changes for each group.

4. In the installer container, apply the changes using the same SSH connection parameters as in the check:

   ```
   dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> \
     --ssh-user=<USERNAME> --ssh-host=<MASTER_IP>
   ```

   The command displays the plan of changes and asks for the `Do you want to CHANGE objects state in the cloud?` confirmation before replacing each node. To replace the node, enter `y`. The command also asks you to confirm that the master node name matches its address.

   Before confirming the replacement of the next master node, check etcd and the control plane using the master node verification procedure.

5. Check that the nodes of the group are recreated:

   ```
   d8 k get nodes -l node.deckhouse.io/group=<NODE_GROUP_NAME>
   ```

   Replace `<NODE_GROUP_NAME>` with the node group name. For master nodes, use `master`. Wait until the new nodes reach the `Ready` status.

How to change the instance type for nodes with the CloudPermanent type?

To change the instance type for nodes with the CloudPermanent type, follow these steps:

1. Make a backup of etcd and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the update of the master nodes.
4. Make sure that Deckhouse queue is empty. To view the status of all Deckhouse job queues, run the following command:

   ```
   d8 s queue list
   ```

   Example output (queues are empty):

```
Summary:
- 'main' queue: empty.
- 88 other queues (0 active, 88 empty): 0 tasks.
- no tasks to handle.
```

5. Run the appropriate edition and version of the Deckhouse installer container **on the local machine** (change the container registry address if necessary):

```
DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]'
'[:lower:]' )
docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
  registry.deckhouse.ru/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
```

6. **In the installer container**, run the following command to check the state before working:

```
dhctl terraform check --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-
user=<USERNAME> \
  --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-
HOST>
```

   The command output should indicate that Terraform found no inconsistencies and no changes are required.

7. **In the installer container**, run the command to edit the cluster configuration (specify the addresses of all master nodes in the `--ssh-host` parameter):

```
dhctl config edit provider-cluster-configuration --ssh-agent-private-
keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> \
  --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-
HOST>
```

8. Edit the `instanceClass` parameter of the desired node group by changing the instance type and save the changes. Example settings for the `masterNodeGroup` of the Yandex Cloud provider:

```
masterNodeGroup:
 replicas: 3  # required number of master nodes
 instanceClass:
   cores: 4     # change the number of CPUs
   memory: 8192  # change the memory size (in MB)
   # other instance parameters...
   externalIPAddresses:
   - "Auto"     # for each master node
   - "Auto"
   - "Auto"
```

9. **In the installer container**, run the following command to perform nodes upgrade:

   You should read carefully what converge is going to do when it asks for approval.

   When the command is executed, the nodes will be replaced by new nodes with confirmation on each node. The replacement will be performed one by one in reverse order (2,1,0).

```
dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME>
\
  --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-
HOST>
```

   Repeat the steps below (Sec. 9-12) for each master node one by one, starting with the node with the highest number (suffix 2) and ending with the node with the lowest number (suffix 0).

10. **On the newly created node**, check the systemd-unit log for the `bashible.service`. Wait until the node configuration is complete (you will see a message `nothing to do` in the log):

    ```
    journalctl -fu bashible.service
    ```

11. Make sure the node is listed as an etcd cluster member:

    ```
    for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
      d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
      --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
      --endpoints https://127.0.0.1:2379/ member list -w table
      if [ $? -eq 0 ]; then
        break
      fi
    done
    ```

12. Make sure `control-plane-manager` is running on the node:

    ```
    d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady \
      -l app=d8-control-plane-manager --field-selector spec.nodeName=<MASTER-NODE-N-NAME>
    ```

13. Proceed to update the next node (repeat the steps above).

How to migrate a cloud provider to ModuleConfig-based configuration?

Migration to the new ModuleConfig-based configuration model is supported only for built-in virtualization (DVP), Yandex Cloud, and zVirt. If the cluster uses DVPClusterConfiguration, YandexClusterConfiguration, or ZvirtClusterConfiguration, migrate its configuration using the procedure below.

Deckhouse Platform is transitioning from a single `<PROVIDER>ClusterConfiguration` resource to a model where the cloud provider configuration is split across four separate resources:

- ModuleConfig of the `cloud-provider-<PROVIDER>` module: Provider and layout settings
- Secret with credentials of the `cloud-provider.deckhouse.io/credentials` type: Access to the cloud API
- Provider InstanceClass (for example, DVPInstanceClass): Virtual machine parameters
- NodeGroup: Node group configuration

> ⚠ Migration is mandatory. This is not an optional step: support for `<PROVIDER>ClusterConfiguration` will be removed. Until the migration is completed, Deckhouse Platform updates may be blocked.

The migration is safe. Applying the resources automatically prepared by Deckhouse Platform **does not cause nodes to be recreated**. However, explicit administrator action is required, as the resources have to be reviewed and applied manually.

How to migrate

1. Wait for the migration alert. Each provider has its own, for example, `D8CloudProviderDVPMigrationPending` for DVP, `D8CloudProviderYandexCloudMigrationPending` for Yandex Cloud, and `D8CloudProviderZvirtMigrationPending` for zVirt. The alert means the module has detected the legacy configuration and prepared manifests for the transition.
2. Review the prepared resources in the `d8-migration-resources` Secret in the `d8-cloud-provider-<PROVIDER>` namespace:

    ```
    d8 k -n d8-cloud-provider-<PROVIDER> get secret d8-migration-resources -o
    jsonpath='{.data.resources\.yaml}' | base64 -d
    ```

    Example for built-in virtualization:

```
d8 k -n d8-cloud-provider-dvp get secret d8-migration-resources -o
jsonpath='{.data.resources\.yaml}' | base64 -d
```

3. Verify that the manifests match the expected cluster configuration (ModuleConfig, credentials Secret, InstanceClass, and NodeGroup).
4. Apply the resources:

   ```
   d8 k -n d8-cloud-provider-<PROVIDER> get secret d8-migration-resources -o
   jsonpath='{.data.resources\.yaml}' | base64 -d | d8 k apply -f -
   ```

   Example for built-in virtualization:

   ```
   d8 k -n d8-cloud-provider-dvp get secret d8-migration-resources -o
   jsonpath='{.data.resources\.yaml}' | base64 -d | d8 k apply -f -
   ```

5. Wait until the alert disappears. The module clears it automatically once it detects that all required resources are in place.

How to delete the legacy secret

After the migration of a cluster deployed in built-in virtualization, Yandex Cloud, or zVirt, the provider settings are defined in ModuleConfig, and you can manually delete the legacy `d8-provider-cluster-configuration` Secret in the `kube-system` namespace.

To delete the Secret, follow these steps:

1. Make sure the migration is complete and its alert no longer fires. For built-in virtualization, it is the `D8CloudProviderDVPMigrationPending` alert, for Yandex Cloud, the `D8CloudProviderYandexCloudMigrationPending` alert, and for zVirt, the `D8CloudProviderZvirtMigrationPending` alert. If you delete the Secret before the migration is complete, the cloud provider module stops working correctly.
2. Check the number of nodes in node groups of the `CloudPermanent` type:

   ```
   d8 k get nodegroups \
     -o custom-
   columns='NAME:.metadata.name,TYPE:.spec.nodeType,MIN_PER_ZONE:.spec.cloudInstance
   s.minPerZone'
   ```

   After the Secret is deleted, `dhctl converge` takes the number of nodes in these groups from the `spec.cloudInstances.minPerZone` parameter. If the parameter is not set for a node group of the `CloudPermanent` type, `dhctl converge` fails.
3. Make sure the cloud infrastructure data, such as network IDs and zones, is stored in a separate Secret. The command must print a non-empty value:

   ```
   d8 k -n d8-cloud-provider-<PROVIDER> get secret d8-candi-cloud-provider-discovery-data \
     -o jsonpath='{.data.cloud-provider-discovery-data\.json}'
   ```

   Replace `<PROVIDER>` with `dvp` for built-in virtualization, `yandex` for Yandex Cloud, or `zvirt` for zVirt.

   If the command prints nothing or the Secret is not found, the data is stored only in the legacy Secret. If you delete it without a copy of the data, the `terraform-manager` module is disabled. The `cloud-provider-yandex` module also loses the IDs of the network, subnets, and route table that the platform created in Yandex Cloud. Copy the data to a separate Secret and delete the temporary file:

```
d8 k -n kube-system get secret d8-provider-cluster-configuration \
  -o jsonpath='{.data.cloud-provider-discovery-data\.json}' \
  | base64 -d > /tmp/discovery-data.json

d8 k -n d8-cloud-provider-<PROVIDER> create secret generic d8-candi-cloud-provider-discovery-data \
  --from-file=cloud-provider-discovery-data.json=/tmp/discovery-data.json \
  --dry-run=client -o yaml \
  | d8 k apply -f -

rm /tmp/discovery-data.json
```

Then repeat the check and make sure the command prints a non-empty value.

4. Back up the Secret. The Secret contains cloud credentials, so store the file securely:

```
d8 k -n kube-system get secret d8-provider-cluster-configuration \
  -o yaml > d8-provider-cluster-configuration-backup.yaml
```

5. Allow deletion of the Secret. The Secret is protected by a webhook that rejects deletion without the `deckhouse.io/allow-delete` annotation:

```
d8 k -n kube-system annotate secret d8-provider-cluster-configuration \
  deckhouse.io/allow-delete=true
```

6. Delete the Secret:

```
d8 k -n kube-system delete secret d8-provider-cluster-configuration
```

What to do if it takes a long time to switch to custom nodes in lower-priority groups?

When using multiple node groups with different priorities in a cloud cluster (the `spec.cloudInstances.priority` parameter), switching to nodes from groups with lower priority can take a long time. An example of this scenario is when groups of preemptible nodes (spot, etc.) are set to the highest priority, and if such instances are unavailable, ordering nodes from other groups takes a very long time.

When provisioning nodes, the cluster autoscaler sequentially selects the group with the highest priority that is **not in a backoff state**. A backoff is a temporary lock on a group following a failed attempt to provision a node (for example, due to a lack of instances of the required type in the cloud).

How it works when using multiple node groups:

1. The cluster autoscaler attempts to provision a node in the group with the highest priority.
2. If the node is not provisioned within the time specified by the `max-node-provision-time` parameter, the attempt is considered a failure.
3. The group is marked as `failed` and blocked for the duration specified in the `initial-node-group-backoff-duration` parameter.
4. If the same group fails again, the lockout time is doubled, but does not exceed the time specified in the `max-node-group-backoff-duration` parameter.
5. The cluster autoscaler selects the next highest-priority group that is not locked out.

Here:

Parameter	Default value	Description
`initial-node-group-backoff-duration`	5 minutes	Initial duration of the group lockout after the first failure. Doubles after each failed node ordering attempt
`max-node-group-backoff-duration`	30 minutes	Maximum duration of the group lockout

Parameter	Default value	Description
`max-node-provision-time`	15 minutes	The time after which the cluster autoscaler considers a node provisioning attempt to have failed

If these parameters are set to their default values, switching to node ordering in lower-priority groups may take a considerable amount of time (for more details, see this example).

These settings can be adjusted to speed up the switching of nodes in lower-priority groups. To set the desired values for the `initial-node-group-backoff-duration`, `max-node-group-backoff-duration`, and `max-node-provision-time` parameters, edit the `cluster-autoscaler` Deployment object in the `d8-cloud-instance-manager` namespace. The parameters are specified in the `args` field of the `cluster-autoscaler` container. Example:

```
...
    containers:
     - name: cluster-autoscaler
       args:
       - --initial-node-group-backoff-duration=1m # The initial duration of the group
lockout after the first failure has been reduced.
       - --max-node-provision-time=5m # The time after which the cluster autoscaler
considers a node request to have failed has been reduced.
...
```

If you encounter issues with node ordering in a cluster with a single node group

If cloud cluster uses only one node group (for example, exclusively for ordering spot or preemptible nodes) and you encounter issues with ordering such nodes during automatic scaling, follow these steps:

1. Create one or more InstanceClass objects to be used when creating instances in the cluster. In the InstanceClass, specify node types that differ from those listed in the group mentioned above.

   > **i** In DP, InstanceClass objects vary depending on the provider. Examples: AWSInstanceClass, AzureInstanceClass, YandexInstanceClass.

2. Create one or more new node groups (NodeGroup). In the `spec.cloudInstances.classReference` parameter, specify the InstanceClass objects created in the previous step. In the `spec.cloudInstances.priority` parameter, set the priority of the node group.
3. If necessary, modify the `max-node-provision-time`, `max-node-group-backoff-duration`, and `initial-node-group-backoff-duration` parameters to speed up switching to lower-priority groups.

Example of the node ordering process with default settings

Suppose there are 3 groups of nodes with different priorities:

- **Group A** (priority 50)
- **Group B** (priority 30)
- **Group C** (priority 0)

In this case, the node ordering process might be as follows:

Time	Event
10:00	The cluster autoscaler attempts to order a node in **A**
10:15	The attempt to provision a node in **A** within 15 minutes (`max-node-provision-time`) fails → **A** blocked for 5 minutes (`initial-node-group-backoff-duration`)
10:15:xx	The cluster autoscaler attempts to order a node in **B** (next in priority, not blocked)

Time	Event
10:30	The attempt to provision a node in **B** within 15 minutes (`max-node-provision-time`) fails → **B** blocked for 5 minutes (`initial-node-group-backoff-duration`)
10:30:xx	The cluster autoscaler attempts to order a node in **A** again, as the lockout period (the default value for `initial-node-group-backoff-duration` is 5 minutes) has ended
10:45	The attempt to order a node in **A** fails again → **A** is blocked for 10 minutes (`initial-node-group-backoff-duration` for **A** is doubled)
…	And so on, until the lockout time for **A** and **B** exceeds 15 minutes (`max-node-provision-time`). In this case, the queue may not reach group **C** for about 1.5 hours

What to do if the resources generated by an object are not created after adding the object?

If the required resources do not appear after creating an object in the system (for example, dexAuthenticator), follow these steps:

1. Check if there are any critical alerts in the cluster that may block the creation of the required objects. To do this, use the command:

   ```
   d8 k get clusteralerts.deckhouse.io
   ```

   Example output:

   ```
   NAME               ALERT                                          SEVERITY
   AGE   LAST RECEIVED   STATUS
   012f602592aa7a91   K8SSchedulerTargetDown                         3
   16h   54s             firing
   0836dc893d5ecc65   KubernetesDeploymentReplicasUnavailable        5
   15h   62s             firing
   08742f87d62d0063   NTPDaemonOnNodeDoesNotSynchronizeTime          5
   16h   46s             firing
   172cfd38d2f7fd19   D8DeckhouseQueueIsHung                         7
   12h   66s             firing
   1c5705daf731f5cf   D8StrongholdNoActiveNodes                      3
   16h   55s             firing
   1d2c2f7d69f69f4b   D8DeckhouseIsNotOnReleaseChannel               9
   12h   53s             firing
   205a551243d795f3   D8LogShipperAgentNotScheduledInCluster         7
   15h   63s             firing
   2e34039aa7a3018e   D8NodeIsNotUpdating                            9
   12h   47s             firing
   31baf9a70d657275   D8StrongholdClusterNotHealthy                  7
   16h   55s             firing
   ```

   For more information about alerts, see the The list of alerts section.

2. Check the Deckhouse task queue:

   ```
   d8 s queue list
   ```

   Example output (queues are empty):

```
Summary:
- 'main' queue: empty.
- 88 other queues (0 active, 88 empty): 0 tasks.
- no tasks to handle.
```

If there are many unprocessed or long-running tasks in the queue, this may indicate problems.

3. Analyze DP logs and events:
   - To view logs in real time, use the command:

     ```
     d8 k -n d8-system logs -f -l app=deckhouse
     ```

     Example output:

     ```
     {"level":"info","logger":"addon-operator","msg":"ConvergeModules task for
     OperatorStartup in phase '', trigger is Operator-
     Startup","binding":"ConvergeModules","event.type":"OperatorStartup","queue"
     :"main","task.flow":"start","task.id":"fde0eb3b-5c3e-4da6-a0d8-
     a52f8ae03428","time":"2025-11-26T08:29:33Z"}
     {"level":"warn","logger":"addon-operator.converge-
     modules","msg":"ConvergeModules: functional scheduler not
     finished","binding":"ConvergeModules","event.type":"OperatorStartup","queue
     ":"main","task.id":"fde0eb3b-5c3e-4da6-a0d8-a52f8ae03428","time":"2025-11-
     26T08:29:33Z"}
     ```

     When analyzing logs, pay special attention to warnings (`WARNING`) and error messages (`ERROR`).

   - To view events, use the command:

     ```
     d8 k -n d8-system get events
     ```

     Example output:

     ```
     LAST SEEN   TYPE      REASON              OBJECT
     MESSAGE
     11m         Warning   Unhealthy           pod/deckhouse-5886c9bd77-vgdbw
     Readiness probe failed: HTTP probe failed with statuscode: 500
     7m22s       Normal    SuccessfulDelete    replicaset/deckhouse-5886c9bd77
     Deleted pod: deckhouse-5886c9bd77-vgdbw
     7m20s       Normal    Scheduled           pod/deckhouse-6bc5c4494-fwx6z
     Successfully assigned d8-system/deckhouse-6bc5c4494-fwx6z to sandbox1-
     master-0
     7m20s       Normal    Pulling             pod/deckhouse-6bc5c4494-fwx6z
     Pulling image "dev-registry.deckhouse.io/sys/deckhouse-
     oss@sha256:17ac07634e17422df52720264cddec3916ed6985a77782dc8a24fe5352290e6e
     "
     ```

   When analyzing events, pay special attention to those with the `Warning` type.

Deckhouse

How can I check DP versions available in different release channels?

For information about the current DP versions across all release channels, visit releases.deckhouse.io.

How to check the job queue in Deckhouse?

How to check the status of all Deckhouse task queues?

To view the status of all Deckhouse job queues, run the following command:

```
d8 s queue list
```

Example output (queues are empty):

```
Summary:
- 'main' queue: empty.
- 88 other queues (0 active, 88 empty): 0 tasks.
- no tasks to handle.
```

How to view the status of the main task queue?

To view the status of the Deckhouse `main` task queue, run the following command:

```
d8 s queue main
```

Example output (38 tasks in the `main` queue):

```
Queue 'main': length 38, status: 'run first task'
```

Example output (the `main` queue is empty):

```
Queue 'main': length 0, status: 'waiting for task 0s'
```

What should I do if DP is not receiving updates from the configured channel?

- Ensure the correct release channel is configured.
- Check that DNS resolution for the Deckhouse image registry is working correctly.

  Get and compare the IP addresses of `registry.deckhouse.io` from both a node and the `deckhouse` Pod. They must match.

  Example of obtaining an IP of `registry.deckhouse.io` from a node:

  ```
  getent ahosts registry.deckhouse.io
  ```

  Example output:

  ```
  185.193.90.38    STREAM registry.deckhouse.io
  185.193.90.38    DGRAM
  185.193.90.38    RAW
  ```

  Example of obtaining an IP of `registry.deckhouse.io` from the `deckhouse` Pod:

  ```
  d8 k -n d8-system exec -ti svc/deckhouse-leader -c deckhouse -- getent ahosts
  registry.deckhouse.io
  ```

  Example output:

  ```
  185.193.90.38    STREAM registry.deckhouse.io
  185.193.90.38    DGRAM  registry.deckhouse.io
  ```

  If the resulted IPs do not match, check DNS settings on the node. Pay attention to the `search` domain list in `/etc/resolv.conf`, which affects name resolution in the `deckhouse` Pod. If the `search` parameter in `/etc/resolv.conf` file specifies a domain with wildcard DNS resolution configured, this may lead to incorrect IP address resolution for the Deckhouse image registry (see example below).

Example DNS settings that may cause issues resolving the DP image registry IP address

Below is an example of how DNS settings may result in different resolution behavior on the node and in a Kubernetes Pod:

- Example of `/etc/resolv.conf` on the node:

  ```
  nameserver 10.0.0.10
  search company.my
  ```

  > **i** On nodes, the default `ndot` setting is **1** (`options ndots:1`), while in Kubernetes Pods, it's **5**. This causes different resolution logic for DNS names with 5 or fewer dots on a node and on the Pod.

- The DNS zone `company.my` has a wildcard entry `*.company.my` that resolves to `10.0.0.100`. This means any undefined DNS name in the `company.my` zone resolves to `10.0.0.100`.

Taking into account the `search` parameter in `/etc/resolv.conf`, when accessing `registry.deckhouse.io` from a node, the system will attempt to resolve the IP address for `registry.deckhouse.io` (because it considers it fully qualified due to the default `options ndots:1` setting).

However, when accessing `registry.deckhouse.io` from a Kubernetes Pod, considering the `options ndots:5` setting used by default in Kubernetes and the `search` parameter, the system will first attempt to resolve the name `registry.deckhouse.io.company.my`. This name will resolve to the IP address `10.0.0.100` because, according to the `company.my` DNS zone's wildcard configuration, `*.company.my` is resolved to `10.0.0.100`. As a result, the Pod will fail to connect to the `registry.deckhouse.io` host and will be unable to download information about available Deckhouse updates.

Does Deckhouse support realtime (rt) and low-latency Linux kernels?

In general, realtime (rt) and lowlatency kernels are supported with no extra configuration needed for Deckhouse Platform. Such kernels have been tested with DP EE version v1.75.7 and above on the following OSes and kernels:

- CentOS 9 Stream, linux-5.14.0-706.el9.x86_64+rt
- RedOS 8, linux-6.12.85-1.red80.x86_64-rt
- Astra Linux 1.7.5, linux-5.15-lowlatency

How can I know when a new DP version is available for the cluster?

As soon as a new version appears on the configured release channel:

- The `DeckhouseReleaseIsWaitingManualApproval` alert will appear if the cluster is in manual update mode.
- A new DeckhouseRelease custom resource will be created. To see the list of releases, run `d8 k get deckhousereleases`. If the new version is in `Pending` state, it means it hasn't been installed yet. Possible reasons:
  - Manual update mode is enabled.
  - Automatic update mode is enabled and update windows are scheduled, but the window hasn't started yet.
  - Automatic update mode is enabled and update windows are not scheduled, but the update is delayed by a random period to reduce load on the container image registry. The `status.message` field of the DeckhouseRelease resource will show a corresponding message.
  - The `update.notification.minimalNotificationTime` parameter is set, and the delay period hasn't elapsed.

How can I receive information about upcoming updates in advance?

You can get information about upcoming minor DP version updates on the release channel in one of the following ways:

- Enable manual update mode. A new DeckhouseRelease resource and the `DeckhouseReleaseIsWaitingManualApproval` alert will appear when a new version is available.
- Enable automatic update mode and set a delay using the `minimalNotificationTime` parameter. A new DeckhouseRelease resource will appear when a new version is available. If you also set a webhook URL in the `update.notification.webhook` parameter, a notification will be sent about the upcoming update.

How can I tell that the update was successful?

If the `DeckhouseUpdating` alert is gone, the update has finished.

You can also check the status of DP releases in the cluster with the following command:

```
d8 k get deckhouserelease
```

Example output:

```
NAME       PHASE        TRANSITIONTIME   MESSAGE
v1.46.8    Superseded   13d
v1.46.9    Superseded   11d
v1.47.0    Superseded   4h12m
v1.47.1    Deployed     4h12m
```

The `Deployed` status means the cluster has switched to the corresponding version, but it doesn't guarantee that the update has been successful.

To ensure the update completed successfully, check the state of the `deckhouse` Pod with the following command:

```
d8 k -n d8-system get pods -l app=deckhouse
```

Example output:

```
NAME                     READY   STATUS    RESTARTS   AGE
deckhouse-7844b47bcd-qtbx9   1/1     Running   0          1d
```

- If the Pod is `Running` and shows `1/1` under `READY`, it means the update completed successfully.
- If the Pod is `Running` but shows `0/1` under `READY`, it means the update is still in progress. If it stays like this for more than 20–30 minutes, it may indicate a problem with DP that requires investigation.
- If the Pod is not `Running`, it may indicate a problem with DP that requires investigation.

If something goes wrong

- Check the logs using the following command:

  ```
  d8 k -n d8-system logs -f -l app=deckhouse | jq -Rr 'fromjson? | .msg'
  ```

- Collect debug information and contact DP technical support.

How can I tell that an update is in progress?

During an update:

- The `DeckhouseUpdating` alert is active.
- The `deckhouse` Pod is not in the `Ready` state. If the Pod stays in a non-`Ready` state for a long time, it may indicate an issue with DP that requires investigation.

What to do if there are problems updating DP?

Deckhouse Platform update fails, one or more Deckhouse pods are in an unworkable state

If the Deckhouse Platform update fails, one or more Deckhouse pods in the `d8-system` namespace are in an unworkable state. Perform the following steps:

1. Check the Deckhouse logs using the command:

   ```
   d8 k -n d8-system logs -f -l app=deckhouse | jq -Rr 'fromjson? | .msg'
   ```

   If there are any problems, information about them will be included in the output. When analyzing logs, pay special attention to warnings (`WARNING`) and error messages (`ERROR`).

2. Check Deckhouse events using the command:

```
d8 k -n d8-system describe po -l app=deckhouse | awk '
/^Name:/ {
    pod = $2;
    print "=== " pod " ===";
    in_events = 0
}
/Events:/ {
    in_events = 1;
    next
}
in_events && /^$/ {
    in_events = 0;
    print "---"
}
in_events && !/^Events:/ {
    print $0
}
' | sed '/^---$/N;/^\n$/D'
```

Pod events contain key information about problems (e.g., planning errors, image loading errors, etc.). When analyzing events, pay special attention to those with the `Warning` type.

Example output:

```
Type     Reason     Age                     From     Message
----     ------     ----                    ----     -------
Warning  Unhealthy  4m44s (x1918 over 154m)  kubelet  Readiness probe failed:
HTTP probe failed with statuscode: 500
```

DP update is stuck in the Release is suspended status

The status `Release is suspended` indicates that it has been postponed and is currently unavailable (not recommended) for installation. In this case, it is recommended to remain on the latest available release or on the one currently installed (it will have the status `Deployed`).

To view the list of releases, use the command:

```
d8 k get deckhousereleases.deckhouse.io
```

Example output:

```
NAME       PHASE        TRANSITIONTIME   MESSAGE
v1.69.13   Skipped      3h46m
v1.69.14   Skipped      3h46m
v1.69.15   Skipped      3h46m
v1.69.16   Superseded   160m
v1.70.12   Suspended    49d              Release is suspended
v1.70.13   Skipped      36d
v1.70.14   Skipped      34d
v1.70.15   Skipped      28d
v1.70.16   Skipped      19d
v1.70.17   Deployed     160m
v1.71.3    Suspended    14d              Release is suspended
```

IAM

What to do if there are problems applying DexProvider settings?

If you have changed the DexProvider settings in the `user-authn` module and one of the following problems occurs:

- No changes are visible (settings are not applied).

- When attempting to log in to the platform's web interface with any type of authorization, a `500 Internal Server Error` occurs without a detailed description.

Perform the following steps:

1. Check the status of the dex deployment:

   ```
   d8 k -n d8-user-authn get pod
   ```

   Example output:

   ```
   NAME                                      READY   STATUS    RESTARTS   AGE
   dex-5ddb779b7d-6pbhs                      2/2     Running   0          20h
   kubeconfig-generator-7c46977b9f-5kdmc     1/1     Running   0          20h
   ```

   If the module is functioning properly and the correct configuration is specified in DexProvider, all pods will have the status `Running`.

2. Check the logs for the problematic pod:

   ```
   d8 k -n d8-user-authn logs dex-<pod-name>
   ```

   Based on the information from the logs, correct the configuration in the DexProvider resource and wait for the dex pods to restart. Within a few minutes, the pods will restart automatically, and the platform's web interface (located at `console.<CLUSTER_NAME_TEMPLATE>`) will become available and will reflect the changes made to the DexProvider resource.

Kubernetes and Scheduling

What to do when the API server is overloaded?

The following signs may indicate problems with API server load and memory consumption:

- `kubectl (d8)` responds slowly or does not respond at all (commands are executed slowly or not at all).
- Pods are recreated in the cluster for no apparent reason.

If these signs are present, perform the following actions:

1. Check the resource consumption of API server pods. To do this, use the command:

   ```
   d8 k -n kube-system top po -l component=kube-apiserver
   ```

   Pay attention to `MEMORY` consumption and `CPU`.

   Example output:

   ```
   NAME                                CPU(cores)   MEMORY(bytes)
   kube-apiserver-sandbox1-master-0    251m         1476Mi
   ```

2. Check the metrics in Grafana.

   To view the metrics, open the dashboard "Home" → "Dashboards" → "Kubernetes Cluster" → "Control Plane Status". Review the graphs related to the API server ("Kube-apiserver CPU Usage", "Kube-apiserver Memory Usage", "Kube-apiserver latency", etc.).

3. Review the API server audit logs to identify the source of high memory consumption. One common cause of high memory consumption is a large number of requests.

How to check the Kubernetes version in use?

To check the Kubernetes version in use, run the command:

```
d8 k get nodes
```

Example output:

```
NAME                  STATUS   ROLES                  AGE    VERSION
frontend-0            Ready    frontend               118d   v1.31.9
master-0              Ready    control-plane,master   118d   v1.31.9
master-1              Ready    control-plane,master   118d   v1.31.9
master-2              Ready    control-plane,master   118d   v1.31.9
system-0              Ready    system                 118d   v1.31.9
system-1              Ready    system                 118d   v1.31.9
worker-0              Ready    worker                 37d    v1.31.9
worker-1              Ready    worker                 19d    v1.31.9
```

Network

Is the ingress-nginx module supported? Will it affect passing a PCI DSS audit?

The `ingress-nginx` module remains supported by Deckhouse Platform for the entire platform support lifecycle and does not depend on the upstream project's status. The Deckhouse team tracks vulnerabilities in the controller and related components (NGINX, Lua modules, base images), delivers fixes in DP releases, and provides a migration path toward Gateway API.

Flant is the vendor responsible for support. Together with ongoing module maintenance and vulnerability management, this allows passing a PCI DSS audit and meets expectations for vendor accountability for a platform component.

Virtualization

How to use Ansible to provision virtual machines?

Ansible is an automation tool for running tasks on remote servers over SSH. This example shows how to use Ansible with virtual machines (VMs) in the `demo-app` project.

The example assumes that:

- `demo-app` namespace contains a VM named `frontend`.
- VM has a `cloud` user with SSH access.
- Private SSH key on the machine where Ansible runs is stored in `/home/user/.ssh/id_rsa`.

1. Create an `inventory.yaml` file:

   ```
   ---
   all:
     vars:
       ansible_ssh_common_args: '-o ProxyCommand="d8 v port-forward --stdio=true %h
   %p"'
       # Default user for SSH access.
       ansible_user: cloud
       # Path to private key.
       ansible_ssh_private_key_file: /home/user/.ssh/id_rsa
     hosts:
       # Host name in the format <VM_NAME>.<NAMESPACE>.
       frontend.demo-app:
   ```

2. Check the virtual machine `uptime`:

   ```
   ansible -m shell -a "uptime" -i inventory.yaml all

   # frontend.demo-app | CHANGED | rc=0 >>
   # 12:01:20 up 2 days,  4:59,  0 users,  load average: 0.00, 0.00, 0.00
   ```

If you do not want to use an inventory file, pass all parameters on the command line:

```
ansible -m shell -a "uptime" \
  -i "frontend.demo-app," \
  -e "ansible_ssh_common_args='-o ProxyCommand=\"d8 v port-forward --stdio=true %h
%p\"'" \
  -e "ansible_user=cloud" \
  -e "ansible_ssh_private_key_file=/home/user/.ssh/id_rsa" \
  all
```

How to automatically generate inventory for Ansible?

Instead of manually creating an inventory file, you can use the `d8 v ansible-inventory` command, which automatically generates an Ansible inventory from virtual machines in the specified namespace. The command is compatible with the ansible inventory script interface.

The `d8 v ansible-inventory` command requires `d8` v0.27.0 or higher. The command works only for virtual machines that have the main cluster network (Main) connected.

Only machines in the `Running` phase that have an assigned IP address get into the inventory. Host names are formatted as `<VM_NAME>.<NAMESPACE>` (for example, `frontend.demo-app`).

1. Optionally set host variables via annotations (for example, the SSH user):

   ```
   d8 k -n demo-app annotate vm frontend vars.ansible.deckhouse.io/ansible_user="cloud"
   ```

2. Run Ansible with a dynamically generated inventory:

   ```
   ANSIBLE_INVENTORY_ENABLED=yaml ansible -m shell -a "uptime" all -i <(d8 v ansible-
   inventory -n demo-app -o yaml)
   ```

> **i** The `<(...)` construct is necessary because Ansible expects a file or script as the source of the host list. Simply specifying the command in quotes won't work, because Ansible tries to execute the string as a script. The `<(...)` construct passes the command output as a file that Ansible can read.

1. Or save the inventory to a file and run the check:

   ```
   d8 v ansible-inventory --list -o yaml -n demo-app > inventory.yaml
   ansible -m shell -a "uptime" -i inventory.yaml all
   ```

How to use cloud-init to configure virtual machines?

Cloud-init is used for initial guest OS configuration on first boot. The configuration is written in YAML and starts with the `#cloud-config` directive.

> **⚠** When using cloud images (for example, official distribution images), you must provide a cloud-init configuration. Without it, some distributions do not configure network connectivity, and the virtual machine becomes unreachable on the network, even if the main network (Main) is attached.
>
> In addition, cloud images do not allow login by default — you must either add SSH keys for the default user or create a new user with SSH access. Otherwise, you will not be able to access the virtual machine.

Updating and installing packages

Example `cloud-config` for updating the system and installing packages from a list:

```
#cloud-config
# Update package lists.
package_update: true
# Upgrade installed packages to latest versions.
package_upgrade: true
# List of packages to install.
packages:
  - nginx
  - curl
  - htop
# Commands to run after package installation.
runcmd:
  - systemctl enable --now nginx.service
```

Creating a user

Example `cloud-config` for creating a local user with a password and SSH key:

```
#cloud-config
# List of users to create.
users:
   # Username.
  - name: cloud
    # Password hash.
    passwd: "<PASSWORD_HASH>"
    # Do not lock the account.
    lock_passwd: false
    # Sudo privileges without a password prompt.
    sudo: ALL=(ALL) NOPASSWD:ALL
    # Default shell.
    shell: /bin/bash
    # SSH keys for access.
    ssh-authorized-keys:
      - <SSH_PUBLIC_KEY>
# Allow password authentication via SSH.
ssh_pwauth: true
```

To generate a password hash for the `passwd` field, run:

```
mkpasswd --method=SHA-512 --rounds=4096
```

Creating a file with required permissions

Example `cloud-config` for creating a file with specified access permissions:

```
#cloud-config
# List of files to create.
write_files:
   # File path.
  - path: /opt/scripts/start.sh
    # File content.
    content: |
      #!/bin/bash
      echo "Starting application"
    # File owner, user and group.
    owner: cloud:cloud
    # Access permissions in octal format.
    permissions: '0755'
```

Configuring disk and filesystem

Example `cloud-config` for disk partitioning, filesystem creation, and mounting:

```
#cloud-config
# Disk partitioning setup.
disk_setup:
  # Disk device.
  /dev/sdb:
    # Partition table type, gpt or mbr.
    table_type: gpt
    # Automatically create partitions.
    layout: true
    # Do not overwrite existing partitions.
    overwrite: false

# Filesystem setup.
fs_setup:
    # Filesystem label.
  - label: data
    # Filesystem type.
    filesystem: ext4
    # Partition device.
    device: /dev/sdb1
    # Automatically detect partition.
    partition: auto

# Filesystem mounting.
mounts:
  # [device, mount_point, fs_type, options, dump, pass]
  - ["/dev/sdb1", "/mnt/data", "ext4", "defaults", "0", "2"]
```

Configuring network interfaces for additional networks

> **i** The settings described in this section apply only to additional networks. The main network (Main) is configured automatically via cloud-init and does not require manual configuration.

Additional networks are configured manually via cloud-init. The `write_files` block creates the configuration files, and the `runcmd` block applies the settings.

Connecting additional networks to a virtual machine is covered in Additional network interfaces.

The following examples cover common ways to configure networking in the guest OS:

- systemd-networkd
- Netplan (Ubuntu)
- ifcfg (RHEL/CentOS)
- Alpine Linux

Example `cloud-config` for distributions that use `systemd-networkd` (Debian, CoreOS, and others):

```
#cloud-config
write_files:
  - path: /etc/systemd/network/10-eth1.network
    content: |
      [Match]
      Name=eth1

      [Network]
      Address=192.168.1.10/24
      Gateway=192.168.1.1
      DNS=8.8.8.8

runcmd:
  - systemctl restart systemd-networkd
```

Example `cloud-config` for Ubuntu and other systems that use `Netplan`:

```
#cloud-config
write_files:
  - path: /etc/netplan/99-custom.yaml
    content: |
      network:
        version: 2
        ethernets:
          eth1:
            addresses:
              - 10.0.0.5/24
            gateway4: 10.0.0.1
            nameservers:
              addresses: [8.8.8.8]
          eth2:
            dhcp4: true

runcmd:
  - netplan apply
```

Example `cloud-config` for RHEL-compatible distributions that use the `ifcfg` scheme and `NetworkManager`:

```
#cloud-config
write_files:
  - path: /etc/sysconfig/network-scripts/ifcfg-eth1
    content: |
      DEVICE=eth1
      BOOTPROTO=none
      ONBOOT=yes
      IPADDR=192.168.1.10
      PREFIX=24
      GATEWAY=192.168.1.1
      DNS1=8.8.8.8

runcmd:
  - nmcli connection reload
  - nmcli connection up eth1
```

Example `cloud-config` for distributions that use the traditional `/etc/network/interfaces` format (Alpine and similar):

```
#cloud-config
write_files:
  - path: /etc/network/interfaces
    append: true
    content: |
      auto eth1
      iface eth1 inet static
          address 192.168.1.10
          netmask 255.255.255.0
          gateway 192.168.1.1

runcmd:
  - /etc/init.d/networking restart
```

How to increase the DVCR size?

The DVCR volume size is set in the `virtualization` module ModuleConfig (`spec.settings.dvcr.storage.persistentVolumeClaim.size`). The new value must be greater than the current one.

1. Check the current DVCR size:

   ```
   d8 k get mc virtualization -o
   jsonpath='{.spec.settings.dvcr.storage.persistentVolumeClaim}'
   ```

   Example output:

   ```
   {"size":"58G","storageClass":"linstor-thick-data-r1"}
   ```

2. Increase `size` using `patch` (set the value you need):

   ```
   d8 k patch mc virtualization \
     --type merge -p '{"spec": {"settings": {"dvcr": {"storage":
   {"persistentVolumeClaim": {"size":"59G"}}}}}}'
   ```

   Example output:

   ```
   moduleconfig.deckhouse.io/virtualization patched
   ```

3. Verify that ModuleConfig shows the new size:

   ```
   d8 k get mc virtualization -o
   jsonpath='{.spec.settings.dvcr.storage.persistentVolumeClaim}'
   ```

   Example output:

   ```
   {"size":"59G","storageClass":"linstor-thick-data-r1"}
   ```

4. Check the current DVCR status:

   ```
   d8 k get pvc dvcr -n d8-virtualization
   ```

   Example output:

   ```
   NAME STATUS VOLUME                                     CAPACITY    ACCESS MODES
   STORAGECLASS           AGE
   dvcr Bound  pvc-6a6cedb8-1292-4440-b789-5cc9d15bbc6b  57617188Ki  RWO
   linstor-thick-data-r1  7d
   ```

How to change the DVCR StorageClass when a PVC already exists?

> ⚠ You can change the DVCR storage StorageClass only by recreating the PVC. All images previously loaded into DVCR are lost, along with data for existing ClusterVirtualImage and VirtualImage resources.

The `spec.settings.dvcr.storage.persistentVolumeClaim.storageClassName` field in the `virtualization` module ModuleConfig sets the StorageClass for the virtual machine image storage volume (DVCR). While a PVC for that volume exists in the `d8-virtualization` namespace, you cannot change the field via the API.

You cannot change `storageClassName` on an existing PVC in place, and DVCR data is not migrated between storage classes.

To change the DVCR StorageClass, perform the following steps:

1. Stop DVCR:

   ```
   d8 k -n d8-virtualization scale deployment dvcr --replicas=0
   ```

2. List PVCs in the `d8-virtualization` namespace and find the PVC for the DVCR volume:

```
d8 k get pvc -n d8-virtualization
```

3. Delete the PVC you found. Replace `<PVC_NAME>` with the resource name. If the command fails because of insufficient permissions, run it as `system:sudouser`:

```
d8 k --as system:sudouser -n d8-virtualization delete pvc/<PVC_NAME>
```

4. Set the new StorageClass in ModuleConfig, substituting the class you need for `<STORAGE_CLASS_NAME>`:

```
d8 k patch mc virtualization --type merge -p '{"spec":{"settings":{"dvcr":{"storage":
{"persistentVolumeClaim":{"storageClassName":"<STORAGE_CLASS_NAME>"}}}}}}'
```

   Example output:

```
moduleconfig.deckhouse.io/virtualization patched
```

5. Start DVCR:

```
d8 k -n d8-virtualization scale deployment dvcr --replicas=1
```

6. Verify the PVC:

```
d8 k get pvc -n d8-virtualization
```

   Example output:

```
NAME   STATUS   VOLUME                                     CAPACITY   ACCESS
MODES   STORAGECLASS          VOLUMEATTRIBUTESCLASS   AGE
dvcr   Bound    pvc-b43f2e33-32cc-435a-aa1d-b53df35b030a   100Gi      RWO
linstor-thin-r1-hdd   <unset>                 34s
```

> **i** The storage for the chosen StorageClass must be reachable from the nodes where DVCR runs: system nodes, or worker nodes if the cluster has no system nodes.

How to install an operating system in a virtual machine from an ISO image?

Below is a typical Windows guest OS installation scenario from an ISO image. Before you begin, host the ISO on an HTTP endpoint reachable from the cluster.

1. Create an empty VirtualDisk for OS installation:

```
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: VirtualDisk
metadata:
  name: win-disk
  namespace: default
spec:
  persistentVolumeClaim:
    size: 100Gi
    storageClassName: local-path
```

2. Create ClusterVirtualImage resources for the Windows OS ISO and the VirtIO driver ISO:

```
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: ClusterVirtualImage
metadata:
  name: win-11-iso
spec:
  dataSource:
    type: HTTP
    http:
      url: "http://example.com/win11.iso"
```

```
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: ClusterVirtualImage
metadata:
  name: win-virtio-iso
spec:
  dataSource:
    type: HTTP
    http:
      url: "https://fedorapeople.org/groups/virt/virtio-win/direct-
downloads/stable-virtio/virtio-win.iso"
```

3. Create a virtual machine (VM):

```
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: VirtualMachine
metadata:
  name: win-vm
  namespace: default
  labels:
    vm: win
spec:
  virtualMachineClassName: generic
  runPolicy: Manual
  osType: Windows
  bootloader: EFI
  cpu:
    cores: 6
    coreFraction: 50%
  memory:
    size: 8Gi
  enableParavirtualization: true
  blockDeviceRefs:
    - kind: VirtualDisk
      name: win-disk
    - kind: ClusterVirtualImage
      name: win-11-iso
    - kind: ClusterVirtualImage
      name: win-virtio-iso
```

4. Start the virtual machine:

```
d8 v start win-vm
```

5. Connect to the VM console and complete the OS installation and VirtIO drivers using the graphical installer.

   VNC connection:

```
d8 v vnc -n default win-vm
```

6. After the installation is complete, restart the virtual machine.

7. For further work, connect via VNC again:

```
d8 v vnc -n default win-vm
```

How to create a golden image for Linux?

A golden image is a pre-configured virtual machine (VM) image that can be used to quickly create new VMs with pre-installed software and settings.

1. Create a virtual machine, install the required software on it, and perform all necessary configurations.
2. Install and configure qemu-guest-agent (recommended):
   - For RHEL/CentOS:

     ```
     yum install -y qemu-guest-agent
     ```

   - For Debian/Ubuntu:

     ```
     apt-get update
     apt-get install -y qemu-guest-agent
     ```

3. Enable and start the service:

   ```
   systemctl enable qemu-guest-agent
   systemctl start qemu-guest-agent
   ```

4. Set the machine run policy to `AlwaysOnUnlessStoppedManually`, otherwise you will not be able to shut it down.
5. Prepare the image. Clean unused filesystem blocks:

   ```
   fstrim -v /
   fstrim -v /boot
   ```

6. Clean network settings:
   - For RHEL:

     ```
     nmcli con delete $(nmcli -t -f NAME,DEVICE con show | grep -v ^lo: | cut -d: -f1)
     rm -f /etc/sysconfig/network-scripts/ifcfg-eth*
     ```

   - For Debian/Ubuntu:

     ```
     rm -f /etc/network/interfaces.d/*
     ```

7. Clean system identifiers:

   ```
   echo -n > /etc/machine-id
   rm -f /var/lib/dbus/machine-id
   ln -s /etc/machine-id /var/lib/dbus/machine-id
   ```

8. Remove the SSH host keys:

   ```
   rm -f /etc/ssh/ssh_host_*
   ```

9. Clean the systemd journal:

   ```
   journalctl --vacuum-size=100M --vacuum-time=7d
   ```

10. Clean package manager cache:

- For RHEL:

  ```
  yum clean all
  ```

- For Debian/Ubuntu:

  ```
  apt-get clean
  ```

11. Clean temporary files:

    ```
    rm -rf /tmp/*
    rm -rf /var/tmp/*
    ```

12. Clean logs:

    ```
    find /var/log -name "*.log" -type f -exec truncate -s 0 {} \;
    ```

13. Clean command history:

    ```
    history -c
    ```

14. On RHEL, reset and restore the SELinux contexts in one of two ways.

    Restore the contexts right away:

    ```
    restorecon -R /
    ```

    Or schedule a relabel for the next boot:

    ```
    touch /.autorelabel
    ```

15. Verify that `/etc/fstab` references UUID or `LABEL` rather than names like `/dev/sdX`:

    ```
    blkid
    cat /etc/fstab
    ```

16. Reset cloud-init state (logs and seed):

    ```
    cloud-init clean --logs --seed
    ```

17. Perform final synchronization and buffer cleanup:

    ```
    sync
    echo 3 > /proc/sys/vm/drop_caches
    ```

18. Shut down the virtual machine:

    ```
    poweroff
    ```

19. Create a VirtualImage resource that references the prepared VM’s VirtualDisk:

```
d8 k apply -f -<<EOF
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: VirtualImage
metadata:
  name: <IMAGE_NAME>
  namespace: <NAMESPACE>
spec:
  dataSource:
    type: ObjectRef
    objectRef:
      kind: VirtualDisk
      name: <SOURCE_DISK_NAME>
EOF
```

Or create a ClusterVirtualImage resource so the image is available cluster-wide for all projects:

```
d8 k apply -f -<<EOF
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: ClusterVirtualImage
metadata:
  name: <IMAGE_NAME>
spec:
  dataSource:
    type: ObjectRef
    objectRef:
      kind: VirtualDisk
      name: <SOURCE_DISK_NAME>
      namespace: <NAMESPACE>
EOF
```

Here, `<IMAGE_NAME>` is the name of the image being created, `<NAMESPACE>` is the namespace of the prepared machine, and `<SOURCE_DISK_NAME>` is the name of its disk.

20. Create a new VirtualDisk from the resulting image:

```
d8 k apply -f -<<EOF
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: VirtualDisk
metadata:
  name: <VM_DISK_NAME>
  namespace: <NAMESPACE>
spec:
  dataSource:
    type: ObjectRef
    objectRef:
      kind: VirtualImage
      name: <IMAGE_NAME>
EOF
```

Here, `<VM_DISK_NAME>` is the name of the disk of the new machine.

After completing these steps, you will have a golden image that can be used to quickly create new virtual machines with pre-installed software and configurations.

How to restore the cluster if images from registry.deckhouse.io cannot be pulled after a license change?

After a license change on a cluster with `containerd v1` and removal of the outdated license, images from `registry.deckhouse.io` may stop being pulled. Nodes then retain the outdated configuration file `/etc/containerd/conf.d/dvcr.toml`, which is not removed automatically. Because of it, the `registry` module does not start, and without it DVCR does not work.

Applying a NodeGroupConfiguration (NGC) manifest removes the file on the nodes. After the `registry`

module starts, delete the manifest, since this is a one-time fix.

1. Save the manifest to a file (for example, `containerd-dvcr-remove-old-config.yaml`):

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: NodeGroupConfiguration
   metadata:
     name: containerd-dvcr-remove-old-config.sh
   spec:
     weight: 32 # Must be in range 32–90.
     nodeGroups: ["*"]
     bundles: ["*"]
     content: |
       # Copyright 2023 Flant JSC
       # Licensed under the Apache License, Version 2.0 (the "License");
       # you may not use this file except in compliance with the License.
       # You may obtain a copy of the License at
       #     http://www.apache.org/licenses/LICENSE-2.0
       # Unless required by applicable law or agreed to in writing, software
       # distributed under the License is distributed on an "AS IS" BASIS,
       # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
       # See the License for the specific language governing permissions and
       # limitations under the License.

       rm -f /etc/containerd/conf.d/dvcr.toml
   ```

2. Apply the saved manifest:

   ```
   d8 k apply -f containerd-dvcr-remove-old-config.yaml
   ```

3. Verify that the `registry` module is running:

   ```
   d8 k -n d8-system -o yaml get secret registry-state | yq -C -P '.data | del .state |
   map_values(@base64d) | .conditions = (.conditions | from_yaml)'
   ```

   Example output when the `registry` module has started successfully:

   ```
   conditions:
   # ...
     - lastTransitionTime: "..."
       message: ""
       reason: ""
       status: "True"
       type: Ready
   ```

4. Delete the one-time NodeGroupConfiguration manifest:

   ```
   d8 k delete -f containerd-dvcr-remove-old-config.yaml
   ```

The migration procedure is covered in Migrating container runtime to containerd v2.

How to redirect traffic to a virtual machine?

A virtual machine runs in a Kubernetes cluster, so traffic reaches it the same way it reaches any other workload. Routing is handled by the standard Kubernetes Service resource, which selects targets by labels.

1. Create a service with the required settings.

   For example, consider a virtual machine with the label `vm: frontend-0`, an HTTP service exposed on ports 80 and 443, and SSH access on port 22:

```
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: VirtualMachine
metadata:
  name: frontend-0
  namespace: dev
  labels:
    vm: frontend-0
spec: ...
```

2. To route network traffic to the virtual machine's ports, create a service:

   This service listens on ports 80 and 443 and forwards traffic to the corresponding ports of the target virtual machine. SSH access from outside is provided on port 2211:

```
apiVersion: v1
kind: Service
metadata:
  name: frontend-0-svc
  namespace: dev
spec:
  type: LoadBalancer
  ports:
  - name: ssh
    port: 2211
    protocol: TCP
    targetPort: 22
  - name: http
    port: 80
    protocol: TCP
    targetPort: 80
  - name: https
    port: 443
    protocol: TCP
    targetPort: 443
  selector:
    vm: frontend-0
```

Why is only one connection method available for a virtual machine?

You can connect to a virtual machine (VM) via the serial console (`d8 v console`) or VNC (`d8 v vnc`). These methods use different communication channels with the guest OS and depend on its configuration. Both methods are covered in Connecting to a virtual machine.

The sections below describe common situations where only one connection method works.

Why does VNC not work when the serial console is available?

VNC displays the guest OS screen and requires virtual terminal support in the kernel. The serial console works independently of the graphics subsystem.

Check in the guest OS whether virtual terminal support is enabled in the kernel configuration:

```
cat /boot/config-$(uname -r) | grep CONFIG_VT
```

The output should show `CONFIG_VT=y`:

```
CONFIG_VT=y
```

If the output shows `CONFIG_VT is not set`, rebuild the kernel with the option enabled or use an OS image with a suitable kernel configuration.

Why does the serial console not work when VNC is available?

The serial console connects to the `ttyS0` port in the guest OS. If the `getty` service for this port is not running, `d8 v console` will not show a login prompt even though VNC continues to work.

In the guest OS, enable and start the `serial-getty` service for `ttyS0`:

```
sudo systemctl enable --now serial-getty@ttyS0.service
```

Then connect to the serial console again.

How to provide a Windows answer file (Sysprep)?

Unattended Windows installation uses an answer file (`unattend.xml` or `autounattend.xml`).

The example answer file below:

- Sets the English UI language and keyboard layout.
- Connects the `VirtIO` drivers for the setup stage (the order of devices in `blockDeviceRefs` on the VirtualMachine resource must match the paths in the file).
- Creates disk layout for installation with EFI.
- Creates the `cloud` administrator and the regular `user` account.

          <span class="nt">&lt;Order&gt;</span>3<span class="nt">&lt;/Order&gt;</span>
          <span class="nt">&lt;PartitionID&gt;</span>4<span class="nt">&lt;/PartitionID&gt;</span>
          <span class="nt">&lt;Label&gt;</span>Windows<span class="nt">&lt;/Label&gt;</span>
          <span class="nt">&lt;Letter&gt;</span>C<span class="nt">&lt;/Letter&gt;</span>
          <span class="nt">&lt;Format&gt;</span>NTFS<span class="nt">&lt;/Format&gt;</span>
        <span class="nt">&lt;/ModifyPartition&gt;</span>
      <span class="nt">&lt;/ModifyPartitions&gt;</span>
    <span class="nt">&lt;/Disk&gt;</span>
    <span class="nt">&lt;WillShowUI&gt;</span>OnError<span class="nt">&lt;/WillShowUI&gt;</span>
  <span class="nt">&lt;/DiskConfiguration&gt;</span>
  <span class="nt">&lt;ImageInstall&gt;</span>
    <span class="nt">&lt;OSImage&gt;</span>
      <span class="nt">&lt;InstallTo&gt;</span>
        <span class="nt">&lt;DiskID&gt;</span>0<span class="nt">&lt;/DiskID&gt;</span>
        <span class="nt">&lt;PartitionID&gt;</span>4<span class="nt">&lt;/PartitionID&gt;</span>
      <span class="nt">&lt;/InstallTo&gt;</span>
    <span class="nt">&lt;/OSImage&gt;</span>
  <span class="nt">&lt;/ImageInstall&gt;</span>
  <span class="nt">&lt;UserData&gt;</span>
    <span class="nt">&lt;ProductKey&gt;</span>
      <span class="nt">&lt;Key&gt;&lt;PRODUCT_KEY&gt;&lt;/Key&gt;</span>
      <span class="nt">&lt;WillShowUI&gt;</span>OnError<span class="nt">&lt;/WillShowUI&gt;</span>
    <span class="nt">&lt;/ProductKey&gt;</span>
    <span class="nt">&lt;AcceptEula&gt;</span>true<span class="nt">&lt;/AcceptEula&gt;</span>
  <span class="nt">&lt;/UserData&gt;</span>
  <span class="nt">&lt;UseConfigurationSet&gt;</span>false<span class="nt">&lt;/UseConfigurationSet&gt;
</span>
<span class="nt">&lt;/component&gt;</span>   <span class="nt">&lt;/settings&gt;</span>   <span
class="nt">&lt;settings</span> <span class="na">pass=</span><span class="s">"generalize"</span><span
class="nt">&gt;&lt;/settings&gt;</span>   <span class="nt">&lt;settings</span> <span class="na">pass=

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Release notes for Deckhouse Platform

> Patch release descriptions are generated automatically. To expand a description, click the version number.

Version 1.78

Important

- The v1 implementation of the container registry management, used up to and including DP 1.77 (the `Proxy` and `Local` modes set in the `registry` section of the `deckhouse` ModuleConfig) has been removed. A cluster can no longer be installed in these modes, and the update to DP 1.78 is blocked while the cluster runs `Proxy` or `Local`, or `Direct` without the `registry` ModuleConfig configured. Migrate the cluster to the `registry` module on DP 1.77 before updating; the procedures are described in the module FAQ. Update to DP 1.78 only from DP 1.77.1 or later: that is the first release that checks which registry implementation the cluster runs. An update that skips it, for example an LTS release hop or an update constraint from an earlier release, can install DP 1.78 on a cluster still in `Proxy` or `Local` mode, which is not supported.
- In Deckhouse Commander, checking, converging and deleting a cluster whose stored resources still set `registry.mode` to `Proxy` or `Local` in the `deckhouse` ModuleConfig now stop with an error and change nothing. Before these operations, bring the resources in line with the cluster: replace the `deckhouse` ModuleConfig in them with the cluster's own and add the cluster's `registry` ModuleConfig, if it has one.

Version 1.77

Important

- Support for Kubernetes 1.36 has been added, while support for Kubernetes 1.31 has been discontinued. The default Kubernetes version (used when the `kubernetesVersion` parameter is set to `Automatic`) has been changed to 1.34.
- Control plane components will be restarted during the update.
- All Ingress NGINX Controller pods will be restarted.
- If the `enableMultiTenancy` setting of the `user-authz` module is enabled, existing RoleBinding and ClusterRoleBinding objects that were previously ignored because of ClusterAuthorizationRule limitations become effective after the update. Before updating, review the RoleBinding and ClusterRoleBinding objects assigned to users, and modify or remove those that should not grant access.
- If the DP cluster uses custom roles based on the legacy RBACv2 scheme, the `D8UserAuthzLegacyRBACv2CustomRoleFound` alert will fire after the update. Such roles must be

migrated to the new scheme before updating to DP 1.78, otherwise the update will be blocked. The migration procedure is described in the `user-authz` module FAQ.

- If the cluster uses the v1 implementation of the container registry management (the `registry` section of the `deckhouse` ModuleConfig) in the `Proxy` or `Local` mode, or in the `Direct` mode without the `registry` ModuleConfig configured, it must be migrated to the `registry` module before updating to DP 1.78, otherwise the update will be blocked. The migration procedures are described in the `registry` module FAQ.
- If the `metallb` module configuration is managed through GitOps, temporarily disable synchronization from your repository before the update. After the update, replace the BGP configuration in your repository from ModuleConfig with the MetalLoadBalancerConfiguration, MetalLoadBalancerBGPPeer, and MetalLoadBalancerPool custom resources, and then re-enable synchronization.
- If the cluster uses NetworkPolicy objects with the `ipBlock: 0.0.0.0/0` rule, after the update they will also apply to intra-cluster traffic. It is recommended that you review such policies before the update and adjust them if necessary.
- In the AWS, Azure, and GCP providers, the default CNI has been changed to Cilium. Before creating or updating a cluster, make sure that the Linux kernel version is 5.8 or later and that network policies and firewalls do not block the UDP ports required for Cilium to operate in VXLAN mode. Failure to meet these requirements may result in cluster creation or update failures, or in loss of network connectivity between nodes. For detailed requirements, refer to “Network interaction”.
- The vSphere, Huawei Cloud, OpenStack, and VCD providers have been migrated from Terraform to OpenTofu. The migration is performed automatically and requires no manual actions.
- The Yandex Cloud and OpenStack providers have been migrated from Machine Controller Manager (MCM) to Cluster API (CAPI). The management engine is chosen per CloudEphemeral node group. Groups that already exist keep running on MCM, and new groups are created on CAPI by default, so a single cluster can contain groups of both kinds. To move an existing group, refer to “How to migrate node groups to Cluster API (CAPI)”.
- The following modules are now loaded from external sources and are developed on an independent release cycle (no manual migration actions are required):
  - Monitoring modules:
    - `extended-monitoring`
    - `log-shipper`
    - `loki`
    - `monitoring-custom`
    - `monitoring-deckhouse`
    - `monitoring-kubernetes`
    - `monitoring-ping`
    - `okmeter`
    - `operator-prometheus`
    - `prometheus`
    - `prometheus-metrics-adapter`
    - `prometheus-pushgateway`
    - `upmeter`
  - The `ingress-nginx` module.
- The `monitoring-kubernetes-control-plane` module has been merged into the `control-plane-manager` module. Monitoring of control plane components is now performed by the `control-plane-manager` module.

Deckhouse subsystem

- A policy has been added to the `deckhouse` module that prevents non-system users from setting or modifying the `heritage` label. This prevents accidental creation of resources that DP may recognize as its own.
- The reliability of updating clusters that use external modules (ModuleSource) has been improved. The update starts only after the modules have been preloaded, preventing their temporary unavailability during the update.
- Support has been added to the `registry` module for installing a cluster with the container registry operating in `Local` mode. This makes it possible to deploy static clusters without access to an external registry, including in air-gapped environments.

Kubernetes & Scheduling subsystem

- Changes in the `descheduler` module:
  - Added the `descheduler_pod_evictions_total` metric with information about the workload to which the evicted pod belongs.
  - Added the “Workload Happiness” Grafana dashboard, which displays the workload happiness score, workload distribution across nodes, and the module activity history (evictions, strategy execution, and timeline).
- Changes in the `vertical-pod-autoscaler` module:
  - Added the `VerticalPodAutoscalerDeprecatedUpdateModeAuto` alert and the “VPA Deprecated Update Mode” Grafana dashboard to detect VerticalPodAutoscaler objects that use the deprecated `updateMode: Auto mode`.
  - Improved the reliability of the `vertical-pod-autoscaler` webhook deployment. Fixed a component startup ordering issue that could cause errors during updates.
- Changes in the `control-plane-manager` module:
  - The module has been migrated to a new internal implementation for managing control plane components. Added the new ControlPlaneNode and ControlPlaneOperation custom resources to track node state and control plane component update operations.
  - Added automatic etcd defragmentation, which is enabled by default for multi-master clusters and runs when fragmentation exceeds 40%. A defragmentation schedule can be configured in the module settings.
  - Several settings have been moved to the module ModuleConfig. Automatic migration and alerts notifying about the need to update the configuration have also been added:
    - Kubernetes API publishing settings (`publishAPI`) from the `user-authn` module.
    - The `encryptionAlgorithm` parameter from ClusterConfiguration.
    - The `resourcesRequests` parameter for control plane components from the `global` ModuleConfig.
- Added a patch to `kube-scheduler` that prevents scheduling new pods onto nodes that are undergoing graceful shutdown.
- Accelerated etcd updates in single-master clusters. Eliminated control plane component downtime that occurred during updates.
- Reduced the risk of `kube-controller-manager` throttling under high controller load.
- Accelerated pod startup by enabling parallel pulling of multiple container images.
- Enabled the `KubeletEnsureSecretPulledImages` feature gate by default in the kubelet configuration to comply with CIS Benchmark requirements.

IAM subsystem

- Changes in the `user-authn` module:
  - Authentication protection in Dex has been strengthened: rate limiting has been added for authentication endpoints, LDAP/Crowd accounts are now automatically blocked after a series of failed sign-in attempts, and external accounts can now be blocked and unblocked manually.
  - The UserOperation resource now supports permanent user locking (`spec.lock.for: permanent`). Audit logs for account operations have also been extended: they now include information about the operation initiator, operation type, and target user.
  - Added the DexProviderCheck resource for verifying authentication providers (LDAP, OIDC, and others). It allows connection and credential issues to be diagnosed before they affect user sign-in.
  - Added the `Custom` complexity level to the password policy settings, allowing password requirements to be configured flexibly according to corporate standards.
  - Added support for specifying custom labels and annotations in the new `spec.podMetadata` field of the DexAuthenticator custom resource, for example, annotations for managing the Istio sidecar container.
  - DexAuthenticator now works correctly in namespaces with ResourceQuota and policies that require resource limits for all containers. Fixed an issue that could prevent the authenticator

pod from starting.

- Changes in the `user-authz` module:
  - The RBACv2 role model aggregation label scheme changes in DP 1.78. Added the `D8UserAuthzLegacyRBACv2CustomRoleFound` alert, which detects custom roles based on the legacy scheme. Such roles must be migrated to the new scheme before updating to DP 1.78; otherwise, they will stop working and the update will be blocked. The migration procedure is described in the module FAQ.
  - If the `enableMultiTenancy` setting is enabled, user permissions are now determined by the combination of ClusterAuthorizationRule, AuthorizationRule, and standard RBAC rules (RoleBinding/ClusterRoleBinding). After the update, existing RBAC bindings that were previously ignored because of ClusterAuthorizationRule limitations may become effective. It is recommended to review such bindings before the update. For details, refer to “Using ClusterAuthorizationRule and AuthorizationRule together with RBAC”.
  - Added the `D8UserAuthzPermissionBrowserUnavailable` alert, which notifies about the unavailability of the user permissions browsing service (`permission-browser-apiserver`).

Security subsystem

- Changes in the `admission-policy-engine` module:
  - SecurityPolicy exceptions (SecurityPolicyException) can now be configured at the individual container level instead of only for the entire pod. This allows security requirements to be relaxed for a specific sidecar or init container without removing restrictions from the entire pod. For details, see the module documentation.
  - Added the built-in ValidatingAdmissionPolicy `deny-deckhouse-finalizers.deckhouse.io`, which prevents manual removal of `deckhouse.io` finalizers from resources. This prevents incorrect object deletion and the creation of orphan resources.
- Added a mechanism to the `multitenancy-manager` module for granting cluster-wide resources to projects. DP administrators can now define which cluster resources are available to each project and specify default values for them. The mechanism can be used by any DP module to publish its own cluster resources.
- Added the ability to list resources across all accessible namespaces without cluster-wide permissions. The `d8 k get <resource> -A --scope=<accessible|projects|system|project:NAME>` command returns only the objects the user has access to instead of returning a `403 Forbidden` error. For details, see “Resource listing with access-based filtering”.
- ACL filtering of the namespace list now supports `watch` requests. The `d8 k get ns -w` command displays changes in real time without requiring the command to be re-run.
- The cainjector component of the `cert-manager` module is now enabled automatically when resources using `cert-manager` CA injection are detected. It no longer needs to be enabled manually or kept running at all times.

Cluster & Infrastructure subsystem

- Changes in `dhctl` (CLI installer):
  - Added a preflight check for disk name length in cloud providers. If the name exceeds the allowed limit, the installation is aborted before infrastructure provisioning begins.
  - Improved the interactive mode of `dhctl`: added a dedicated area for logs of current operations, and made the output more compact by displaying progress instead of a stream of service messages. Full logs are still available in debug mode and during non-interactive execution.
  - Improved the preflight check for the `deckhouse` user. Repeated bootstrap now correctly handles an existing user, and additional checks help prevent permission-related issues.
  - Fixed issues with cleaning up temporary processes and SSH connections after running the `converge` and `destroy` commands.
  - Fixed the `dhctl lock release` command in interactive mode.
  - Fixed issues in the `dhctl converge-migration` command that could cause migration failures in certain scenarios.
  - Improved the reliability of control plane `converge` operations. Checks are now performed in

a more appropriate order, and etcd status messages have become more informative.

- Changes in the `node-manager` module:
  - Added Instance API v1alpha2. Instance status and error information is now consolidated into a single resource, simplifying diagnostics.
  - Reduced the wait time for MachineDeployment creation for AWS Spot instances. If AWS cannot allocate Spot instances because of insufficient capacity, retries begin sooner.
  - Added the `spec.kubelet.seccompDefault` parameter to the NodeGroup resource, allowing the RuntimeDefault seccomp profile to be enabled by default for all workloads without explicit seccomp settings.
- Reduced the probability of false restarts of the CSI Controller in all cloud provider modules during short delays by increasing the liveness probe timeout.
- Changes in the `cloud-provider-dvp` module:
  - Added support for live disk migration between StorageClass objects without stopping the virtual machine. Migration is performed automatically when the StorageClass changes.
  - The module configuration has been migrated to the unified ModuleConfig contract. Permanent and Ephemeral nodes are now configured in the same way through InstanceClass and NodeGroup, without a separate ProviderClusterConfiguration. This simplifies cluster configuration, enables schema versioning and conversion without breaking compatibility, and prepares cloud providers for an independent release cycle outside the DP core. For details, refer to “Cluster and Infrastructure” in the DP FAQ.
  - Fixed an issue that could leave LoadBalancer Services in the `Pending` state without creating the parent load balancer. Improved conflict handling during ServiceWithHealthchecks updates and load balancer status synchronization.
  - StorageClass objects created through Cluster API clusters now always use the `WaitForFirstConsumer` mode regardless of the parent cluster configuration. During updates, managed StorageClass objects with an incompatible `volumeBindingMode` are also recreated automatically. This eliminates an issue that could block cluster updates and synchronization because of the immutable `volumeBindingMode` field.
- The `cloud-provider-openstack`, `cloud-provider-huaweicloud`, `cloud-provider-vsphere`, and `cloud-provider-vcd` modules now use OpenTofu instead of Terraform. This makes it possible to use an open infrastructure platform compatible with Terraform, reduces dependency on Terraform licensing changes, and aligns these providers with other cloud provider modules that already use OpenTofu.
- The OpenStack and Yandex Cloud providers now use Cluster API, the industry-standard framework for machine management in Kubernetes. To ensure a smooth transition, the legacy mode based on Machine Controller Manager (MCM) remains supported. Existing node groups keep running on MCM, while new ones are created on Cluster API.
- Improved virtual machine deletion handling in the `cloud-provider-huaweicloud` module, increasing resource cleanup reliability and preventing false deletion errors. Virtual machines that remain in the deleting state for more than 24 hours are now marked with the corresponding status, simplifying diagnostics.
- Updated the CSI plugin and CSI Syncer versions in the `cloud-provider-vsphere` module, and fixed known vulnerabilities in Cloud Controller Manager, the CSI plugin, and Terraform Manager. This improves integration security and ensures the use of up-to-date component versions.
- Added support for the `vcd.cpi.flant.com/load-balancer-ip` annotation for LoadBalancer Services in the `cloud-provider-vcd` module. It allows assigning a predefined external IP address to the load balancer. If both the annotation and the `spec.loadBalancerIP` field are specified, the annotation takes precedence.

Network subsystem

- Changes in the `istio` module:
  - Added support for Istio 1.27. Users now have access to the new features of the latest Istio release using an operatorless mode.
  - Expanded ambient mesh support. New settings provide more explicit control over ambient mesh, allow using waypoint proxies for Layer 7 traffic processing, and enable the HBONE protocol for encrypting traffic between pods without requiring a sidecar container to run in every pod.

- Changes in the `cni-cilium` module:
  - Changed the behavior of NetworkPolicy objects with the `ipBlock: 0.0.0.0/0` rule in the new module version. The rule now also applies to intra-cluster traffic.
  - Reduced CPU consumption by Cilium agents. The freed resources become available to user workloads.
- Changes in the `ingress-nginx` module:
  - Added support for IngressNginxController v1.15.
  - Updated the load calculation formula for Ingress NGINX Controller pods used for horizontal scaling of LoadBalancer, LoadBalancerWithProxyProtocol, and LoadBalancerWithSSLPassthrough inlets. The controller now adds and removes replicas in a timely manner, resulting in more stable behavior under load.
  - Updated the IngressNginxController API to v2. The `spec.resourcesRequests` resource consumption settings have been replaced with the extended `spec.resourcesManagement` settings, including support for resource limits. Compatibility with the v1 API is preserved automatically.
  - Implemented isolated configuration validation, making it possible to restore full NGINX configuration validation without reducing the security level.
- Added authorization for the Hubble web interface in the `cilium-hubble` module. Access to cluster network telemetry can now be restricted by user groups to improve security.
- In the `metallb` module, BGP mode configuration has been moved from ModuleConfig to the dedicated MetalLoadBalancerPool, MetalLoadBalancerBGPPeer, and MetalLoadBalancerConfiguration custom resources. The existing configuration will be migrated automatically, so no manual changes in the cluster are required. All new BGP settings must be configured through these resources.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.77.10

Fixes

- **[node-manager]** Reduce node-manager Helm release Secret size to avoid exceeding the 1 MiB etcd limit on clusters with many Static or Hybrid NodeGroups.

1.77.9

Know before update

- Pods using common/nginx-static (registry-proxy, basic-auth, deckhouse-tools, documentation) will be restarted.
- Static pods and DaemonSet pods of `kubernetes-api-proxy` will restart.
- The registry-packages-proxy pods will be restarted.
- bashible-apiserver no longer skips such ModuleSources, so their CA is added to the node configuration. Bashible will be rerun on all nodes.

Fixes

- **[candi]** Bump base images to v3.1.28.
- **[ci]** Add Fomichev to codeowners for candi/base_images.yml
- **[cloud-provider-azure]** Disable the node-ipam controller in the cloud-controller-manager to prevent duplicate pod CIDRs and conflicting routes.
- **[cloud-provider-openstack]** Fix OpenStackCluster rendering when network lists are missing or empty
- **[cloud-provider-vcd]** preserve VM not-found errors to allow orphaned Node cleanup
- **[cloud-provider-vcd]** optimize VM cache refresh and avoid blocking cache reads
- **[cloud-provider-yandex]** quote label values in generated MachineClass manifests
- **[common]** Update nginx in common/nginx-static to 1.30.7 to fix CVEs.
  Pods using common/nginx-static (registry-proxy, basic-auth, deckhouse-tools, documentation) will be restarted.
- **[deckhouse-controller]** Deckhouse no longer crash-loops on a module dm-verity device left incomplete by an interrupted `veritysetup open`; such a device is now removed automatically.
- **[deckhouse-controller]** Releases of a still-embedded module no longer raise manual approval alerts once the module has a deployed release.
- **[docs]** Add note for using Ubuntu 26.04.
- **[node-manager]** The links in the FAQ on cleaning up a static node now lead to the section of the

sds-replicated-volume FAQ on evicting DRBD resources from a node.
- **[node-manager]** Disable HTTP keep-alives in kubernetes-api-proxy `/readyz` probes so connections close immediately after each check.
  Static pods and DaemonSet pods of `kubernetes-api-proxy` will restart.
- **[node-manager]** Restore the default maxSurge behavior for NodeGroups with maxSurgePerZone set to 0.
- **[node-manager]** Fix `StaticInstance` getting stuck in a bootstrap loop after cleanup, and status patches failing on legacy conditions.
- **[node-manager]** Nodes trust the registry CA from a ModuleSource that has `dockerCfg` set again.
  bashible-apiserver no longer skips such ModuleSources, so their CA is added to the node configuration. Bashible will be rerun on all nodes.
- **[registry-packages-proxy]** Reject CSE node packages with untrusted manifest signatures, including requests through registry aliases and cached downloads.
  The registry-packages-proxy pods will be restarted.

1.77.8

Know before update

- Dex pods restart. A client of Dex that expects HTTP 429 on the refresh of a locked user, HTTP 500 for a deleted one, or `invalid_request` for a claimed or expired refresh token gets HTTP 400 `invalid_grant`. The password and token exchange grants and the sign-in page answer as before.
- Existing clusters are unaffected; the default zone set (ru-central1-a, ru-central1-b, ru-central1-d, ru-central1-e) is statically pinned. To use ru-central1-f, list it in `zones` instead of one of the default zones; the dropped zone’s subnet is replaced by a new subnet in ru-central1-f and the nodes in it are recreated.
- containerd restarts on all nodes. On nodes where the old AppArmor profile is already loaded, the fix applies after a node reboot.

Features

- **[cloud-provider-yandex]** Add ru-central1-f zone support via explicit zone selection with a four-zone limit.
- **[cloud-provider-yandex]** Add ru-central1-f zone support via explicit zone selection with a four-zone limit.
  Existing clusters are unaffected; the default zone set (ru-central1-a, ru-central1-b, ru-central1-d, ru-central1-e) is statically pinned. To use ru-central1-f, list it in `zones` instead of one of the default zones; the dropped zone’s subnet is replaced by a new subnet in ru-central1-f and the nodes in it are recreated.

Fixes

- **[admission-policy-engine]** Pods with a Localhost AppArmor profile set in `securityContext` are no longer denied by the Baseline policy.
- **[ci]** Pass the werf meta repo to the dev site and documentation deploy jobs, matching the builds.
- **[common]** Updated `golang.org/x/net`, `golang.org/x/text`, `google.golang.org/grpc` and `github.com/klauspost/compress` in the Kubernetes 1.31 CSI sidecars of CSE to fix CVEs.
- **[control-plane-manager]** Fixed ControlPlaneOperation failures on clusters whose root CAs have a non-default subject.
- **[dhctl]** The bootstrap terminal no longer shows glued lines, FAILED for bashible step attempts that recovered, or “Unhandled Error” from client-go.
- **[docs]** Fix highlighting the L2 menu on module pages in the documentation.
- **[registrypackages]** Fix AppArmor denying signals between processes of one container on Ubuntu kernels 7.0.0-41 and later.
  containerd restarts on all nodes. On nodes where the old AppArmor profile is already loaded, the fix applies after a node reboot.
- **[user-authn]** Dex answers the refresh of a locked user, of a user deleted from the local store or LDAP, and of a claimed or expired refresh token with `invalid_grant` (HTTP 400), so that applications and a Dex that signs in through this one send the user to sign in.
  Dex pods restart. A client of Dex that expects HTTP 429 on the refresh of a locked user, HTTP 500 for a deleted one, or `invalid_request` for a claimed or expired refresh token gets HTTP 400 `invalid_grant`. The password and token exchange grants and the sign-in page answer as before.

1.77.7

Know before update

- A cluster that uses `Proxy` or `Local` of the previous registry implementation, or `Direct` without the `registry` ModuleConfig, is not updated to DP 1.78, as before. This now also applies from the moment such a mode is set in the `deckhouse` ModuleConfig, before the switch starts. Migrate as

described in “Migrating from the previous implementation to the current one” in the registry documentation. Clusters already prepared for the migration are not affected.
- A node that joins while a registry-packages-proxy pod of the previous release is still running on a master waits until a pod of this release answers.
- Cilium agent pods will be restarted.
- Flannel pods will be restarted.
- On a NodeGroup with `spec.gpu`, a failing GPU check used to abort the bashible run and be retried forever, so the node never configured kubelet and never received updates from any other module. Such a node now converges and only its GPU stays unusable. If `/usr/bin/nvidia-container-runtime` is absent, containerd is now configured with `runc` as the default runtime instead of `nvidia`; on a node whose configuration previously selected `nvidia` this changes the containerd config and therefore restarts containerd. Previously such a node could not start any container at all.
- Pods of the kube-proxy, cni-cilium, cni-flannel, and cni-simple-bridge agent DaemonSets will be restarted because their cni-migration-init-checker init container image is updated.
- The controller and agent pods will be restarted.
- The registry in-cluster proxy and node services pods will be restarted.
- The terraform-manager pods will be restarted.
- istiod, istio-cni, ingress gateways, Kiali, api-proxy and metadata-exporter pods will be restarted.
- node-controller, capi-controller-manager, machine-controller-manager and bashible-apiserver do not run on a master tainted with a key from `global.modules.placement.customTolerationKeys`. Remove such taints from the master NodeGroup before the update.
- simple-bridge pods will be restarted.

Features

- **[docs]** Implement glossary with term linking.
- **[docs]** Added the “System requirements” page with deployment options and resource requirements for containers, virtual machines and combined workloads.
- **[node-manager]** Alert when a NodeGroup uses the deprecated built-in GPU support while the `gpu` module is disabled.

Fixes

- **[candi]** A GPU problem no longer blocks node convergence.
  On a NodeGroup with `spec.gpu`, a failing GPU check used to abort the bashible run and be retried forever, so the node never configured kubelet and never received updates from any other module. Such a node now converges and only its GPU stays unusable. If `/usr/bin/nvidia-container-runtime` is absent, containerd is now configured with `runc` as the default runtime instead of `nvidia`; on a node whose configuration previously selected `nvidia` this changes the containerd config and therefore restarts containerd. Previously such a node could not start any container at all.
- **[candi]** GPU compute capability check no longer requires `bc`.
- **[candi]** Persist `net.core.bpf_jit_harden` for GPU nodes in an own sysctl drop-in instead of editing distribution files that may be absent.
- **[candi]** bashible verifies the rpp-get binary against the image digest from its bundle before running it; a substituted bootstrap proxy on a master can no longer hand a binary to the nodes.
  A node that joins while a registry-packages-proxy pod of the previous release is still running on a master waits until a pod of this release answers.
- **[candi]** Fixed an intermittent bootstrap hang where kube-apiserver never started because kubelet read its manifest while it was being written.
- **[candi]** A new cloud node sets up the provider network before it installs bootstrap packages, so it can download them from a master in another zone.
- **[chrony]** Fixed known vulnerabilities in chrony-exporter.
- **[cloud-provider-dvp]** Fixes DVP CSI staging so volumes with filesystems detected by Kubernetes SafeFormatAndMount are preserved and unformatted volumes are formatted without using lsblk.
- **[cloud-provider-dvp]** Creates ModuleConfig/cloud-provider-dvp automatically when it is missing.
- **[cni-cilium]** The ipv4-options-guard sidecar no longer writes to the host `/etc`, so Cilium agents start on Deckhouse Engine nodes.
  Cilium agent pods will be restarted.
- **[cni-flannel]** The ipv4-options-guard sidecar no longer writes to the host `/etc`, so Flannel pods start on Deckhouse Engine nodes.
  Flannel pods will be restarted.
- **[cni-simple-bridge]** The ipv4-options-guard sidecar no longer writes to the host `/etc`, so simple-bridge pods start on Deckhouse Engine nodes.
  simple-bridge pods will be restarted.
- **[common]** Fixed known vulnerabilities in the cni-migration-controller and cni-migration-init-checker images.
  Pods of the kube-proxy, cni-cilium, cni-flannel, and cni-simple-bridge agent DaemonSets will be restarted because their cni-migration-init-checker init container image is updated.
- **[common]** added mountpoint in ipv4-options-guard
- **[common]** Updated `golang.org/x/net`, `golang.org/x/text`, `google.golang.org/grpc` and

`github.com/klauspost/compress` in CSI sidecars to fix CVEs.
- **[control-plane-manager]** Preserve custom TLS certificates when enabling a default Gateway.
- **[control-plane-manager]** The migration hook for the api listener is added.
- **[deckhouse]** Fixed a memory leak in webhook-handler, which kept the kubernetes monitors of replaced hooks running after every hook reload.
- **[deckhouse-controller]** Fixed image pulls for modules served by ModulePullOverride when another source updates its registry or the override is not ready during Deckhouse startup.
- **[dhctl]** Fixed known vulnerabilities in dhctl dependencies.
- **[docs]** Move the language switch from the header to the footer
- **[documentation]** Add the language switch to the footer.
- **[istio]** Fixed CVEs in the istio module images (go-jose, golang.org/x/net).
  istiod, istio-cni, ingress gateways, Kiali, api-proxy and metadata-exporter pods will be restarted.
- **[local-path-provisioner]** Updated `golang.org/x/net`, `golang.org/x/text` and `github.com/klauspost/compress` to fix CVEs.
- **[metallb]** Fixed BGP migration to preserve pool allocation flags and allow users to manage migrated resources after switching ModuleConfig to version 3.
- **[node-manager]** Master controllers leave an unreachable master after about 100 seconds and are not evicted from a single master.
- **[node-manager]** Master controllers no longer tolerate keys from `customTolerationKeys`, so a key that repeats a built-in one no longer blocks pod updates.
  node-controller, capi-controller-manager, machine-controller-manager and bashible-apiserver do not run on a master tainted with a key from `global.modules.placement.customTolerationKeys`. Remove such taints from the master NodeGroup before the update.
- **[node-manager]** A node-manager release no longer waits for capi-controller-manager when neither capi nor its webhooks change.
- **[node-manager]** Fixed known vulnerabilities in the bashible-apiserver, node-controller, node-group-exporter, kubernetes-api-proxy, d8-shutdown-inhibitor and capi-controller-manager images.
- **[node-manager]** Fixed constant NodeGroup status updates by node-controller on every Node update.
- **[registry]** Fixed known vulnerabilities in the docker-auth image.
  The registry in-cluster proxy and node services pods will be restarted.
- **[registry]** Fixed known vulnerabilities in the nodeservices-manager, docker-auth, mirrorer and syncer images.
- **[registry]** The update to DP 1.78 is held as soon as `registry.mode` `Proxy` or `Local`, or a switch between `Direct` and `Unmanaged`, is set in the `deckhouse` ModuleConfig, and the message of the held release lists the migration steps for each mode.
  A cluster that uses `Proxy` or `Local` of the previous registry implementation, or `Direct` without the `registry` ModuleConfig, is not updated to DP 1.78, as before. This now also applies from the moment such a mode is set in the `deckhouse` ModuleConfig, before the switch starts. Migrate as described in “Migrating from the previous implementation to the current one” in the registry documentation. Clusters already prepared for the migration are not affected.
- **[registry-packages-proxy]** The bootstrap port serves the manifest and the layer of the rpp-get image, so a node can verify the binary it installs.
- **[registry-packages-proxy]** Fixed known vulnerabilities in registry-packages-proxy.
- **[registrypackages]** Fixed known vulnerabilities in the cfssl and d8-bcheck packages.
- **[registrypackages]** Bump golang.org/x/net to v0.62.0 in d8-bcheck to fix CVE-2026-78661 and CVE-2026-97045.
- **[registrypackages]** Fixed known vulnerabilities in the rpp-get package.
- **[registrypackages]** Fixed known vulnerabilities in auth_server and registry of the docker-registry package.
- **[registrypackages]** rpp-get tries every registry-packages-proxy endpoint before an attempt fails and retries connection timeouts, so a node that reaches only the master of its own zone during bootstrap joins the cluster.
- **[service-with-healthchecks]** Go dependencies are updated.
  The controller and agent pods will be restarted.
- **[terraform-manager]** Fixed known vulnerabilities in opentofu.
  The terraform-manager pods will be restarted.
- **[terraform-manager]** Fixed known vulnerabilities in opentofu and in the terraform-manager-dvp image.
- **[tools]** The e2e directories of modules no longer reach the Deckhouse image.
- **[user-authn]** Default DKP gateway requirement is removed from dex-authenticator template.

1.77.6

Know before update

- Applying a discovered address restarts the Deckhouse Pod once.
- Cilium agent pods will be restarted. With DSR, the DSR IPv4 option is stripped before the packet reaches the pod.
- Control plane components (kube-apiserver, kube-controller-manager, kube-scheduler, etcd) and kubelet will be restarted.

- Flannel pods will be restarted.
- In ambient mode with Istio 1.27 or later, on nodes with legacy iptables, `istio-cni-node` switches from nftables to legacy iptables. Pods that were added to the mesh before the update keep their nftables rules. Restart these pods after the update. Otherwise, removing such a pod from the mesh without a restart leaves its old redirect rules in place, and the pod loses network connectivity.
- The controller and agent pods will be restared.
- The metallb components (controller, speaker, l2lb) will restart after the update.
- containerd will be restarted on all nodes.
- kube-proxy pods will be restarted.
- simple-bridge pods will be restarted.

Features

- **[cni-cilium]** Added a CVE-2026-98432 mitigation that filters IPv4 TCP SYN packets with IP options in the host and pod network namespaces (`ipv4OptionsGuard`; `Enforce` for new clusters, `Audit` for existing ones).
  Cilium agent pods will be restarted. With DSR, the DSR IPv4 option is stripped before the packet reaches the pod.
- **[cni-flannel]** Added a CVE-2026-98432 mitigation that filters IPv4 TCP SYN packets with IP options in the host and pod network namespaces (`ipv4OptionsGuard`; `Enforce` for new clusters, `Audit` for existing ones).
  Flannel pods will be restarted.
- **[cni-simple-bridge]** Added a CVE-2026-98432 mitigation that filters IPv4 TCP SYN packets with IP options in the host and pod network namespaces (`ipv4OptionsGuard`; `Enforce` for new clusters, `Audit` for existing ones).
  simple-bridge pods will be restarted.
- **[docs]** Add static-routing-manager architecture module section.
- **[docs]** Add cni-flannel and cni-simple-bridge modules architecture section.

Fixes

- **[admission-policy-engine]** Fixed CVE-2026-116585, CVE-2026-116586 and CVE-2026-116587 in `github.com/go-jose/go-jose/v4` and CVE-2026-78661 and CVE-2026-97045 in `golang.org/x/net`.
- **[admission-policy-engine]** Switch ratify to go-jose v4 to fix CVE-2026-116585, CVE-2026-116586, CVE-2026-116587.
- **[admission-policy-engine]** An unavailable Gatekeeper no longer blocks system components in namespaces that opted into security policy checks, which could deadlock the cluster together with the CNI agent.
- **[cert-manager]** Bump x/net to v0.62.0 and go-jose to v4.1.6 to fix CVE-2026-78661, CVE-2026-97045, CVE-2026-116585, CVE-2026-116586, CVE-2026-116587.
- **[ci]** Svace stages are rebuilt in every svace pipeline.
- **[cloud-provider-dvp]** Fixes x/net, x/text and kin-openapi CVEs in all module images.
- **[cloud-provider-openstack]** Fixes creation of nodes with `rootDiskSize` when the node availability zone does not exist in Cinder.
- **[cloud-provider-openstack]** fix CloudEphemeral node creation in non-default availability zones via automatic Cinder-AZ discovery and new OpenStackInstanceClass.volumeTypeMap field
- **[cni-cilium]** Fixed file descriptor, connection and lock leaks in Cilium found by static analysis.
- **[common]** Bump x/net in kube-rbac-proxy to v0.62.0 to fix CVE-2026-78661 and CVE-2026-97045.
- **[control-plane-manager]** The basic audit policy records an exec into a pod (`pods/exec`) in all namespaces again, as it did before Deckhouse 1.77.
- **[control-plane-manager]** Fixed a goroutine leak in the helm release deprecation scan when listing releases fails.
- **[control-plane-manager]** Updated go-jose, x/net and klauspost/compress in control plane components to fix known vulnerabilities.
  Control plane components (kube-apiserver, kube-controller-manager, kube-scheduler, etcd) and kubelet will be restarted.
- **[deckhouse]** Resolve `registry.d8-system.svc` to a node running the in-cluster registry proxy during bootstrap, instead of always to `127.0.0.1`.
  Applying a discovered address restarts the Deckhouse Pod once.
- **[deckhouse]** Update runtime dependencies and document unaffected vulnerability paths.
- **[deckhouse]** The `d8-main` Telemetry no longer references the `deckhouse-tracing` provider when the module doesn’t register it.
- **[deckhouse-controller]** Prevent module hooks from running with unavailable snapshots while waiting for Deckhouse to restart after a module update
- **[deckhouse-controller]** A pending module release no longer loses its Kubernetes, Deckhouse and module requirements, so an update that the cluster does not satisfy stays pending instead of disabling the module.
- **[dhctl]** Keep the SSH host list and master readiness checks in sync with the infrastructure state during master converge.
- **[dhctl]** Bump go-jose to v4.1.6 to fix CVE-2026-116585, CVE-2026-116586, CVE-2026-116587.

- **[docs]** Fix docs build config errors in werf includes.
- **[documentation]** Fix HTML parser vulnerabilities in docs-builder by updating golang.org/x/net to v0.62.0.
- **[go_lib]** Package proxy streams the full package body when the cache skips writing it.
- **[istio]** Fixed ambient mode on nodes with legacy iptables, where `istio-cni-node` crashed on Istio 1.25 and used nftables instead of legacy iptables on Istio 1.27 and later.
  In ambient mode with Istio 1.27 or later, on nodes with legacy iptables, `istio-cni-node` switches from nftables to legacy iptables. Pods that were added to the mesh before the update keep their nftables rules. Restart these pods after the update. Otherwise, removing such a pod from the mesh without a restart leaves its old redirect rules in place, and the pod loses network connectivity.
- **[kube-proxy]** Fixed known vulnerabilities in the kube-proxy images.
  kube-proxy pods will be restarted.
- **[local-path-provisioner]** `config.json` of the provisioner is serialized from a structure, and the CRD accepts in `spec.path` only an absolute path without quotes, backslashes, whitespace and control characters. A crafted path can no longer add manifests to the module release.
- **[metallb]** Fixed CVE-2026-78661 and CVE-2026-97045 in the metallb and l2lb images.
  The metallb components (controller, speaker, l2lb) will restart after the update.
- **[multitenancy-manager]** Fixed CVE-2026-116585, CVE-2026-116586 and CVE-2026-116587 in `github.com/go-jose/go-jose/v4` and CVE-2026-78661 and CVE-2026-97045 in `golang.org/x/net`.
- **[node-manager]** kube-rbac-proxy in capi-controller-manager and node-controller no longer listens on all addresses of a node that has no addresses yet, so it does not take the controller's port.
- **[node-manager]** Fixed known vulnerabilities in the integrity-controller and integrity-containerd-configurator images (CSE).
- **[node-manager]** Fixes x/net CVEs in the caps-controller-manager image.
- **[registry]** Require brackets around IPv6 upstream registry URL hosts and accept bracketed addresses with or without a port.
- **[registry-packages-proxy]** Fixed registry-packages-proxy hanging after a cache error and serving corrupted packages, which blocked node updates.
- **[registry-packages-proxy]** Bump go-jose to v4.1.6 to fix CVE-2026-116585, CVE-2026-116586, CVE-2026-116587.
- **[registrypackages]** Updated go-jose, x/net and klauspost/compress in containerd, runc and crictl to fix known vulnerabilities.
  containerd will be restarted on all nodes.
- **[registrypackages]** Support rebuilding legacy image layers and preserve verity data in CSE.
- **[service-with-healthchecks]** Status updates were refactored.
  The controller and agent pods will be restared.
- **[user-authn]** Local users keep the passwords they changed in Dex when the cluster updates from 1.76.
- **[user-authn]** Fixed CVE-2026-116585, CVE-2026-116586 and CVE-2026-116587 in `github.com/go-jose/go-jose/v4` and CVE-2026-78661 and CVE-2026-97045 in `golang.org/x/net`.
- **[user-authn]** Bump go-oidc in dex-authenticator to v3.11.0 to fix CVE-2026-116585, CVE-2026-116586, CVE-2026-116587.
- **[user-authz]** Fixed CVE-2026-78661 and CVE-2026-97045 in `golang.org/x/net`.
- **[vertical-pod-autoscaler]** Fix a panic in vpa-updater and vpa-admission-controller when a pod with a container without resources is capped to a LimitRange of type Pod.

1.77.5

Know before update

- After a reset, the previous password cannot be reused when passwordHistoryLimit is set; the current password cannot be set again through the change form, and a lowered passwordHistoryLimit applies at the next password change.
- Cilium agent and operator pods will be restarted.
- Control plane components and kubelet will be restarted.
- CoreDNS pods will be restarted.
- Node-local-dns safe updater will be restarted.
- TLS connections from nodes to hosts whose certificates chain to `emSign ECC Root CA - G3` or Comodo `AAA Certificate Services` (eMudhra / emSign issued) will fail. Reissue such certificates from another CA before the update.
- The `cert-manager` controller pod restarts.
- The controller and agent pods will be restarted.
- cni-flannel pods will be restarted.
- kube-proxy pods will be restarted.
- network-policy-engine pods will be restarted.
- node-local-dns pods will be restarted.

Features

- **[control-plane-manager]** The basic audit policy logs Pod status updates from kubelet with the request body, so container terminations and their reasons get into the audit log.
- **[deckhouse]** Migrated package release management to nelm v2 while keeping the v1 install and delete behaviour.
- **[user-authn]** DexAuthenticator logins, logouts, failed and denied logins, CSRF mismatches and failed session refreshes are delivered as security events when the `security-events-manager` module is enabled.

Fixes

- **[admission-policy-engine]** Fixed CVE-2026-114437 in `github.com/go-chi/chi/v5` and CVE-2026-63209 in `github.com/klauspost/compress`.
- **[candi]** The first master bootstrap waits for `kube-apiserver` readiness instead of failing the control-plane step on `connection refused`.
- **[cert-manager]** The metrics proxy of the controller is no longer restarted by its liveness probe while its node is short of CPU.
  The `cert-manager` controller pod restarts.
- **[cilium-hubble]** Fixed a known vulnerability in the Hubble relay image.
- **[cloud-provider-dvp]** Fixed deletion of load balancers backed by ServiceWithHealthchecks, which failed because the child Service is protected by the `heritage - deckhouse` label in the parent cluster.
- **[cloud-provider-huaweicloud]** Recreated the etcd disk when a master VM is recreated.
- **[cloud-provider-openstack]** CAPI now mirrors MCM — `configDrive` honors `externalNetworkDHCP`, and additional networks always produce ports
- **[cloud-provider-vcd]** Fixes the module getting stuck in Error on upgrade from 1.76 because of the immutable selector of the `capcd-controller-manager` Deployment.
- **[cni-cilium]** Fixed a known vulnerability in the Cilium images.
  Cilium agent and operator pods will be restarted.
- **[cni-flannel]** Fixed known vulnerabilities in the flanneld image.
  cni-flannel pods will be restarted.
- **[control-plane-manager]** Updated Go dependencies of Kubernetes control plane components to fix known vulnerabilities.
  Control plane components and kubelet will be restarted.
- **[control-plane-manager]** The cluster-wide controllers of `control-plane-manager` run in a single pod regardless of the `highAvailability` setting or an etcd arbiter.
- **[control-plane-manager]** Control plane components are no longer restarted in parallel when a node is NotReady or after a certificate renewal.
- **[control-plane-manager]** Fixed a Deckhouse crash caused by a helm release `Secret` or `ConfigMap` with too short release data.
- **[control-plane-manager]** removed unused executable files from the etcd-backup image
- **[control-plane-manager]** In CSE, `availableVersions` in `d8-cluster-kubernetes` lists only Kubernetes versions that can be set.
- **[deckhouse]** Restore ClusterAdmin read access to ModuleSettingsDefinition so the console can show module settings again.
- **[deckhouse]** Show the Terminating phase while package repositories are being deleted
- **[deckhouse]** Update d8 CLI and scoped runtime VEX exceptions for known vulnerabilities.
- **[deckhouse-controller]** A module enabled in the bundle is no longer disabled when its ModuleConfig does not set `enabled`.
- **[deckhouse-controller]** Module sources now scan the registry every 30 minutes by default, reducing registry load
- **[istio]** added limit paralle in common images
- **[istio]** Fixed CVE-2026-63209 in istio images.
- **[istio]** Fixed istio module installation with nelm v2 when Istio is managed by the istio operator (versions below 1.27).
- **[istio]** Fixed `alliance-healthcheck` keeping the sidecar of the previous Istio version after a `globalVersion` change.
- **[kube-dns]** Fixed a known vulnerability in the CoreDNS image.
  CoreDNS pods will be restarted.
- **[kube-proxy]** Fixed known vulnerabilities in the kube-proxy init-container image.
  kube-proxy pods will be restarted.
- **[kube-proxy]** Fixed known vulnerabilities in the kube-proxy images.
  kube-proxy pods will be restarted.
- **[multitenancy-manager]** Fixed CVE-2026-63209 in `github.com/klauspost/compress`.
- **[network-policy-engine]** Fixed known vulnerabilities in the kube-router image.
  network-policy-engine pods will be restarted.
- **[node-local-dns]** Fixed DNS errors during node-local-dns pod restarts in clusters with Cilium.
- **[node-local-dns]** Fixed a known vulnerability in the node-local-dns CoreDNS image.
  node-local-dns pods will be restarted.
- **[node-local-dns]** Node-local-dns safe updater logic was updated to match the Kubernetes logic.
  Node-local-dns safe updater will be restarted.
- **[openvpn]** Fixed known vulnerabilities in the ovpn-admin and easyrsa-migrator images.
- **[registry]** In the `Proxy` mode, reuse upstream auth challenges and tokens instead of requesting them before every request to the upstream registry.

- **[registry]** Fix the registry static pod stuck in `ImagePullBackOff` after a registry image update on a single master in the `Proxy` and `Local` modes.
- **[registrypackages]** Nodes stop trusting `emSign ECC Root CA - G3` and Comodo `AAA Certificate Services`, the roots behind the compromised eMudhra intermediate CAs. TLS connections from nodes to hosts whose certificates chain to `emSign ECC Root CA - G3` or Comodo `AAA Certificate Services` (eMudhra / emSign issued) will fail. Reissue such certificates from another CA before the update.
- **[registrypackages]** Update containerdv2 patch
- **[service-with-healthchecks]** CVEs were fixed.
  The controller and agent pods will be restarted.
- **[user-authn]** dex-authenticator no longer writes the request headers, cookies included, to the log when the CSRF cookie is missing.
- **[user-authn]** A password reset of a local user keeps the replaced password in the password history, and the password change form refuses the current password in every case.
  After a reset, the previous password cannot be reused when passwordHistoryLimit is set; the current password cannot be set again through the change form, and a lowered passwordHistoryLimit applies at the next password change.

1.77.4

Know before update

- Cilium agent and operator pods will be restarted.
- CoreDNS pods will be restarted.
- NodeGroups that already have preemptible: true under the CAPI engine keep their current regular VMs until the next rollout (any rollout-triggering InstanceClass change or manual-rollout-id); after that rollout their nodes become preemptible VMs and are rotated every ~20h.
- Upgrade does not recreate any node. NodeGroups that already have preemptible: true under the CAPI engine keep their current regular VMs; Machines created after the upgrade (scale-up, replacement) are preemptible, so such NodeGroups run mixed VMs until a full rollout (any rollout-triggering InstanceClass change or the manual-rollout-id annotation). Preemptible VMs are rotated every ~20h.
- metallb pods will be restarted.
- node-local-dns pods will be restarted.

Features

- **[control-plane-manager]** The `etcd` dashboard is reworked to find the cause of slow `etcd` - disk, network, leader, `kube-apiserver` load or page cache.

Fixes

- **[chrony]** Bump golang.org/x/net in chrony_exporter to fix CVE-2026-78669.
- **[cilium-hubble]** Fixed known vulnerabilities in the Hubble relay and UI images.
- **[cloud-provider-aws]** Allow bootstrapping clusters in AWS regions unknown to the bundled terraform-provider-aws, such as `ap-southeast-6`.
- **[cloud-provider-dvp]** A DVP cluster migrated to the new provider configuration format keeps its `networkPolicy - None` instead of silently switching to `Isolated`.
- **[cloud-provider-dvp]** Clusters with `networkPolicy - None` in the provider configuration no longer get NetworkPolicies created for LoadBalancer Services.
- **[cloud-provider-yandex]** Preemptible nodes are created as preemptible VMs and rotated before the 24h limit when a NodeGroup is managed by the CAPI engine.
  Upgrade does not recreate any node. NodeGroups that already have preemptible: true under the CAPI engine keep their current regular VMs; Machines created after the upgrade (scale-up, replacement) are preemptible, so such NodeGroups run mixed VMs until a full rollout (any rollout-triggering InstanceClass change or the manual-rollout-id annotation). Preemptible VMs are rotated every ~20h.
- **[cloud-provider-yandex]** Preemptible nodes are created as preemptible VMs and rotated before the 24h limit when a NodeGroup is managed by the CAPI engine.
  NodeGroups that already have preemptible: true under the CAPI engine keep their current regular VMs until the next rollout (any rollout-triggering InstanceClass change or manual-rollout-id); after that rollout their nodes become preemptible VMs and are rotated every ~20h.
- **[cni-cilium]** Fixed known vulnerabilities in the Cilium images.
  Cilium agent and operator pods will be restarted.
- **[common]** Fixed known vulnerabilities in the CNI migration images.
- **[deckhouse]** Bump containerd to v2.2.10 and dependencies to fix CVEs
- **[dhctl]** Bump golang.org/x/net to fix CVE-2026-78669.
- **[docs]** Update terminology in the documentation and SEO improvements.
- **[documentation]** Update documentation building rules.
- **[istio]** Added VEX for CVE-2026-85747 in pilot and proxyv2 images.
- **[kube-dns]** Fixed known vulnerabilities in the CoreDNS and sts-pods-hosts-appender images.
  CoreDNS pods will be restarted.
- **[metallb]** Fixed known vulnerabilities in the MetalLB images.

metallb pods will be restarted.
- **[node-local-dns]** Fixed known vulnerabilities in the node-local-dns images.
  node-local-dns pods will be restarted.
- **[node-manager]** Updates otel, grpc and x/crypto dependencies of node-controller to fix CVEs.
- **[node-manager]** fixed private build
- **[node-manager]** Bump golang.org/x/net to fix CVE-2026-78669, CVE-2026-78663, CVE-2026-97032.
- **[registry]** Bump golang.org/x/net in nodeservices-manager to fix CVE-2026-78669.
- **[registry-packages-proxy]** Bump golang.org/x/net to fix CVE-2026-78669.
- **[registrypackages]** Fixed known vulnerabilities in the kubernetes-cni package.
- **[registrypackages]** Bump golang.org/x/net, golang.org/x/crypto and OpenTelemetry in rpp-get and the docker-registry auth_server to fix CVE-2026-78669, CVE-2026-56855, CVE-2026-81870.
- **[terraform-manager]** Bump golang.org/x/net in opentofu to fix CVE-2026-78669.
- **[vertical-pod-autoscaler]** The admission-controller webhook now serves HTTP/1.1 only and no longer exposes

1.77.3

Know before update

- Before, such an entry stopped the webhook from reloading the rules, so subjects of rules added later, and every subject after a restart of the webhook, were not limited to their namespaces. Subjects of a rule whose only entry is invalid now get no namespace through the entries of that rule.
- Bumping `deckhouse lib helm` from `1.72.11` to `1.72.24` also drops the `drbd.linbit.com` taint tolerations from `helm_lib_tolerations`, so pods rendered through it no longer tolerate `lost-quorum`, `force-io-error` and `ignore-fail-over`, and aligns the VPA `maxAllowed` memory to the recommender’s 64Mi quantum.
- Exec and attach requests in user namespaces reach Gatekeeper again, as in Deckhouse 1.73 and 1.74. Every constraint that matches them is evaluated again, including a constraint without `match.kinds` or with `kinds: ["*"]` whose policy does not check `input.review.operation`. Before updating, check that such constraints do not deny `kubectl exec` and `kubectl attach` for users who need them.
- In a cluster with the `proxy` parameter of `ClusterConfiguration` set, the `cert-manager` controller sends requests to the ACME server, HashiCorp Vault and the DNS provider APIs through the proxy server. The `HTTP-01` self-check also requests the domain through the proxy server. If the proxy server cannot reach the issuer or the public address of the cluster, add these addresses to `noProxy`.
- In single-replica installations a new controller pod reconciles projects only after the previous pod has stopped and released the lease. If the previous pod is lost without a shutdown, for example together with its node, the new pod starts reconciling projects 60 to about 78 seconds after it starts.
- Machines are not recreated on update. Machines created before the update keep the standard network type and no labels until the NodeGroup is rolled out (change a rolling InstanceClass field or set the `manual-rollout-id` annotation on the NodeGroup). Machines stuck in provisioning because of `additionalSubnets` become ready without recreation.
- Such identities can write ClusterAuthorizationRules, Users and Groups that carry `SuperAdmin` or `cluster-admin`. A ClusterAuthorizationRule gives this right only without `namespaceSelector` and `limitNamespaces` and, with multi-tenancy on, only with `allowAccessToSystemNamespaces: true`, even if it grants `cluster-admin`.
- The cloud MachineHealthCheck is updated in existing clusters. A node in Ready=False is replaced after 10 minutes instead of 5 (Ready=Unknown still after 5), and remediation stops while more than 50% of the cluster’s CAPI machines are unhealthy.
- The controller and agents will be restarted.
- The grant webhooks are now removed together with the module. On a cluster where `multitenancy-manager` is already disabled at the update, the `cluster-objects-grants-defaulting` and `cluster-objects-grants-validator` webhook configurations left by earlier versions stay, and writes to grantable resources in project namespaces (for example, removing a PVC finalizer) keep failing with `service "multitenancy-manager" not found`. Delete them by hand: `d8 k delete mutatingwebhookconfiguration cluster-objects-grants-defaulting` `d8 k delete validatingwebhookconfiguration cluster-objects-grants-validator` Nothing has to be done on clusters where the module is enabled.

Features

- **[admission-policy-engine]** Report the availability of the module components with alerts.
- **[cert-manager]** Add the `highAvailability` parameter to control the HA mode of the module independently of the global setting.
- **[cert-manager]** `cert-manager` uses the cluster-wide proxy server from the `proxy` parameter of `ClusterConfiguration`.
  In a cluster with the `proxy` parameter of `ClusterConfiguration` set, the `cert-manager` controller sends requests to the ACME server, HashiCorp Vault and the DNS provider APIs through the proxy server. The `HTTP-01` self-check also requests the domain through the proxy server. If

the proxy server cannot reach the issuer or the public address of the cluster, add these addresses to `noProxy`.
- **[cloud-provider-dvp]** Makes CCM create NPs on every lb creation while using networkPolicy - Restricted
- **[cni-cilium]** Added an alert and a release requirement that block the Cilium update while CiliumNetworkPolicy or CiliumClusterwideNetworkPolicy objects use the `fromRequires` or `toRequires` fields.
- **[deckhouse]** ModuleSource scans skip unchanged release channels using a cheap registry HEAD request instead of pulling the whole release image every cycle.
- **[deckhouse-controller]** Added the update settings of applications: the `spec.update` field of an Application and the global `applications.update` parameter. Deckhouse merges them with the update settings of the `deckhouse` module but doesn't apply them to application updates yet.
- **[docs]** Add user-authz module architecture section.
- **[docs]** Add service-with-healthchecks module architecture section.
- **[documentation]** The in-cluster documentation now includes the guides.
- **[documentation]** Documentation updates for DP CSE 1.77.
- **[multitenancy-manager]** A new alert warns about a user project template named `simple`, which the built-in template of the same name overwrites after the update.
- **[user-authz]** The new `D8UserAuthzLegacyRBACv2CapabilityBindingFound` alert lists the bindings to built-in capabilities that the next minor release renames without aliases, and names the new name of each capability.
- **[user-authz]** The new `D8UserAuthzLegacyRBACv2CustomCapabilityFound` alert lists custom capabilities that extend the namespace roles only through labels the next role scheme does not select.
- **[user-authz]** New `D8UserAuthzLimitNamespacesEntryNeedsRewrite` and `D8UserAuthzLimitNamespacesEntryInvalid` alerts report ClusterAuthorizationRule `limitNamespaces` entries that are anchored only in part or are not valid regular expressions.

Fixes

- **[admission-policy-engine]** Fixed Gatekeeper policies for `kubectl exec` and `kubectl attach` being skipped in user namespaces.
  Exec and attach requests in user namespaces reach Gatekeeper again, as in Deckhouse 1.73 and 1.74. Every constraint that matches them is evaluated again, including a constraint without `match.kinds` or with `kinds: ["*"]` whose policy does not check `input.review.operation`. Before updating, check that such constraints do not deny `kubectl exec` and `kubectl attach` for users who need them.
- **[admission-policy-engine]** Disabling the module deletes the webhook configurations before Gatekeeper, so the uninstall no longer blocks `exec` and the Deckhouse queue.
- **[admission-policy-engine]** Fixed CVE-2026-78659, CVE-2026-78660, CVE-2026-78663, CVE-2026-78669 and CVE-2026-97032 in `golang.org/x/net` and CVE-2026-56851 in `golang.org/x/text`.
- **[candi]** Restored the lost `kubelet-disable-k-panic-check` patch for k8s 1.35 and 1.36, so kubelet no longer enforces `kernel.panic=10` on these versions.
- **[candi]** New nodes reboot on the first bashible run again when a step requests it. Only the first master skips this reboot.
- **[cert-manager]** The webhook keeps serving requests during a rollout and during a rotation of its CA, and the controller waits for the API server at startup instead of restarting.
- **[cert-manager]** The `spec.certificateOwnerRef` field of a certificate no longer causes an endless Secret update loop when it differs from the global owner reference setting that `cleanupOrphanSecrets` enables in the `CertManager` HTTPS mode, and is applied to an already issued Secret.
- **[cert-manager]** Fixed CVE-2026-78659, CVE-2026-78660, CVE-2026-78663, CVE-2026-78669 and CVE-2026-97032 in `golang.org/x/net`.
- **[chrony]** Bump golang.org/x/crypto in chrony_exporter to fix CVE-2026-56855, CVE-2026-78662.
- **[cloud-provider-dvp]** The CSI driver reports a volume as detached from a node only after the disk is released by the node virtual machine, so with virtualization that keeps the VM listed on the disk until it is released, the volume is not attached to two nodes at once.
- **[cloud-provider-dvp]** The CSI driver reports the volume limit of a node, so the scheduler does not place more volumes on a node than its virtual machine can attach.
- **[cloud-provider-dvp]** Stop infinite check/converge loop caused by the DVP controller annotation on the cloud-init Secret.
- **[cloud-provider-vsphere]** Fixed master node creation when the datastore is set as a path with parent folders.
- **[cloud-provider-yandex]** Restored `additionalSubnets`, `networkType` and VM labels (`nodes.parameters.labels`, `additionalLabels`) for CAPI-managed Yandex nodes.
  Machines are not recreated on update. Machines created before the update keep the standard network type and no labels until the NodeGroup is rolled out (change a rolling InstanceClass field or set the `manual-rollout-id` annotation on the NodeGroup). Machines stuck in provisioning because of `additionalSubnets` become ready without recreation.
- **[cloud-provider-zvirt]** VMs are now actually removed from zVirt on NodeGroup scale-down and cluster destroy
- **[common]** Fixed a `kube-apiserver` panic on JSON Patch requests whose `add`/`replace` of the

whole document or `test` operation lacks the `value` field; such requests are now rejected with a validation error.
- **[common]** kube-apiserver returns a single short validation error for an invalid `fieldManager` instead of an error for every invalid character.
- **[common]** Fixed CVE-2026-78659, CVE-2026-78660, CVE-2026-78663, CVE-2026-78669 and CVE-2026-97032 in `golang.org/x/net` in kube-rbac-proxy.
- **[control-plane-manager]** Keep `resource.k8s.io/v1beta1` enabled in `kube-apiserver` 1.34.
- **[deckhouse]** Fixed CVEs in d8 CLI dependencies by updating d8 to v0.33.25.
- **[deckhouse]** Restore kubectl plugin lookup in d8 k and d8 kubectl
- **[deckhouse]** Update runtime libraries and VEX exceptions for known vulnerabilities
- **[deckhouse-controller]** Deleting an Application now also deletes objects with the `werf.io/ownership: anyone` or `werf.io/resource-policy` annotation, such as Jobs deployed only on install, if the package lists their kinds in `orphanResources`. Only `helm.sh/resource-policy: keep` protects an object.
- **[descheduler]** Fixed CVE-2026-81870 in descheduler by bumping OpenTelemetry Go modules to v1.45.0.
- **[dhctl]** Preserve existing SSH keys when switching to the temporary converge user.
- **[dhctl]** Destroy and abort of a static cluster now fail instead of reporting success when a control-plane node was not cleaned because of an SSH error or cleanup timeout.
- **[dhctl]** Bump golang.org/x/crypto and OpenTelemetry to fix CVE-2026-56855, CVE-2026-78662, CVE-2026-81870, CVE-2026-81871, CVE-2026-81872.
- **[docs]** Correct typo in managed-rabbit key in modules library.
- **[docs]** Improve documentation clarity and fix typos.
- **[docs]** Fixed tab switching on pages with several tab sets of the same name and opening hidden tabs by an anchor link.
- **[docs]** Enhance tab activation logic in the documentation.
- **[docs]** Enhance tab shortcode functionality.
- **[docs]** Remove raw tags from usage documentation.
- **[docs]** Show expand icon on non-collapsible top-level CRD parameters in the documentation.
- **[docs]** Added experimental module enable note to the lifecycle badge.
- **[docs]** Added registry module port 5001 to Deckhouse ports documentation
- **[docs]** Rendered all versions from oss.yaml versions array.
- **[docs]** Update hugo to 0.168.0 in docs-builder
- **[docs]** Page with DNS names full list was added in to reference.
- **[helm_lib]** Size the resources of a module whose `resourcesManagement` names a fractional quantity, instead of rendering a zero limit.
  Bumping `deckhouse_lib_helm` from `1.72.11` to `1.72.24` also drops the `drbd.linbit.com` taint tolerations from `helm_lib_tolerations`, so pods rendered through it no longer tolerate `lost-quorum`, `force-io-error` and `ignore-fail-over`, and aligns the VPA `maxAllowed` memory to the recommender’s 64Mi quantum.
- **[istio]** Fixed CVEs in istio, kiali and operator images (golang.org/x/net, golang.org/x/text).
- **[multitenancy-manager]** Disabling the module now removes the cluster-objects grant webhooks, which used to stay behind and block writes in project namespaces.
  The grant webhooks are now removed together with the module. On a cluster where `multitenancy-manager` is already disabled at the update, the `cluster-objects-grants-defaulting` and `cluster-objects-grants-validator` webhook configurations left by earlier versions stay, and writes to grantable resources in project namespaces (for example, removing a PVC finalizer) keep failing with `service "multitenancy-manager" not found`. Delete them by hand: `d8 k delete mutatingwebhookconfiguration cluster-objects-grants-defaulting` `d8 k delete validatingwebhookconfiguration cluster-objects-grants-validator` Nothing has to be done on clusters where the module is enabled.
- **[multitenancy-manager]** The controller takes its leader lease with any number of replicas, so a rollout of a single-replica installation no longer has two pods upgrading project Helm releases at once.
  In single-replica installations a new controller pod reconciles projects only after the previous pod has stopped and released the lease. If the previous pod is lost without a shutdown, for example together with its node, the new pod starts reconciling projects 60 to about 78 seconds after it starts.
- **[multitenancy-manager]** The Project conversions of the next release are registered in advance, so reads and writes of projects keep working while webhook-handler is updated in HA mode.
- **[multitenancy-manager]** Fixed CVE-2026-78659, CVE-2026-78660, CVE-2026-78663, CVE-2026-78669 and CVE-2026-97032 in `golang.org/x/net`.
- **[multitenancy-manager]** The webhooks no longer leave zombie processes in webhook-handler until it runs out of pids.
- **[node-manager]** Fixed cluster-autoscaler using node group names without the cluster prefix after a Deckhouse restart, which stopped autoscaling and triggered the `D8ClusterAutoscalerTooManyErrors` alert.
- **[node-manager]** Fixed cluster-autoscaler stopping autoscaling of all node groups and restarting every two hours when an MCM node group has `minPerZone` equal to `maxPerZone`.
- **[node-manager]** Fixed CVEs in cluster-autoscaler Go dependencies (OpenTelemetry, and grpc and x/crypto for Kubernetes 1.31).
- **[node-manager]** A StaticInstance whose StaticMachine was deleted is returned to Pending and

becomes available for bootstrapping again instead of staying out of the pool forever.
- **[node-manager]** Fixed cluster-autoscaler not scaling CAPI node groups up from zero for pods requesting ephemeral storage, and putting the whole scale-up of a multi-zone node group into a single zone.
- **[node-manager]** Bump golang.org/x/crypto and OpenTelemetry in bashible-apiserver and capi-controller-manager.
- **[node-manager]** Fixed the CAPI MachineHealthCheck replacing cloud nodes that take longer than 5 minutes to become Ready after registering, and limited remediation to when at most half of the CAPI machines are unhealthy.
  The cloud MachineHealthCheck is updated in existing clusters. A node in Ready=False is replaced after 10 minutes instead of 5 (Ready=Unknown still after 5), and remediation stops while more than 50% of the cluster's CAPI machines are unhealthy.
- **[node-manager]** Fixed node-manager failing to apply its values in the BE, SE, SE+, EE, FE and CSE editions when a CAPI node group has a known boot disk size.
- **[registry]** Build docker-auth from the new fork repository at flant-1.0.0, which fixes CVE-2026-81870.
- **[registrypackages]** Fixed CVEs in crictl 1.31.
- **[service-with-healthchecks]** Go deps are updated.
  The controller and agents will be restarted.
- **[terraform-manager]** Bump opentofu to 1.12.7 to fix CVE-2026-56855, CVE-2026-78662.
- **[tools]** Remove d8-gpu namespace from integrity check.
- **[user-authn]** The `idTokenTTL` description and the `D8UserAuthnIDTokenTTLTooLong` alert say that a value of 6 hours or more is replaced with `5h59m` by the next settings version, and what lowering it does to DexAuthenticator sessions and issued ID tokens.
- **[user-authn]** Restrict the Job that issues the `basic-auth-proxy` certificate to the read-only front-proxy CA files and cover it with a SecurityPolicyException.
- **[user-authn]** A DexClient or a DexAuthenticator in a namespace whose name YAML reads as a number or a boolean no longer breaks the user-authn release.
- **[user-authn]** A DexAuthenticator with a name longer than 45 characters no longer logs its users out on every run of the hook.
- **[user-authn]** The DexAuthenticator validating webhook no longer logs a jq error for an object without additionalApplications.
- **[user-authn]** Errors the webhook scripts of user-authn, user-authz and multitenancy-manager write to stderr are logged as warnings instead of info messages.
- **[user-authn]** Protected applications keep serving users during a short dex outage and during restarts.
- **[user-authn]** Fixed CVE-2026-78659, CVE-2026-78660, CVE-2026-78663, CVE-2026-78669 and CVE-2026-97032 in `golang.org/x/net`.
- **[user-authn]** The webhooks no longer leave zombie processes in webhook-handler until it runs out of pids.
- **[user-authz]** The authorization webhook no longer restarts while the API server is unreachable, which could deadlock the control plane on bootstrap or an API server restart with multitenancy enabled.
- **[user-authz]** a `kube-apiserver` health probes no longer fail when `authz-webhook` is unavailable.
- **[user-authz]** The identity-assign check treats an identity with every permission across the cluster, such as a subject of `cluster-admin` bound by a ClusterRoleBinding, as SuperAdmin. Such identities can write ClusterAuthorizationRules, Users and Groups that carry `SuperAdmin` or `cluster-admin`. A ClusterAuthorizationRule gives this right only without `namespaceSelector` and `limitNamespaces` and, with multi-tenancy on, only with `allowAccessToSystemNamespaces: true`, even if it grants `cluster-admin`.
- **[user-authz]** The RBACv2 roles d8:manage:* and d8:use:role:* keep the rights of the modules that have already switched to the capability labels of the next release while the upgrade to it is in progress.
- **[user-authz]** The authorization webhook keeps applying ClusterAuthorizationRules when a `limitNamespaces` entry is not a valid regular expression; the entry is left out, and its rule covers fewer namespaces.
  Before, such an entry stopped the webhook from reloading the rules, so subjects of rules added later, and every subject after a restart of the webhook, were not limited to their namespaces. Subjects of a rule whose only entry is invalid now get no namespace through the entries of that rule.
- **[user-authz]** The `D8UserAuthzLegacyRBACv2CustomRoleFound` alert lists every custom role that selects capabilities by the `rbac.deckhouse.io/kind: manage|use` label or by the aggregation label of a lineage the next role model does not collect, or that loses its RoleBindings in the namespaces of the modules, and the FAQ describes how to prepare such a role before the update without losing access.
- **[user-authz]** An AuthorizationRule in a namespace whose name YAML reads as a number, a boolean or null no longer breaks the module's bindings.
- **[user-authz]** Managers who assign roles by range can again change DexProviders, UserOperations, Users and Groups of identities that hold a ClusterAuthorizationRule.
- **[user-authz]** The authorization webhook answers the requests in flight when it restarts instead of denying them.

- **[user-authz]** Fixed CVE-2026-78659, CVE-2026-78660, CVE-2026-78663, CVE-2026-78669 and CVE-2026-97032 in `golang.org/x/net` and CVE-2026-56851 in `golang.org/x/text`.
- **[user-authz]** The webhooks no longer leave zombie processes in webhook-handler until it runs out of pids.

1.77.2

Know before update

- A StaticInstance whose connectivity check fails now keeps its reservation for the whole bootstrap window instead of returning to the pool on every failed attempt, and the bootstrap (20 min) and cleanup (10 min) timeouts, which previously never fired, are now reachable. If nothing ever ran on the host, the bootstrap timeout returns the instance to the pool after 20 minutes as before. If the host was already bootstrapped in part, the instance returns only through MachineHealthCheck remediation (nodeStartupTimeoutSeconds: 1200) plus the cleanup timeout, so it becomes available again roughly 20 + 10 minutes after the failure, and remediation reboots the host as part of the cleanup.
- A cluster still on 1.76 whose user-authn ModuleConfig sets idTokenTTL to 6h or more updates to this release without Deckhouse crash-looping, and stays on it until idTokenTTL is lowered below 6h. A cluster already crash-looping on 1.77.0 or 1.77.1 does not recover by itself, since the release controller runs in the pod that is down; set failurePolicy Ignore on the module-configs.deckhouse-webhook.deckhouse.io webhook of the deckhouse-webhook ValidatingWebhookConfiguration, lower idTokenTTL below 6h, and restart the deckhouse pod.
- Clusters bootstrapped before v1.55 were switched to the `Baseline` default PSS policy in 1.77, which denies privileged workloads in user namespaces. After the update, the default policy on these clusters becomes less strict: it is switched back to `Privileged`, and privileged pods in user namespaces pass admission again. To keep the `Baseline` policy, set `settings.podSecurityStandards.defaultPolicy: Baseline` explicitly in the `admission-policy-engine` ModuleConfig.
- Clusters whose `d8-system/install-data` ConfigMap holds an empty or invalid version and whose `podSecurityStandards.defaultPolicy` isn’t set were switched to the `Baseline` default PSS policy in 1.77. After the update, the default policy on these clusters becomes less strict: it is switched back to `Privileged`. To keep the `Baseline` policy, set `settings.podSecurityStandards.defaultPolicy: Baseline` explicitly in the `admission-policy-engine` ModuleConfig.
- Deckhouse 1.78 makes `Baseline` the default PSS policy for all clusters. On clusters bootstrapped with a Deckhouse version lower than v1.55 or with an unknown bootstrap version, the `PodSecurityStandardsDefaultPolicyNotSet` alert fires, and the update to 1.78 is blocked until `settings.podSecurityStandards.defaultPolicy` is set explicitly in the `admission-policy-engine` ModuleConfig. To keep the current behavior, set `defaultPolicy: Privileged`. To switch to `Baseline` or `Restricted`, make sure that the workloads in non-system namespaces comply with the chosen policy first.
- In Deckhouse CSE, a DexProvider that already has `enableBasicAuth: true` keeps it after the update, and any change to its `oidc` or `ldap` section is rejected until `enableBasicAuth` is set to `false`. The same holds for an LDAP provider that combines `insecureNoSSL` with `startTLS`, `insecureSkipVerify` or `rootCAData`. Set `enableBasicAuth: false` and resolve the LDAP TLS settings on such providers.
- The `d8-kube-proxy` pods will be restarted on all nodes.
- Two Go hooks registered in one file shared a derived name, so the Kubernetes-binding half lost its bindings and the `d8_cluster_objects_grant_violated` series was recomputed only by the periodic scan. The series itself was never missing; it could lag a policy change by up to two minutes.
- dhctl converge no longer deadlocks on master replacement or externalIPAddresses removal in Yandex Cloud; the terraform-manager provider release is patched to detach one-to-one NAT before deleting a reserved address.

Features

- **[admission-policy-engine]** Added the `PodSecurityStandardsDefaultPolicyNotSet` alert that fires when the `install-data` ConfigMap is missing and the default PSS policy must be set explicitly in the ModuleConfig.
- **[admission-policy-engine]** The `PodSecurityStandardsDefaultPolicyNotSet` alert now fires when `podSecurityStandards.defaultPolicy` isn’t set and the `Privileged` policy is derived from the bootstrap version. The update to Deckhouse 1.78 is blocked until the policy is set explicitly.
  Deckhouse 1.78 makes `Baseline` the default PSS policy for all clusters. On clusters bootstrapped with a Deckhouse version lower than v1.55 or with an unknown bootstrap version, the `PodSecurityStandardsDefaultPolicyNotSet` alert fires, and the update to 1.78 is blocked until `settings.podSecurityStandards.defaultPolicy` is set explicitly in the `admission-policy-engine` ModuleConfig. To keep the current behavior, set `defaultPolicy: Privileged`. To switch to `Baseline` or `Restricted`, make sure that the workloads in non-system namespaces comply with the chosen policy first.
- **[deckhouse-controller]** Add the `x-deckhouse-immutable`, `x-deckhouse-ui-group`, and `x-`

`deckhouse-enum-switch-settings` extensions to Application package settings schemas; the Application webhook rejects changes to `x-deckhouse-immutable` fields after the settings were applied.
- **[deckhouse-controller]** When an Application is deleted, Deckhouse also deletes the objects of the kinds listed in the package's `orphanResources` value that the application left in its namespace.
- **[docs]** Add user-authn-controller, user-api and basic-auth-proxy components to user-authn module architecture section.
- **[docs]** Rename DKP->DP and replace PNG->SVG architecture section
- **[docs]** Fix links to architecture diagrams
- **[docs]** Add alb module architecture section.
- **[docs]** Add managed services modules architecture documentation section.
- **[docs]** Add sdn module architecture section.

Fixes

- **[admission-policy-engine]** Restored the `Privileged` default PSS policy for clusters bootstrapped before v1.55 (without the `install-data` ConfigMap).
  Clusters bootstrapped before v1.55 were switched to the `Baseline` default PSS policy in 1.77, which denies privileged workloads in user namespaces. After the update, the default policy on these clusters becomes less strict: it is switched back to `Privileged`, and privileged pods in user namespaces pass admission again. To keep the `Baseline` policy, set `settings.podSecurityStandards.defaultPolicy: Baseline` explicitly in the `admission-policy-engine` ModuleConfig.
- **[admission-policy-engine]** Fixed CVEs in the `gatekeeper` and `ratify` images.
- **[admission-policy-engine]** Fixed the default Pod Security Standards (PSS) policy being switched to `Baseline` without notice when the bootstrap version in the `d8-system/install-data` ConfigMap is empty or invalid. Such clusters now get the `Privileged` policy.
  Clusters whose `d8-system/install-data` ConfigMap holds an empty or invalid version and whose `podSecurityStandards.defaultPolicy` isn't set were switched to the `Baseline` default PSS policy in 1.77. After the update, the default policy on these clusters becomes less strict: it is switched back to `Privileged`. To keep the `Baseline` policy, set `settings.podSecurityStandards.defaultPolicy: Baseline` explicitly in the `admission-policy-engine` ModuleConfig.
- **[candi]** remove d8-bcheck in cleanup_static_node
- **[candi]** containerd integrity errors are written to `/var/log/containerd/containerd-integrity.log` on RED OS 8.
- **[cert-manager]** Fixed CVEs in the cert-manager images.
- **[cert-manager]** Gateway API integration is now enabled automatically when the Gateway and HTTPRoute CRDs are installed.
- **[chrony]** Bump golang.org/x/crypto to v0.55.0 in chrony_exporter to fix CVE-2026-56854.
- **[ci]** update werf to v2.74.2-dk.1
- **[ci]** Add allowed alerts for D8Monitoring for e2e which uses 1.77+
- **[ci]** The documentation changes validation resolves symlinked related language files.
- **[ci]** Fix changelog-generator image tag in changelog-update job to use the shared CI_IMAGES_TAG
- **[ci]** add skip docs validation label
- **[cloud-provider-dvp]** Fixed the `D8CloudProviderDVPMigrationPending` alert that kept firing after the migration resources were applied.
- **[cloud-provider-dvp]** Fixes CVE vulnerabilities in cloud-provider-dvp images.
- **[cloud-provider-dvp]** Fixes cluster bootstrap getting stuck when `capdvp-controller-manager` and the validation webhook cannot reach the API server and DNS before the CNI is ready.
- **[cloud-provider-openstack]** Fixes cluster bootstrap getting stuck when `capo-controller-manager` cannot reach the API server and DNS before the CNI is ready.
- **[cloud-provider-vcd]** Batch VM cache refresh on cache miss
- **[cloud-provider-vcd]** Fixes cluster bootstrap getting stuck when `capcd-controller-manager` cannot reach the API server and DNS before the CNI is ready.
- **[cloud-provider-yandex]** fix "Address in use" failures when replacing nodes and when removing external IP addresses
  dhctl converge no longer deadlocks on master replacement or externalIPAddresses removal in Yandex Cloud; the terraform-manager provider release is patched to detach one-to-one NAT before deleting a reserved address.
- **[common]** Fix kubelet podSandbox order
- **[common]** fixed private build cni-migration-*
- **[common]** Fix CVEs in the `kube-rbac-proxy` image.
- **[common]** Fixed known vulnerabilities in the CoreDNS image used by the node-local-dns module.
- **[control-plane-manager]** A new etcd `maxDbSize` is applied without a `deckhouse` restart.
- **[control-plane-manager]** Fix kubectl exec through Kubernetes API published with Gateway API.
- **[deckhouse]** set releaseChannel in CSE
- **[deckhouse]** Fix setting Scaled before Installed.
- **[deckhouse]** Remove leftover symlink-backend entries when deploying packages with the erofs backend.
- **[deckhouse]** Fix random startup failures with 'waitid - no child processes' when restoring erofs modules.

- **[deckhouse]** Fix CVEs in deckhouse-cli.
- **[dhctl]** Restoring of handling api_server_url and api_server_token in dhctl
- **[dhctl]** Bump google.golang.org/grpc to v1.83.2 to fix CVE-2026-84304 and CVE-2026-84445.
- **[dhctl]** Fixed terraform-auto-converger, terraform-state-exporter and `dhctl converge` failing on cloud clusters whose `cloud-provider-<name>` ModuleConfig has no `spec.enabled` field. dhctl now treats `spec.enabled` as optional and a ModuleConfig without it as disabled.
- **[dhctl]** Fixed the terraform-auto-converger init container failing on clusters already migrated to OpenTofu - the migration check now skips planning when no Terraform state is stored in the cluster.
- **[docs]** Fixed FAQ section for ansible inventory.
- **[docs]** Register the ports of csi-hitachi and csi-mind-ustor, list the registry storage ports, and drop storage ports that are no longer bound in the host network from the ports reference.
- **[docs]** Fix search hanging when IndexedDB upgrade is blocked.
- **[docs]** Removed mentions of Cilium from the inter-cluster cooperation documentation page.
- **[istio]** Fixed the istio module getting stuck when switching `globalVersion` from 1.21 while proxies are still connected to the 1.21 control plane.
- **[istio]** Fix leaking istiod control plane after removing an Istio version or disabling the module.
- **[istio]** Switching back to Istio 1.21 no longer removes the `networking.istio.io/v1` API from the Istio CRDs and no longer breaks the istio release.
- **[istio]** Deckhouse update requirements now take into account Istio control planes that are still being removed.
- **[istio]** The Istio operator now recovers Helm releases stuck in the `pending-*` or `uninstalling` state.
- **[kube-dns]** Set resource limits for the `render-etc-hosts-with-cluster-domain-aliases` init container so that pods can be created in namespaces with a ResourceQuota on `limits.cpu/limits.memory`.
- **[kube-proxy]** Fixed kube-proxy failing to start on Kubernetes 1.36 and higher because of the removed `TopologyAwareHints` feature gate.
  The `d8-kube-proxy` pods will be restarted on all nodes.
- **[metallb]** Fixed creation of `BGPPeer` objects on Kubernetes 1.36+, which blocked BGP sessions and LoadBalancer IP announcements in BGP mode.
- **[multitenancy-manager]** The grant-violation hook re-evaluates policies on change again, not only on its two-minute schedule.
  Two Go hooks registered in one file shared a derived name, so the Kubernetes-binding half lost its bindings and the `d8_cluster_objects_grant_violated` series was recomputed only by the periodic scan. The series itself was never missing; it could lag a policy change by up to two minutes.
- **[multitenancy-manager]** Fixed vulnerabilities in the `multitenancy-manager` image.
- **[node-manager]** Increase the capi-controller-manager VPA maximum memory recommendation to prevent health-check failures and restarts under memory pressure.
- **[node-manager]** Stop caps-controller-manager from rewriting StaticInstance objects in a hot loop when a connectivity check fails, which caused a sustained load on etcd.
  A StaticInstance whose connectivity check fails now keeps its reservation for the whole bootstrap window instead of returning to the pool on every failed attempt, and the bootstrap (20 min) and cleanup (10 min) timeouts, which previously never fired, are now reachable. If nothing ever ran on the host, the bootstrap timeout returns the instance to the pool after 20 minutes as before. If the host was already bootstrapped in part, the instance returns only through MachineHealthCheck remediation (nodeStartupTimeoutSeconds: 1200) plus the cleanup timeout, so it becomes available again roughly 20 + 10 minutes after the failure, and remediation reboots the host as part of the cleanup.
- **[node-manager]** Fix duplicate NVIDIA GPU dashboards when the gpu module is enabled.
- **[node-manager]** Bump google.golang.org/grpc to v1.83.2 in bashible-apiserver to fix CVE-2026-84304 and CVE-2026-84445.
- **[node-manager]** Bump golang.org/x/crypto to v0.55.0 and google.golang.org/grpc to v1.83.2 in capi-controller-manager to fix CVE-2026-56854, CVE-2026-84304 and CVE-2026-84445.
- **[node-manager]** Fixes CVE vulnerabilities in caps-controller-manager.
- **[node-manager]** Hooks no longer fail the module run when a NodeGroup, Node or NodeUser is deleted between the snapshot and the patch. Such failures delayed the readiness of the `deckhouse` pod in clusters that delete NodeGroups often.
- **[registry]** Bump dependencies in registry.
- **[registry]** Bump golang.org/x/crypto in nodeservices-manager to fix CVE-2026-56854, add VEX statements for x/crypto/ssh findings.
- **[registrypackages]** Bumped `containerd` to 1.7.36 / 2.2.9 and OpenTelemetry to 1.45.0 in `containerd` and `crictl` to fix CVEs.
- **[service-with-healthchecks]** Fixed metrics endpoints being reachable without going through kube-rbac-proxy authorization.
- **[terraform-manager]** Bump google.golang.org/grpc to v1.82.2 in opentofu to fix CVE-2026-84445. CVE-2026-84304 is not exploitable in opentofu and is covered by VEX.
- **[terraform-manager]** Fixed the `to-tofu-migrator` init container of `terraform-auto-converger` failing to resolve the provider bundle digest, which kept auto-converge from starting.
- **[user-authn]** An idTokenTTL of 6h or more no longer stops Deckhouse from starting; it raises the D8UserAuthnIDTokenTTLTooLong alert and blocks the update to the next minor release until it is

lowered.
A cluster still on 1.76 whose user-authn ModuleConfig sets idTokenTTL to 6h or more updates to this release without Deckhouse crash-looping, and stays on it until idTokenTTL is lowered below 6h. A cluster already crash-looping on 1.77.0 or 1.77.1 does not recover by itself, since the release controller runs in the pod that is down; set failurePolicy Ignore on the module-configs.deckhouse-webhook.deckhouse.io webhook of the deckhouse-webhook ValidatingWebhookConfiguration, lower idTokenTTL below 6h, and restart the deckhouse pod.
- **[user-authn]** Fixed CVEs in the module images.
- **[user-authn]** In Deckhouse CSE, a DexProvider with `enableBasicAuth` is rejected, since the edition does not ship the basic authentication proxy; the CSE copy of the CRD also gets the LDAP TLS checks of the module.
  In Deckhouse CSE, a DexProvider that already has `enableBasicAuth: true` keeps it after the update, and any change to its `oidc` or `ldap` section is rejected until `enableBasicAuth` is set to `false`. The same holds for an LDAP provider that combines `insecureNoSSL` with `startTLS`, `insecureSkipVerify` or `rootCAData`. Set `enableBasicAuth: false` and resolve the LDAP TLS settings on such providers.
- **[user-authz]** Fixed CVEs in the `permission-browser-apiserver` image.
- **[user-authz]** The authorization webhook answers 500 and logs the real error instead of terminating when it cannot marshal a response.

1.77.1

Know before update

- A Deckhouse release suspended on its release channel is no longer applied by clusters that are behind and reach it through a step-by-step update. The suspend flag lives only in the release-channel image; previously it was dropped when the target release was built from its per-version image, so lagging clusters updated to a suspended release anyway.
- After the update, the controller adds the annotations and labels of every ServiceWithHealthchecks to the Service created for it. If a ServiceWithHealthchecks of the `LoadBalancer` type carries annotations that configure the load balancer (`network.deckhouse.io/load-balancer-ips`, `network.deckhouse.io/load-balancer-shared-ip-key` and similar), the load balancer controller applies them and may assign a different address to the service, which causes a short interruption of the connections.
- CAPI NodeGroups whose MachineDeployment was stuck on an old MachineTemplate are rolled to the current InstanceClass after the update, within maxSurgePerZone/maxUnavailablePerZone. Groups already on the current template are not touched.
- D8UserAuthzRenderSlow requires at least three renders averaging above 30 seconds over 30 minutes, D8UserAuthzReleaseSlow at least two releases averaging above 5 minutes over one hour, and both must hold for 15 minutes. Severities are one step lower (6 and 7). Their descriptions now point at CPU shortage on the node rather than at the number of ClusterAuthorizationRules, which does not affect render time.
- During the first `user-authz` release after the update the per-role bindings are protected from the release engine, the aggregated ones are created, and the per-role bindings are deleted right after the release. Permissions granted through annotated ClusterRoles stay in place throughout. The `user-authz.deckhouse.io/access-level` label is now set automatically on annotated ClusterRoles. In audit logs, access granted through annotated ClusterRoles is attributed to `user-authz:<level>:custom` instead of the individual ClusterRole.
- Endpoints for pods in a terminal phase (Failed/Succeeded) are no longer published. In DVP clusters this prevents traffic from being routed to a VirtualMachine IP that has been reused by another pod. Pods being deleted are now published with the serving and terminating conditions, which enables the graceful shutdown flow for consumers. Pod readiness is derived from the PodReady condition, and stale probe results are reset when a pod becomes not ready, is recreated, or changes its IP.
- The `descheduler` Deployment in `d8-descheduler` restarts once on upgrade to pick up the new argument. Descheduling behavior is unchanged for workloads that do not implement their own eviction policy.
- The `service-with-healthchecks` controller and agent are restarted. A `ServiceWithHealthchecks` that was left in `NotAllEndpointsAreReady` with no EndpointSlice recovers automatically once the updated agent starts, no manual action is needed.
- The installer, the deckhouse ServiceAccount, holders of the cluster administrator kubeconfig and the kube-system / d8-system ServiceAccounts can create a User or a Group named by an existing authorization rule without the acknowledgement annotation. Every other requester is checked as before.

Features

- **[candi]** Base images updated to v3
- **[descheduler]** Always run the descheduler with the upstream `EvictionsInBackground` feature gate enabled.
  The `descheduler` Deployment in `d8-descheduler` restarts once on upgrade to pick up the new argument. Descheduling behavior is unchanged for workloads that do not implement their own eviction policy.
- **[docs]** Add managed-valkey module architecture section.

- **[docs]** Refactor build pipeline and add CSE edition support.
- **[docs]** Update virtualization module architecture section according to release v1.10.0
- **[docs]** Add monitoring-kubernetes module architecture section.
- **[docs]** Add documentation for Managed PostgreSQL service.
- **[docs]** Add extended-monitoring module architecture section.
- **[docs]** Add registry-packages-proxy module architecture section.
- **[docs]** Expand the documentation for virtualization.
- **[docs]** Add istio module architecture section.
- **[registry]** Migration part of new registry implementation.
- **[user-authn]** Update the Dex authentication page to the new Deckhouse branding, with light and dark themes selected by the user's system settings.

Fixes

- **[candi]** Fix hanging sysctl tuner on nodes with many loop and dm devices
- **[candi]** containerd v2 no longer starts without the `erofs` snapshotter, and loads the `erofs` module before start.
- **[cert-manager]** Restore the `cert-manager` and `cainjector` permissions that were lost against the upstream chart, including access to `ListenerSet` resources.
- **[chrony]** Fixed the unit-detection condition in the `disable-ntp-on-node.sh` node step.
- **[cloud-provider-aws]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-aws]** Fixed CVEs in the cloud-provider-aws module.
- **[cloud-provider-azure]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-azure]** Fix multimaster bootstrap by falling back to the `d8-masters-kubernetes-data-device-path` Secret when the master data device LUN is not provided via cloud-init.
- **[cloud-provider-dvp]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-dvp]** Fixed CVEs in the cloud-provider-dvp module.
- **[cloud-provider-gcp]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-gcp]** Fixed CVEs in the cloud-provider-gcp module.
- **[cloud-provider-huaweicloud]** Fixed CVEs in the cloud-provider-huaweicloud module.
- **[cloud-provider-openstack]** Fixed CVEs in the cloud-provider-openstack module.
- **[cloud-provider-yandex]** Fixed CVEs in the cloud-provider-yandex module.
- **[cloud-provider-zvirt]** Resize the boot disk of a recreated VM, let a replaced VM actually power off, and recreate the VM when customNetworkConfig changes.
- **[deckhouse]** Exclude all Python test files from webhook image.
- **[deckhouse]** Keep `x-kubernetes-sensitive-data` on CRDs that have a conversion webhook.
- **[deckhouse]** Allow editing and deleting the resources of an application under maintenance.
- **[deckhouse-controller]** Honor a channel-level release suspend for clusters that reach the suspended version through a step-by-step update.
  A Deckhouse release suspended on its release channel is no longer applied by clusters that are behind and reach it through a step-by-step update. The suspend flag lives only in the release-channel image; previously it was dropped when the target release was built from its per-version image, so lagging clusters updated to a suspended release anyway.
- **[deckhouse-controller]** Stop the module source registry fan-out from replaying and flooding the main queue with duplicate moduleRun tasks.
- **[deckhouse-controller]** Do not commit the package repository registry checksum when no application could be annotated, which left them all on stale registry settings.
- **[docs]** Fix broken JUnit XML report links on the Kubernetes conformance page.
- **[docs]** Clarify global storageClass behavior for Prometheus
- **[docs]** Fix alert rendering in OpenAPI specs.
- **[istio]** Waypoints are no longer advertised as cross-network east-west gateways.
- **[istio]** Enable Istio Gateway API deployment and gatewayclass controllers for istiod 1.27 and 1.29.
- **[istio]** Document that ambient-mode workloads cannot take part in federation or multicluster.
- **[istio]** Fix istiod RBAC rules that drifted away from upstream.
- **[multitenancy-manager]** Refresh grant webhook CA bundles after the admission certificate is rotated.
- **[node-manager]** node-controller reads the CAPI instance-class checksum from a helm-rendered ConfigMap instead of a possibly stale MachineTemplate, so MachineDeployments follow InstanceClass changes and their bootstrap Secrets keep a valid token.
  CAPI NodeGroups whose MachineDeployment was stuck on an old MachineTemplate are rolled to the current InstanceClass after the update, within maxSurgePerZone/maxUnavailablePerZone. Groups already on the current template are not touched.
- **[node-manager]** node-controller no longer removes taints set by other components on the first reconcile of Static and CloudPermanent nodes.
- **[registry]** Fix the order in which the Unmanaged params are stored for the fallback to the Legacy mode.
- **[registry]** Fix the security context in the registry module for CSE.
- **[registry-packages-proxy]** Bump golang.org/x/{crypto,net,sys,text} to clear 24 CVEs, including CVE-2026-56854 (CRITICAL) and CVE-2026-25681, CVE-2026-39821, CVE-2026-46600 (HIGH).
- **[registrypackages]** Fix dm-verity devices that could never be closed for containerd 2.2.7 (CSE only).
- **[registrypackages]** Bumped containerd to 1.7.35/2.2.8; bumped grpc, x/crypto, and websocket

in containerd, crictl, and Kubernetes 1.32–1.36 gomod patches.
- **[registrypackages]** Fsync the EROFS layer blob in `containerd` before committing snapshot metadata, so an unclean shutdown can no longer leave an unmountable image layer.
- **[service-with-healthchecks]** Annotations and labels of a ServiceWithHealthchecks are now copied to the Service created for it.
  After the update, the controller adds the annotations and labels of every ServiceWithHealthchecks to the Service created for it. If a ServiceWithHealthchecks of the `LoadBalancer` type carries annotations that configure the load balancer (`network.deckhouse.io/load-balancer-ips`, `network.deckhouse.io/load-balancer-shared-ip-key` and similar), the load balancer controller applies them and may assign a different address to the service, which causes a short interruption of the connections.
- **[service-with-healthchecks]** Stopped publishing terminated pods in EndpointSlices and started publishing pods being deleted as terminating endpoints.
  Endpoints for pods in a terminal phase (Failed/Succeeded) are no longer published. In DVP clusters this prevents traffic from being routed to a VirtualMachine IP that has been reused by another pod. Pods being deleted are now published with the serving and terminating conditions, which enables the graceful shutdown flow for consumers. Pod readiness is derived from the PodReady condition, and stale probe results are reset when a pod becomes not ready, is recreated, or changes its IP.
- **[service-with-healthchecks]** Fixed a load balancer losing all its endpoints for good after a target pod was replaced.
  The `service-with-healthchecks` controller and agent are restarted. A `ServiceWithHealthchecks` that was left in `NotAllEndpointsAreReady` with no EndpointSlice recovers automatically once the updated agent starts, no manual action is needed.
- **[tools]** Bump d8-cli to v0.33.17 - `d8 mirror push` restores the release channel tags of the installer image, so `docker run <repo>/install:<channel>` works against a mirrored registry
- **[tools]** Bump d8-cli to v0.33.19 - closes the CVE findings in the bundled d8 binary (grpc 1.83.2 and x/image 0.45.0) and adds resume of interrupted d8 data and snapshot transfers
- **[user-authz]** The identity collision check no longer applies to the platform's own identities, so a retried bootstrap creates the initial User again instead of timing out.
  The installer, the deckhouse ServiceAccount, holders of the cluster administrator kubeconfig and the kube-system / d8-system ServiceAccounts can create a User or a Group named by an existing authorization rule without the acknowledgement annotation. Every other requester is checked as before.
- **[user-authz]** Grant custom ClusterRoles (annotated with `user-authz.deckhouse.io/access-level`) through one aggregated ClusterRole per access level, so the number of bindings per ClusterAuthorizationRule/AuthorizationRule no longer depends on the number of such roles. During the first `user-authz` release after the update the per-role bindings are protected from the release engine, the aggregated ones are created, and the per-role bindings are deleted right after the release. Permissions granted through annotated ClusterRoles stay in place throughout. The `user-authz.deckhouse.io/access-level` label is now set automatically on annotated ClusterRoles. In audit logs, access granted through annotated ClusterRoles is attributed to `user-authz:<level>:custom` instead of the individual ClusterRole.
- **[user-authz]** Group the module alerts under a group named apart from the alerts themselves, so the incident shelf accepts them.
- **[user-authz]** The D8UserAuthzRenderSlow and D8UserAuthzReleaseSlow alerts no longer fire on a single slow render or release, such as a cluster bootstrap under CPU pressure or the one-time migration pass.
  D8UserAuthzRenderSlow requires at least three renders averaging above 30 seconds over 30 minutes, D8UserAuthzReleaseSlow at least two releases averaging above 5 minutes over one hour, and both must hold for 15 minutes. Severities are one step lower (6 and 7). Their descriptions now point at CPU shortage on the node rather than at the number of ClusterAuthorizationRules, which does not affect render time.

Version 1.76

Important

- The fencing-agent component of the `node-manager` module now uses a gossip-based protocol (memberlist library) for distributed node health monitoring. This reduces the risk of false worker node reboots when the control plane is unavailable or the API server is under heavy load.

- Fixed an issue where `cluster-autoscaler` could get stuck after a failed machine creation in the cloud (for errors other than `ResourceExhausted`). The cluster now automatically recovers its ability to scale after temporary cloud provider failures.

Deckhouse subsystem

- Added support for deploying a DP cluster using the `Proxy` mode for accessing the container registry.

- `Kubectl` on cluster nodes has been replaced with the `d8 k` alias (Deckhouse CLI utility).

- Changes in `dhctl` (CLI installer):
  - Added support for running `dhctl` as a standalone binary without downloading the full image with all dependencies. Required components are pulled from the registry during execution, reducing startup time.
  - Added validation of public SSH keys. Invalid keys are now detected earlier, before they can cause connection issues.
  - Improved handling of TLS certificates for registries. The system certificate pool is now used together with a custom CA.
  - Added validation of InstanceClass against the selected cloud provider before installation, allowing early detection and installation abort in case of misconfiguration.
  - Fixed namespace configuration during bootstrap. `Dhctl` now updates settings even if the namespace already exists.
- Improved multi-master resiliency. Kubernetes versions are now correctly detected even when some master nodes are unavailable. Kube-apiserver no longer routes requests to etcd nodes in the learner state.

Kubernetes & Scheduling subsystem

- The `d8-cluster-kubernetes` ConfigMap now includes supported Kubernetes versions (`supportedVersions`), versions available for upgrade and downgrade (`availableVersions`), the current automatic version (`automaticVersion`).
- Changes in the `descheduler` module:
  - Upgraded to version 0.35.1. Added namespace filtering via label selectors and other improvements (see the module changelog for details).
  - Added the `deschedulingInterval` parameter to control how often descheduling runs: `Frequent`, `Moderate`, or `Rare`.
  - Added the `RemovePodsHavingTooManyRestarts` strategy, which evicts pods exceeding a restart threshold, freeing node resources from pods in `CrashLoopBackOff` state.
  - The module now automatically uses the Kubernetes Metrics API when the `metrics.k8s.io` API group is available in the cluster. This provides real resource consumption data for strategies to use.
- The `vertical-pod-autoscaler` module updated to version 1.6.0. Key changes:
  - The `InPlaceOrRecreate` mode is now used by default. In this mode, VPA attempts to adjust pod requests and limits without recreating pods (in-place updates).
  - Reduced likelihood of pod restarts when in-place updates are not possible (via the `--in-place-skip-disruption-budget` flag), also `minReplicas` value is no longer considered for in-place updates.
- VPA memory recommendations are now rounded to 64 MiB, improving readability and reducing unnecessary pod restarts caused by minor recommendation fluctuations.
- For Kubernetes 1.34 and later, the `DRAExtendedResource` feature gate is enabled by default.
- Added the `D8EtcdHighRequestsLatency` alert to detect high etcd request latency, which can lead to API server timeouts. A corresponding metric has been added to the “Control Plane Status” dashboard.

IAM subsystem

- Changes in the `user-authn` module:
  - Disabled the insecure OAuth 2.0 Implicit Flow. In that flow, access tokens are passed in URL fragments, posing leakage risks (for example, via the `Referer` header, browser history, or logs). Any integrations using the Authorization Code Flow are unaffected.
  - Added SAML 2.0 support via the DexProvider resource. DP clusters can now be connected to such identity providers as AD FS, Okta, Keycloak, OneLogin, and Shibboleth.
  - Added refresh token support for SAML in Dex. This allows DexAuthenticator и kubeconfig-generator to refresh tokens without a manual user login.
  - Added Single Logout (SLO) support. The identity provider can end user sessions via

`/saml/slo/{connector}`.

- Fixed stale cache issue on the login page by adding a Dex build-based `cache` parameter to the CSS URL.

- In multitenancy mode, users without permissions defined via ClusterAuthorizationRule no longer see all namespaces in the Deckhouse web UI. The default behavior is now deny-by-default: users get an empty namespace list unless access is explicitly granted. This does not affect privileged groups (`system:masters`, `kubeadm:cluster-admins`). Documentation of the `user-authz` module now includes an example for granting access to all namespaces.
- Added support for the `service-with-health-checks` module in isolated projects. A NetworkPolicy exception for the `d8-service-with-healthchecks` namespace has been added to the project template, which allows module agents to verify service availability and correctly operate under conditions of network isolation.

Security subsystem

- Gatekeeper upgraded to 3.22.0 and Ratify to 1.4.0. Key changes include a unified CEL and Rego policy behavior, added namespace context support in policies, and a CLI tool for policy benchmarking.
- The `denyVulnerableImages` setting has been moved from `admission-policy-engine` to `operator-trivy`, making it the single owner of this logic.
- The `cert-manager` module upgraded to 1.20.0. Key changes include added support for Azure DNS Private Zones in the DNS01 challenge, added annotation `acme.cert-manager.io/http01-ingress-ingressclassname` for redefining IngressClasses in HTTP-01 solvers, and security fixes.
- Updated vulnerable Go dependencies in `multitenancy-manager` (`go-jose`, `golang.org/x/crypto`, `grpc`, etc.).

Cluster & Infrastructure subsystem

- Changes in the `node-manager` module:
  - Improved draining hook event generation for better observability of the node eviction process.
  - Fixed StaticInstance issue causing infinite infrastructure deletion loops. That prevents infinite cleanup and queueing cycles.
  - Apiserver-proxy rewritten from NGINX to native Go implementation for better stability and reconnection speed.
- Changes in the `cloud-provider-dvp` module:
  - Added hybrid cluster support. Static master nodes and cloud worker nodes can now be used in a single cluster.
  - Improved converge reliability. Reworked the mechanism of resource readiness check and added the fail-fast behavior for possible errors when creating the infrastructure.
  - Added default StorageClass inheritance for Cluster API child clusters.
  - Improved VM lifecycle handling, reducing potential problems when deleting VMs and associated objects.
  - Added support for the `masterNodeGroup.instanceClass.additionalDisks` parameter that lets you configure additional disks for master nodes.
- Changes in the `cloud-provider-aws` module:
  - Spot node draining logic was moved into DP, making the spot node handling more unified.
  - Fixed handling of regions without `DescribeInstanceTopology`, reducing the number of false IAM errors.
- Changes in the `cloud-provider-openstack` module:
  - Added `ipMode: Proxy` support for LoadBalancer in Kubernetes 1.32 and later.
  - Added the `csiDriver.fsGroupPolicy` parameter for the CSI driver, which defines whether the volume supports changing owner and permissions before mounting.
- Changes in the `cloud-provider-vsphere` module:

    - Enabled the CSI snapshotter, enabling volume snapshotting.
    - Fixed zone and datastore detection. Now the only considered zones are the ones specified in the provider configuration.
- In the `cloud-provider-azure` module, added support for NVMe disks on Gen2 VMs.
- In the `cloud-provider-gcp` module, added `enableNestedVirtualization` and `additionalDisks` parameters to GCPInstanceClass, which let you configure nodes for workloads using virtualization and storage scenarios.
- In the `cloud-provider-yandex` module, fixed converge failure when removing externalIPAddresses.
- DVP, Huawei Cloud, and zVirt providers were migrated to Cluster API `v1beta2`.
- For Huawei Cloud and VCD providers, added SecurityPolicyException resources and enabled security policy validations.

Network subsystem

- Added support for handling incoming traffic via Gateway API using the `alb` module.
- Changes in the `cni-cilium` module:
    - Added conntrack table synchronization for live VM migration.
    - Added ICMP (ping) support via ExternalIP for LoadBalancer services with MetalLB.
- Added support for switching between supported CNI plugins in DP clusters.
- In the `node-local-dns` module, added `disableIPv6` parameter to disable IPv6 DNS resolution.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.76.18

Know before update

- All ingress-nginx controllers' pods will be restarted.
- Cilium agent pods will be restarted.
- Cilium agent pods will be restarted. With DSR, the DSR IPv4 option is stripped before the packet reaches the pod.
- Flannel pods will be restarted.
- Flannel pods will be restarted. The guard metrics use host port 4294.
- In ambient mode with Istio 1.27 or later, on nodes with legacy iptables, `istio-cni-node` switches from nftables to legacy iptables. Pods that were added to the mesh before the update keep their nftables rules. Restart these pods after the update. Otherwise, removing such a pod from the mesh without a restart leaves its old redirect rules in place, and the pod loses network connectivity.
- Pods using the updated nginx images roll out in the affected modules, including the ingress failover proxy where enabled.
- TLS connections from nodes to hosts whose certificates chain to `emSign ECC Root CA - G3` or Comodo `AAA Certificate Services` (eMudhra / emSign issued) will fail. Reissue such certificates from another CA before the update.
- The Istio pods will be restarted. Application sidecars will be updated only after the application pods are recreated.
- loki
- simple-bridge pods will be restarted.
- simple-bridge pods will be restarted. The guard metrics use host port 4294.

Features

- **[cni-cilium]** Added a CVE-2026-98432 mitigation that filters IPv4 TCP SYN packets with IP options in the host and pod network namespaces (`ipv4OptionsGuard`; `Enforce` for new clusters, `Audit` for existing ones).
  Cilium agent pods will be restarted. With DSR, the DSR IPv4 option is stripped before the packet reaches the pod.
- **[cni-flannel]** Added a CVE-2026-98432 mitigation that filters IPv4 TCP SYN packets with IP options in the host and pod network namespaces (`ipv4OptionsGuard`; `Enforce` for new clusters, `Audit` for existing ones).
  Flannel pods will be restarted. The guard metrics use host port 4294.
- **[cni-simple-bridge]** Added a CVE-2026-98432 mitigation that filters IPv4 TCP SYN packets with IP options in the host and pod network namespaces (`ipv4OptionsGuard`; `Enforce` for new

clusters, `Audit` for existing ones).
simple-bridge pods will be restarted. The guard metrics use host port 4294.

Fixes

- **[candi]** Bump base images to v3.1.28.
- **[cloud-provider-vcd]** Reduce node initialization delays and restore automatic cleanup of orphaned Nodes in VCD clusters.
- **[cni-cilium]** The ipv4-options-guard sidecar no longer writes to the host `/etc`, so Cilium agents start on Deckhouse Engine nodes.
  Cilium agent pods will be restarted.
- **[cni-flannel]** The ipv4-options-guard sidecar no longer writes to the host `/etc`, so Flannel pods start on Deckhouse Engine nodes.
  Flannel pods will be restarted.
- **[cni-simple-bridge]** The ipv4-options-guard sidecar no longer writes to the host `/etc`, so simple-bridge pods start on Deckhouse Engine nodes.
  simple-bridge pods will be restarted.
- **[common]** Updated the shared static nginx binary to 1.30.7 to address security vulnerabilities. Pods using the updated nginx images roll out in the affected modules, including the ingress failover proxy where enabled.
- **[deckhouse]** Show the Terminating phase while package repositories are being deleted
- **[deckhouse]** ModuleSource scans skip modules whose release channel has not changed, using a manifest HEAD request instead of pulling the release image.
- **[deckhouse-controller]** Module sources now scan the registry every 30 minutes by default, reducing registry load
- **[deckhouse-controller]** Prevent module hooks from running with unavailable snapshots while waiting for Deckhouse to restart after a module update
- **[deckhouse-controller]** A pending module release no longer loses its Kubernetes, Deckhouse and module requirements, so an update that the cluster does not satisfy stays pending instead of disabling the module.
- **[deckhouse-controller]** Pre-download modules enabled by the bundle when their ModuleConfig omits enabled, preventing upgrades from getting stuck.
- **[deckhouse-controller]** Releases of a still-embedded module no longer raise manual approval alerts once the module has a deployed release.
- **[dhctl]** Added the ability to retry a timed-out node drain during converge, and raised drain attempts from 5 to 10.
- **[docs]** Added registry module port 5001 to Deckhouse ports documentation
- **[docs]** Update terminology in the documentation and SEO improvements.
- **[go_lib]** Package proxy streams the full package body when the cache skips writing it.
- **[ingress-nginx]** Nginx was updated to 1.30.7.
  All ingress-nginx controllers' pods will be restarted.
- **[istio]** Fixed CVEs in istio images (x/net, x/crypto, klauspost/compress, x/text).
  The Istio pods will be restarted. Application sidecars will be updated only after the application pods are recreated.
- **[istio]** Fixed ambient mode on nodes with legacy iptables, where `istio-cni-node` crashed on Istio 1.25 and used nftables instead of legacy iptables on Istio 1.27 and later.
  In ambient mode with Istio 1.27 or later, on nodes with legacy iptables, `istio-cni-node` switches from nftables to legacy iptables. Pods that were added to the mesh before the update keep their nftables rules. Restart these pods after the update. Otherwise, removing such a pod from the mesh without a restart leaves its old redirect rules in place, and the pod loses network connectivity.
- **[loki]** fix kind version grafanaDatasource. Disable module loki block queue without module prometheus
  loki
- **[node-manager]** kube-rbac-proxy in capi-controller-manager no longer listens on all addresses of a node that has no addresses yet, so it does not take the controller's port.
- **[registry-packages-proxy]** Fixed registry-packages-proxy hanging after a cache error and serving corrupted packages, which blocked node updates.
- **[registrypackages]** Nodes stop trusting `emSign ECC Root CA - G3` and Comodo `AAA Certificate Services`, the roots behind the compromised eMudhra intermediate CAs.
  TLS connections from nodes to hosts whose certificates chain to `emSign ECC Root CA - G3` or Comodo `AAA Certificate Services` (eMudhra / emSign issued) will fail. Reissue such certificates from another CA before the update.

1.76.17

Know before update

- A diff will appear in the Terraform state for the base infrastructure: the E zone will be added. Because of this, the Terraform check will fail on the first master node. Run `dhctl converge` for the base infrastructure, and everything should get back to normal.

Features

- **[cloud-provider-yandex]** Add support for the `ru-central1-e` zone in Yandex Cloud.
  A diff will appear in the Terraform state for the base infrastructure: the E zone will be added. Because of this, the Terraform check will fail on the first master node. Run `dhctl converge` for the base infrastructure, and everything should get back to normal.
- **[documentation]** The in-cluster documentation now includes the guides.

Fixes

- **[candi]** Restored the lost `kubelet-disable-k-panic-check` patch for k8s 1.35, so kubelet no longer enforces `kernel.panic=10` on this version.
- **[ci]** add skip docs validation label
- **[ci]** Delete tests registry images
- **[cloud-provider-azure]** use .normal.apiserverEndpoints in data device Secret fallback
- **[cloud-provider-vsphere]** Fixed master node creation when the datastore is set as a path with parent folders.
- **[deckhouse]** Restore kubectl plugin lookup in d8 k and d8 kubectl
- **[dhctl]** Prevent dhctl converge from panicking when kubeconfig is used without an SSH host.
- **[docs]** Removed mentions of Cilium from the inter-cluster cooperation documentation page.
- **[docs]** Added experimental module enable note to the lifecycle badge.
- **[docs]** Rendered all versions from oss.yaml versions array.
- **[istio]** The Istio operator now recovers Helm releases stuck in the `pending-*` or `uninstalling` state.

1.76.16

Features

- **[docs]** Add managed services modules architecture documentation section.

Fixes

- **[ci]** Fix changelog-generator image tag in changelog-update job to use the shared CI_IMAGES_TAG
- **[cloud-provider-vcd]** Fixes cluster bootstrap getting stuck when `capcd-controller-manager` cannot reach the API server and DNS before the CNI is ready.
- **[istio]** Aligned CNI templates with upstream and fixed Istio 1.25 compatibility.
- **[istio]** Fixed the istio module getting stuck when switching `globalVersion` from 1.21 while proxies are still connected to the 1.21 control plane.
- **[istio]** Fix leaking istiod control plane after removing an Istio version or disabling the module.
- **[istio]** Switching back to Istio 1.21 no longer removes the `networking.istio.io/v1` API from the Istio CRDs and no longer breaks the istio release.

1.76.15

Know before update

- A StaticInstance whose connectivity check fails now keeps its reservation for the whole bootstrap window instead of returning to the pool on every failed attempt, and the bootstrap (20 min) and cleanup (10 min) timeouts, which previously never fired, are now reachable. If nothing ever ran on the host, the bootstrap timeout returns the instance to the pool after 20 minutes as before. If the host was already bootstrapped in part, the instance returns only through MachineHealthCheck remediation (nodeStartupTimeoutSeconds: 1200) plus the cleanup timeout, so it becomes available again roughly 20 + 10 minutes after the failure, and remediation reboots the host as part of the cleanup.
- The `self-signed-generator` init container now carries the fixed `10m` / `25Mi` it was always meant to have, the same as the identical init container of `user-api`, instead of the sum of the main container limits. A DexAuthenticator that set large limits no longer gets that sum as burst: generating the self-signed certificate then takes 3 to 4 seconds instead of under a second. It happens once per pod start and needs no action.
- log-shipper

Features

- **[docs]** Add istio module architecture section.
- **[docs]** Add user-authn-controller, user-api and basic-auth-proxy components to user-authn module architecture section.

Fixes

- **[cert-manager]** Restore the `cert-manager` and `cainjector` permissions that were lost against the upstream chart, including access to `ListenerSet` resources.
- **[chrony]** Fixed the unit-detection condition in the `disable-ntp-on-node.sh` node step.
- **[cloud-provider-aws]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-azure]** Fix multimaster bootstrap by falling back to the `d8-masters-kubernetes-data-device-path` Secret when the master data device LUN is not provided via

cloud-init.
- **[cloud-provider-azure]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-dvp]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-gcp]** fix GetCapacity not implemented error spam in logs
- **[cloud-provider-vcd]** Batch VM cache refresh on cache miss
- **[cloud-provider-yandex]** fix “Address in use” failures when replacing nodes and when removing external IP addresses
- **[deckhouse]** In upmeter, the `monitoring-and-autoscaling/alertmanager` probe is disabled by default and is turned on with the new `alertmanagerProbe.enabled` setting.
- **[deckhouse]** Fixed the CVEs reported for the v1.76.14 scan slice across all Observability team module images by bumping grpc to v1.83.2, the OpenTelemetry family to v1.45.0, kin-openapi to v0.149.0, cel-go to v0.29.0, golang.org/x/crypto to v0.55.0 and the rest of the golang.org/x/* set, by moving pushgateway to 1.11.3 and image-availability-exporter to 0.16.0, and by building the log-shipper reloader with Go 1.25.13; advisories without a reachable fix are mitigated via VEX.
- **[deckhouse-controller]** Stop the module source registry fan-out from replaying and flooding the main queue with duplicate moduleRun tasks.
- **[deckhouse-controller]** Do not commit the package repository registry checksum when no application could be annotated, which left them all on stale registry settings.
- **[descheduler]** Fix duplicate enabled key in doc-ru-deschedulers.yaml
- **[docs]** Fixed FAQ section for ansible inventory.
- **[istio]** Fix istiod RBAC rules that drifted away from upstream.
- **[log-shipper]** Fixed an invalid VRL script generated by the `replaceValue` transformation. log-shipper
- **[node-manager]** Stop caps-controller-manager from rewriting StaticInstance objects in a hot loop when a connectivity check fails, which caused a sustained load on etcd.
  A StaticInstance whose connectivity check fails now keeps its reservation for the whole bootstrap window instead of returning to the pool on every failed attempt, and the bootstrap (20 min) and cleanup (10 min) timeouts, which previously never fired, are now reachable. If nothing ever ran on the host, the bootstrap timeout returns the instance to the pool after 20 minutes as before. If the host was already bootstrapped in part, the instance returns only through MachineHealthCheck remediation (nodeStartupTimeoutSeconds: 1200) plus the cleanup timeout, so it becomes available again roughly 20 + 10 minutes after the failure, and remediation reboots the host as part of the cleanup.
- **[tools]** Bump d8-cli to v0.32.6 - `d8 mirror push` restores the release channel tags of the installer image, so `docker run <repo>/install:<channel>` works against a mirrored registry
- **[tools]** Bump d8-cli to v0.32.7 - closes the CVE findings in the bundled d8 binary (grpc 1.83.2, x/image 0.45.0, x/crypto 0.55.0 and x/mod 0.40.0)
- **[upmeter]** Fixed ListenerSet upmeter namespace.
- **[user-authn]** Render a valid Deployment for a DexAuthenticator whose `resources` limits are fractional or below the init container requests.
  The `self-signed-generator` init container now carries the fixed `10m` / `25Mi` it was always meant to have, the same as the identical init container of `user-api`, instead of the sum of the main container limits. A DexAuthenticator that set large limits no longer gets that sum as burst: generating the self-signed certificate then takes 3 to 4 seconds instead of under a second. It happens once per pod start and needs no action.

1.76.14

Know before update

- D8UserAuthzRenderSlow requires at least three renders averaging above 30 seconds over 30 minutes, D8UserAuthzReleaseSlow at least two releases averaging above 5 minutes over one hour, and both must hold for 15 minutes. Severities are one step lower (6 and 7). Their descriptions now point at CPU shortage on the node rather than at the number of ClusterAuthorizationRules, which does not affect render time.
- During the first `user-authz` release after the update the per-role bindings are protected from the release engine, the aggregated ones are created, and the per-role bindings are deleted right after the release. Permissions granted through annotated ClusterRoles stay in place throughout. The `user-authz.deckhouse.io/access-level` label is now set automatically on annotated ClusterRoles. In audit logs, access granted through annotated ClusterRoles is attributed to `user-authz:<level>:custom` instead of the individual ClusterRole.
- The `service-with-healthchecks` controller and agent are restarted. A `ServiceWithHealthchecks` that was left in `NotAllEndpointsAreReady` with no EndpointSlice recovers automatically once the updated agent starts, no manual action is needed.

Features

- **[docs]** Add extended-monitoring module architecture section.
- **[docs]** Add registry-packages-proxy module architecture section.

Fixes

- **[service-with-healthchecks]** Fixed a load balancer losing all its endpoints for good after a

target pod was replaced.
The `service-with-healthchecks` controller and agent are restarted. A `ServiceWithHealthchecks` that was left in `NotAllEndpointsAreReady` with no EndpointSlice recovers automatically once the updated agent starts, no manual action is needed.
- **[user-authn]** Fixed DexAuthenticator pod creation under ResourceQuota by setting init container CPU/memory limits to the sum of main container limits.
- **[user-authz]** Grant custom ClusterRoles (annotated with `user-authz.deckhouse.io/access-level`) through one aggregated ClusterRole per access level, so the number of bindings per ClusterAuthorizationRule/AuthorizationRule no longer depends on the number of such roles. During the first `user-authz` release after the update the per-role bindings are protected from the release engine, the aggregated ones are created, and the per-role bindings are deleted right after the release. Permissions granted through annotated ClusterRoles stay in place throughout. The `user-authz.deckhouse.io/access-level` label is now set automatically on annotated ClusterRoles. In audit logs, access granted through annotated ClusterRoles is attributed to `user-authz:<level>:custom` instead of the individual ClusterRole.
- **[user-authz]** Group the module alerts under a group named apart from the alerts themselves, so the incident shelf accepts them.
- **[user-authz]** The D8UserAuthzRenderSlow and D8UserAuthzReleaseSlow alerts no longer fire on a single slow render or release, such as a cluster bootstrap under CPU pressure or the one-time migration pass.
  D8UserAuthzRenderSlow requires at least three renders averaging above 30 seconds over 30 minutes, D8UserAuthzReleaseSlow at least two releases averaging above 5 minutes over one hour, and both must hold for 15 minutes. Severities are one step lower (6 and 7). Their descriptions now point at CPU shortage on the node rather than at the number of ClusterAuthorizationRules, which does not affect render time.

1.76.13

Know before update

- A Deckhouse release suspended on its release channel is no longer applied by clusters that are behind and reach it through a step-by-step update. The suspend flag lives only in the release-channel image; previously it was dropped when the target release was built from its per-version image, so lagging clusters updated to a suspended release anyway.
- After the update, the controller adds the annotations and labels of every ServiceWithHealthchecks to the Service created for it. If a ServiceWithHealthchecks of the `LoadBalancer` type carries annotations that configure the load balancer (`network.deckhouse.io/load-balancer-ips`, `network.deckhouse.io/load-balancer-shared-ip-key` and similar), the load balancer controller applies them and may assign a different address to the service, which causes a short interruption of the connections.
- Endpoints for pods in a terminal phase (Failed/Succeeded) are no longer published. In DVP clusters this prevents traffic from being routed to a VirtualMachine IP that has been reused by another pod. Pods being deleted are now published with the serving and terminating conditions, which enables the graceful shutdown flow for consumers. Pod readiness is derived from the PodReady condition, and stale probe results are reset when a pod becomes not ready, is recreated, or changes its IP.

- The SSH key and sudo password in `SSHCredentials` (used by CAPS to reach static nodes) are now returned as `<omitted>` to callers without `get` on the `sshcredentials/sensitive` subresource, masked in the audit log, and encrypted in etcd when `apiserver.encryptionEnabled` is on. `d8:manage:infrastructure:viewer` and `:manager` no longer see these values. CAPS still does, and so does every holder of a `deckhouse.io` wildcard, since `*` matches subresources: `SuperAdmin`, the `kubeadm:cluster-admins` group, and the `deckhouse` and `webhook-handler` SAs of `d8-system`.

  For masked readers the `last-applied-configuration` annotation disappears from `get -o yaml`, and creating an `SSHCredentials` with `<omitted>` fails with `422 Invalid` — editing still works. Treat previously exposed keys as leaked and rotate them. With `apiserver.encryptionEnabled` on, rewrite existing objects to encrypt them: `d8 k get sshcredentials -o json | d8 k replace -f -`.

- The `descheduler` Deployment in `d8-descheduler` restarts once on upgrade to pick up the new argument. Descheduling behavior is unchanged for workloads that do not implement their own eviction policy.
- The `service-with-healthchecks` status logic was heavily refactored to reduce API and etcd load. If you rely on `lastProbeTime` observability on every probe, explicitly enable `verboseStatus` in the module configuration.
- The installer, the deckhouse ServiceAccount, holders of the cluster administrator kubeconfig and the kube-system / d8-system ServiceAccounts can create a User or a Group named by an existing authorization rule without the acknowledgement annotation. Every other requester is checked as before.

Features

- **[descheduler]** Always run the descheduler with the upstream `EvictionsInBackground` feature gate enabled.
  The `descheduler` Deployment in `d8-descheduler` restarts once on upgrade to pick up the new argument. Descheduling behavior is unchanged for workloads that do not implement their own eviction policy.
- **[docs]** Add managed-valkey module architecture section.
- **[docs]** Add monitoring-kubernetes module architecture section.
- **[docs]** Add documentation for Managed PostgreSQL service.

Fixes

- **[ci]** Add REGCTL_CONFIG
- **[ci]** Fix regctl in 1.76 build.
- **[common]** Quote user-controlled values in the prometheus, upmeter, prometheus-pushgateway and extended-monitoring templates to prevent YAML injection into the module release.
- **[deckhouse]** validate the hardlink target when extracting module and package images
- **[deckhouse-controller]** Honor a channel-level release suspend for clusters that reach the suspended version through a step-by-step update.
  A Deckhouse release suspended on its release channel is no longer applied by clusters that are behind and reach it through a step-by-step update. The suspend flag lives only in the release-channel image; previously it was dropped when the target release was built from its per-version image, so lagging clusters updated to a suspended release anyway.
- **[deckhouse-controller]** Fix tests for check_release_tests
- **[docs]** Documented the identity collision rules for local Group and User objects and the allow-access-to-kubernetes annotation, and corrected the described scope of a security subsystem manage role.
- **[docs]** add static cluster OS change for master nodes and Stronghold backup alerts
- **[node-manager]** Fix NodeCapacity calculation.

- **[node-manager]** Hide the CAPS SSH key and sudo password in SSHCredentials from users without the `sshcredentials/sensitive` subresource.
  The SSH key and sudo password in `SSHCredentials` (used by CAPS to reach static nodes) are now returned as `<omitted>` to callers without `get` on the `sshcredentials/sensitive` subresource, masked in the audit log, and encrypted in etcd when `apiserver.encryptionEnabled` is on. `d8:manage:infrastructure:viewer` and `:manager` no longer see these values. CAPS still does, and so does every holder of a `deckhouse.io` wildcard, since `*` matches subresources: `SuperAdmin`, the `kubeadm:cluster-admins` group, and the `deckhouse` and `webhook-handler` SAs of `d8-system`.

  For masked readers the `last-applied-configuration` annotation disappears from `get -o yaml`, and creating an `SSHCredentials` with `<omitted>` fails with `422 Invalid` — editing still works. Treat previously exposed keys as leaked and rotate them. With `apiserver.encryptionEnabled` on, rewrite existing objects to encrypt them: `d8 k get sshcredentials -o json | d8 k replace -f -`.

- **[service-with-healthchecks]** Fixed an API server overload issue (“status storm”), resolved validation errors for ClusterIP services, corrected pod readiness evaluation logic, and improved code quality.
  The `service-with-healthchecks` status logic was heavily refactored to reduce API and etcd load. If you rely on `lastProbeTime` observability on every probe, explicitly enable `verboseStatus` in the module configuration.
- **[service-with-healthchecks]** Annotations and labels of a ServiceWithHealthchecks are now copied to the Service created for it.
  After the update, the controller adds the annotations and labels of every ServiceWithHealthchecks to the Service created for it. If a ServiceWithHealthchecks of the `LoadBalancer` type carries annotations that configure the load balancer (`network.deckhouse.io/load-balancer-ips`, `network.deckhouse.io/load-balancer-shared-ip-key` and similar), the load balancer controller applies them and may assign a different address to the service, which causes a short interruption of the connections.
- **[service-with-healthchecks]** Stopped publishing terminated pods in EndpointSlices and started publishing pods being deleted as terminating endpoints.
  Endpoints for pods in a terminal phase (Failed/Succeeded) are no longer published. In DVP clusters this prevents traffic from being routed to a VirtualMachine IP that has been reused by another pod. Pods being deleted are now published with the serving and terminating conditions, which enables the graceful shutdown flow for consumers. Pod readiness is derived from the PodReady condition, and stale probe results are reset when a pod becomes not ready, is recreated, or changes its IP.
- **[user-authz]** The identity collision check no longer applies to the platform’s own identities, so a retried bootstrap creates the initial User again instead of timing out.
  The installer, the deckhouse ServiceAccount, holders of the cluster administrator kubeconfig and the kube-system / d8-system ServiceAccounts can create a User or a Group named by an existing authorization rule without the acknowledgement annotation. Every other requester is checked as before.

1.76.12

Know before update

- The `vpa-recommender` pod is restarted and recommendations are recalculated with the new granularity. Memory recommendations will generally become lower (less over-provisioning), CPU recommendations become multiples of 10m. VPA objects with `updateMode: Auto/Recreate` may evict and recreate pods to apply the updated requests.
- ValidatingAdmissionPolicy reserved-public-hosts-* is removed. Ingresses that were denied because they matched publicDomainTemplate are allowed again. settings.reservedPublicHosts in ModuleConfig deckhouse remains accepted and is ignored. Enforcement returns in a later release.

Fixes

- **[deckhouse]** Stop reserving platform public hostnames at admission; keep the ModuleConfig field so existing settings still validate.
  ValidatingAdmissionPolicy reserved-public-hosts-* is removed. Ingresses that were denied because they matched publicDomainTemplate are allowed again. settings.reservedPublicHosts in ModuleConfig deckhouse remains accepted and is ignored. Enforcement returns in a later release.
- **[deckhouse]** Fixed goroutine and memory leak in upmeter-agent caused by per-request HTTP clients leaving idle keep-alive connections to Prometheus open forever.
- **[deckhouse-controller]** Fixed a bug when PackageRepository always used a HTTPS scheme.
- **[docs]** Add InPlaceOrRecreate to VPA modes list and move Auto to a warning alert.
- **[local-path-provisioner]** Add wildcard tolerations to the helper pod template so PVC provisioning works on tainted nodes after local-path-provisioner v0.0.32+.
- **[user-authn]** Commander releases older than 1.18 can grant Kubernetes API access on DexClient again.
- **[vertical-pod-autoscaler]** Reduce VPA memory recommendation rounding from 64Mi to 16Mi and round CPU recommendations up to 10m.
  The `vpa-recommender` pod is restarted and recommendations are recalculated with the new granularity. Memory recommendations will generally become lower (less over-provisioning), CPU recommendations become multiples of 10m. VPA objects with `updateMode: Auto/Recreate` may evict and recreate pods to apply the updated requests.

1.76.11

Know before update

- Containers attached through the `pods/ephemeralcontainers` subresource were not seen by the module's webhook, so no policy was evaluated for them: SecurityPolicy, OperationPolicy, Pod Security Standards and image signature verification were all bypassed by `kubectl debug`. After the update these requests are validated.

  On clusters with restricted Pod Security Standards, `deny-exec` or strict SecurityPolicy, typical debug images (root user, writable root filesystem, interactive `-it`) will now be rejected. Adjust the policies or use a SecurityPolicyException for the namespaces where debugging must stay available.

  The webhook uses `failurePolicy: Fail`, so while Gatekeeper is unavailable `kubectl debug` will not work in user namespaces. System namespaces are excluded from the webhook and are not affected.

- Creating a `Group` or a `User`, or renaming an existing one, so that `Group.spec.name` matches a group subject or `User.spec.email` matches a user subject of an existing AuthorizationRule or ClusterAuthorizationRule is now rejected, preventing an unintended privilege grant. The email is compared after lowercasing, since that is the form that reaches the token. Set the `user-authz.deckhouse.io/allow-authorization-rule-collision` annotation to `"true"` on the object if the collision is intentional. Already existing objects keep working and only produce a warning. Any declarative flow that manages both the rule and the identity is affected, not only one that deletes and recreates the identity: a first-time apply denies the `Group` or `User` whenever the rule happens to be applied first, and nothing guarantees the order. Add the annotation to such objects before upgrading. Deleting a `Group` or a `User` whose name is still a subject of a rule now produces a warning, since the rule keeps granting that name.

- On upgrade, every DexAuthenticator that carries the `dexauthenticator.deckhouse.io/allow-access-to-kubernetes` annotation gets a freshly generated client secret, because it previously received the client secret of the privileged `kubernetes` OAuth2 client instead. Its pods roll once and users of those applications may have to sign in again. Each rotation is written to the Deckhouse log as `Rotating DexAuthenticator client secret that reused the shared kubernetes client secret`, with the authenticator name and namespace.

  If that annotation was ever used outside the `d8-*` and `kube-*` namespaces, the shared secret must be considered disclosed to anyone who could read Secrets in those namespaces, and has to be rotated by hand. Deleting the Secret alone does not rotate it: while the value is non-empty in

memory the owning hook re-renders the same one. Rotate it as follows.

1. If a GitOps tool syncs the `d8-user-authn` namespace, exclude `Secret/kubernetes-dex-client-app-secret` from that sync first, otherwise it is restored to the old value.
2. Blank the stored value: `kubectl -n d8-user-authn patch secret kubernetes-dex-client-app-secret --type merge -p '{"data":{"secret":""}}'`
3. Drop the in-memory copy: `kubectl -n d8-system rollout restart deployment/deckhouse`
4. Check that `kubectl -n d8-user-authn get secret kubernetes-dex-client-app-secret -o jsonpath='{.data.secret}'` now differs from the previous value. If it does not, the module re-rendered the old value before the restart took effect; repeat steps 2 and 3.

The blast radius of that rotation is wider than the `kubernetes` client alone. The same value is the client secret of the `kubeconfig-generator`, `kubeconfig-publish-api` and every `kubeconfig-<slug>` OAuth2 client, and it is passed to basic-auth-proxy as `--ldap-client-secret`. In-cluster consumers are re-rendered and their pods roll automatically, but kubeconfig files already downloaded from the kubeconfig generator carry the old client secret and can no longer refresh their tokens, so their users must download a new kubeconfig. Already issued ID tokens keep working until they expire, at most `settings.idTokenTTL`.

Deleting and recreating a DexAuthenticator is always a safe way to force a fresh per-authenticator secret: the credentials Secret is regenerated with the resource. Its content is owned by Deckhouse, so no GitOps change is needed for the per-authenticator rotation itself.

- Only a subject allowed to update the user-authn ModuleConfig, or the Deckhouse service account, may add the `dexclient.deckhouse.io/allow-access-to-kubernetes` or `dexauthenticator.deckhouse.io/allow-access-to-kubernetes` annotation. Objects that already carry it keep working and stay editable by their owners as long as they are updated in place. A GitOps controller that deletes and recreates such an object instead of patching it will have the recreation denied, and the object will come back without access to the Kubernetes API unless the controller's service account is allowed to update the user-authn ModuleConfig.
- Project administrators (user-authz Admin access level) can no longer create, update or delete SecurityPolicyException resources; the permission now requires ClusterAdmin. Clusters that granted accessLevel Admin to untrusted tenants over RBAC v1 were exposed to node-level privilege escalation. RBAC v2 use/manage roles were never affected.
- Setting the annotation no longer requires write access to the user-authn ModuleConfig. Module administrators are unaffected, as their roles already carry the new permission, and so are the platform's own components in `d8-system` and `kube-system`. Any other subject that sets the annotation, a cluster provisioner in particular, has to be granted `create` on the subresource, which for a single namespace is:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: allow-access-to-kubernetes
  namespace: <namespace>
rules:
- apiGroups: ["deckhouse.io"]
  resources: ["dexclients/allow-access-to-kubernetes", "dexauthenticators/allow-access-to-
kubernetes"]
  verbs: ["create"]
```

  bound to the subject with a RoleBinding in the same namespace, or with a ClusterRole and a ClusterRoleBinding to grant it cluster-wide.
- The `d8:manage:permission:subsystem:kubernetes:view_resources` role no longer grants `nodes/proxy`, `nodes/log`, `nodes/metrics` and `nodes/stats`. Users holding `d8:manage:kubernetes:viewer`, `d8:manage:infrastructure:viewer` or any role aggregating them lose access to the kubelet API through `/api/v1/nodes/<node>/proxy/...`. `nodes` themselves stay readable. Automation that relied on reaching the kubelet API with one of these roles must be granted a dedicated role explicitly.
- `spec.oidc.scopes` items are now validated against `^\S+$` in both served versions of DexProvider. A scope containing whitespace could never work, because OAuth2 passes scopes as a space-delimited list, but it was previously admitted and silently broke authentication. Stored objects are not invalidated, however a DexProvider holding such a value is rejected on its next write until the value is corrected, which also affects a GitOps flow that reapplies the object unchanged.

Features

- **[docs]** Add previous page and next page buttons to modules documentation

Fixes

- **[admission-policy-engine]** Admission policies are now evaluated for ephemeral containers added with `kubectl debug`.
  Containers attached through the `pods/ephemeralcontainers` subresource were not seen by the module's webhook, so no policy was evaluated for them: SecurityPolicy, OperationPolicy, Pod Security Standards and image signature verification were all bypassed by `kubectl debug`. After the update these requests are validated.

  On clusters with restricted Pod Security Standards, `deny-exec` or strict SecurityPolicy, typical debug images (root user, writable root filesystem, interactive `-it`) will now be rejected. Adjust the policies or use a SecurityPolicyException for the namespaces where debugging must stay available.

  The webhook uses `failurePolicy: Fail`, so while Gatekeeper is unavailable `kubectl debug` will not work in user namespaces. System namespaces are excluded from the webhook and are not affected.

- **[admission-policy-engine]** Restrict SecurityPolicyException write access to ClusterAdmin, closing a tenant-to-node privilege escalation.
  Project administrators (user-authz Admin access level) can no longer create, update or delete SecurityPolicyException resources; the permission now requires ClusterAdmin. Clusters that granted accessLevel Admin to untrusted tenants over RBAC v1 were exposed to node-level privilege escalation. RBAC v2 use/manage roles were never affected.
- **[cloud-provider-yandex]** A Node that cannot be resolved to a Yandex Instance no longer blocks target group synchronization for the whole cluster.
- **[cloud-provider-zvirt]** Prevent capz-controller-manager from crashlooping without diagnostics when zVirt tags cannot be created.
- **[deckhouse]** bump addon-operator to run the module startup phase unconditionally
- **[deckhouse]** Deleted module documentation when a module is disabled.
- **[deckhouse]** The reserved public hosts policies no longer make every aggregated apiserver in the cluster watch all ConfigMaps, which left permission-browser-apiserver permanently unready and stopped namespace deletion cluster-wide.
- **[docs]** Fix the upmeter web UI Ingress name in SLA documentation
- **[testing]** Copy Helm render capabilities per render instead of mutating the shared defaults, and allow tests to declare available API kinds.
- **[user-authn]** Quote DexProvider-derived values rendered into the basic-auth-proxy Deployment and the Dex configuration file to prevent YAML injection.
- **[user-authn]** Reject whitespace in DexProvider OIDC scopes, which the OAuth2 protocol cannot represent.
  `spec.oidc.scopes` items are now validated against `^\S+$` in both served versions of DexProvider. A scope containing whitespace could never work, because OAuth2 passes scopes as a space-delimited list, but it was previously admitted and silently broke authentication. Stored objects are not invalidated, however a DexProvider holding such a value is rejected on its next write until the value is corrected, which also affects a GitOps flow that reapplies the object unchanged.

- **[user-authn]** Issue a dedicated OAuth2 client secret per DexAuthenticator instead of reusing the shared cluster client secret.
  On upgrade, every DexAuthenticator that carries the `dexauthenticator.deckhouse.io/allow-access-to-kubernetes` annotation gets a freshly generated client secret, because it previously received the client secret of the privileged `kubernetes` OAuth2 client instead. Its pods roll once and users of those applications may have to sign in again. Each rotation is written to the Deckhouse log as `Rotating DexAuthenticator client secret that reused the shared kubernetes client secret`, with the authenticator name and namespace.

  If that annotation was ever used outside the `d8-*` and `kube-*` namespaces, the shared secret must be considered disclosed to anyone who could read Secrets in those namespaces, and has to be rotated by hand. Deleting the Secret alone does not rotate it: while the value is non-empty in memory the owning hook re-renders the same one. Rotate it as follows.

  1. If a GitOps tool syncs the `d8-user-authn` namespace, exclude `Secret/kubernetes-dex-client-app-secret` from that sync first, otherwise it is restored to the old value.
  2. Blank the stored value: `kubectl -n d8-user-authn patch secret kubernetes-dex-client-app-secret --type merge -p '{"data":{"secret":""}}'`
  3. Drop the in-memory copy: `kubectl -n d8-system rollout restart deployment/deckhouse`
  4. Check that `kubectl -n d8-user-authn get secret kubernetes-dex-client-app-secret -o jsonpath='{.data.secret}'` now differs from the previous value. If it does not, the module re-rendered the old value before the restart took effect; repeat steps 2 and 3.

  The blast radius of that rotation is wider than the `kubernetes` client alone. The same value is the client secret of the `kubeconfig-generator`, `kubeconfig-publish-api` and every `kubeconfig-<slug>` OAuth2 client, and it is passed to basic-auth-proxy as `--ldap-client-secret`. In-cluster consumers are re-rendered and their pods roll automatically, but kubeconfig files already downloaded from the kubeconfig generator carry the old client secret and can no longer refresh

their tokens, so their users must download a new kubeconfig. Already issued ID tokens keep working until they expire, at most `settings.idTokenTTL`.

Deleting and recreating a DexAuthenticator is always a safe way to force a fresh per-authenticator secret: the credentials Secret is regenerated with the resource. Its content is owned by Deckhouse, so no GitOps change is needed for the per-authenticator rotation itself.

- **[user-authn]** Drop the dead per-DexAuthenticator redirect URI from the privileged kubernetes OAuth2 client.
- **[user-authn]** Adding the allow-access-to-kubernetes annotation to a DexClient or a DexAuthenticator now requires cluster-level authority over the user-authn module.
  Only a subject allowed to update the user-authn ModuleConfig, or the Deckhouse service account, may add the `dexclient.deckhouse.io/allow-access-to-kubernetes` or `dexauthenticator.deckhouse.io/allow-access-to-kubernetes` annotation. Objects that already carry it keep working and stay editable by their owners as long as they are updated in place. A GitOps controller that deletes and recreates such an object instead of patching it will have the recreation denied, and the object will come back without access to the Kubernetes API unless the controller's service account is allowed to update the user-authn ModuleConfig.
- **[user-authn]** The policy gating the allow-access-to-kubernetes annotation no longer applies to platform components, and proves authority with a create permission on the dexclients/allow-access-to-kubernetes and dexauthenticators/allow-access-to-kubernetes subresources instead of write access to the user-authn ModuleConfig.
  Setting the annotation no longer requires write access to the user-authn ModuleConfig. Module administrators are unaffected, as their roles already carry the new permission, and so are the platform's own components in `d8-system` and `kube-system`. Any other subject that sets the annotation, a cluster provisioner in particular, has to be granted `create` on the subresource, which for a single namespace is:

  ```
  apiVersion: rbac.authorization.k8s.io/v1
  kind: Role
  metadata:
    name: allow-access-to-kubernetes
    namespace: <namespace>
  rules:
  - apiGroups: ["deckhouse.io"]
    resources: ["dexclients/allow-access-to-kubernetes", "dexauthenticators/allow-access-to-
  kubernetes"]
    verbs: ["create"]
  ```

  bound to the subject with a RoleBinding in the same namespace, or with a ClusterRole and a ClusterRoleBinding to grant it cluster-wide.
- **[user-authz]** Reject local Group names and User emails that collide with a subject already granted privileges by an authorization rule.
  Creating a `Group` or a `User`, or renaming an existing one, so that `Group.spec.name` matches a group subject or `User.spec.email` matches a user subject of an existing AuthorizationRule or ClusterAuthorizationRule is now rejected, preventing an unintended privilege grant. The email is compared after lowercasing, since that is the form that reaches the token. Set the `user-authz.deckhouse.io/allow-authorization-rule-collision` annotation to `"true"` on the object if the collision is intentional. Already existing objects keep working and only produce a warning. Any declarative flow that manages both the rule and the identity is affected, not only one that deletes and recreates the identity: a first-time apply denies the `Group` or `User` whenever the rule happens to be applied first, and nothing guarantees the order. Add the annotation to such objects before upgrading. Deleting a `Group` or a `User` whose name is still a subject of a rule now produces a warning, since the rule keeps granting that name.
- **[user-authz]** Remove node subresources from the RBACv2 viewer permission role
  The `d8:manage:permission:subsystem:kubernetes:view resources` role no longer grants `nodes/proxy`, `nodes/log`, `nodes/metrics` and `nodes/stats`. Users holding `d8:manage:kubernetes:viewer`, `d8:manage:infrastructure:viewer` or any role aggregating them lose access to the kubelet API through `/api/v1/nodes/<node>/proxy/...`. `nodes` themselves stay readable. Automation that relied on reaching the kubelet API with one of these roles must be granted a dedicated role explicitly.

1.76.10

Know before update

- Fixes recreation of all CloudEphemeral nodes on upgrade to 1.76.9. The MachineDeployment replica count was dropped and the MachineDeployment was scaled to zero.
- Values taken from `Project.spec.parameters` are now quoted where they are substituted into the shipped project templates, and a parameter that changes the structure of the rendered manifests rather than only their values is refused for any template, including custom ones. An

administrator name may no longer contain control characters, and `clusterLogDestinationName` must be a Kubernetes object name or empty. Both are checked from the reconcile loop as well as at admission, so a project already carrying such a value goes into an error state on its next reconcile rather than at its next edit; the same holds for a custom template that turns a parameter into several objects or into YAML, which is refused when the project is created, edited, or reconciled with a change to apply. The module's admission policy now also matches CREATE, so objects labelled `heritage: multitenancy-manager` can only be created by the module itself.

- `d8:manage:permission:module:multitenancy-manager:edit` no longer grants write access to `projecttemplates`. A `ProjectTemplate` renders into a release applied by a ServiceAccount bound to `cluster-admin`, and its `spec.resourcesTemplate` is arbitrary, so authoring one is equivalent to holding `cluster-admin` and is not a module-level permission.

  Reading templates stays in `d8:manage:permission:module:multitenancy-manager:view`, and creating a `Project` on an existing template stays in the edit role. The legacy `ClusterAdmin` access level and the `kubeadm:cluster-admins` group keep the right. A subject that authored templates through the manager role has to be granted one of those instead.

- network-gateway pod's will be restarted

Features

- **[docs]** Add gpu module architecture section.
- **[docs]** Added cilium-hubble module architecture section.
- **[docs]** Added adaptive-resource-management module architecture section.
- **[docs]** Added operator-trivy module architecture section.
- **[docs]** Added managed-postgres and managed-memcached modules architecture sections.
- **[docs]** Add pod-reloader module architecture section.
- **[docs]** Add secrets-store-integration module architecture section.

Fixes

- **[cloud-provider-vcd]** Fixes an intermittent "network still in use" error during cluster deletion with the WithNAT placement strategy.
- **[deckhouse]** Fix values validation failing on the injected registry
- **[deckhouse-controller]** The module-documentation build request timeout to docs-builder is configurable via DOCUMENTATION_BUILD_TIMEOUT (default 120s) instead of a fixed 10s that canceled healthy full-site builds.
- **[docs]** Fix issues in managed-postgres and managed-memcached modules architecture sections.
- **[docs]** Clarify which integrity control mechanisms are available in which DKP editions and correct the DKP module integrity description.
- **[docs]** Link GPU driver install examples to gpu module FAQ
- **[docs]** Updated the Deckhouse Kubernetes Platform GUI installer links on the installation page from the `#gui-install` anchor to the `/gs/installer/` path.
- **[docs]** Corrected the documentation that incorrectly stated DKP supports only Bearer token authentication for container registries.
- **[docs]** Module documentation no longer gets stuck in Error under load; docs-builder builds are cancelable and no longer pile up redundant full-site rebuilds behind requests whose clients already timed out.
- **[istio]** Restore Istiod pod anti-affinity for Istio 1.25 installations managed by the Sail Operator.
- **[multitenancy-manager]** A project parameter can no longer inject objects into the rendered project manifests.
  Values taken from `Project.spec.parameters` are now quoted where they are substituted into the shipped project templates, and a parameter that changes the structure of the rendered manifests rather than only their values is refused for any template, including custom ones. An administrator name may no longer contain control characters, and `clusterLogDestinationName` must be a Kubernetes object name or empty. Both are checked from the reconcile loop as well as at admission, so a project already carrying such a value goes into an error state on its next reconcile rather than at its next edit; the same holds for a custom template that turns a parameter into several objects or into YAML, which is refused when the project is created, edited, or reconciled with a change to apply. The module's admission policy now also matches CREATE, so objects labelled `heritage: multitenancy-manager` can only be created by the module itself.

- **[multitenancy-manager]** The module manager role no longer grants authoring of project templates.
  `d8:manage:permission:module:multitenancy-manager:edit` no longer grants write access to `projecttemplates`. A `ProjectTemplate` renders into a release applied by a ServiceAccount bound to `cluster-admin`, and its `spec.resourcesTemplate` is arbitrary, so authoring one is equivalent to holding `cluster-admin` and is not a module-level permission.

  Reading templates stays in `d8:manage:permission:module:multitenancy-manager:view`, and creating a `Project` on an existing template stays in the edit role. The legacy `ClusterAdmin` access level and the `kubeadm:cluster-admins` group keep the right. A subject that authored templates through the manager role has to be granted one of those instead.

- **[network-gateway]** Fixed user and group in ConfigMap
  network-gateway pod's will be restarted
- **[node-manager]** Pin MachineDeployment minReadySeconds to 1 so the MachineSet apply converges.
- **[node-manager]** MachineDeployment `spec.replicas` is no longer dropped on upgrade, so cloud nodes are not recreated.
  Fixes recreation of all CloudEphemeral nodes on upgrade to 1.76.9. The MachineDeployment replica count was dropped and the MachineDeployment was scaled to zero.

1.76.9

Know before update

- The node-local-dns DaemonSet pods will restart after the update.

Features

- **[docs]** Add upmeter module architecture section.
- **[docs]** Add descheduler module architecture section.
- **[docs]** Add cni-cilium module architecture section.

Fixes

- **[cloud-provider-aws]** Do not fail the node bootstrap or update when `linux-modules-extra` is unavailable for the running kernel.
- **[deckhouse]** Locate CRDs by repository contents.
- **[deckhouse]** stop false drift detection reinstalling packages with helm hooks
- **[deckhouse]** An unset `settings.update.mode` now defaults to `AutoPatch` instead of silently running as `Auto`.
- **[deckhouse]** Fix a minor Deckhouse release being auto-applied as a patch when no Deployed release object is present.
- **[deckhouse]** limit the impact of a failed documentation build
- **[deckhouse]** Surface layer read errors instead of extracting a truncated image
- **[deckhouse]** Do not inject source registry into a still-embedded module
- **[deckhouse-controller]** Module releases rendered with nelm no longer raise false absent-resource alerts.
- **[deckhouse-controller]** nelm now takes over fields left by the old Helm 3 engine, so stale fields get removed on module upgrade.
- **[docs]** Clarify that DKP does not support version downgrades
- **[docs]** Add nil-safety guards for OpenAPI extraction to prevent panics.
- **[docs]** Fixed incorrect description of allowedHostPaths in SecurityPolicy documentation.
- **[docs]** Fix broken documentation links
- **[docs]** Clarified AutoPatch update mode and external module update settings.
- **[docs]** Fixed ModuleUpdatePolicy example in release channel FAQ.
- **[documentation]** Fix a memory leak in the documentation builder so memory is released between builds; add CPU/memory limits and an opt-in profiling endpoint.
- **[istio]** Add missing tools to proxyv2 images so the application-aware proxy termination hook works correctly.
- **[istio]** Fix graceful draining of established HTTP connections when application pods terminate.
- **[istio]** Create the ConfigMaps required for additional JWKS root CA certificates.
- **[keepalived]** Fixed Python linking in the keepalived module image.
- **[network-gateway]** Fixed Python linking in the network-gateway module image.
- **[node-local-dns]** Bump Go dependencies in the coredns helper image to fix known CVEs.
  The node-local-dns DaemonSet pods will restart after the update.
- **[registry]** Fix DKP bootstrap retry by keeping the `registry-init` secret.
- **[registrypackages]** Rebuild kubernetes-cni with updated Go dependencies to fix CVEs.
- **[tools]** Fixed module release validation incorrectly failing for `!optional` dependencies when the required module doesn't exist in the cluster.
- **[user-authn]** ClusterAdmin can watch the Dex storage CRDs (passwords, offlinesessionses), not only list them.

1.76.8

Know before update

- All Ingress-nginx controller pods will be restarted.
- The coredns and kube-dns components will restart after the update.
- The egress-gateway-agent component will restart after the update.
- The node-local-dns components will restart after the update.
- The service-with-healthchecks components (controller, agent) will restart after the update.

Features

- **[docs]** Update node-termination-handler behaviour in cloud-provider-aws module architecture section

Fixes

- **[cloud-provider-dvp]** skip foreign nodes in cloud controller manager
- **[cni-cilium]** Bump Go dependencies in the egress-gateway-agent image to fix known CVEs.
  The egress-gateway-agent component will restart after the update.
- **[deckhouse]** Skip the multiple CNI check in the enable_cni hook while a CNI migration is in progress to avoid a stuck Deckhouse queue.
- **[deckhouse-controller]** Re-derive the module release chain and align the from-to gap check with the release updater so intermediate releases are created instead of the chain freezing
- **[deckhouse-controller]** ModuleDocumentation will not be created for embedded modules.
- **[ingress-nginx]** Nginx version is updated to 1.30.4.
  All Ingress-nginx controller pods will be restarted.
- **[kube-dns]** Bump Go dependencies in the sts-pods-hosts-appender-webhook and coredns images to fix known CVEs.
  The coredns and kube-dns components will restart after the update.
- **[node-local-dns]** Bump Go dependencies in the safe-updater and stale-dns-connections-cleaner images to fix known CVEs.
  The node-local-dns components will restart after the update.
- **[service-with-healthchecks]** Bump Go dependencies in the service-with-healthchecks image to fix known CVEs.
  The service-with-healthchecks components (controller, agent) will restart after the update.
- **[user-authn]** Fix Dex token refresh with upstream providers that rotate refresh tokens (GitLab), which logged users out every `idTokenTTL`.
- **[user-authn]** backport fix of 21615
- **[user-authn]** Accessing kubernetes api via gateway api fixed.

1.76.7

Fixes

- **[cloud-provider-huaweicloud]** Fixed the Machine initialization contract — new nodes could not join the cluster.

1.76.6

Know before update

- All ingress-nginx controller pods of v1.10 will be restarted.
- The cilium-hubble components (hubble-ui, hubble-relay) will restart after the update.
- The cni-cilium components (cilium agent, operator) will restart after the update.
- The metallb components (controller, speaker, l2lb) will restart after the update.
- Users with accessLevel ClusterAdmin in ClusterAuthorizationRule gain read and write access to DVPInstanceClass objects; previously all access was denied.
- Users with accessLevel ClusterAdmin in ClusterAuthorizationRule gain read and write access to DynamixInstanceClass objects; previously all access was denied.

Fixes

- **[candi]** Add exception for Oracle Linux UEK kernels for fix CVE-2025-37999 on bashible
- **[cilium-hubble]** Upgrade hubble-ui backend dependencies (cilium v1.17.16, Go 1.25.0) and switch build base image to fix known CVEs.
  The cilium-hubble components (hubble-ui, hubble-relay) will restart after the update.
- **[cloud-provider-dvp]** Fix DVPInstanceClass access for users with user-authz ClusterAdmin role
  Users with accessLevel ClusterAdmin in ClusterAuthorizationRule gain read and write access to DVPInstanceClass objects; previously all access was denied.
- **[cloud-provider-dynamix]** Fix DynamixInstanceClass access for users with user-authz ClusterAdmin role
  Users with accessLevel ClusterAdmin in ClusterAuthorizationRule gain read and write access to DynamixInstanceClass objects; previously all access was denied.
- **[cloud-provider-vsphere]** fix missing default StorageClass annotation when a DatastoreCluster entry sorts before all Datastore entries
- **[cni-cilium]** Bump Go dependencies and backport upstream cilium security patches to fix known CVEs.
  The cni-cilium components (cilium agent, operator) will restart after the update.
- **[common]** Fix curl in debug-container by shipping a static binary
- **[common]** Bump Go dependencies in the cni-migration-controller and cni-migration-init-checker images to fix known CVEs.
- **[deckhouse]** atomically install modules and re-download incomplete versions
- **[deckhouse]** Restore admin access to list moduleconfigs
- **[deckhouse]** Fix hugo CVE.

- **[deckhouse-controller]** Fix maintenance state tracking — module no longer gets stuck in Unmanaged after removing maintenance.
- **[deckhouse-controller]** Force embedded modules back to the “Embedded” source on startup, healing a stale external source that previously stuck until the Module resource was deleted manually.
- **[docs]** Added a note about the termination of support for Ubuntu 20.04 and replace the link to the Docker container registry.
- **[docs]** Added a note about changing the name of the Docker container registry.
- **[documentation]** Bump Hugo version to 0.163.3
- **[ingress-nginx]** Controller 1.10 image uid and gid are set to deckhouse.
  All ingress-nginx controller pods of v1.10 will be restarted.
- **[metallb]** Bump Go dependencies in the metallb and l2lb images to fix known CVEs.
  The metallb components (controller, speaker, l2lb) will restart after the update.
- **[node-manager]** Fix create_rbac_and_certificate_for_kubernetes_api_proxy hook behavior.
- **[user-authn]** User-authn httproutes are refactored.

1.76.5

Know before update

- With enableMultiTenancy, effective access is now the union of CAR (within its limitNamespaces/namespaceSelector), AuthorizationRules, and plain RoleBindings/ClusterRoleBindings. Previously the webhook denied requests outside the CAR scope even when RBAC explicitly granted them: such existing bindings for subjects with a CAR silently become effective after the upgrade — review them. The CAR access level still does not apply outside its namespace limits. AccessibleNamespaces reflects the same union.
- log-shipper

Fixes

- **[cert-manager]** Additional letsencrypt-staging cluster issuer for Gateway API is provided.
- **[ci]** This is a manual cherry-pick the script for the CI fix in the release branch
- **[cilium-hubble]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[cloud-provider-dvp]** fix dvp kubernetes dependency mismatch
- **[cloud-provider-huaweicloud]** Adds patches to the upstream version to make it ignore static nodes
- **[deckhouse]** Bump addon-operator to fix module install with conversion webhooks
- **[deckhouse-controller]** Bump addon-operator to v1.21.22 — propagate module context to nelm logs.
- **[deckhouse-tools]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[docs]** Fix ingressClass description in global settings
- **[docs]** Corrected the link from direct to relative in the alert about the module requirements.
- **[docs]** Corrected the link from direct to relative in the alert about the module requirements for external modules.
- **[docs]** Add missing sidebar title mappings for Istio documentation CR page.
- **[documentation]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[istio]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[log-shipper]** fix daemonset template
  log-shipper
- **[openvpn]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[prometheus]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[registry]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[registry-packages-proxy]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[upmeter]** Gateway API certificate manifest is updated to support any cluster issuer.
- **[user-authn]** Gateway API certificate manifest is updated to support any cluster issuer.
  Kubernetes API HTTProute was updated to return 403 instead of 404.
- **[user-authz]** Honor CAR-independent RBAC in webhook and permission-browser
  With enableMultiTenancy, effective access is now the union of CAR (within its limitNamespaces/namespaceSelector), AuthorizationRules, and plain RoleBindings/ClusterRoleBindings. Previously the webhook denied requests outside the CAR scope even when RBAC explicitly granted them: such existing bindings for subjects with a CAR silently become effective after the upgrade — review them. The CAR access level still does not apply outside its namespace limits. AccessibleNamespaces reflects the same union.

1.76.4

Know before update

- kube-apiserver static pod is reconfigured and restarts on the next control-plane sync.

Features

- **[cloud-provider-dvp]** Add an option to disable the CCM LoadBalancer functionality via ConfigMap.
- **[docs]** Add operator-argo module architecture section
- **[docs]** Add module module architecture section

Fixes

- **[candi]** kube-apiserver no longer caches watches for `ManifestCheckpointContentChunk` resources from `state-snapshotter`.
  kube-apiserver static pod is reconfigured and restarts on the next control-plane sync.
- **[ci]** Fix extract images_digests.
- **[deckhouse]** Fix module metadata (`module.yaml`/`oss.yaml`) missing from in-cluster documentation by allowing these files in `IsDocsPath` (sender) and creating parent directories on extraction in the docs-builder (receiver).
- **[deckhouse]** Fixes an unauthenticated path traversal (CWE-22) in docs-builder by validating moduleName/channels and enforcing base-directory containment before any filesystem operation.
- **[deckhouse]** Remove documentation networkPolicy.
- **[deckhouse]** Add log diagnostic command to ModuleIsNotValid alert description.
- **[deckhouse]** Use metav1.Duration for ModulePullOverride scanInterval
- **[deckhouse-controller]** Fix deckhouse-controller crash loop and hooks receiving silently empty snapshots
- **[deckhouse-controller]** Fixed showing warnings while errors during kubectl edit.
- **[deckhouse-controller]** Fixed ModuleConfig validation.
- **[docs]** Document self-service password reset
- **[documentation]** remove stale fox links
- **[user-authn]** Preserve Dex Password fields (notably groups) when resetting password, locking or unlocking a user, so users are no longer locked out after these operations.

1.76.3

Know before update

- All ingress-nginx controllers pod will be restarted.
- Previously, a transient cluster DNS failure could cause the user-authz-webhook liveness probe to fail and restart the pod, which combined with the fail-closed authorization webhook (failurePolicy: Deny) could deny all API requests, including cluster-admins, until DNS recovered.

Features

- **[deckhouse-controller]** harden migrated modules check
- **[istio]** Custom annotations for Ingress Controller
- **[istio]** Custom extension providers
- **[istio]** JWKS extra root CA implementation

Fixes

- **[ci]** fix unlimited upmeter iterations
- **[cloud-provider-vcd]** add werf deploy-dependency annotations to capcd webhook configurations to fix DMT lint and prevent race on install/upgrade
- **[deckhouse]** Fix serialize docs builder builds.
- **[dhctl]** Preflight checks are no longer re-run on every dhctl-server restart when the cluster config is unchanged.
- **[docs]** Fix broken-link. Module admission
- **[docs]** Change security events docs
- **[ingress-nginx]** The config hashing is fixed.
  All ingress-nginx controllers pod will be restarted.
- **[kube-dns]** Added deploy dependencies for webhook configuration
- **[node-manager]** Creating or re-applying an already-existing StaticInstance no longer fails address validation.
- **[user-authz]** user-authz-webhook now uses the node-local kube-apiserver endpoint for its discovery cache and liveness check, instead of resolving the “kubernetes.default” DNS name. Previously, a transient cluster DNS failure could cause the user-authz-webhook liveness probe to fail and restart the pod, which combined with the fail-closed authorization webhook (failurePolicy: Deny) could deny all API requests, including cluster-admins, until DNS recovered.

1.76.2

Features

- **[docs]** Add registry module architecture section.
- **[istio]** Add deploy dependencies for Istio webhook configurations

Fixes

- **[deckhouse]** fix libs in the python-based images
- **[dhctl]** fix grpc stream cancel deadlock
- **[docs]** Added the ml/ai tag to the ai-models module on the modules homepage.
- **[registry]** Missing copy_custom_certificate for Gateway API path was added.
- **[registry-packages-proxy]** Missing Gateway API objects were added.
- **[vertical-pod-autoscaler]** Ensure VPA mutating webhook is deployed after its admission controller Deployment and Service are ready.

1.76.1

Know before update

- After upgrading to v1.76.0, kubectl logs and exec fail cluster-wide for all users. Manual workaround is available — see PR description.
- All ingress-nginx controller pods using default controller version will be restarted.

Features

- **[deckhouse]** Ensure conversion hooks.
- **[docs]** Add auxiliary components (of virtualization module) architecture page.
- **[docs]** Update csi-scsi-generic module architecture section
- **[docs]** Add deep-link anchors and auto-expand logic for collapsible sections.
- **[docs]** Add page about pod security settings

Fixes

- **[candi]** Fix containerd credential escaping by rendering username/password into auth string.
- **[ci]** remove CSE in deploy
- **[cloud-provider-dvp]** CVE fixes
- **[control-plane-manager]** fix Helm adoption of kubeadm:cluster-admins CRB on upgrade from pre-v1.76
  After upgrading to v1.76.0, kubectl logs and exec fail cluster-wide for all users. Manual workaround is available — see PR description.
- **[deckhouse]** Fix stale application conditions during update over a failed version
- **[deckhouse-controller]** Add alias for legacy bash completion flag.
- **[deckhouse-controller]** add werf dependency to webhook
- **[docs]** Deleted the note about the beta version of the graphical installer on the DKP installation page.
- **[docs]** Update the wording in the FAQ section
- **[ingress-nginx]** Default ingress controller version is reverted to 1.10.
  All ingress-nginx controller pods using default controller version will be restarted.
- **[user-authn]** Fix blank dex error page caused by missing BuildIdentifier in the error template data struct.

Version 1.75

Important

- Support for Kubernetes 1.35 has been added, while support for Kubernetes 1.30 has been discontinued. In future DKP releases, support for Kubernetes 1.31 will be removed. The default Kubernetes version (used when the `kubernetesVersion` parameter is set to `Automatic`) has been changed to 1.33.

- Update to DKP 1.75 will be blocked if the cluster uses one of the following deprecated component versions (they are no longer supported):
  - IngressNginxController v1.9
  - Istio v1.19

- In DKP 1.75.0–1.75.3, the `PodSecurityStandardsViolation` alert may fire immediately after cluster installation. This happens when the `d8-system` namespace is missing the `heritage=deckhouse` label, causing Pod Security Standards policies to be mistakenly applied to DKP system pods. The issue is fixed in DKP 1.75.4.

  For clusters installed on DKP 1.75.0–1.75.3, add the required label manually using the following command:

  ```
  d8 k --as=system:sudouser label namespace d8-system heritage=deckhouse
  ```

- Istio version support changes:
  - Support for Istio 1.19 has been discontinued.
  - Istio 1.21 is now considered deprecated, and support for this version will be discontinued in the upcoming DKP releases. To update Istio, follow the instruction.

- Starting with Kubernetes 1.35, cluster nodes must use cgroup v2. The previous version (cgroup v1) is considered deprecated. If cgroup v2 is not supported on a node, the D8NodeCgroupV2NotSupported alert will be triggered. See the Kubernetes documentation for cgroup v2 migration details.
- Starting with Kubernetes 1.36, cluster nodes must use containerd v2 as the container runtime. Support for containerd v1 will be discontinued. If containerd v2 is not supported on a node, the D8NodeContainerdV2NotSupported alert will be triggered.
- The `vertical-pod-autoscaler` module has been updated from version 1.4.1 to 1.5.1. Starting from version 1.5.0, the `updateMode: Auto` mode is considered deprecated. Users are advised to replace it with `updateMode: InPlaceOrRecreate`. See the vertical scaling documentation for details.
- When issuing new certificates using the `cert-manager` module, the certificate's private key is now re-generated as well. This change mitigates potential security risks.
- Pods handling HTTP-01 challenges via Issuer and ClusterIssuer resources now have default resource requests defined. As a result, these pods consume part of the cluster and project resource quotas upon creation.
- The operator-trivy module is now delivered from an external source and follows an independent release cycle. No manual migration steps are required.

Deckhouse subsystem

- The ModuleSource resource now includes the `scanInterval` parameter to control how frequently the container registry is checked for new modules and versions.
- A dedicated node mode with the `node.deckhouse.io/etcd-arbiter` label has been introduced. In this mode, only etcd runs on the node (no control plane components). This enables a highly available cluster with two master nodes plus a dedicated etcd node, reducing resource requirements compared to the traditional three full master nodes configuration. See the High Availability documentation for details.
- New operating modes have been introduced in the `registry` module: **Proxy** (with image caching) and **Local** (for isolated environments). These modes are currently supported only for already deployed static clusters and are not yet available during DKP cluster installation.
- Container registry access parameters can now be configured via the deckhouse module during DKP cluster installation. Support for the DKP cluster deployment via Direct and Unmanaged modes has been added. The Legacy Unmanaged mode (via InitConfiguration) is preserved for compatibility. If no explicit configuration is provided, the mode is selected automatically.
- Added user shell validation: if a shell other than bash is used, the `dhctl` utility now displays a clear error message.
- Added StaticInstance validation before DKP installation using the corresponding SSHCredentials, preventing `dhctl` from reporting readiness before the cluster deployment is actually complete.
- Extended preflight test coverage to improve cluster deployment predictability.
- Partially reduced usage of netcat in bashible, lowering the number of security system triggers.
- Fixed an issue where cluster installation could not be resumed after interruption.
- Fixed Node object deletion logic during `converge`. The node is now properly removed from the cluster after the corresponding VM is destroyed.
- Fixed the `--skip-resources` flag behavior in `dhctl destroy` command. Specified resources are now correctly skipped.

Kubernetes & Scheduling subsystem

- A new `update-observer` component in the `control-plane-manager` module enables real-time tracking of control plane component updates (kube-apiserver, kube-scheduler, kube-controller-manager) and kubelet on nodes. This helps detect discrepancies and eliminates "blind spots" during Kubernetes updates.
- For all VPA resources managed by DKP, `updateMode: Auto` has been automatically replaced with `updateMode: InPlaceOrRecreate`. For clusters running Kubernetes 1.32 or earlier, the `InPlacePodVerticalScaling` feature gate is automatically enabled in control plane components (kube-apiserver, kube-scheduler, kube-controller-manager) and kubelet. This allows pod resource changes without recreation.

- The descheduler module has been updated to version 0.34. Key changes:
  - Priority-based pod eviction: pods with a higher restart count are evicted first, improving cluster stability during load redistribution.
  - DRA support: proper handling of resources managed via Dynamic Resource Allocation.
  - Default `cpu`, `memory`, and `pods` thresholds removed from `lowNodeUtilization` and `highNodeUtilization` strategies to align with upstream behavior.

IAM subsystem

- Namespace listing behavior has been changed. When requesting all cluster namespaces, users now see only the namespaces they have access to, even without permission to list all namespaces. This improves working with multitenancy and UI.
- The ProjectTemplate resource in the `multitenancy-manager` module now supports the unmanaged and skip-heritage options (set via annotations), allowing administrators to adjust the DKP control degree over resources:
  - `unmanaged`: The module does not manage the lifecycle of objects.
  - `skip-heritage`: DKP retains management but allows modification by external controllers.
- Added support for authenticating to the Kubernetes API via LDAP using Basic authentication instead of OIDC tokens (via the `ldap.enableBasicAuth` parameter in the DexProvider resource).
- The authorization webhook in the `user-authz` module now operates in fail-closed mode: if it's unavailable, authorization is denied. For improved reliability, webhook communication with the apiserver is performed via the cluster node network.
- The `user-authn` module now supports a global user session lifetime limit (via `refreshTokenAbsoluteLifetime`). Re-authentication is required after expiration.
- The `user-authn` module now supports Kerberos (SPNEGO) authentication in DKP.
- Updated kube-apiserver TLS cipher suites. Removed the following insecure ciphers from the `--tls-cipher-suites` flag: TLS_RSA_WITH_AES_256_GCM_SHA384 and TLS_RSA_WITH_AES_128_GCM_SHA256 (considered unsafe due to RSA key exchange). Added TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256 and TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256.
- The anonymous access restriction mechanism for the API server has been modified. Instead of using the `--anonymous-auth=false` flag and a sidecar proxy, the AuthenticationConfiguration resource is now used to allow anonymous access only to `/livez`, `/readyz`, and `/healthz`. This improves cluster resource efficiency. Anonymous probe access remains restricted when public API access is enabled via `publishAPI.enabled`.

Security subsystem

- Fixed serialization of empty arrays and objects in SecurityPolicy and OperationPolicy resources of the `admission-policy-engine` module. Previously, some settings could be applied incorrectly.
- Revised ModSecurity extension implementation. OWASP Core Rule Set (CRS) functionality is now available in all supported IngressNginxController versions.

Cluster & Infrastructure subsystem

- Lifecycle stages updated for cloud provider integration modules:
  - `cloud-provider-dvp` (DVP), `cloud-provider-vcd` (VMware Cloud Director), `cloud-provider-huaweicloud` (Huawei Cloud), and `cloud-provider-zvirt` (zVirt) modules are now General Availability (previously Experimental).
- Added support for swap memory usage by pods. Instead of immediate OOM-kill, a pod can temporarily use swap (if configured and available on the node) and continue running after peak usage. Requires cgroup v2 and sufficient node resources. For details, see the `kubelet.memorySwap` parameter in the NodeGroup resource documentation.
- In the DVP cloud provider:
  - Added the `networkPolicy` parameter to define network traffic rules for workloads within a Project resource.
  - Added `managed-by`, `cluster-uuid`, and `vm_name` labels to all infrastructure objects.
  - Improved CSI driver diagnostics. Diagnostic messages are now displayed directly in PersistentVolumeClaim status.
  - Implemented automatic cleanup of VMBDA objects when a VM is deleted.
  - Fixed an issue where DeckhouseMachine objects could remain in deleting state after VM removal.
  - Fixed an issue where Cloud Controller Manager (CCM) could recreate external load balancers

after the associated Kubernetes Service was deleted.

- In Yandex Cloud, fixed a false NAT warning displayed during installation in configurations where NAT is not used.
- In the `node-manager` module:
  - Cluster API (CAPI) has been updated from 1.10.6 to 1.11.3, improving stability and provider compatibility.
  - Added a dedicated controller for NodeGroup hooks (extracted from DKP), reducing load on master nodes and improving responsiveness and UI feedback.
  - Added per-GPU MIG configuration support. You can now define a distinct set of MIG partitions for each physical GPU on a node. Previously, MIG configuration was applied at the node level and identical across all GPUs. This enables more flexible workload resource allocation on a single node.

Network subsystem

- In IngressNginxController, the `acceptClientIPHeadersFrom` parameter has been added for the following inlets: HostPort, HostPortWithProxyProtocol, LoadBalancer, and LoadBalancerWithProxyProtocol. The parameter defines trusted CIDR ranges for `X-Forwarded-*` headers that should not be overwritten during proxying.
- In the `cni-cilium` module, network observability capabilities have been extended:
  - Added extended metrics for monitoring interactions between specific objects (Pods, Services, Namespaces), configurable via the `extendedMetrics` parameter of the HubbleMonitoringConfig resource.
  - Implemented export of traffic flow logs for analyzing network interactions, configurable via the `flowLogs` parameter of the HubbleMonitoringConfig resource.
- Fixed an issue where, after VM migration in DVP, a LoadBalancer IP address could stop being announced when using MetalLB in BGP mode.
- IngressNginxController version support changes:
  - Support for v1.9 has been discontinued.
  - Support for v1.14 has been added.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.75.16

Fixes

- **[istio]** Add missing tools to proxyv2 images so the application-aware proxy termination hook works correctly.
- **[istio]** Fix graceful draining of established HTTP connections when application pods terminate.

1.75.15

Know before update

- The cilium-hubble components (hubble-ui, hubble-relay) will restart after the update.
- The cni-cilium components (cilium agent, operator) will restart after the update.
- The coredns and kube-dns components will restart after the update.
- The egress-gateway-agent component will restart after the update.
- The metallb components (controller, speaker, l2lb) will restart after the update.
- The node-local-dns DaemonSet pods will restart after the update.
- The node-local-dns components will restart after the update.
- The service-with-healthchecks components (controller, agent) will restart after the update.

Fixes

- **[cilium-hubble]** Upgrade hubble-ui backend dependencies (cilium v1.17.16, Go 1.25.0) and switch build base image to fix known CVEs.
  The cilium-hubble components (hubble-ui, hubble-relay) will restart after the update.
- **[cni-cilium]** Bump Go dependencies in the egress-gateway-agent image to fix known CVEs.
  The egress-gateway-agent component will restart after the update.
- **[cni-cilium]** Bump Go dependencies and backport upstream cilium security patches to fix known CVEs.
  The cni-cilium components (cilium agent, operator) will restart after the update.
- **[deckhouse]** An unset `settings.update.mode` now defaults to `AutoPatch` instead of silently running as `Auto`.
- **[deckhouse]** Fix a minor Deckhouse release being auto-applied as a patch when no Deployed release object is present.

- **[deckhouse]** Surface layer read errors instead of extracting a truncated image
- **[kube-dns]** Bump Go dependencies in the sts-pods-hosts-appender-webhook and coredns images to fix known CVEs.
  The coredns and kube-dns components will restart after the update.
- **[metallb]** Bump Go dependencies in the metallb and l2lb images to fix known CVEs.
  The metallb components (controller, speaker, l2lb) will restart after the update.
- **[node-local-dns]** Bump Go dependencies in the safe-updater and stale-dns-connections-cleaner images to fix known CVEs.
  The node-local-dns components will restart after the update.
- **[node-local-dns]** Bump Go dependencies in the coredns helper image to fix known CVEs.
  The node-local-dns DaemonSet pods will restart after the update.
- **[service-with-healthchecks]** Bump Go dependencies in the service-with-healthchecks image to fix known CVEs.
  The service-with-healthchecks components (controller, agent) will restart after the update.
- **[tools]** Fixed module release validation incorrectly failing for `!optional` dependencies when the required module doesn't exist in the cluster.

1.75.14

Fixes

- **[common]** Fix curl in debug-container by shipping a static binary
- **[deckhouse]** atomically install modules and re-download incomplete versions
- **[deckhouse]** show the allow-disabling annotation hint when disabling a confirmation-required module
- **[deckhouse]** Fix CVEs.
- **[deckhouse-controller]** Fix maintenance state tracking — module no longer gets stuck in Unmanaged after removing maintenance.
- **[docs]** Corrected the link from direct to relative in the alert about the module requirements.

1.75.13

Fixes

- **[deckhouse]** Fix nil pointer panic in resource and namespace informers by using each informer's own logger instead of the possibly-nil Monitor.Logger.
- **[user-authn]** Preserve Dex Password fields (notably groups) when resetting password, locking or unlocking a user, so users are no longer locked out after these operations.

1.75.12

Know before update

- Previously, a transient cluster DNS failure could cause the user-authz-webhook liveness probe to fail and restart the pod, which combined with the fail-closed authorization webhook (failurePolicy: Deny) could deny all API requests, including cluster-admins, until DNS recovered.

Fixes

- **[candi]** fix if node has bashible-uninitialized taint in race condition.
- **[deckhouse]** add cryptography CVE VEX to deckhouse-controller
- **[deckhouse]** Fix module metadata (`module.yaml` / `oss.yaml`) missing from in-cluster documentation by allowing these files in `IsDocsPath` (sender) and creating parent directories on extraction in the docs-builder (receiver).
- **[deckhouse-controller]** Don't create an external module release for a module that is still shipped embedded, so it can't replace or duplicate the embedded copy.
- **[deckhouse-controller]** Disabling modules with confirmation will be rejected without using the annotation.
- **[docs]** Added the ml/ai tag to the ai-models module on the modules homepage.
- **[docs]** Fix broken-link. Module admission
- **[documentation]** Add /app/hugo to docs-builder mount points
- **[user-authz]** user-authz-webhook now uses the node-local kube-apiserver endpoint for its discovery cache and liveness check, instead of resolving the "kubernetes.default" DNS name. Previously, a transient cluster DNS failure could cause the user-authz-webhook liveness probe to fail and restart the pod, which combined with the fail-closed authorization webhook (failurePolicy: Deny) could deny all API requests, including cluster-admins, until DNS recovered.

1.75.11

Know before update

- All ingress-nginx pods will be restarted.

Fixes

- **[common]** Fixed CVE-2026-40898 in CoreDNS by updating the quic-go dependency.
- **[ingress-nginx]** Nginx is updated to 1.30.3.
  All ingress-nginx pods will be restarted.

1.75.10

Features

- **[docs]** Add csi-ceph module architecture section.
- **[docs]** Add Core component (of virtualization module) architecture section.
- **[documentation]** Update editions availability info for stronghold module.

Fixes

- **[candi]** fix cve node-manager and opentofu.
- **[cilium-hubble]** Fixed CVE-2026-29181 in hubble-ui-backend by bumping OpenTelemetry Go to v1.41.0
- **[cilium-hubble]** Fixed CVE-2026-41520 in hubble-ui-backend
- **[cni-cilium]** Fixed CVE-2026-41520 for cilium-bugtool util
- **[cni-flannel]** Reverted module stage from Deprecated back to General Availability to stop false deprecation alerts.
- **[common]** fixed CVE-2026-29181 in the CoreDNS
- **[deckhouse-controller]** A module that conditionally depends on another is no longer disabled when an incompatible version of that dependency is enabled; the enable is rejected instead.
- **[deckhouse-controller]** fix module config validation for disable warnings
- **[docs]** Add a general description of container registers DKP
- **[docs]** Updated the etcd restore documentation.
- **[docs]** Fix CRD version tabs markup and nesting.
- **[istio]** Implement graceful metadata secret renewal for multiclusters.
- **[network-policy-engine]** Reverted module stage from Deprecated back to General Availability to stop false deprecation alerts.
- **[node-manager]** hook to restore apiVersion on CAPI resources.
- **[node-manager]** Fix static NodeGroup readiness calculation.
- **[node-manager]** add rbac policies for persistantvolumes to manage from capi-controller-manager.
- **[tools]** fix d8 build

1.75.9

Know before update

- All Ingress-nginx controller pods will be restarted.

Fixes

- **[admission-policy-engine]** Refactor main documentation page
- **[ingress-nginx]** Nginx was updated to 1.30.2.
  All Ingress-nginx controller pods will be restarted.

1.75.8

Know before update

- Registry pods will be restarted.

Features

- **[docs]** Update deckhouse web modules architecture section.

Fixes

- **[csi-vsphere]** Fixed the Deckhouse queue getting stuck
- **[docs]** Change network-policy-engine and cni-flannel to deprecated.
- **[monitoring-deckhouse]** Fix module-release alerts (`ModuleReleaseIsWaitingManualApproval`, `ModuleReleaseIsOutdated`, `ModuleReleaseIsBlockedByRequirements`, `ModuleIsInMaintenanceMode`, `D8ModuleOutdatedByMajorVersion`) that never fired on 1.75.x clusters due to a `moduleName` → `module` label mismatch introduced when addon-operator was bumped to v1.19.7 in v1.75.1.
- **[registry]** Updated auth image Go dependencies to fix Go CVEs.
  Registry pods will be restarted.
- **[user-authn]** Improve basic-auth-proxy request handling, cache implementation, and shutdown behavior.

1.75.7

Know before update

- All Ingress-nginx controller pods will be restarted.

Features

- **[docs]** Add Deckhouse web modules architecture section.
- **[docs]** Add cert-manager module architecture section.

Fixes

- **[cloud-provider-vsphere]** normalizes new paths and makes bashible resolve existing paths case-insensitively
- **[cni-cilium]** Fixed CVE-2026-35469
- **[deckhouse]** Fix exp modules auto enabling.
- **[deckhouse]** Fixed global configuration generation.
- **[dhctl]** Wait for stronghold cluster sync before node deletion
- **[docs]** Refactored web UI page.
- **[docs]** New screenshots have been added to the Console documentation.
- **[ingress-nginx]** Nginx is updated up to 1.30.1.
  All Ingress-nginx controller pods will be restarted.

1.75.6

Fixes

- **[admission-policy-engine]** Fixed enforcementAction for D8ReplicaLimits, added more template tests.
- **[dhctl]** fix SSH preflight check for StaticInstances with password-only auth.
- **[docs]** Fix broken links in VPA section.
- **[docs]** Fix visibility scope for nested details component
- **[docs]** Add info about kernel requirement for containerdv2 migration.
- **[node-manager]** CAPI crd served version fix
- **[node-manager]** Added cleanup for oversized MCM MachineSet revision history annotation

1.75.5

Know before update

- module pods will be restarted

Features

- **[docs]** Add a Jekyll plugin for tabbed content in the documentation.
- **[istio]** Allow custom ports in metadataEndpoint URLs for IstioFederation and IstioMulticluster CRDs.

Fixes

- **[candi]** Added a Netplan override to force the secondary NIC to use the main routing table, fixing cloud-init PBR conflicts.
- **[common]** Fixed an issue where Trivy could not detect VEX files in coredns images.
- **[deckhouse]** Overwrite currentReleaseImageName on mismatch.
- **[deckhouse]** Allow updating scanInterval on the deckhouse ModuleSource.
- **[istio]** fixed CVEs in module images
  module pods will be restarted
- **[service-with-healthchecks]** Correct RBACv2 is provided.
- **[terraform-manager]** Fix opentofu patches build after pull request 19080.

1.75.4

Know before update

- All Ingress-NGINX controller pods will be restated.
- All pods of Ingress-NGINX controller of 1.10 and 1.12 versions will be restarted.
- Cilium agents will be restarted during the update.
- HPA scaler pods will be restarted.
- Kruise controller will be restarted.
- These changes prevent unnecessary or destructive plan updates that could occur when data sources depend on changing labels and annotations. The behavior of other cloud providers is not affected. If you encounter unexpected converge plans or cluster bootstrap issues when using OpenTofu-based providers (such as dvp, dynamics, zvirt, or yandex), please report them to

Deckhouse Technical Support.
- This update triggers a rolling update of the flannel pods.
- This update triggers a rolling update of the kube-proxy pods.
- This update triggers a rolling update of the network-policy-engine pods.
- istio module pods will be restarted
- istio-cni-nodes will be restarted

Features

- **[docs]** Respect nowrap default for code blocks.
- **[docs]** Update sds-node-configuration module architecture section.
- **[docs]** Add geoproxy and failover to ingress-nginx module architecture section
- **[docs]** Add csi-nfs module architecture section.
- **[docs]** Add public cloud providers aws, azure, and gcp module architecture section.
- **[docs]** Add cloud-provider-vsphere module architecture section.
- **[docs]** Add cloud-provider-openstack module architecture section.
- **[terraform-manager]** Suppress destructive changes when add/remove/change labels and annotations for cloud resources via opentofu.
  These changes prevent unnecessary or destructive plan updates that could occur when data sources depend on changing labels and annotations. The behavior of other cloud providers is not affected. If you encounter unexpected converge plans or cluster bootstrap issues when using OpenTofu-based providers (such as dvp, dynamics, zvirt, or yandex), please report them to Deckhouse Technical Support.

Fixes

- **[admission-policy-engine]** Fix high resource consumption for constraint d8denyexecheritage
- **[candi]** Fix containerd unmount for migration if /var/lib/containerd is mounted manually.
- **[cert-manager]** Disable SecurityPolicyExceptions for cert-manager namespace
- **[cloud-provider-aws]** add information about AWS security group rules limits
- **[cloud-provider-dvp]** Suppress destructive changes when add/remove/change labels and annotations for cloud resources via opentofu.
- **[cloud-provider-vcd]** fix vCD CCM TCP health monitors removal
- **[cni-cilium]** Updated go-jose dependency to v4.1.4 to fix CVE-2026-34986.
  Cilium agents will be restarted during the update.
- **[cni-flannel]** Fixed CVE-2026-33186 by updating google.golang.org/grpc in flanneld.
  This update triggers a rolling update of the flannel pods.
- **[cni-simple-bridge]** Refactored python image source and pip exclusion.
- **[common]** Removed Python completely from the debug-container image as it is no longer needed, resolving corresponding CVEs, and silenced false positives for etcd binaries via VEX.
- **[deckhouse]** Return setting notified for mr.
- **[deckhouse]** Remove notified=false annotation reset from runReleaseDeploy in the module release controller.
- **[deckhouse]** Ensure heritage label on d8-system namespace via hook.
- **[deckhouse-controller]** Add new discoveryv1 scheme to deckhouse controller.
- **[deckhouse-controller]** added extra validation for kubernets version multiple downgrades scenario
- **[dhctl]** Use internal node ip if bastion ip was passed in converge.
- **[docs]** Fix indented Liquid blocks in lists.
- **[docs]** Fix broken links.
- **[docs]** Improved title generation for module documentation pages.
- **[ingress-nginx]** CVE-2025-15566 is fixed in 1.10 and 1.12 controllers.
  All pods of Ingress-NGINX controller of 1.10 and 1.12 versions will be restarted.
- **[ingress-nginx]** Added missing pod security context settings to hpa scaler pods.
  HPA scaler pods will be restarted.
- **[ingress-nginx]** Kruise go dependencies are updated to mitigate latest CVEs.
  Kruise controller will be restarted.
- **[ingress-nginx]** Added fix for CVE-2026-4342.
  All Ingress-NGINX controller pods will be restated.
- **[istio]** fixed CVE-2026-34986
  istio module pods will be restarted
- **[istio]** added iptables wrapper in cni-v1x21x6
  istio-cni-nodes will be restarted
- **[keepalived]** Excluded vulnerable pip-25.3 from keepalived final image to fix CVE-2026-1703
- **[kube-dns]** Refactored hook remove_old_coredns_deploy_and_svc — delegated deletion of original kube-dns service to helm.
- **[kube-proxy]** Fixed CVE-2026-33186 and CVE-2026-24051 in kube-proxy dependencies.
  This update triggers a rolling update of the kube-proxy pods.
- **[network-gateway]** Updated python image source and mitigated pip CVE-2026-1703
- **[network-policy-engine]** Fixed CVE-2026-34040, CVE-2026-33997, and CVE-2026-33186 in network-policy-engine dependencies.
  This update triggers a rolling update of the network-policy-engine pods.
- **[node-manager]** rollback inject capi conversion hook in crds as on-before-helm

- **[node-manager]** optimize node-controller cache resources usage.
- **[registrypackages]** Add vex for CVE-2026-39882
- **[registrypackages]** Remediated CVE-2026-32285 in crictl dependencies.

1.75.3

Know before update

- CoreDNS pods will undergo a rolling restart.

Features

- **[docs]** Add cloud-provider-yandex module architecture section.

Fixes

- **[common]** Fixed CVE-2026-33186 in the CoreDNS image.
  CoreDNS pods will undergo a rolling restart.
- **[deckhouse-controller]** revert nelm to helm
- **[dhctl]** Skip tmp lock for exporter and auto-converger.
- **[node-local-dns]** Fix werf manifest
- **[node-local-dns]** Adapt node-local-dns for air-gapped environments.
- **[node-manager]** deploy capi controller and webhooks before basic resources to prevent race condition during upgrades.
- **[registrypackages]** Added vex with CVE-2026-33186.

1.75.2

Know before update

- All Ingress-NGINX controller pods will be restarted.

Features

- **[cert-manager]** Add alerts for ACME Challenges stuck in pending or error states
- **[docs]** Add cloud providers dynamix, huaweicloud, and zvirt module architecture section.

Fixes

- **[ci]** Use GITHUB_TOKEN for backport action and set required workflow permissions
- **[cilium-hubble]** Fixed CVE-2026-33186 in the hubble-ui image.
- **[cni-cilium]** Fixed CVE-2026-33186, CVE-2026-27142, and CVE-2026-27139 by updating grpc dependency and Go version, and resolved build compatibility issues.
- **[common]** Fixed CVE-2026-24051 in the CoreDNS image.
- **[dhctl]** mitigate CVE-2026-33186
- **[ingress-nginx]** Nelm fixes are backported.
  All Ingress-NGINX controller pods will be restarted.

1.75.1

Know before update

- Registry pods will be restarted.
- ingressgateway, istio-cni-node, istiod, kiali, operator pods will be restarted after update

Features

- **[cloud-provider-zvirt]** add customNetworkConfig
- **[cloud-provider-zvirt]** add customNetworkConfig
- **[loki]** Added generation and usage of a dedicated TLS server certificate for Loki kube-rbac-proxy

Fixes

- **[admission-policy-engine]** Fix SecurityPolicyException handling for hostPorts-only exceptions
- **[cloud-provider-aws]** fix CVE in cloud-provider-aws
- **[cloud-provider-azure]** fix CVEs in cloud-provider-azure
- **[cloud-provider-dvp]** fix CVEs in cloud-provider-dvp
- **[cloud-provider-dvp]** fix CVEs in cloud-provider-dvp
- **[cloud-provider-dvp]** refactored CreateVolume to improve idempotency when disk.status.capacity is not yet reported and standardized gRPC error handling
- **[cloud-provider-huaweicloud]** fix CVEs in cloud-provider-huaweicloud
- **[cloud-provider-huaweicloud]** fix CVEs in cloud-provider-huaweicloud
- **[cloud-provider-openstack]** fix CVE in cloud-provider-openstack module
- **[cloud-provider-yandex]** fix CVEs in cloud-provider-yandex
- **[cloud-provider-zvirt]** fix CVEs in cloud-provider-zvirt

- **[cloud-provider-zvirt]** docs fox
- **[cni-cilium]** fixed mount-points in agent
- **[deckhouse]** Bump nelm version with deadlock fix.
- **[dhctl]** Fix restart bootstrap during creating additional nodes in cloud permanent node groups.
- **[dhctl]** Aix non-strict unmarshalling for metaconfigs.
- **[dhctl]** Fix deadlock in converge.
- **[docs]** Added the display of all used component versions in modules on the OSS info page.
- **[docs]** Add support for highlighting unknown code block types.
- **[docs]** Fix alerts rendering.
- **[docs]** Moving the platform update section to the top in the sidebar.
- **[docs]** Changing the term metka to label in Russian-language documentation.
- **[docs]** Escape HTML in OpenAPI descriptions v2
- **[docs]** Added info about using update-observer according to
- **[extended-monitoring]** fix typo in image-availability-exporter template
- **[istio]** cve fixes
  ingressgateway, istio-cni-node, istiod, kiali, operator pods will be restarted after update
- **[registry]** fixed path in images
- **[registry]** Updated auth image Go dependencies to fix Go CVEs.
  Registry pods will be restarted.
- **[registry-packages-proxy]** fix possible deadlock in cache retention policy
- **[tools]** Added HTTP client proxy support
- **[tools]** Bump lib-helm version to 1.71.2

Version 1.74

Important

- Support for Kubernetes 1.34 has been added, while support for Kubernetes 1.29 has been discontinued. In future DKP releases, support for Kubernetes 1.30 will be removed. The default Kubernetes version (used when the `kubernetesVersion` parameter is set to `Automatic`) has been changed to 1.32.

Major changes

- Added support for managing experimental and alpha Kubernetes features (feature gates) using the `enabledFeatureGates` parameter of the `control-plane-manager` module. For details on managing these features in DKP, refer to the module documentation.

- The `--terminated-pod-gc-threshold` parameter (the termination threshold for evicted pods) is now calculated automatically based on the number of nodes in the cluster. This provides a balance between cluster stability and the ability to perform diagnostics. Threshold values are available in the `control-plane-manager` module documentation.

- The maximum number of pods (`maxPods`) for a node group is now set automatically based on the `podSubnetNodeCIDRPrefix` parameter from ClusterConfiguration (unless explicitly specified). This ensures stable cluster operation.

- Added the `vipAddress` parameter to the HuaweiCloudInstanceClass resource of the Huawei Cloud provider, allowing you to specify a virtual IP address for all nodes in the instance class.

- The Huawei Cloud provider configuration now allows overriding the primary network for the main network interface (`mainNetwork`) and specifying subnets for additional network interfaces (`additionalNetworks`) on both CloudPermanent and CloudEphemeral nodes.

  Warning. When upgrading to DKP 1.74 on Huawei Cloud, a bulk recreation of CloudEphemeral nodes may occur. Due to a temporary node shortage, some Pods may fail to start.

- The archive with debugging data is now collected using the `d8` tool. If you need to collect diagnostic data, follow the instructions.

- Now when hook execution fails, all metrics collected by that hook are preserved. This prevents loss of debugging information and simplifies the following root-cause analysis.

- Fixed a Deckhouse queue freeze in hybrid clusters that occurred when module configuration parameters were incomplete.

Security

- Implemented module integrity control based on the EROFS filesystem to improve security and prevent unauthorized modifications. The new system requires kernel support for dm-verity and EROFS.

Network

- Added support for the SCTP (Stream Control Transmission Protocol). Applications using this protocol can now run in a Deckhouse cluster.
- Added a `geoproxy` auxiliary microservice to the `ingress-nginx` module. This service is aimed at improving the stability of the Ingress NGINX Controller when working with GeoIP databases and provides the following features:
  - MaxMind license saving (databases are downloaded from a single point once a day).
  - Persistent data storage (if components are restarted, it doesn't require accessing the MaxMind servers).
  - Lets you specify a custom mirror for downloading databases.
- Added the Prometheus metric `bpf_progs_complexity_max_verified_insts` to assess the number of instructions in eBPF programs loaded into the kernel on cluster nodes. This metric helps evaluate the compatibility of the networking subsystem with the node kernels. The metric requires Linux kernel version 5.16 or newer.
- Added a new metric (`geoip_version`) and dashboards for monitoring GeoIP functionality in the cluster.
- Fixed issues with simultaneous updates of the `node-local-dns` module and the networking subsystem.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.74.18

Fixes

- **[deckhouse-controller]** Don't create an external module release for a module that is still shipped embedded, so it can't replace or duplicate the embedded copy.
- **[deckhouse-controller]** A module that conditionally depends on another is no longer disabled when an incompatible version of that dependency is enabled; the enable is rejected instead.
- **[istio]** Implement graceful metadata secret renewal for multiclusters.
- **[network-gateway]** Updated dnsmasq to v2.92-alt2 to address multiple security vulnerabilities (CVE-2026-*)
- **[node-local-dns]** Fix name of registry secret in safe-updater deployment

1.74.17

Fixes

- **[node-manager]** Added cleanup for oversized MCM MachineSet revision history annotation

1.74.16

Know before update

- All Ingress-NGINX controller pods will be restarted.
- All pods of Ingress-NGINX controller will be restarted.
- This update triggers a rolling update of the kube-proxy pods.
- istio module pods will be restarted
- module pods will be restarted

Features

- **[docs]** Image zooming and mobile view.
- **[docs]** Add sds-node-configurator module architecture section.
- **[docs]** Add cloud-provider-vcd module architecture section.

Fixes

- **[admission-policy-engine]** cve fixes for ratify
- **[cloud-provider-azure]** fix disk discovery for Ubuntu 22.04 Gen2 VMs with NVMe controllers
- **[cloud-provider-openstack]** Increase interval and timeout for health monitor
- **[cloud-provider-vsphere]** Fix vSphere privilege matrix and describe instructions for setting up environment via vSphere Client
- **[cni-simple-bridge]** Updated base image reference to support new Werf import format.
- **[common]** Fixed an issue where Trivy could not detect VEX files in coredns images.
- **[common]** Removed Python completely from the debug-container image as it is no longer needed, resolving corresponding CVEs, and silenced false positives for etcd binaries via VEX.
- **[deckhouse]** Remove notified=false annotation reset from runReleaseDeploy in the module release controller.
- **[deckhouse]** Fix webhook-handler CVEs.

- **[dhctl]** Added validation of the command execution status code
- **[docs]** Fix vSphere privilege matrix and describe instructions for setting up environment via vSphere Client
- **[documentation]** Fix search.
- **[ingress-nginx]** CVE-2025-15566 is backported.
  All pods of Ingress-NGINX controller will be restarted.
- **[ingress-nginx]** CVE-2026-4342 fix is backported to Dechkouse 1.74.
  All Ingress-NGINX controller pods will be restarted.
- **[istio]** fixed CVEs in module images
  module pods will be restarted
- **[istio]** fixed CVE-2026-39882, CVE-2026-39883 and CVE-2026-35206
  istio module pods will be restarted
- **[istio]** fixed CVE-2026-34986
  istio module pods will be restarted
- **[kube-proxy]** Fixed CVE-2026-33186 and CVE-2026-24051 in kube-proxy dependencies.
  This update triggers a rolling update of the kube-proxy pods.
- **[network-gateway]** Fixed werf import syntax for compatibility with older werf versions.

1.74.15

Know before update

- An additional service daemonset will be added.
- CoreDNS pods will undergo a rolling restart.
- pods in d8-istio namespace will be restarted

Features

- **[docs]** Add snapshot-controller module architecture section.

Fixes

- **[ci]** Use GITHUB_TOKEN for backport action and set required workflow permissions
- **[cilium-hubble]** Fixed CVE-2026-33186 in the hubble-ui image.
- **[cni-cilium]** Fixed CVE-2026-33186, CVE-2026-27142, and CVE-2026-27139 by updating grpc dependency and Go version, and resolved build compatibility issues.
- **[common]** Fixed CVE-2026-33186 in the CoreDNS image.
  CoreDNS pods will undergo a rolling restart.
- **[dhctl]** mitigate CVE-2026-33186
- **[istio]** fixed cve in module images
  pods in d8-istio namespace will be restarted
- **[node-local-dns]** Return stale-dns-connections-cleaner
  An additional service daemonset will be added.
- **[registrypackages]** Added vex with CVE-2026-33186.

1.74.14

Features

- **[docs]** Add cloud-provider-dvp module architecture section.
- **[docs]** Add local-path-provisioner module architecture section.
- **[docs]** Update architecture section.

Fixes

- **[cloud-provider-zvirt]** fix CSI token refresh patch apply
- **[docs]** Added the display of the d8 utility version on the command reference page.
- **[istio]** Reduce CPU and RAM for regenerate multicluster JWT token and sort ingressGateway
- **[tools]** Added HTTP client proxy support

1.74.13

Fixes

- **[cloud-provider-openstack]** fix LB.enabled flag

1.74.12

Know before update

- All Ingress-Nginx controller pods will be restarted.

Fixes

- **[candi]** Added a Netplan override to force the secondary NIC to use the main routing table, fixing cloud-init PBR conflicts.
- **[ingress-nginx]** CVE-2026-3288 fix is backported in all Ingress-Nginx controllers.
  All Ingress-Nginx controller pods will be restarted.
- **[node-manager]** Fixed vulnerabilities.

1.74.11

Know before update

- Kruise controller pod will be restarted.
- Registry pods will be restarted.

Fixes

- **[admission-policy-engine]** Fix template tests
- **[ci]** Add zVirt testing to e2e tests to DKP 1.74.
- **[ci]** Backport the provider instance change and the new containerd version in OpenStack tests to release 1.74.
- **[cloud-provider-aws]** fix getInstancesByIDs to comply with the describeInstanceBatcher.
- **[cloud-provider-openstack]** Add loadBalancer.enabled flag to prevent CCM crashes on k8s 1.32 without Octavia service
- **[docs]** Correct the wording in the cloud-provider-vsphere module docs.
- **[docs]** Updated editions for the modules managed-postgres, managed-valkey and managed-memcached.
- **[ingress-nginx]** Golang versions are updated.
  Kruise controller pod will be restarted.
- **[registry]** Updated auth image Go dependencies to fix Go CVEs.
  Registry pods will be restarted.

1.74.10

Know before update

- All ingress-nginx controller pods will be restared.

Fixes

- **[ingress-nginx]** Nginx and module’s dependencies are updated.
  All ingress-nginx controller pods will be restared.

1.74.9

Know before update

- Workload Pods are no longer denied by unrelated SecurityPolicy checks (e.g. hostNetwork/hostPort) when corresponding policy fields are not explicitly set.

Fixes

- **[admission-policy-engine]** Prevent unintended Gatekeeper constraints from being rendered for SecurityPolicy when boolean fields are omitted.
  Workload Pods are no longer denied by unrelated SecurityPolicy checks (e.g. hostNetwork/hostPort) when corresponding policy fields are not explicitly set.
- **[candi]** Bashible script fix to handle multiple GPUs
- **[candi]** fix if node has bashible-uninitialized taint in race condition.
- **[ci]** Add ignoring of D8NodeContainerdV2NotSupported and D8NodeCgroupV2NotSupported alerts to release 1.74.
- **[cloud-provider-dvp]** added fixes an infinite deletion state of DeckhouseMachine.
- **[deckhouse]** Fix yaml validation in settings.
- **[docs]** Changing module descriptions
- **[docs]** Editing FAQ problems applying dexprovider
- **[docs]** Editing flannel to cillium.
- **[docs]** Adding information about using images sign policy.
- **[istio]** Fixing the list of requests from istiod to gateway API
- **[registrypackages]** added usage GOPROXY in systemctl-power-commands-wrapper

1.74.8

Fixes

- **[docs]** Escape HTML in OpenAPI descriptions
- **[extended-monitoring]** Cleanup exporter metrics when the monitored resource has been

deleted

1.74.7

Fixes

- **[admission-policy-engine]** Convert constraints multi-line output to single-line
- **[candi]** Added a Netplan override to force the secondary NIC to use the main routing table, fixing cloud-init PBR conflicts.
- **[dhctl]** Fix panic in dhctl config render kubeadm-config command.
- **[istio]** Correction of an useless error in the Istio CNI workflow

1.74.6

Know before update

- All current connections powered by EgressGateways will be terminated.

Features

- **[docs]** Added info from `csi-ceph` module about Ceph storage system integration in DKP documentation.

Fixes

- **[cni-cilium]** Fix issue in generating CiliumEgressGatewayPolicy CR.
  All current connections powered by EgressGateways will be terminated.
- **[ingress-nginx]** A false-positive trigger of alert GeoIPDownloadErrorDetectedFromMaxMind is fixed.
- **[node-manager]** Fix panic in cluster-autoscaler caused by nil pointer dereference during node removal simulation.

1.74.5

Know before update

- The ingress nginx controllers’ pods will be restated.

Features

- **[candi]** Display lists of third-party (OSS) components in the modules documentation.
- **[cloud-provider-dvp]** Add validation for VirtualMachineClass and boot images before VM creation

Fixes

- **[admission-policy-engine]** Refactor constraint templates
- **[dhctl]** Improved reliability when connecting to dhctl servers by adding retry logic and better error handling during startup
- **[docs]** Corrections of typos and terms.
- **[docs]** Small imrovements of control-plane management docs
- **[docs]** Improve documentation for cluster network configuration
- **[ingress-nginx]** The CVE-2026-1580, CVE-2026-24512, CVE-2026-24513, CVE-2026-24514 CVEs fixes are backported.
  The ingress nginx controllers’ pods will be restated.
- **[ingress-nginx]** The CVE-2026-1580, CVE-2026-24512, CVE-2026-24513, CVE-2026-24514 CVEs are fixed.
  The ingress nginx controllers’ pods will be restated.
- **[monitoring-kubernetes]** fix kube_persistentvolume_is_local recording rule when there are more than one kube-state-metrics exporter in cluster
- **[prometheus]** Make Grafana redirect ingress pass the annotations validation.
- **[user-authz]** Updated logo on the authentication page.

1.74.4

Know before update

- If the SDN module is used in the cluster, the Cilium agent pods will be restarted.
- Improved documentation clarity for Yandex Cloud NAT instance deployment scenarios
- no impact

Features

- **[docs]** Add the enableNote display to the external modules configuration page.

- **[prometheus]** improve redirects from Grafana to the Deckhouse UI when Grafana is disabled
  no impact

Fixes

- **[cloud-provider-azure]** fixed patch in azure
- **[cloud-provider-dvp]** Fixed VM deletion timeout and improved memory validation error reporting
- **[cloud-provider-dvp]** Cleanup orphaned resources when VM creation fails
- **[cloud-provider-huaweicloud]** fix cve
- **[cloud-provider-vcd]** fix the interaction of legacy and non-legacy components with the API
- **[cloud-provider-vsphere]** fix cve
- **[cni-cilium]** Fix hook discovery_cni_exclusive.go
  If the SDN module is used in the cluster, the Cilium agent pods will be restarted.
- **[docs]** Fixed typo in the OpenStack integration section.
- **[docs]** Added Docker Bearer Token Realm configuration steps for Nexus registry setup.
- **[docs]** Document NAT instance deployment zones for different subnet configurations
  Improved documentation clarity for Yandex Cloud NAT instance deployment scenarios
- **[ingress-nginx]** Fixed useless geoip alerts.
- **[monitoring-kubernetes]** fix kube_persistentvolume_is_local recording rule for not-bound PVCs

1.74.3

Know before update

- Node-local-dns safe-uptader pods will be restarted.

Features

- **[prometheus]** Add prometheus configuration reload failed alert

Fixes

- **[admission-policy-engine]** Fix constraint templates, add additional tests
- **[cloud-provider-aws]** fix cve
- **[cloud-provider-vcd]** fix cve
- **[cloud-provider-yandex]** fix cve
- **[cni-cilium]** Fixed egress-gateway-agent controller logic for deleted resources and disable dev logging.
- **[deckhouse]** Fix module rerun.
- **[docs]** Added a link to the ModuleSource to the explanation table of the editions.
- **[metallb]** Fixed D8MetallbBGPSessionDown alert false positives caused by duplicate metrics without port information.
- **[node-local-dns]** The safe-updater’s logic of detecting if daemonset pods are up-to-date is improved.
  Node-local-dns safe-uptader pods will be restarted.
- **[registry]** Fixed validation of input image list changes in the registry checker.

1.74.2

Know before update

- All pods running kube-rbac-proxy will be restarted.

Features

- **[prometheus]** Replace PrometheusRules with ClusterObservabilityMetricsRulesGroups or ClusterObservabilityPropagatedMetricsRulesGroups when deployed using helm_lib_prometheus_rules helper and the observability module is enabled

Fixes

- **[admission-policy-engine]** fix namespaceSelector for constraints, add CRDs
- **[candi]** Remove duplicate `additional_disks_hashes` definition in static-node Terraform module.
- **[candi]** Updated the bashible step to include Linux kernel versions that address CVE-2025-37999
- **[candi]** Allow manually stopping DVP node VirtualMachines in nested clusters by using runPolicy AlwaysOnUnlessStoppedManually.
- **[cloud-provider-azure]** fixed cve
- **[cloud-provider-dvp]** this PR gives a lot more informational errors and messages to user
- **[cloud-provider-openstack]** fix cve
- **[common]** Latest CVEs are fixed.
  All pods running kube-rbac-proxy will be restarted.
- **[control-plane-manager]** Fix validation for resource-quota-overrides labels
- **[deckhouse]** Fix mpo cleanup.

- **[deckhouse]** Fix module installer cleanup.
- **[deckhouse-controller]** Exclude all service accounts from `d8-` namespaces in `d8ms-prefix` ValidatingAdmissionPolicy.
- **[ingress-nginx]** Latest CVEs are fixed.
  All pods running kube-rbac-proxy will be restarted.
- **[kube-dns]** Reverts
- **[log-shipper]** Fixed incorrect apiVersion in ClusterLogDestination documentation examples.
- **[node-manager]** Change NodeGroup maxPods validation from hard rejection to warning.
- **[registry]** Omitted the auth field in DockerConfig when credentials (username and password) are empty.

1.74.1

Know before update

- Prevents creation of Projects with too-long names that would lead to invalid generated Kubernetes resource names.
- deckhouse queue
- deckhouse queue blocked

Features

- **[common]** Enrich debug-container image with nsenter and /bin/sh symlink.
- **[common]** Resource quota ignore mechanism for pvc and pods
- **[dhctl]** Skipped application edition validation for standalone builds.

Fixes

- **[candi]** remove excessive netcat calls from d8-shutdown-inhibitor
- **[candi]** Add pause and kubernetes-api-proxy registry packages to bashible `bb-package-fetch` to prevent node failures during containerd major upgrades.
- **[control-plane-manager]** Fixed vulnerabilities
- **[deckhouse]** Fix module docs rendering.
- **[deckhouse]** Fix module enabling.
- **[deckhouse-controller]** fix copy-custom-certificate hook
- **[docs]** Added link to NVIDIA Container Toolkit docs.
- **[docs]** Fixed typo.
- **[docs]** Fixed the logic of generating the revision table.
- **[extended-monitoring]** Add namespace-scoped overrides
- **[ingress-nginx]** Improved stability of geoproxy service startup.
- **[kube-dns]** Refactored hook remove_old_coredns_deploy_and_svc — delegated deletion of original kube-dns service to helm.
- **[multitenancy-manager]** Add validation to restrict Project name length to 53 characters.
  Prevents creation of Projects with too-long names that would lead to invalid generated Kubernetes resource names.
- **[node-manager]** remove excessive netcat calls from d8-shutdown-inhibitor
- **[node-manager]** It fixes issues in the DaemonSet manifest for fencing module.
- **[tools]** Add check values not null in prometheusRule or ClusterObservabilityPropagatedMetricsRulesGroup
  deckhouse queue
- **[tools]** Add check values not null in prometheusRule or ClusterObservabilityPropagatedMetricsRulesGroup
  deckhouse queue blocked
- **[user-authn]** Quote service names to prevent digit-only names from breaking yaml parser
- **[user-authz]** Allow project-scoped roles to access Cluster-wide objects

Version 1.73

Important

- This release includes several important security improvements. Multiple known vulnerabilities have been fixed, including one in the user-authn module (CVE-2025-22868) that could potentially allow bypassing authentication checks. It is recommended that you schedule this update. See the Security section for details.
- The `dashboard` module will be removed in future DKP versions. Use the Deckhouse web UI instead (requires the `console` module to be enabled).
- The `runtime-audit-engine` module is now loaded from an external source (the `deckhouse` ModuleSource).
- All DKP components will be restarted during the update.

Major changes

- Added support for changing the registry settings (via the `mode` parameter) in `Unmanaged` mode, similar to `Direct` mode. A new parameter `checkMode` has been added to control registry validation behavior:
  - `Default`: Verifies the availability of all system module images and the deckhouse-controller images.
  - `Relax`: Verifies only the deckhouse-controller images.
- Updated requirements for the `email` field of the User object: the email address must now be in lowercase. Existing users will not be affected.
- Dex updated to **v2.44.0**. It now allows authentication through available identity providers if one of them is down, and supports authentication via identity providers through a proxy.
- The User object status now displays the reason for user lockout (controlled by the `lockout` parameter).
- Added the `additionalDisks` parameter for the Deckhouse Virtualization Platform integration provider, allowing creation and attachment of additional disks to VMs in a NodeGroup (`size` and StorageClass must be specified). This simplifies data distribution across multiple disks.
- Added support for `additionalMetadata` in objects (networks, VMs, disks) for the VMware Cloud Director integration provider. Metadata is merged with existing data, with `additionalMetadata` values taking precedence. Changing `additionalMetadata` triggers recreation of CloudEphemeral node groups that use the affected VCDInstanceClass.
- For the VMware vSphere integration provider, you can now specify an SPBM storage policy ID (via the `storagePolicyID` parameter) and configure automatic creation of a StorageClass for each available SPBM policy. You can now explicitly select a policy for master and worker nodes and use the corresponding storage classes.
- Added alerts to help plan module deprecation or migration:
  - `ModuleIsDeprecated`: Notifies when a module is deprecated and nearing end of support.
  - `D8ModuleOutdatedByMajorVersion`: Notifies when a module is behind by one or more major versions.
- Added `GeoIPDownloadErrorDetected` alert to notify about MaxMind GeoIP database download issues.
- The update notification workflow has changed — a release is applied only after the notification is successfully delivered to the configured webhook. If delivery fails, the update is paused until the webhook is restored.
- Reorganized in-cluster documentation. All module documentation (including connected ones) is now located under the Modules section. Search has been updated.
- For Ingress NGINX Controller v1.10, added the option to enable the profiler (via the `nginxProfilingEnabled` parameter). Enabling the profiler increases resource consumption but may be useful for debugging controller issues.
- Added support for custom HTTP authentication headers (via the `headers` parameter of UpmeterRemoteWrite) when sending SLA monitoring metrics via Prometheus Remote Write protocol.
- Optimized DKP core module loading, reducing startup time in clusters with many modules.
- Audit logs now show which OIDC provider issued the authentication token
- Deckhouse CLI (`d8`) updated to v0.23.0:
  - Added the `d8 status` command, which provides a quick cluster summary (nodes, releases, Deckhouse pods, alerts, registry, Deckhouse settings, CNI, queue state).
  - Added the `d8 k debug` command, which runs the DKP built-in debug container (image can be overridden via `--image`). This simplifies interactive pod debugging.
  - Added the `--watch` flag to the `d8 system queue list` command to track queue state changes.

Security

- Improved baseline container security. Updated security profiles for the following modules to restrict privileges and access rights to the minimum required: `cni-cilium`, `cni-flannel`, `cni-simple-bridge`, `ingress-nginx`, `istio`, `keepalived`, `kube-dns`, `kube-proxy`, `node-local-dns`, `network-gateway`, `network-policy-engine`, `open-vpn`.
- Added the `allowRbacWildcards` flag to the SecurityPolicy, controlling whether wildcards are

allowed in Role and RoleBinding definitions (set to `true` by default). Security policies can now also restrict interactive connections to pods (`CONNECT` for `pods/exec` and `pods/attach`) within namespaces.

- Added support for preventing creation of pods with specific tolerations from a list (`policies.disallowedTolerations` parameter in the operational policy). This helps prevent user workloads from running on nodes reserved for special tasks.
- Enhanced security in Ingress NGINX Controller v1.12 (distroless image, vulnerability fixes, and other improvements).
- Fixed known vulnerabilities in the following modules: `operator-trivy`, `registry`, `user-authn`, `cloud-provider-dvp`, `multitenancy-manager`, `admission-policy-engine`, `ingress-nginx`, `alertmanager`, `metallb`, `istio`, `node-local-dns`, `kube-apiserver`.

Network

- For the VMware Cloud Director integration provider, added support for LoadBalancer backed by VMware NSX Advanced Load Balancer (ALB/Avi) when using `NSX-T`. Requires the Load Balancer feature to be enabled on the Edge Gateway. If LoadBalancer is enabled after cluster creation, DKP automatically detects and applies the change within an hour. For open ports, DKP creates corresponding `Pool + Virtual Service` pairs. If there is a firewall, add allow rules for the LoadBalancer's external IP address and relevant ports.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.73.14

Know before update

- All Ingress-Nginx controller pods will be restarted.
- All ingress-nginx controller pods will be restared.
- All modules of the ingress-nginx module will be restarted.
- Registry pods will be restarted.
- The ingress nginx controllers' pods will be restated.

Fixes

- **[admission-policy-engine]** added mount-points in ratify
- **[admission-policy-engine]** deny_vulnerable_images webhook must use module status instead of moduleconfig
- **[candi]** cve fix for admission-policy-engine, cert-manager, user-authn, multitenancy-manager
- **[candi]** Updated pwru tool to v1.0.11 to fix CVE-2025-68121.
- **[candi]** Updated pwru tool to v1.0.11 to fix CVE-2025-68121.
- **[chrony]** mitigate CVE-2025-58181
- **[common]** Fixed vulnerability CVE-2026-24051.
- **[control-plane-manager]** Fixed vulnerabilities.
- **[documentation]** Fixed HTTP/404 error when opening modules documentation from the Web interface.
- **[extended-monitoring]** Fixed CVE-2025-47914, CVE-2025-58181
- **[ingress-nginx]** CVE-2026-3288 fix is backported in all Ingress-Nginx controllers.
  All Ingress-Nginx controller pods will be restarted.
- **[ingress-nginx]** Golang and Altlinux updates are reverted.
  All modules of the ingress-nginx module will be restarted.
- **[ingress-nginx]** Nginx and module's dependencies are updated.
  All ingress-nginx controller pods will be restared.
- **[ingress-nginx]** The CVE-2026-1580, CVE-2026-24512, CVE-2026-24513, CVE-2026-24514 CVEs fixes are backported.
  The ingress nginx controllers' pods will be restated.
- **[loki]** Fixed CVE-2025-47914, CVE-2025-58181
- **[monitoring-kubernetes]** Fixed CVE-2025-47914, CVE-2025-58181
- **[node-local-dns]** Fixed CVEs
- **[node-manager]** Fixed vulnerabilities.
- **[operator-prometheus]** Fixed CVE-2025-47914, CVE-2025-58181
- **[prometheus]** Fixed CVE-2025-47914, CVE-2025-58181, CVE-2025-65637
- **[prometheus-metrics-adapter]** Fixed CVE-2025-47914, CVE-2025-58181
- **[prometheus-pushgateway]** Fixed CVE-2025-47914, CVE-2025-58181, CVE-2025-22872, CVE-2025-22868
- **[registry]** Updated auth image Go dependencies to fix Go CVEs.
  Registry pods will be restarted.
- **[registry]** Updated auth image Go dependencies to fix Go CVEs.
  Registry pods will be restarted.

- **[registrypackages]** Fixed vulnerability CVE-2026-24051.
- **[upmeter]** Add proper securityContext to the upmeter probe to meet the restricted security profile constraints.
- **[upmeter]** Fixed CVE-2025-47914, CVE-2025-58181, CVE-2025-65637

1.73.13

Know before update

- config module loki ↓

Fixes

- **[candi]** Updated the bashible step to include Linux kernel versions that address CVE-2025-37999
- **[cni-cilium]** Fixed vulnerabilities.
- **[cni-flannel]** Bump version and fixed vulnerabilities.
- **[istio]** Fix CVE for Istio version 1.21 and 1.25
- **[kube-dns]** Fixed vulnerabilities.
- **[kube-proxy]** Fixed vulnerabilities.
- **[kube-proxy]** Fixed vulnerabilities.
- **[loki]** disable send analytics report to stats.grafana.org
  config module loki ↓
- **[network-policy-engine]** Fixed vulnerabilities.
- **[node-local-dns]** Bump version and fixed vulnerabilities.
- **[openvpn]** Fixed vulnerabilities.
- **[registry]** Omitted the auth field in DockerConfig when credentials (username and password) are empty.

1.73.12

Fixes

- **[cloud-provider-vsphere]** fix stale session for cloud-data-discoverer
- **[istio]** fixing the CVE in Kiali

1.73.11

Fixes

- **[dashboard]** Fixed CVE-2025-30204 by updating dashboard components
- **[deckhouse]** Fix module enabling.
- **[registrypackages]** Update integrity patch for containerd (cse only).

1.73.10

Fixes

- **[cloud-provider-dvp]** Added functionality to wait for a disk to be attached to a VM
- **[cloud-provider-huaweicloud]** fix CSI unpublishValidation for non exist ECS instance
- **[registrypackages]** Update integrity patch for containerd (cse only).
- **[service-with-healthchecks]** Fixed CVEs
- **[user-authz]** cache namespace label checks in the user-authz webhook via informer to avoid per-request apiserver GETs

1.73.9

Features

- **[ci]** Add DVP e2e for the cse edition

Fixes

- **[deckhouse-controller]** Fix conversions for external modules
- **[dhctl]** Fix parallel bootstrap cloud permanent nodes

1.73.8

Know before update

- Ingress Nginx controller dashboards are fixed
- The MTU will be updated on all interfaces of all pods.

Fixes

- **[cloud-provider-yandex]** cloud-provider-yandex CVE’s was fixed
- **[cni-cilium]** The MTU configuration has been updated.
  The MTU will be updated on all interfaces of all pods.
- **[deckhouse-controller]** Fix “multiple readiness hooks found” error on hook registration retry after failure.
- **[deckhouse-controller]** Fix deprecated and experimental module metrics not being reset when module is disabled.
- **[dhctl]** Fix panic during destroy. Change opentofu log level to INFO.
- **[docs]** The current editions are listed on the page about installation in a closed environment.
- **[docs]** Fixed links to the Getting Started in the documentation.
- **[prometheus]** Fix namespace label value in the Ingress Nginx controller and several other metrics
  Ingress Nginx controller dashboards are fixed
- **[user-authn]** Fix BadRequest after the change password redirect when password policy is enabled
- **[user-authn]** Fix login error 500 with password policy enabled.

1.73.7

Know before update

- Allows scaling control-plane from 1→3 in clusters where ControlPlaneKubeletLocalMode=true.
- The instructions for reducing the number of master nodes have not been updated for a long time, and for a long time now, the conversion to reducing the number of master nodes in clusters in a cloud installation is automatic.
- upmeter check

Features

- **[ci]** Add Deckhouse Virtualization Platform testing to e2e tests.
- **[docs]** Added Commander support for DVP EE in the Platform Editions table.

Fixes

- **[candi]** Add missing debian 13 version to detect_bundle
- **[cloud-provider-huaweicloud]** fix Provider ID
- **[control-plane-manager]** Fix “etcd join” phase for control-plane scaling in v1.33.
  Allows scaling control-plane from 1→3 in clusters where ControlPlaneKubeletLocalMode=true.
- **[deckhouse-controller]** Fixed verifying migrated modules
- **[deckhouse-controller]** fix conversion applying for external modules
- **[dhctl]** Fix StaticInstance readiness check and refactoring readiness check for resources.
- **[docs]** Outdated instructions for reducing the number of master nodes in cloud clusters have been fixed. Users will correctly perform the converge of cloud clusters.
  The instructions for reducing the number of master nodes have not been updated for a long time, and for a long time now, the conversion to reducing the number of master nodes in clusters in a cloud installation is automatic.
- **[kube-dns]** Improved /etc/hosts renderer compatibility with admission-policy-engine Restricted mode.
- **[log-shipper]** Update documentation.
- **[upmeter]** fix securityxontext for statefulset
  upmeter check

1.73.6

Fixes

- **[cloud-provider-vsphere]** fix cloud-data-discoverer (SPBM)

1.73.5

Know before update

- node-exporter pods will be rollout restarted during upgrade

Features

- **[ci]** Add static e2e for the cse edition
- **[ci]** Add static e2e for the cse edition
- **[docs]** Added documentation about configuration of the Kubernetes audit policy.

Fixes

- **[cloud-provider-azure]** fix build image for azure ccm
- **[cni-cilium]** Some issues have been fixed in the EgressGateway.

- **[dhctl]** Fix converge manifests for static cluster in commander.
- **[monitoring-kubernetes]** remove the Docker traces from the module code
  node-exporter pods will be rollout restarted during upgrade

1.73.4

Know before update

- Ingress-Nginx controller’s pods of 1.9 version will be restarted.
- erroneous alerts for node disk usage are fixed

Fixes

- **[cloud-provider-dvp]** add missing field to Cluster
- **[cloud-provider-yandex]** Terraform auto converger was failed for WithNATInstance layout.
- **[deckhouse]** Fix validation logic for a disabled module
- **[dhctl]** Validate WithNATInstance Yandex layout params only in bootstrap.
- **[dhctl]** Added nil check to dhctl during converge in migrator
- **[extended-monitoring]** drop metrics when extended monitoring is disabled for node(s)
  erroneous alerts for node disk usage are fixed
- **[ingress-nginx]** A symlink to the new opentelemetry config path is added.
  Ingress-Nginx controller’s pods of 1.9 version will be restarted.
- **[ingress-nginx]** Fixed CVEs
- **[monitoring-kubernetes]** Rollout changes for resources metrics kubelet
- **[node-manager]** Fix panic in registry packages proxy if image not found.
- **[operator-trivy]** Fix CIS Benchmark report template
- **[operator-trivy]** fix CVE-2025-52881 CVE-2024-25621 on image trivy
- **[registrypackages]** Update containerd to 1.7.29 / 2.1.5 and runc to 1.3.3

1.73.3

Know before update

- the extended monitoring will only be enabled when the label is explicitly set on a namespace

Fixes

- **[control-plane-manager]** Add vex for CVE-2025-31133, CVE-2025-52881 .
- **[deckhouse]** Add umask before creating first-control-plane-bashible-ran file
- **[dhctl]** Fix getting passphrase for key from connection config for cli.
- **[dhctl]** Move yandex withNATInstance layout settings from preflights to preparator.
- **[documentation]** Fix module’s deployment and configuration.
- **[extended-monitoring]** Fix extended-monitoring.deckhouse.io/enabled label handling
  the extended monitoring will only be enabled when the label is explicitly set on a namespace
- **[monitoring-kubernetes]** fix CVE-2025-52881 for node-exporter
- **[prometheus]** Fix description for not usable CVE
- **[registrypackages]** Fixes CVE in kubernetes-cni

1.73.2

Fixes

- **[ingress-nginx]** CVEs fixed
- **[istio]** Kiali’s CVE-2024-28180 is fixed.
- **[multitenancy-manager]** fix CVE-2024-25621 CVE-2025-64329
- **[node-manager]** fix cve and vex
- **[operator-trivy]** fix CVE-2025-52881 CVE-2024-25621
- **[operator-trivy]** Add grep to node-collector and improve error reporting
- **[user-authn]** Rollback patch for handling insecureSkipEmailVerified condition

1.73.1

Features

- **[docs]** Added manifest for internal LB VK Cloud.
- **[docs]** Added info from `csi-netapp` module about NetApp storage integration in DKP documentation.
- **[istio]** Added access log format setting for proxy sidecars.

Fixes

- **[admission-policy-engine]** Prohibit only creation or modification for objects with vulnerable images

- **[admission-policy-engine]** Fixed proxy support for trivy-provider
- **[candi]** Remove proxy-environment for kubelet when proxy disabled
- **[ci]** Fix e2e upgrade tests.
- **[ci]** fix grafana vex
- **[ci]** fix trickster vex
- **[ci]** Fix missing edition suffixes in prerelease build.
- **[cloud-provider-dvp]** Correct the calculation of the path to the device
- **[cloud-provider-vsphere]** fix vSphere storageClass template
- **[cni-cilium]** fixed connectivity dashboard
- **[deckhouse]** Fix race conditions in test
- **[deckhouse-controller]** fix bash completion
- **[docs]** Small fix on the “Security event audit” page.
- **[docs]** Fixed the description for the 4239 port in the reference table.
- **[docs]** Updated installer block in GS.
- **[docs]** Added a link to the DVP integration page in the virtualization overview.
- **[istio]** The same owner is specified for the files that are used to run in the operator container.
- **[metallb]** Disabled unnecessary speaker functionality.
- **[monitoring-kubernetes]** Fixed CVE-2025-22870, CVE-2025-22872.
- **[prometheus]** Fix plur in vex for tricster
- **[prometheus-pushgateway]** Fixed CVE-2025-22869, CVE-2025-22868, CVE-2025-22870.
- **[registrypackages]** Update runc to 1.3.1.

Version 1.72

Important

- All DKP components will be restarted during the update.
- To use experimental modules in the cluster, you now need to explicitly enable the allowExperimentalModules parameter. By default, experimental modules are disabled. Modules that were enabled before the update will not be automatically disabled. However, if an experimental module enabled prior to the update is manually disabled during the update process, you will need to grant permission to use experimental modules again in order to re-enable it.
- If there are WireGuard interfaces on the cluster nodes, you must update the Linux kernel to version 6.8 or higher.

Major changes

- Added a new registry module and the ability to adjust container registry parameters without restarting all DKP components. Two modes for working with the container registry are now available in DKP: `Unmanaged` (the approach used in previous versions) and `Direct` (a new mode). In `Direct` mode, DKP creates a virtual container registry address in the cluster that all DKP components use. Changing the container registry address (for example, switching to a different registry or changing the DKP edition in the cluster) in this mode does not trigger a forced restart of all DKP components.

- Added support for recursive DNS servers (configured via the recursiveSettings section of the `cert-manager` module). They are used to verify the existence of a DNS record before starting the ACME DNS-01 domain ownership validation process. This is useful if the same domain is used both publicly and within the cluster, or if the domain has dedicated authoritative DNS servers.

- Introduced separation of modules into critical and functional using the `critical` flag in `module.yaml`. Critical modules are started first. Functional modules are started after the bootstrap process is complete. Their tasks run in parallel and do not block the queue in case of failure. This speeds up cluster installation and improves fault tolerance when starting modules.

- You can now enable logging of all DNS queries (the enableLogs parameter of the `node-local-dns` module).

- In the `cloud-provider-vcd` module, a new WithNAT layout has been added for cluster deployment. It automatically configures NAT and, if necessary, firewall rules for accessing nodes through a bastion host. It also supports both `NSX-T` and `NSX-V`. This makes it possible to deploy a cluster in VMware Cloud Director without pre-configuring the environment (unlike the `Standard` layout).

Security

- Added the fields `user-authn.deckhouse.io/name` and `user-authn.deckhouse.io/preferred_username` to Kubernetes audit log events. These fields display user claims from the OIDC provider, improving authentication monitoring and troubleshooting.

- Kubernetes versions 1.30–1.33 have been updated to the latest patch releases.

- For the AWS provider, added the ability to disable the creation of default security groups (the disableDefaultSecurityGroup parameter). When disabled, security groups must be created manually and explicitly specified in AWSClusterConfiguration, AWSInstanceClass, and NodeGroup. This new feature provides greater control over security settings.
- Added support for password policies for local users (configured in the passwordPolicy section). You can now enforce a minimum password complexity, set password expiration, require password rotation, prevent reuse of old passwords, and lock accounts after a specified number of failed login attempts. These changes allow administrators to centrally enforce password requirements and improve cluster security.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.72.13

Fixes

- **[istio]** Reduce CPU and RAM for regenerate multicluster JWT token and sort ingressGateway

1.72.12

Fixes

- **[deckhouse-controller]** Fix conversions for external modules
- **[deckhouse-controller]** Fixed verifying migrated modules
- **[deckhouse-controller]** Fixed a crash during external module updates with conversions that caused ModuleRelease to fail validation due to a forbidden property error.
- **[istio]** Fixed AuthorizationPolicy CRD insufficiency for Istio 1.25.

1.72.11

Fixes

- **[cert-manager]** Mark module as critical for cluster
- **[deckhouse-controller]** fix deckhouse update accidentally minor skip
- **[istio]** Erroneous option in 1.25 control-plane helm template fixed.
- **[registrypackages]** Fixed permissions for directory with cni-plugins in PCI-DSS clusters
- **[tools]** update dmt version to 0.1.53

1.72.10

Fixes

- **[ci]** Delete an extra entry from the changelog.
- **[cloud-provider-vsphere]** fix hook logick
- **[deckhouse-controller]** fix possibility deadlock
- **[istio]** Reduce RAM for regenerate multicluster JWT token

1.72.9

Fixes

- **[candi]** Switch node hostname in discover_node_ip.sh to locked hostname
- **[candi]** fixed version of containerd image in bashible step
- **[deckhouse]** Fixes bug when module`s config values unchanged after enabling.
- **[deckhouse-controller]** Add more mutexes to shell-operator framework
- **[dhctl]** Change default ssh mode
- **[ingress-nginx]** The is reverted.
- **[ingress-nginx]** Enable ExecuteHookOnEvents on hook set_annotation_validation_suspended.go

1.72.8

Fixes

- **[cloud-provider-dvp]** fix single-node LoadBalancer bug and add multi-LB per node support
- **[cloud-provider-vsphere]** cloud-data-discoverer fixes
- **[node-manager]** Enable SSHLegacyMode if SSHPrivateKey is not empty and fix gossh panic.

1.72.7

Fixes

- **[cloud-provider-huaweicloud]** add rule to d8:cloud-provider-huaweicloud:cloud-controller-manager account for list pods as needed
- **[node-manager]** CAPI crd served version fix
- **[node-manager]** shutdown inhibitor use three-state GracefulShutdownPostpone condition so kubelet waits for the final decision before ending pods

1.72.6

Fixes

- **[candi]** Fix nodeuser deletion.
- **[cloud-provider-vsphere]** cloud-data-discoverer fixes
- **[deckhouse-controller]** Ensure `afterDeleteHelm` hooks receive Kubernetes snapshots by stopping monitors after hook execution
- **[dhctl]** Fixing bashible steps when it does not respond to the limit on the number of attempts
- **[dhctl]** Fix start and keep-alive behavior, do not change host if any kube-proxies has been started.
- **[node-manager]** CAPI crd served version fix
- **[vertical-pod-autoscaler]** Disable vpa for k8s-metacollector in module runtime-audit-engine

1.72.5

Fixes

- **[cloud-provider-vsphere]** cloud-data-discoverer fixes
- **[cni-cilium]** Fixed 1.14 -> 1.17 migration mechanism
- **[cni-cilium]** improved migration to 1.17 logic
- **[node-manager]** capi crd served version fix

1.72.4

Fixes

- **[cloud-provider-openstack]** fix openstack ccm deployment
- **[deckhouse]** Fix maintenance mode label ignore rule.
- **[ingress-nginx]** lowers the severity level of the IngressNginxController alert from 3 to 4

1.72.3

Fixes

- **[dhctl]** Add timeout to ssh client dial and fix stop.
- **[dhctl]** Fix ssh client start with bastion in dhctl.
- **[dhctl]** Fix deadlock while reading dhctl singlethreaded server logs
- **[dhctl]** Fixed the behaviour of the attach operation when there are no keys in SSHConfig, only a password
- **[docs]** Containerdv2 migration FAQ fix
- **[ingress-nginx]** fix set_annotation_validation_suspended.go hook to set correct metric
- **[ingress-nginx]** fix set_annotation_validation_suspended.go hook to set correct metric
- **[loki]** Change stage to Preview

1.72.2

Know before update

- The ingress-nginx pods of 1.10 will be restarted.

Fixes

- **[docs]** Added the Local path provisioner storage section to the documentation sidebar, including Overview, Examples, Reference, and FAQ entries.
- **[ingress-nginx]** Fixed nginx segfaults when opentelemetry is enabled.
  The ingress-nginx pods of 1.10 will be restarted.
- **[node-manager]** Fix node update approval hook for CAPI nodes.

1.72.1

Fixes

- **[deckhouse]** add check for user-authn in enabled script
- **[deckhouse]** fix editions list in check deckhouse edition hook
- **[dhctl]** Fix ssh client initialising in Commander Attach and Commander Detach operations

- **[node-manager]** Some minor fixes for nvidia gpu templates to improve security.

Version 1.71

Important

- Prometheus has been replaced with Deckhouse Prom++. If you want to keep using Prometheus, disable the `prompp` module manually before upgrading DKP by running the command `d8 system module disable prompp`.
- Support for Kubernetes 1.33 has been added, while support for Kubernetes 1.28 has been discontinued. In future DKP releases, support for Kubernetes 1.29 will be removed. The default Kubernetes version (used when the `kubernetesVersion` parameter is set to `Automatic`) has been changed to 1.31.
- Upgrading the cluster to Kubernetes 1.31 requires a sequential update of all nodes, with each node drained. You can control how node updates requiring workload disruptions are applied using the `disruptions` parameter section.
- The built-in `snapshot-controller` and `static-routing-manager` modules will now be replaced with their external counterparts of the same name, sourced via ModuleSource `deckhouse`.
- The new version of Cilium requires nodes to run Linux kernel version 5.8 or newer. If any node in the cluster has a kernel older than 5.8, the Deckhouse Kubernetes Platform upgrade will be blocked. Cilium Pods will be restarted.
- All DKP components will be restarted during the update.

Major changes

- You can now enforce two-factor authentication for static users. This is configured via the `staticUsers2FA` parameter section of the `user-authn` module.
- Added support for GPUs on nodes. Three GPU resource sharing modes are now available: Exclusive (no sharing), TimeSlicing (time-based sharing), and MIG (a single GPU split into multiple instances). The NodeGroup spec.gpu parameter section is used to configure the GPU resource sharing mode. Using a GPU on a node requires installing the NVIDIA Container Toolkit and the GPU driver.
- When enabling a module (with `d8 system module enable`) or editing a ModuleConfig resource, a warning is now displayed if multiple module sources are found. In such a case, explicitly specify the module source using the source parameter in the module's configuration.
- Improved error handling for module configuration. Module-related errors no longer block DKP operations. Instead, they are now displayed in the status fields of Module and ModuleRelease objects.
- Improved virtualization support:
  - Added a provider for integration with Deckhouse Virtualization Platform (DVP), enabling deployment of DKP clusters on top of DVP.
  - Added support for nested virtualization on nodes in the `cni-cilium` module.
- The `node-manager` module now includes several enhancements for improved node reliability and manageability:
  - You can now prevent a node from restarting if it still hosts critical Pods (labeled with `pod.deckhouse.io/inhibit-node-shutdown`). This can be necessary for workloads with stateful components, such as long-running data migrations.
  - Introduced API version `v1alpha2` for the SSHCredential resource, where the `sudoPasswordEncoded` parameter allows specifying the `sudo` password in Base64 format.
  - The `capiEmergencyBrake` parameter allows you to disable Cluster API (CAPI) in emergency scenarios, preventing potentially destructive changes. Its behavior is similar to the existing `mcmEmergencyBrake` setting.
- Added a pre-installation check to verify connectivity to the DKP container image registry.
- Improved the log file rotation mechanism when using short-term log storage (via the `loki` module). Added the `LokiInsufficientDiskForRetention` alert to warn about insufficient disk space for log retention.
- The documentation now includes a reference for the Deckhouse CLI (`d8` utility) commands and parameters.
- When using CEF encoding for collecting logs from Apache Kafka or socket sources, you can now configure auxiliary CEF fields such as Device Product, Device Vendor, and Device ID.

- The `passwordHash` field in the NodeUser resource is no longer required. This allows you to create users without passwords — for example, in clusters that use external authentication systems (such as PAM or LDAP).
- Added support for CRI Containerd v2 with CgroupsV2. The new version introduces a different configuration format and includes a mechanism to migrate between Containerd v1 and v2. You can change the CRI type used on nodes via the `cri.type` parameter and configure it using `cri.containerdV2`.

Security

- Container image signature verification is now available in DKP SE+. This feature is now supported in DKP SE+ and EE.
- The `log-shipper`, `deckhouse-controller`, and `Istio` (version 1.21) modules have been migrated to distroless builds. This improves security and ensures a more transparent and controlled build process.
- New audit rules have been added to track interactions with containerd. The following are now monitored: access to the `/run/containerd/containerd.sock` socket, modifications to the `/etc/containerd` and `/var/lib/containerd` directories and the `/opt/deckhouse/bin/containerd` file.
- Known vulnerabilities have been fixed in the following modules: `loki`, `extended-monitoring`, `operator-prometheus`, `prometheus`, `prometheus-metrics-adapter`, `user-authn`, and `cloud-provider-zvirt`.

Network

- Added support for Istio version 1.25.2, which uses the Sail operator instead of the deprecated Istio Operator. Also added support for Kiali version 2.7, without Ambient Mesh support. Istio version 1.19 is now considered deprecated.
- Added support for encrypting traffic between nodes and Pods using the WireGuard protocol (via the `encryption.mode` parameter).
- Fixed the logic for determining service readiness in the ServiceWithHealthcheck resource. Previously, Pods without an IP address (for example, in `Pending` state) could be mistakenly included in the load balancing list.
- Added support for the least-conn load balancing algorithm. This algorithm directs traffic to the service backend with the fewest active connections, improving performance for connection-heavy applications (such as WebSocket services). To use this algorithm, enable the `extraLoadBalancerAlgorithmsEnabled` parameter in the `cni-cilium` module settings and use the `service.cilium.io/lb-algorithm` annotation on the service and set it to a supported value: random, maglev, or least-conn.
- Fixed an issue in Cilium 1.17 `cilium-operator` where IP addresses were not reused after a `CiliumEndpoint` was deleted. The issue was caused by improper cleanup of priority filters, which could lead to IP pool exhaustion in large clusters.
- Refined the list of ports used for networking:
  - Added and updated:
    - `4287/UDP`: WireGuard port used for CNI Cilium traffic encryption.
    - `4295-4297/UDP`: Used by the `cni-cilium` module for VXLAN encapsulation of inter-pod traffic in multiple nested virtualization — when DKP with the `virtualization` module enabled is deployed inside virtual machines that are also created in DKP with the `virtualization` module enabled.
    - `4298/UDP`: Used by the `cni-cilium` module for VXLAN encapsulation of traffic between pods if the cluster was deployed on DKP version starting from **1.71** (for clusters deployed on DKP versions up to **1.71**, see the note for ports `4299/UDP`, `8469/UDP`, and `8472/UDP`).
    - `4299/UDP`: Port **for clusters deployed on DKP versions 1.64–1.70.** Used by the `cni-cilium` module for VXLAN encapsulation of traffic between pods. Updating DKP to newer versions will not change the port used unless the `virtualization` module is enabled.
    - `8469/UDP`: Port **for clusters deployed on DKP version 1.63 and below with the `virtualization` module enabled prior to DKP version 1.63.** Used by the `cni-cilium` module for VXLAN encapsulation of traffic between pods. Updating DKP to newer versions will not change the occupied port
    - `8472/UDP`: Port **for clusters deployed on DKP version 1.63 and below.** Used by the `cni-cilium` module for VXLAN encapsulation of traffic between pods. Updating DKP to newer versions will not change the occupied port if the `virtualization` module

is not enabled. **Note** that in such clusters, enabling the `virtualization` module on DKP before version 1.70 changes the port:
  - Enabling the `virtualization` module on DKP version 1.63 and below will change it to `8469/UDP` and will not change with subsequent DKP updates
  - Enabling the `virtualization` module on DKP starting from version 1.64 will change it to `4298/UDP` and will not change with subsequent DKP updates
- Removed:
  - `49152`, `49153/TCP`: Previously used for live migration of virtual machines (in the `virtualization` module). Migration now occurs over the Pod network.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.71.10

Features

- **[deckhouse-controller]** ignore migrate module if disabled

Fixes

- **[deckhouse-controller]** fix deckhouse update accidentally minor skip
- **[istio]** Reduce CPU and RAM for regenerate multicluster JWT token and sort ingressGateway
- **[local-path-provisioner]** Fix CVE in local-path-provisioner module

1.71.9

Fixes

- **[cni-cilium]** Fixed 1.14 -> 1.17 migration mechanism

1.71.8

Fixes

- **[deckhouse]** Fix module source updating fails.
- **[vertical-pod-autoscaler]** Disable vpa for k8s-metacollector

1.71.7

Fixes

- **[candi]** Fix arg `encryption-provider-config` for kubeadm configuration.
- **[candi]** Disable immutable flag on erofs files in cleanup node stage.

1.71.6

Fixes

- **[cni-cilium]** Fixed the infinite loop in the “cilium migration” bashible step and improved synchronization between bashible and safe-agent-updater.

1.71.5

Know before update

- If wireguard interface is present on nodes, then cilium-agent upgrade will stuck. Upgrading the linux kernel to 6.8 is required.
- main and longterm Prometheuses will be rollout-restarted

Fixes

- **[candi]** Changed ExecStartPre in d8-shutdown-inhibitor.service
- **[candi]** Added warnings to the VMware Cloud Director environment documentation about Edge requirements
- **[cni-cilium]** Add a compatibility check for the Cilium version and the kernel version, if WireGuard is installed on the node
  If wireguard interface is present on nodes, then cilium-agent upgrade will stuck. Upgrading the linux kernel to 6.8 is required.
- **[cni-cilium]** Added a migration mechanism, which was implemented through the node group disruptive updates with approval.
- **[cni-cilium]** fixed invalid annotation name for lb-algorithm in docs
- **[deckhouse-controller]** fix module config ensure

- **[docs]** Fix relative links in the multitenancy-manager module documentation.
- **[docs]** Added steps that patch secret and prevented the image pull fail.
- **[docs]** Add containerv2 additional registry examples
- **[docs]** Add new requirement and commands to meet containerdv2
- **[docs]** Fixed command syntax for Docker container run in documentation.
- **[docs]** Add new requirement and commands to meet containerdv2 requirements
- **[docs]** Fix D8KubernetesStaleTokensDetected alert description.
- **[docs]** There should be one disk in the template.
- **[docs]** Updates for Observability docs.
- **[log-shipper]** Documentation updates.
- **[loki]** Documentation updates.
- **[monitoring-custom]** Documentation updates.
- **[monitoring-kubernetes]** Documentation updates.
- **[monitoring-ping]** Documentation updates.
- **[prometheus]** fix securityContext indentation in the Prometheus main and longterm resources main and longterm Prometheuses will be rollout-restarted
- **[prometheus]** Documentation updates.
- **[upmeter]** Documentation updates.

1.71.4

Know before update

- low

Features

- **[docs]** Added descriptions of the problem of using Cilium and Elastic together
  low

Fixes

- **[cloud-provider-vsphere]** ignore ept_rvi_mode and hv_mode
- **[docs]** Fix mentions of ingress-nginx module in docs.
- **[ingress-nginx]** Fix mentions of ingress-nginx module in docs.
- **[prometheus]** Fix mentions of ingress-nginx module in docs.

1.71.3

Features

- **[candi]** Add rosa 12.6.
- **[deckhouse-controller]** add validation for module source changes

Fixes

- **[candi]** containerd migration fix
- **[cni-cilium]** fixed hostPort workability with extraLoadBalancerAlgorithmsEnabled.
- **[log-shipper]** Fix matchExpressions values validation for ClusterLoggingConfig
- **[node-manager]** Hide Nvidia GPU dashboards if there is no GPU nodes in a cluster.
- **[node-manager]** containerd migration fix

1.71.2

Know before update

- Users will know how to configure KeyCloak and dexProvider to get user rights in dashboard and console.
- default
- if there are several ModuleSources with the prompp module available, the “deckhouse” ModuleSource will be used.

Features

- **[admission-policy-engine]** Added the ability to specify allowedServiceTypes and blockWildcardDomains in the SecurityPolicy object
- **[deckhouse-controller]** add leader election for non ha clusters
- **[user-authn]** Add allowedGroup in dexProvider OIDC

Fixes

- **[admission-policy-engine]** Fix validation policy for pods with skip-pss-check labels
- **[ci]** fix e2e creds
- **[ci]** fix e2e creds

- **[ci]** Run changelog check only on tag pushes to enforce release documentation
- **[ci]** create resources before deckhouse manifest and mutating webhook for prom rules for e2e tests
- **[ci]** Run changelog check only on tag pushes to enforce release documentation
- **[ci]** create resources before deckhouse manifest and mutating webhook for prom rules for e2e tests
- **[cloud-provider-aws]** Fix root_block_device converge.
- **[cni-cilium]** Fixed least-conn logs when feature is disabled
- **[deckhouse-controller]** fix new snapshot logic bag
- **[deckhouse-controller]** add more verbosity to snapshot error
- **[dhctl]** Fix false-positive staticinstance ip duplication preflight checks fails.
- **[docs]** Correction of KeyCloak documentation in d8-user-authn
  Users will know how to configure KeyCloak and dexProvider to get user rights in dashboard and console.
- **[docs]** Refactored table of supported OS versions.
- **[istio]** Added missed documentation about version 1.25
- **[metallb]** Fixed overwriting of Service `status` field by module components.
- **[metallb]** avoid double prefixes in the dashboard names.
  default
- **[node-manager]** Changed draining logic in update_approval
- **[node-manager]** fixed render nvidia-mig-manager
- **[prometheus]** use the “deckhouse” ModuleSource as the default for the prompp ModuleConfig if there are several ModuleSources with the prompp module available, the “deckhouse” ModuleSource will be used.
- **[runtime-audit-engine]** Improve memory footprint by switching to the stdlib memory allocator instead of jemalloc

1.71.1

Features

- **[docs]** Added documentation with recommendations for generating self-signed certificates

Fixes

- **[ci]** add sh symlink to bash to the deckhouse-controller
- **[ci]** Fix listing of changed modules.
- **[control-plane-manager]** correct indentation of the ‘certSANs’ in v1beta4 template.
- **[monitoring-ping]** Reducing PROCESSOR time consumption by changing the method of waiting for incoming packets.
- **[user-authn]** fix dex oidc connector insecureSkipVerify and rootCAData options

Version 1.70

Important

- The `ceph-csi` module has been removed. Use the `csi-ceph` module instead. Deckhouse will not be updated as long as `ceph-csi` is enabled in the cluster. For `csi-ceph` migration instructions, refer to the module documentation.
- Version 1.12 of the Ingress NGINX Controller has been added. The default controller version has been changed to 1.10. All Ingress controllers that do not have an explicitly specified version (via the `controllerVersion` parameter in the IngressNginxController resource or the `defaultControllerVersion` parameter in the `ingress-nginx` module) will be restarted.
- The `falco events` metric (from the `runtime-audit-engine` module) has been removed. The `falco events` metric was considered deprecated since DKP 1.68. Use the `falcosecurity falcosidekick_falco_events_total` metric instead. Dashboards and alerts based on the `falco_events` metric may stop working.
- All DKP components will be restarted during the update.

Major changes

- In the `Auto` update mode, patch version updates (for example, from `v1.70.1` to `v1.70.2`) are now applied taking into account the update windows, if they are set. Previously, in this update mode, only minor version updates (for example, from `v1.69.x` to `v1.70.x`) were applied with consideration to update windows, while patch version updates were applied as they appeared on a release channel.
- A node can now be rebooted if the corresponding Node object has the `update.node.deckhouse.io/reboot` annotation set.
- When cleaning up a static node, any local users created by Deckhouse Kubernetes Platform are

now also removed.
- Added synchronization monitoring for Istio in multi-cluster configurations. A new alert `D8IstioRemoteClusterNotSynced` has been introduced and triggers in the following cases:
  - The remote cluster is offline.
  - The remote API endpoint is not reachable.
  - The remote `ServiceAccount` token is invalid or expired.
  - There is a TLS or certificate issue between the clusters.
- The `deckhouse-controller collect-debug-info` command now also collects debug information for `Istio`, including:
  - Resources in the `d8-istio` namespace.
  - CRDs from the `istio.io` and `gateway.networking.k8s.io` groups.
  - `Istio` logs.
  - `Sidecar` logs of a single randomly selected user application.
- A new monitoring dashboard has been added to display OpenVPN certificate status. Upon expiration, server certificates will now be reissued, and client certificates will be removed. The following alerts have been added:
  - `OpenVPNClientCertificateExpired`: Warns about expired client certificates.
  - `OpenVPNServerCACertificateExpired`: Warns about an expired OpenVPN CA certificate.
  - `OpenVPNServerCACertificateExpiringSoon` and `OpenVPNServerCACertificateExpiringInAWeek`: Warn when an OpenVPN CA certificate is expiring in less than 30 or 7 days, respectively.
  - `OpenVPNServerCertificateExpired`: Warns about an expired OpenVPN server certificate.
  - `OpenVPNServerCertificateExpiringSoon` and `OpenVPNServerCertificateExpiringInAWeek`: Warn when an OpenVPN server certificate is expiring in less than 30 or 7 days, respectively.
- Monitoring dashboards have been renamed and updated:
  - “L2LoadBalancer” renamed to “MetalLB L2”; pool and column filtering added.
  - “Metallb” renamed to “MetalLB BGP”; pool and column filtering added. The ARP request panel has been removed.
  - “L2LoadBalancer / Pools” renamed to “MetalLB / Pools”.
- The `upmeter` module’s PVC size has been increased to accommodate data retention for 13 months. In some cases, the previous PVC size was insufficient.
- The ModuleSource resource status now includes information about module versions in the source.
- The Module resource status now includes information about the module’s lifecycle stage. A module can move through the following stages in its lifecycle: Experimental, Preview, General Availability, and Deprecated. For details on module lifecycle stages and how to evaluate its stability, refer to the corresponding section in the documentation.
- It is now possible to use stronger or more modern encryption algorithms (such as `RSA-3072`, `RSA-4096`, or `ECDSA-P256`) for control plane cluster certificates instead of the default `RSA-2048`. You can use the `encryptionAlgorithm` parameter in the ClusterConfiguration resource to configure this.
- The `descheduler` module can now be configured to evict pods that are using local storage. Use the `evictLocalStoragePods` parameter in the module configuration to adjust this.
- You can now adjust the logging level of the Ingress controller using the `controllerLogLevel` parameter in the IngressNginxController resource. The default log level is `Info`. Controlling the logging level can help prevent log collector overload during Ingress controller restarts.

Security

- The severity level of alerts indicating security policy violations has been raised from 7 to 3.
- The configuration for `Yandex Cloud`, `Zvirt`, and `Basis Dynamix` providers now uses `OpenTofu` instead of `Terraform`. This enables easier provider updates, such as applying fixes for known vulnerabilities (CVEs).
- CVE vulnerabilities have been fixed in the following modules: `chrony`, `descheduler`, `dhctl`, `node-manager`, `registry-packages-proxy`, `falco`, `cni-cilium`, and `vertical-pod-autoscaler`.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.70.19

Fixes

- **[ci]** Fix render workflow job.
- **[istio]** Reduce CPU and RAM for regenerate multicluster JWT token and sort ingressGateway

Chore

- **[runtime-audit-engine]** Update CI file

1.70.18

Fixes

- **[istio]** The metrics-exporter's template is fixed, it blocked the main queue if `controlPlane.nodeSelector` setting was configured.

1.70.17

Fixes

- **[istio]** fixed an error in processing custom input gateway addresses using the configuration option of the alliance.ingressGateway.advertise module.

1.70.16

Fixes

- **[cloud-provider-aws]** fix root_block_device converge
- **[runtime-audit-engine]** Improve memory footprint by switching to the stdlib memory allocator instead of jemalloc

1.70.15

Fixes

- **[control-plane-manager]** correct indentation of the 'certSANs' in v1beta4 template.

1.70.14

Fixes

- **[cloud-provider-dvp]** fix logic of work with disks and coreFraction validation
- **[cloud-provider-huaweicloud]** fix virtualMachineClassName in terraform
- **[deckhouse]** Filter deleted pvcs in storage class change hook.
- **[deckhouse]** Filter deleted pvcs in storage class change hook.
- **[deckhouse-controller]** make metrics more verbose

1.70.13

Know before update

- Users can now restore etcd backups and scale their master nodes efficiently without encountering previous errors.

Fixes

- **[control-plane-manager]** Fixed issues with etcd backup restoration process, ensuring reliable master node scaling from 1 to 3.
  Users can now restore etcd backups and scale their master nodes efficiently without encountering previous errors.
- **[deckhouse-controller]** fix nil annotations map for module fetcher
- **[ingress-nginx]** Validation is switched off temporarily.
- **[prometheus]** Fix fake longterm emptydir alert.

1.70.12

Features

- **[cloud-provider-huaweicloud]** add enterprise_project_id

Fixes

- **[dhctl]** TLS support on dhctl edition checking step.

1.70.11

Fixes

- **[docs]** remove Yandex Cloud’s api-gateway.editor and connection-manager.editor roles

1.70.10

Features

- **[docs]** Add unified manual about edition switch

Fixes

- **[dhctl]** Fix dhctl output in case of invalid config
- **[dhctl]** Release infrastructure dependency lock.

1.70.9

Fixes

- **[control-plane-manager]** Fix default behaviour for etcd backup.
- **[ingress-nginx]** fixed geoip issues in validator
- **[ingress-nginx]** Automatic geoip updating feature was reverted.

1.70.8

Fixes

- **[docs]** Delete the mention that addresses are allocated starting from 10 from internalNetworkCIDR in vcd cloud-provider

1.70.7

Know before update

- When called collect-debug-info command in cluster without Istio, user see errors, but archive create correct

Fixes

- **[control-plane-manager]** fix kubeadm v1beta4 config
- **[deckhouse-controller]** fix wrong behavior of Pending ModuleReleases
- **[ingress-nginx]** fixed `node-selector` and `tolerations` in validator `pod`
- **[istio]** Fix for collecting debugging resources in collect-debug-info about Istio
  When called collect-debug-info command in cluster without Istio, user see errors, but archive create correct
- **[node-local-dns]** Improved stability for clusters with poor node-to-node connection quality by increasing node-local-dns to kube-dns healthcheck timeouts.

1.70.6

Fixes

- **[control-plane-manager]** audit-log-maxage value to 30 days
- **[deckhouse]** Fix obsolete config alert stuck after deleting module config.
- **[deckhouse]** Remove unnecessary modules downloading.
- **[docs]** Rendered SSHHost and SSHConfig specs.
- **[ingress-nginx]** fixed an issue with the snapshot retrieval mechanism
- **[ingress-nginx]** fix missing proxy client cert in validator deployment
- **[ingress-nginx]** Ingress resource validation in ingress-nginx controller re-enabled.
- **[openvpn]** Added a migration hook to mitigate false positive `OpenVPNClientCertificateExpired` alerts.
- **[user-authz]** Add patch verb for service accounts

1.70.5

Know before update

- loki statefulset will be rollout restarted

Fixes

- **[loki]** Fix several bugs introduced while implementing loki disk based retention
  loki statefulset will be rollout restarted
- **[prometheus]** Add headers field to values spec

1.70.4

Know before update

- operator-prometheus

Features

- **[cloud-provider-dvp]** Add vmClassName to the config
- **[operator-prometheus]** Add to documetation for operator-prometheus CRD. operator-prometheus
- **[snapshot-controller]** Automatic snapshot-controller MC creation for future switch to external module

Fixes

- **[cloud-provider-dvp]** Fix cherry-pick conflicts pr
- **[ingress-nginx]** Ingress resource validation in ingress-nginx controller re-enabled.

1.70.3

Fixes

- **[cloud-provider-yandex]** Handle hybrid clusters case in the to_tofu_migrate_metric hook
- **[cloud-provider-zvirt]** fix UUID validation regex
- **[deckhouse-controller]** fixes default maintenance value which prevents stuck metric
- **[deckhouse-tools]** deckhouse-tools fix deployment render
- **[docs]** Updated conversions message.
- **[node-local-dns]** Changed container liveness port.
- **[node-manager]** fixed update for static clusters

1.70.2

Fixes

- **[candi]** memory.available calculation python2 fix
- **[openvpn]** Fixed condition of alert triggering for client certificate.
- **[service-with-healthchecks]** change port kube-rbac-proxy in agent DaemonSet

1.70.1

Know before update

- prometheus

Features

- **[cloud-provider-dvp]** Add vmClassName to the config
- **[prometheus]** Validation prometheus remotewrite ca webhook prometheus

Fixes

- **[candi]** Added a check to the bashible step for the presence of a previously created symlink and where it leads to
- **[candi]** bashible bb-discover-node-name use node name from kubelet certificate
- **[ci]** returned the condition when the branch was not found
- **[ci]** fix kubernetes version info in the release file
- **[cloud-provider-vcd]** Fix unexpected behavior with legacy API versions in VCD
- **[deckhouse-controller]** fix deckhouse crds mechanism
- **[dhctl]** Fix unexpected behavior with legacy API versions in VCD
- **[docs]** Update docs about Keycloak configuration for IP
- **[operator-trivy]** Add support anon registry creds for bdu updater.
- **[user-authz]** fix error with webhook system-roles

Version 1.69

Important

- Support for Kubernetes 1.32 has been added, while support for Kubernetes 1.27 has been discontinued. The default Kubernetes version has been changed to 1.30. In future DKP releases, support for Kubernetes 1.28 will be removed.

- All DKP components will be restarted during the update.

Major changes

- The `ceph-csi` module is now deprecated. Plan to migrate to the `csi-ceph` module instead. For details, refer to the Ceph documentation.
- You can now grant access to Deckhouse web interfaces using user names via the `auth.allowedUserEmails` field. Access restriction is configured together with the `auth.allowedUserGroups` parameter in configuration of the following modules with web interfaces: `cilium-hubble`, `dashboard`, `deckhouse-tools`, `documentation`, `istio`, `openvpn`, `prometheus`, and `upmeter` (example for `prometheus`).
- A new dashboard **Cilium Nodes Connectivity Status & Latency** has been added to Grafana in the `cni-cilium` module. It helps monitor node network connectivity issues. The dashboard displays a connectivity matrix similar to the `cilium-health status` command, using metrics that are already available in Prometheus.
- A new `D8KubernetesStaleTokensDetected` alert has been added in the `control-plane-manager` module that is triggered when stale service account tokens are detected in the cluster.
- You can now create a Project from an existing namespace and adopt existing objects into it. To do this, annotate the namespace and its resources with `projects.deckhouse.io/adopt`. This lets you switch to using Projects without recreating cluster resources.
- A `Terminating` status has been added to ModuleSource and ModuleRelease resources. The new status will be displayed when an attempt to delete one of them fails.
- The installer container now automatically configures cluster access after a successful bootstrap. A `kubeconfig` file is generated in `~/.kube/config`, and a local TCP proxy is set up through an SSH tunnel. This allows you to use kubectl locally right away without manually connecting to the control-plane node via SSH.
- Changes to Kubernetes resources in multi-cluster and federation setups are now tracked directly via Kubernetes API. This enables faster synchronization between clusters and eliminates the use of outdated certificates. In addition, mounting of ConfigMap and Secret resources into Pods has been removed to eliminate family system compromise risks.
- A new dynamicforward plugin has been added to CoreDNS, improving DNS query processing in the cluster. It integrates with `node-local-dns`, continuously monitors `kube-dns` endpoints, and automatically updates the list of DNS forwarders. If the control-plane node is unavailable, DNS queries are still forwarded to available endpoints, improving cluster stability.
- A new log rotation approach has been introduced in the `loki` module. Now, old logs are automatically removed when disk usage exceeds a threshold: either 95% of PVC size or PVC size minus the size required to store two minutes of log data at the configured ingestion rate (`ingestionRateMB`). The `retentionPeriodHours` parameter no longer controls the data retention and is used for monitoring alerts only. If `loki` begins removing old logs before the set period is reached, a `LokiRetentionPerionViolation` alert will be triggered, informing the user that they must reduce the value of `retentionPeriodHours` or increase the PVC size.
- A new `nodeDrainTimeoutSecond` parameter lets you set the maximum timeout when attempting to drain a node (in seconds) for each NodeGroup resource. Previously, you could only use the default value (10 minutes) or reduce it to 5 minutes using the `quickShutdown` parameter, which is now deprecated.
- The `openvpn` module now includes a `defaultClientCertExpirationDays` parameter, allowing you to define the lifetime of client certificates.

Security

- Known vulnerabilities have been addressed in the following modules: `ingress-nginx`, `istio`, `prometheus`, and `local-path-provisioner`.

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.69.17

Know before update

- Users can now configure containerd to pull images from private registries, easing deployments in private environments.

Features

- **[docs]** Add command to view all falco audit rules to docs.
- **[istio]** Validating jwt token exp time less than 30 days
- **[node-manager]** Added support for configuring private HTTP container registries in containerd. Users can now configure containerd to pull images from private registries, easing deployments in private environments.

Fixes

- **[docs]** Removed port 22322 from setup docs.
- **[istio]** Fix istiod CPU leak when the order of the ingressGateways array is changed
- **[istio]** Reduce RAM for regenerate multicluster JWT token

1.69.16

Fixes

- **[control-plane-manager]** audit-log-maxage value to 30 days
- **[deckhouse]** Fix obsolete config alert stuck after deleting module config.

1.69.15

Know before update

- Prevent important data loss when using wide retention intervals.

Fixes

- **[loki]** Fix incorrect indices sort function used in disk-based retention.
  Prevent important data loss when using wide retention intervals.

1.69.14

Fixes

- **[deckhouse-controller]** fixes default maintenance value which prevents stuck metric
- **[node-manager]** fixed update for static clusters

1.69.13

Fixes

- **[istio]** The `alliance.ingressGateway.advertise` option was fixed up.

1.69.12

Fixes

- **[dashboard]** fix display workload metrics on dashboard

1.69.11

Know before update

- In L2 mode, the Public IP address will not be marked as free in the pool after deleting the LoadBalancer Service. As a temporary fix, you can restart the MetalLB controller pods.
- fix static e2e tests for fe/upgrade

Fixes

- **[ci]** fix static e2e tests for fe/upgrade
  fix static e2e tests for fe/upgrade
- **[istio]** proxy-buffer-size increased in kiali Ingress.
- **[metallb]** Reverted the fix for handling deleted Services and revising the IP pools in L2 mode. The correct fix is under construction.
  In L2 mode, the Public IP address will not be marked as free in the pool after deleting the LoadBalancer Service. As a temporary fix, you can restart the MetalLB controller pods.

1.69.10

Fixes

- **[deckhouse-controller]** Added validation according to `RFC 1123` for module names added to `ModuleSource`.
- **[docs]** Fix apiVersion for s3 storageclass

1.69.9

Fixes

- **[metallb]** Fixed deprecated CRD addresspools.metallb.io deletion.
- **[network-gateway]** Fix python path

1.69.8

Fixes

- **[cloud-provider-yandex]** fix synchronizing TGs
- **[deckhouse]** Gracefully restore deployed modules on HA installations.

1.69.7

Fixes

- **[docs]** Fixed new layouts at documentation.
- **[kube-dns]** Fixed release upgrade issue with removed d8-kube-dns-redirect service.

1.69.6

Fixes

- **[cni-cilium]** Fixed race condition when deleting element from ipcache map during VM migration.
- **[docs]** Fix broken links in the Storage overview.
- **[metallb]** Fixed IP pool exhaustion on LoadBalancer deletion.
- **[node-manager]** Revert cluster autoscaler

1.69.5

Features

- **[candi]** Add rosa 12.6.

Fixes

- **[cloud-provider-yandex]** fix WithNATInstance clusters converge
- **[control-plane-manager]** Stale service account alert upd
- **[node-manager]** Autoscaler - remove additional cordon node by mcm provider.

1.69.4

Features

- **[deckhouse-controller]** sequential processing of module releases
- **[deckhouse-controller]** sequential processing of module releases
- **[testing]** Add e2e tests for autoscaler and enable it permanent for GCP.
- **[testing]** Add e2e tests for autoscaler and enable it permanent for GCP

Fixes

- **[candi]** Return support `.cri.notManaged.criSocketPath`.
- **[deckhouse]** Restore only ready mpo.
- **[dhctl]** <Disable caching metaconfig during converge and disable converge deckhouse manifests.
- **[dhctl]** Fix incorrect behavior that fails sudoers preflight check if password contains whitespaces.
- **[docs]** Fixed Dynamix layout at documentation.
- **[docs]** Add support of `x-doc-d8Editions` array instead of `x-doc-d8Revision` field to JSON schema renderer.
- **[node-manager]** Increase verbosity and revert versions and fix bug with unsupported mcm annotation
- **[upmeter]** upmeter sa token rotation
- **[user-authn]** Add separate ServiceAccount to basic-auth-proxy.
- **[user-authz]** Exclude deckhouse clusterrolebindings from webhook.

1.69.3

Know before update

- Ingress-nginx controller pods of v1.9 will be restated.

Fixes

- **[control-plane-manager]** Stale service account alert fix.
- **[deckhouse]** Limit module name.
- **[deckhouse]** Fix mpo/source requeue.
- **[docs]** Add info about debug GrafanaDashboardDefenition.
- **[extended-monitoring]** Fix x509_certificate_exporter_resources deployment
- **[ingress-nginx]** All necessary shared libraries are added to the container image.
  Ingress-nginx controller pods of v1.9 will be restated.
- **[kube-dns]** Expanded pattern for `stubZones` to allow underscores (`_`) in domain names.
- **[user-authn]** Fix secret generation on empty data field in the dex client app secret.

1.69.2

Know before update

- the grafana deployment will be rollout restarted

Fixes

- **[deckhouse]** Gracefully restore deployed modules on HA installations.
- **[prometheus]** enable WAL for the grafana SQLite database to prevent locking errors, thus fixing in-dashboard alerting.
  the grafana deployment will be rollout restarted

1.69.1

Know before update

- fixes the bug introduced in v1.69.0
- release upgrade will be blocked on AWS-based clusters where SA doesn't have DescribeAddressesAttribute and DescribeInstanceTopology roles. They are required for new Terraform AWS Provider version.

Features

- **[deckhouse]** enable UnmetCloudConditions check
  release upgrade will be blocked on AWS-based clusters where SA doesn't have DescribeAddressesAttribute and DescribeInstanceTopology roles. They are required for new Terraform AWS Provider version.
- **[deckhouse-controller]** rename module flag `managementState` to `maintenance`.
- **[dhctl]** add variable time range to request counter
- **[node-manager]** enable UnmetCloudConditions check
- **[node-manager]** UnmetCloudConditions requirement and alert

Fixes

- **[ci]** Use fixed werf version.
- **[cloud-provider-vcd]** Add a hook to set `legacyMode` based on the detected `VCD API` version
- **[deckhouse]** Clear deployed release`s message.
- **[deckhouse]** Delete deckhouse epslices.
- **[deckhouse-controller]** Fix runtime handling for the global config.
- **[dhctl]** fix bootstrap and abort config preparation
- **[docs]** Fix d8 install commands.
- **[loki]** fix storage capacity calculator hook for Loki
  fixes the bug introduced in v1.69.0
- **[operator-trivy]** Add proxy env variables support to the trivy server.

Version 1.68

Important

- After the update, the UID will change for all Grafana data sources created using the GrafanaAdditionalDatasource resource. If a data source was referenced by UID, that reference will no longer be valid.

Major changes

- A new parameter, `iamNodeRole`, has been introduced for the AWS provider. It lets you specify the

name of the IAM role to bind to all AWS instances of cluster nodes. This can come in handy if you need to grant additional permissions (for example, access to ECR, etc.).

- Creating nodes of the CloudPermanent type now takes less time. Now, CloudPermanent nodes are created in parallel. Previously, they were created in parallel only within a single group.
- Monitoring changes:
  - Support for monitoring certificates in secrets of the `Opaque` type has been added.
  - Support for monitoring images in Amazon ECR has been added.
  - A bug that could cause partial loss of metrics when Prometheus instances were restarted has been fixed.
- When using a multi-cluster Istio configuration or federation, you can now explicitly specify the list of addresses used for inter-cluster requests. Previously, these addresses were determined automatically; however, in some configurations, they could not be resolved.
- The DexAuthenticator resource now has a `highAvailability` parameter that controls high availability mode. In high availability mode, multiple replicas of the authenticator are launched. Previously, high availability mode of all authenticators was determined by a global parameter or by the `user-authn` module. All authenticators deployed by DKP now inherit the high availability mode of the corresponding module.
- Node labels can now be added, removed, or modified using files stored on the node in the `/var/lib/node_labels` directory and its subdirectories. The full set of applied labels is stored in the `node.deckhouse.io/last-applied-local-labels` annotation.
- Support for the Huawei Cloud provider has been added.
- The new `keepDeletedFilesOpenedFor` parameter in the `log-shipper` module allows you to configure the period to keep the deleted log files open. This way, you can continue reading logs from deleted pods for some time if log storage is temporarily unavailable.
- TLS encryption for log collectors (Elasticsearch, Vector, Loki, Splunk, Logstash, Socket, Kafka) can now be configured using secrets, rather than by storing certificates in the ClusterLogDestination resources. The secret must reside in the `d8-log-shipper` namespace and have the `log-shipper.deckhouse.io/watch-secret: true` label.
- In the project status under the `resources` section, you can now see which project resources have been installed. Those resources are marked with `installed: true`.
- A new parameter, `--tf-resource-management-timeout`, has been added to the installer. It controls the resource creation timeout in cloud environments. By default, the timeout is set to 10 minutes. This parameter applies only to the following clouds: AWS, Azure, GCP, OpenStack.

Security

Known vulnerabilities have been addressed in the following modules:

- `admission-policy-engine`
- `chrony`
- `cloud-provider-azure`
- `cloud-provider-gcp`
- `cloud-provider-openstack`
- `cloud-provider-yandex`
- `cloud-provider-zvirt`
- `cni-cilium`
- `control-plane-manager`
- `extended-monitoring`
- `descheduler`
- `documentation`
- `ingress-nginx`
- `istio`
- `loki`
- `metallb`
- `monitoring-kubernetes`
- `monitoring-ping`
- `node-manager`
- `operator-trivy`
- `pod-reloader`
- `prometheus`
- `prometheus-metrics-adapter`
- `registrypackages`
- `runtime-audit-engine`
- `terraform-manager`

- `user-authn`
- `vertical-pod-autoscaler`
- `static-routing-manager`

Mandatory component restart

The following components will be restarted after updating DKP to 1.68:

- Kubernetes Control Plane
- Ingress controller
- Prometheus, Grafana
- `admission-policy-engine`
- `chrony`
- `cloud-provider-azure`
- `cloud-provider-gcp`
- `cloud-provider-openstack`
- `cloud-provider-yandex`
- `cloud-provider-zvirt`
- `cni-cilium`
- `control-plane-manager`
- `descheduler`
- `documentation`
- `extended-monitoring`
- `ingress-nginx`
- `istio`
- `kube-state-metrics`
- `log-shipper`
- `loki`
- `metallb`
- `monitoring-kubernetes`
- `monitoring-ping`
- `node-manager`
- `openvpn`
- `operator-trivy`
- `prometheus`
- `prometheus-metrics-adapter`
- `pod-reloader`
- `registrypackages`
- `runtime-audit-engine`
- `service-with-healthchecks`
- `static-routing-manager`
- `terraform-manager`
- `user-authn`
- `vertical-pod-autoscaler`

The complete list of changes, including the updated components, is available in the changelog on GitHub.

1.68.15

Fixes

- **[dhctl]** Do not create a local-converger lock for commanderMode
- **[docs]** Fixed the parameter generator for modules on Hugo.
- **[docs]** This reverts commit cf9d7590da7c4b23c7eab10da37abc16397faf87.

1.68.14

Fixes

- **[deckhouse-controller]** fix module release force behaviour
- **[deckhouse-controller]** fix module release force behaviour
- **[runtime-audit-engine]** Fix CrashLoopBack due to invalid config.

1.68.13

Know before update

- Grafana deployment will be rollout restarted.

Fixes

- **[prometheus]** Enables WAL for Grafana SQLite database to prevent locking errors, thus fixing in-

dashboard alerting.
Grafana deployment will be rollout restarted.

1.68.12

Fixes

- **[ci]** Use fixed werf version.
- **[cloud-provider-zvirt]** fix invalid zvirt csi template
- **[node-local-dns]** Stale-dns-connection-cleaner file permissions and security context are fixed.

1.68.11

Fixes

- **[cloud-provider-zvirt]** fix zvirt-csi-driver patching (token refresh fix patch)
- **[node-manager]** partial rollback of changes in images cluster-autoscaler

1.68.10

Features

- **[deckhouse-controller]** restore releases only by deckhouse-controller and in deployed state

Fixes

- **[deckhouse-controller]** fix suspend release
- **[node-manager]** handle_node_template hook ignore metallb label
- **[runtime-audit-engine]** copy falcosecurity_falcosidekick_falco_events_total metric to falco_events for backward compatibility

1.68.9

Fixes

- **[node-manager]** partial rollback of changes in images cluster-autoscaler

1.68.8

Features

- **[cert-manager]** Bump cert-manager version up to 1.17.1. This fixes acme confirmation for cloudflare provider.

Fixes

- **[docs]** FIx local docimentation build and run.
- **[docs]** The information label with the editions has been removed from the global settings page.
- **[ingress-nginx]** Fixed the display of ports in the examples in the CRDs.
- **[istio]** Fixed the display of ports in the examples in the CRDs.

1.68.7

Know before update

- Ingress-nginx pods will restart. The validation of the generated NGINX configuration during the validation of `Ingress` resources is disabled until finding a way of running validations safely.

Fixes

- **[ingress-nginx]** latest CVE fixes backported.
  Ingress-nginx pods will restart. The validation of the generated NGINX configuration during the validation of `Ingress` resources is disabled until finding a way of running validations safely.

1.68.6

Fixes

- **[candi]** Fix errors in bashible steps.
- **[deckhouse]** Fix erroneous inclusions in 1.68
- **[deckhouse]** Fix module config ignored.
- **[deckhouse]** Fix checking automatic kubernetes version in managed clusters.
- **[deckhouse]** Fix module config ignored.

- **[deckhouse]** Explicitly set ports in d8-kube-dns deployment.
- **[deckhouse]** Set EnabledByModuleConfig condition by default for modules without this condition.
- **[deckhouse]** Fix module condition race.
- **[deckhouse-controller]** Fix applying releases and their metrics.
- **[deckhouse-controller]** Fix applying releases and their metrics.
- **[deckhouse-tools]** d8-cli build fix
- **[docs]** Corrected a typo in the NFSStorageClass name in the NFS data storage section.
- **[docs]** Added SE and SE+ restrictions for Istio.
- **[log-shipper]** Add delete parsed_data to final kafka transform render

1.68.5

Features

- **[prometheus]** add grafana enable flag

Fixes

- **[candi]** Fix `disable_unattended_upgrades` bashible step
- **[docs]** Correct mistakes in the crds for the Storage section in Deckhouse Kubernetes Platform.
- **[docs]** Update Deckhouse CLI installation guide
- **[docs]** Fixed sidebar behaviour with links.
- **[docs]** Correct mistakes in the documentation for the storage section in Deckhouse Kubernetes Platform.
- **[extended-monitoring]** Minor certificate alerts improvements
- **[metallb]** Add clearing of alert metric group D8MetallbObsoleteLayer2PoolsAreUsed
- **[operator-trivy]** Updated info about databases with vulnerabilities.

1.68.4

Fixes

- **[candi]** Fix add_node_users.sh search for sudoersd_path.
- **[deckhouse-controller]** Fix DeckhouseRelease approval in the Manual update mode.
- **[dhctl]** Escape special shell characters in sudo preflight check.
- **[docs]** Fixed typos at VMware configuration parameters.
- **[upmeter]** Add D8UpmeterDiskUsage alert.

1.68.3

Fixes

- **[deckhouse]** Add initial module config validation.
- **[deckhouse-controller]** Update addon-operator.
- **[dhctl]** sudoPassword from the connection-config not used in dhctl CLI and dhctl server
- **[metallb]** Fixed module startup error with empty Selector value in SVC.

1.68.2

Know before update

- The links in the alerts will be correct when the documentation module is enabled.

Fixes

- **[admission-policy-engine]** Fix wildcard apparmor profile.
- **[deckhouse-controller]** fix deckhouse-release check loop
- **[deckhouse-tools]** Fix tools links pointing to wrong path
- **[metallb]** Fixed alerts for EE edition.
- **[monitoring-applications]** Fix module dependencies. The `monitoring-applications` module was affected and disabled by the enabled script.
- **[node-local-dns]** Fix module dependencies. The `monitoring-applications` module was affected and disabled by the enabled script.
- **[prometheus]** Changes the links in alert’s template about alerts from url to relative links
  The links in the alerts will be correct when the documentation module is enabled.
- **[service-with-healthchecks]** Fixed several issues.
- **[upmeter]** Fixed metallb module probe.

1.68.1

Know before update

- kubernetes-api will be restarted.

- okmeter daemonset pods will be rollout restarted

Features

- **[candi]** Add a new layout for HuaweiCloud provider with support for VPC peering connections.
- **[docs]** Add new description info for conversions.

Fixes

- **[candi]** Fix update_node_labels.sh to work on python2.
- **[candi]** Reduce `request-timeout` in kubernetes-api to 60s.
  kubernetes-api will be restarted.
- **[ci]** CI_COMMIT_TAG does not found in deckhouse controller
- **[ci]** fix standalone-installer build
- **[ci]** cloud providers CVE fixes, use single images for cloud-provider-zvirt and cloud-provider-yandex
- **[cloud-provider-vcd]** fix CVE, bump ccm, use go 1.23, use werf images and src-artifact
- **[deckhouse]** Fix stuck overridden status in ms.
- **[deckhouse]** Fix module.yaml ignored when weight == 0.
- **[node-manager]** fix autoscaler RBAC for zvirt and dynamix
- **[okmeter]** drop service account fields from the okmeter daemonset manifest
  okmeter daemonset pods will be rollout restarted
- **[user-authn]** Fix cronjob security context.

Embedded Deckhouse Platform modules

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The admission-policy-engine module

> Available with limitations in: **Open/CE, Core, BE, SE, SE+**
>
> Available without limitations in: **Ultimate/EE**

> Included in extensions: **Advanced Infrastructure Security**

> The module lifecycle stage: General Availability

The `admission-policy-engine` module implements support for admission security policies in a Kubernetes cluster.

Admission policies are rules applied to objects (e.g., Pod and Service) at the time of their creation or modification in the cluster (but not during their operation), based on the information provided in their manifest. These policies are aimed at formalizing parameters that are allowed or prohibited in object manifests.

Policies are divided into three categories:

- Pod Security Standards: Policies that comply with the relevant Pod Security Standards.
- Operational policies: Policies for creating additional requirements for objects by validating the values of parameters that are **not directly related** to security (for example, a list of allowed prefixes for container images, an image download policy, a list of required container images, etc.).
- Security policies: Policies for creating additional requirements on objects by validating the values of security-related parameters (e.g., container access to the host's IPC or PID namespaces, privilege lists for containers, etc.).

> These policies complement each other. If multiple policies are applied to a single namespace, objects are validated against each of them. If even one policy is violated, the object will not be created.

In addition to policies that prohibit using parameters different from the set requirements, the module supports the SecurityPolicyException resource, which allows creating fine-grained exceptions from security policy checks. With this resource, you can allow using specific parameters for individual pods or containers without changing security policies applied to the entire namespace.

How validation failure messages are displayed

Depending on how pods are created, there are differences in how the API generates messages regarding validation failures (violations of established policies):

- If a pod is created directly, the validation error is returned in the API response indicating a validation failure (policy violation).
- If pods are created via a Deployment and the pods potentially violate a policy, the creation of such Deployment will be rejected.
- If pods are created via a Deployment that already existed before the policy was enabled, the required number of ReplicaSets is created, which in turn attempt to create the pods. In this case, the validation error is not returned in the API response but is displayed in the namespace events or the corresponding ReplicaSet events.

Controller-level validation

Policies validate pod-creating controllers at `CREATE` and `UPDATE` time. This provides early feedback when a workload is created or updated, before any Pod is launched, and also surfaces creation denials when deploying via CI (CI rarely creates Pods directly, and Pod creation errors from controllers are often not displayed).

⚠ By default, a controller that violates a policy with `enforcementAction: Deny` gets a warning instead of a denial. The Pods the controller creates are still denied. The module checks controllers in separate constraints named `d8-controllers-<NAME>` with `enforcementAction: warn`. The `ControllerPolicyViolation` alert reports such controllers, one alert for each policy and namespace. This is a temporary default for the transition to controller-level validation. To check controllers with the action of the policy now, set `controllerValidationEnforcement` to `Policy`. In a future release, `Policy` will become the default.

The following objects are validated:

API group	Resource kind	Operations
(core)	Pod	`CREATE`, `UPDATE`, `DELETE`
apps	Deployment, StatefulSet, DaemonSet	`CREATE`, `UPDATE`, `DELETE`
(core)	ReplicationController	`CREATE`, `UPDATE`, `DELETE`
batch	Job, CronJob	`CREATE`, `UPDATE`, `DELETE`
(core)	pods/exec, pods/attach	`CONNECT`

`DELETE` is intercepted so that a policy can forbid deleting a resource: a rule that inspects `input.review.operation` only runs if the request reaches Gatekeeper.

⚠ The webhook uses `failurePolicy: Fail`. While Gatekeeper is unavailable, both creating and deleting the resource kinds listed above is blocked. To restore operations, bring the `gatekeeper-controller-manager` deployment back up.

⚠ Controller-level checks run against the **original pod template** (`spec.template`), not against the manifest that results from all mutations. Pod-level validation, in contrast, happens after all mutating actions — for example, after LimitRange adds default `resources`, or a mutating webhook adds `securityContext`. Keep this in mind when using security policies.

labelSelector semantics for controllers

When building policies that are applied based on object labels (`match.labelSelector`), keep in mind that selection is performed against the `metadata.labels` of the reviewed object. For Pods these are the pod's labels. For controllers (Deployment, StatefulSet, and others) these are the controller's **top-level** `metadata.labels`, not the pod template's `metadata.labels` (`spec.template.metadata.labels`).

As a result, a selector that matches the pods a controller creates does not by itself trigger a controller-level check, and an exclusion selector (`NotIn`/`DoesNotExist`) that excludes those pods may not take effect at the controller level. In both cases the controller itself must be matched by the `labelSelector`.

This also applies to the `security.deckhouse.io/skip-pss-check` label, which excludes an object from the Pod Security Standards constraints. The label is read from the reviewed object's own `metadata.labels`, so a workload that carries it only on the pod template (`spec.template.metadata.labels`) is exempt at the Pod level but still checked at the controller level. To exempt such a workload completely, set the label on the controller's top-level `metadata.labels` as well. Unlike SecurityPolicyException, this cannot be resolved from the pod template: the exclusion is evaluated by Gatekeeper's `match.labelSelector`, before any policy code runs.

SecurityPolicyException label resolution for controllers

For controller kinds, SecurityPolicyException (SPE) labels and annotations are taken from the **pod template's metadata** (`spec.template.metadata`), not from the controller's top-level metadata. This ensures SPEs apply to the pods the controller creates, not to the controller object itself.

Configuring controller-level validation

Controller-level validation is configured by four settings with different scopes:

1. The `controllerValidation` module parameter enables or disables controller-level validation for every constraint that reads a pod spec. Despite living in the `podSecurityStandards` section, it applies to Pod Security Standards, OperationPolicy and SecurityPolicy alike.
2. The `controllerValidationEnforcement` module parameter sets what happens to a controller that violates a denying policy: `Warn` (default) accepts it with a warning, `Policy` denies it. It applies to the Pod Security Standards and to every OperationPolicy and SecurityPolicy without `spec.controllerValidation.mode`.
3. The `controllerValidationExcludedPolicies` module parameter lists the Pod Security Standards rules that are checked on Pods only. It applies to the Pod Security Standards only.
4. The `spec.controllerValidation` section of an OperationPolicy or a SecurityPolicy configures that policy.

`mode: Enforce` checks controllers with the action of the policy, `mode: Warn` only warns about them, and `mode: Disabled` checks only Pods. `Enforce` and `Warn` check controllers even when the module parameter disables it, and a policy without `mode` follows the module parameters. `excludedPolicies` lists the rules of the policy that are checked on Pods only; the module exclusion list does not apply to a policy.

Exclude a rule from controller-level validation when a mutating webhook makes the Pod compliant while the controller's pod template is not. For example, the Vertical Pod Autoscaler sets `resources.requests` on the Pod, while the pod template may set `limits` only. A container that sets no `resources` at all already passes the controller-level check in the lenient mode, so the exclusion matters when `resources` are set partially. The following OperationPolicy checks the image registry on controllers and the resource requests on Pods only:

```
apiVersion: deckhouse.io/v1alpha1
kind: OperationPolicy
metadata:
  name: requests-set-by-vpa
spec:
  enforcementAction: Deny
  controllerValidation:
    mode: Enforce
    excludedPolicies:
      - requiredResources
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          operation-policy.deckhouse.io/enabled: "true"
  policies:
    allowedRepos:
      - registry.example.com
    requiredResources:
      requests:
        - cpu
        - memory
```

A Deployment whose pod template sets `limits` but no `requests` is accepted, and its Pods are denied unless the Vertical Pod Autoscaler sets the requests.

The rules of the Pod Security Standards are excluded in the module settings. They are named as the parameters of the SecurityPolicy objects the standards are published with, see Rules of the standards. The following example checks `allowPrivilegeEscalation` and `requiredDropCapabilities` on Pods only:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: admission-policy-engine
spec:
  version: 1
  settings:
    podSecurityStandards:
      controllerValidationExcludedPolicies:
        - allowPrivilegeEscalation
        - requiredDropCapabilities
```

Some rules are checked by one constraint and are excluded together: listing any rule of a group checks the whole group on Pods only. The groups are:

- `allowHostPID` and `allowHostIPC`;
- `allowHostNetwork` and `allowedHostPorts`;
- `fsGroup`, `runAsUser`, `runAsGroup` and `supplementalGroups`;
- `allowedUnsafeSysctls` and `forbiddenSysctls`.

`allowedCapabilities` and `requiredDropCapabilities` are excluded one by one.

When a rule is checked on Pods only:

- controllers (Deployment, StatefulSet, DaemonSet, Job, CronJob, ReplicationController) are not checked against it on creation or update;
- SecurityPolicyException labels on `spec.template.metadata.labels` of controllers are not resolved for it, since it is not applied to controllers;
- Pods are still checked against it at launch time.

Lenient mode for fields that may be filled in before the pod is created

Some constraints use a **lenient mode** for fields that may be absent from a controller's pod template and still be present on the Pod the controller creates. This prevents denying a workload whose pods would in fact be compliant.

The following constraints skip violations for absent fields when reviewing controllers, while still enforcing them when a field is **explicitly set** to a disallowed value. The decision is made per container: a container that omits the field is treated leniently even if another container in the same pod template sets it.

Constraint	Skipped fields (when absent on controllers)	What may fill the field in
`D8RequiredResources`	`container.resources` (when neither `limits` nor `requests` is set)	LimitRange
`D8AllowedUsers`	`runAsUser`, `runAsGroup`, `fsGroup`, `supplementalGroups` (with `MustRunAs` / `MustRunAsNonRoot`)	A mutating webhook, including a Gatekeeper `Assign` mutator

For example, a Deployment without `resources` in its pod template is **not** denied by `D8RequiredResources`, because a LimitRange in the namespace may add default `requests` and `limits`. If `resources` is set partially (for example, only `limits.memory` but not `limits.cpu`), the violation is still enforced.

`D8RequiredResources` relies on an in-tree component. `D8AllowedUsers` does not: in a cluster without a matching mutator it gets no controller-level enforcement of these fields, and the violation surfaces at Pod creation instead. Pod Security Admission is not one of the sources listed above — it only validates and never modifies an object.

`D8AllowedSeccompProfiles` needs no lenient mode: a container that sets no profile in any source is allowed on a Pod as well, so controllers and Pods already behave the same.

Constraints with limited controller-level coverage

Some checks depend on data that only exists after mutation, so they cannot deny a controller even though they deny its pods.

`D8AutomountServiceAccountToken` detects the token mount either from `spec.automountServiceAccountToken: true` or from a container that mounts `/var/run/secrets/kubernetes.io/serviceaccount`. The ServiceAccount admission plugin adds that mount to the Pod, not to the controller's pod template. A workload that simply omits `automountServiceAccountToken` therefore passes the controller-level check, and the denial appears when its pods are created. To get the denial at the controller level, set `automountServiceAccountToken: false` explicitly in the pod template.

Pod validation when policies are modified or new ones are added

For all three policy categories (Pod Security Standards, operational, and security policies), there is no provision for automatically recreating existing pods when changing existing policies or adding new ones. Pods that existed prior to changes being made to the policy in use or prior to a new policy being added will continue to run until they are restarted. Upon restart, they will be validated against the new rules.

The `admission-policy-engine` module provides alerts for such cases. Each alert fires once for each policy and namespace with violating objects:

Alert	What it reports
`PodSecurityStandardsViolation`	Running pods that violate a Pod Security Standard
`OperationPolicyViolation`	Existing objects that violate an OperationPolicy
`SecurityPolicyViolation`	Existing objects that violate a SecurityPolicy
`ControllerPolicyViolation`	Pod-creating controllers that violate a policy with `enforcementAction: Deny` and are only warned about during the transition period, see Controller-level validation

The `policy` label of an alert names the policy: the name of the OperationPolicy or SecurityPolicy, or `d8-pod-security-baseline` or `d8-pod-security-restricted` for the Pod Security Standards. The `namespace` label is the namespace of the violating objects.

An alert is an ObservabilityAlert resource in the namespace of the violating objects, so the users of the namespace see it. An alert for cluster-scoped objects is a ClusterObservabilityAlert resource.

To list the alerts in a namespace, run the following command, where `<NAMESPACE>` is the namespace:

```
d8 k -n <NAMESPACE> get observabilityalerts
```

Output example:

```
NAME                                                    SEVERITY   STATUS   DURATION
SUMMARY
AGE
PodSecurityStandardsViolation-07243a74fddd8234-1792744609   3          Firing   1h
Pods in the `app` namespace violate the `d8-pod-security-baseline` Pod Security Standard.
1h
SecurityPolicyViolation-8f21cd962274a252-1792744609         3          Firing   1h
Objects in the `app` namespace violate the `restricted-app` SecurityPolicy.
1h
```

To list the alerts in every namespace and the alerts for cluster-scoped objects, run the following commands:

```
d8 k get observabilityalerts -A
d8 k get clusterobservabilityalerts
```

To view an alert, run the following command:

```
d8 k -n <NAMESPACE> get observabilityalert <ALERT_NAME> -o yaml
```

The description of the alert contains a Prometheus query that lists the violating objects and the rules they break.

Pod Security Standards

Pod Security Standards (`PSS`) is an official Kubernetes standard that defines three security levels for pods, limiting their privileges. Restrictions are enforced by prohibiting the setting of certain parameters in the pod manifest.

A layered structure is used — each higher level of protection uses all the rules of the previous level and adds its own.

The following protection levels are regulated:

- `Privileged`: An unrestricted policy with the widest possible level of permissions (no restrictions).
- `Baseline`: A minimally restrictive policy that prevents the most known and popular ways of privilege escalation. Allows using the standard (minimally specified) pod configuration.
- `Restricted`: A policy with significant restrictions. Imposes the strictest requirements on pods.

> **i** In the Deckhouse Platform, these policies are implemented using Gatekeeper and enforced by the admission controllers of the `admission-policy-engine` module, rather than the Kubernetes Pod Security Admission controller. Only the policy descriptions are taken from Kubernetes.

You can read more about each set of policies and their restrictions in the Kubernetes documentation.

Configuring PSS policies for namespaces is done by setting a special label `security.deckhouse.io/pod-policy=<POLICY_NAME>` on the corresponding namespace. The default policy can be overridden globally (in the module settings).

> **i** In namespaces named `d8-*` and `kube-*`, the `restricted` standard applies in the `warn` mode, whatever the default policy and the namespace labels. A violation is recorded in the audit and shown in the web interface Deckhouse Platform, and the workload still starts. If the module that owns the namespace has enabled policy checks for it, the standard is also applied there with the enforcement action configured for that namespace. The `security.deckhouse.io/pod-policy-action` label cannot lower the action below `warn` in these namespaces: with `dryrun`, the user still receives warnings. In such a namespace each violation is reported by both checks, so the API server response and the audit contain it twice. The module dashboard counts such a violation once.

> **i** When the `multitenancy-manager` module is enabled, it creates its own OperationPolicy objects (for example, in the `default` namespace). These are not affected by the `podSecurityStandards` settings.

Example of setting the `Restricted` policy for all pods in the `my-namespace` namespace:

```
d8 k label ns my-namespace security.deckhouse.io/pod-policy=restricted
```

Additionally, it is possible to configure the policy enforcement mode. The following modes are supported:

- `deny`: Prohibit starting pods that do not satisfy the policy.
- `warn`: Start pods that do not satisfy the policy, but issue a warning.
- `dryrun`: Start pods that do not satisfy the policy, do not issue a warning to the user, but record violations in

security reports.

Configuring the policy enforcement mode is done by setting the label `security.deckhouse.io/pod-policy-action=<POLICY ACTION>` on the corresponding namespace. To set the policy enforcement mode globally, use the `enforcementaction` parameter.

Example of setting the `warn` mode for PSS policies for all pods in the `my-namespace` namespace:

```
d8 k label ns my-namespace security.deckhouse.io/pod-policy-action=warn
```

Rules of the standards

The module publishes the rules of the standards as two SecurityPolicy objects, `d8-pod-security-baseline` and `d8-pod-security-restricted`. The rules are written in the format of the SecurityPolicy parameters, the same ones you use in your own security policies. `d8-pod-security-restricted` lists every rule a `Restricted` namespace is checked against, the `Baseline` rules included. Two values in the rules have no counterpart in the SecurityPolicy description: `""` and `undefined` in `seccompProfiles.allowedProfiles` allow a container that sets no seccomp profile, and `type: ""` in `seLinux` allows a container that sets no SELinux type.

To view the rules of the `Restricted` standard, run the following command:

```
d8 k get securitypolicy d8-pod-security-restricted -o yaml
```

The `spec.policies` section lists the rules, and the `spec.controllerValidation` section shows the controller-level validation settings taken from the module configuration.

The objects describe the standards and enforce nothing by themselves. The module applies the standards to namespaces by the `security.deckhouse.io/pod-policy` label and the module settings, and `spec.match` of the objects shows the application namespaces the standard applies to with the default enforcement mode. The objects are managed by the module and cannot be modified. Configure the standards in the module settings. If a SecurityPolicy of your own is already named `d8-pod-security-baseline` or `d8-pod-security-restricted`, the module keeps your policy and does not publish that standard. The standard is still enforced. To see its rules, rename your policy.

Operational policies

Operational policies are rules aimed at achieving application security best practices, but not directly related to the validation of classic security-related parameters (for example, a list of allowed prefixes for container images, an image download policy, a list of required container images, etc.).

Operational policies are described using the `OperationPolicy` custom resource. In this resource, each parameter is responsible for a separate check applied to resources. Using the OperationPolicy custom resource allows you to define additional requirements for the resources being created (high-level declarative operational policies) without explicitly interacting with Gatekeeper.

We recommend setting the following minimum set of operational policies:

```
apiVersion: deckhouse.io/v1alpha1
kind: OperationPolicy
metadata:
  name: common
spec:
  enforcementAction: Deny
  policies:
    allowedRepos:
      - myrepo.example.com
      - registry.deckhouse.ru
    requiredResources:
      limits:
        - memory
      requests:
        - cpu
        - memory
    disallowedImageTags:
      - latest
    requiredProbes:
      - livenessProbe
      - readinessProbe
    maxRevisionHistoryLimit: 3
    imagePullPolicy: Always
    priorityClassNames:
    - production-high
    - production-low
    checkHostNetworkDNSPolicy: true
    checkContainerDuplicates: true
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          custom-operation-policy/enabled: "true"
```

Policy application is implemented through settings located in the `spec.match` parameter.

When specifying:

```
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          custom-operation-policy/enabled: "true"
```

To apply the above policy, it is sufficient to add the label `custom-operation-policy/enabled: "true"` to the desired namespace. Unlike `PSS`, the label name can be anything. Only a match between the label in the policy selector and the corresponding namespace is required.

You can read more detailed information about using selectors in the selector setup description.

It is also possible to specify the action to be applied for the policy. The `spec.enforcementAction` parameter is used for this. The following modes are supported:

- `Deny`: Prohibit starting pods that do not satisfy the policy.
- `Warn`: Start pods that do not satisfy the policy, but issue a warning.
- `Dryrun`: Start pods that do not satisfy the policy, do not issue a warning to the user, but record violations in security reports.

Based on this example, you can create your own policy with the necessary settings.

Security policies

Security policies are rules aimed at achieving application security best practices by validating the values of security-related parameters.

Security policies are described using the `SecurityPolicy` custom resource. In this resource, each parameter is responsible for a separate check applied to resources. Using this resource, it is possible to construct a security policy similar to a PSS policy of any level. Using the custom SecurityPolicy resource allows you to define additional requirements for the resources being created (high-level declarative security policies) without explicitly interacting with Gatekeeper.

Example of a security policy:

```
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicy
metadata:
  name: mypolicy
spec:
  enforcementAction: Deny
  policies:
    allowHostIPC: true
    allowHostNetwork: true
    allowHostPID: false
    allowPrivileged: false
    allowPrivilegeEscalation: false
    allowedFlexVolumes:
    - driver: vmware
    allowedHostPorts:
    - max: 4000
      min: 2000
    allowedProcMount: Unmasked
    allowedAppArmor:
    - unconfined
    allowedUnsafeSysctls:
    - kernel.*
    allowedVolumes:
    - hostPath
    - projected
    fsGroup:
      ranges:
      - max: 200
        min: 100
      rule: MustRunAs
    readOnlyRootFilesystem: true
    requiredDropCapabilities:
    - ALL
    runAsGroup:
      ranges:
      - max: 500
        min: 300
      rule: RunAsAny
    runAsUser:
      ranges:
      - max: 200
        min: 100
      rule: MustRunAs
    seccompProfiles:
      allowedLocalhostFiles:
      - my_profile.json
      allowedProfiles:
      - Localhost
    supplementalGroups:
      ranges:
      - max: 133
        min: 129
      rule: MustRunAs
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          security-policy: mypolicy
```

⚠ The `allowPrivilegeEscalation` and `allowPrivileged` parameters default to `false` — even if not explicitly specified. This means that containers will not be able to run in privileged mode or escalate privileges. To allow such behavior, set the parameter to `true`.

Policy application is implemented through settings located in the `spec.match` parameter.

When specifying:

```
match:
  namespaceSelector:
    labelSelector:
      matchLabels:
        security-policy: mypolicy
```

To apply the above policy, it is sufficient to add the label `security-policy: mypolicy` to the desired namespace. Unlike `PSS`, the label name can be anything. Only a match between the label in the policy selector and the corresponding namespace is required.

You can read more detailed information about using selectors in the selector setup description.

It is also possible to specify the action to be applied for the policy. The `spec.enforcementAction` parameter is used for this. The following modes are supported:

- `Deny`: Prohibit starting pods that do not satisfy the policy.
- `Warn`: Start pods that do not satisfy the policy, but issue a warning.
- `Dryrun`: Start pods that do not satisfy the policy, do not issue a warning to the user, but record violations in security reports.

Security policy exceptions

SecurityPolicyException is a resource that lets you create fine-grained exceptions from security policy checks for individual pods and containers. It allows you to avoid excluding an entire namespace from checks and instead define only the necessary exceptions from a specific rule for a pod or container.

Adding exceptions

To add exceptions for a pod or container, do the following:

1. Create a SecurityPolicyException object describing the required exceptions.

   It is recommended that you describe the reason for each exception in the rule's `metadata` field (for example, `metadata.description`). This makes auditing and maintenance easier.

2. In the pod template (usually via `spec.template.metadata.labels` in a Deployment, StatefulSet, or DaemonSet resource), add one of the following labels referencing the exception:

   - `security.deckhouse.io/security-policy-exception: <exception-name>`: Exception for the entire pod.
   - `security.deckhouse.io/security-policy-exception.container.<container-name>: <exception-name>`: Exception for a specific container.

Priority when selecting an exception for a container:

1. The label `security.deckhouse.io/security-policy-exception.container.<container-name>` is checked first.
2. If the container-specific label is absent, the exception from `security.deckhouse.io/security-policy-exception` is used.

> ⚠ If a container-specific label is set for a container but it points to an invalid or non-existent SecurityPolicyException object, it still has priority over the global label and may lead to pod placement denial.

Configuration example

For this example, consider a pod that requires:

- Permission to use the `hostNetwork` parameter for the entire pod.
- Permission to use the `privileged` parameter only for the `sample-init` container.

Without the SecurityPolicyException resource, allowing these parameters would require implementing a custom security policy where these settings could be allowed for any pod in the cluster.

With SecurityPolicyException, it is enough to create only the following resources:

- Exception to allow the `hostNetwork` parameter:

```
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicyException
metadata:
  name: allow-hostnetwork-pod
spec:
  network:
    hostNetwork:
      allowedValue: true
      metadata:
        description: >-
          Pod requires host network mode for node-level network diagnostics.
```

- Exception to allow the `privileged` parameter in the `sample-init` container:

```
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicyException
metadata:
  name: allow-privileged-init-container
spec:
  securityContext:
    privileged:
      allowedValue: true
      metadata:
        description: >-
          Container init requires privileged mode to access host-level networking
features.
```

After that, the corresponding labels need to be added to the pod template:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: example
spec:
  template:
    metadata:
      labels:
        # General exception applicable to the entire pod.
        security.deckhouse.io/security-policy-exception: allow-hostnetwork-pod
        # Exception applicable to the sample-init container.
        security.deckhouse.io/security-policy-exception.container.sample-init: allow-
privileged-init-container
    spec:
      hostNetwork: true
    ...
    containers:
      - name: sample-init
        securityContext:
          privileged: true
```

Modifying Kubernetes resources

The module allows you to use the Gatekeeper Custom Resources to modify objects in the cluster, such as:

- AssignMetadata — defines changes to the `metadata` section of a resource.
- Assign — any change outside the `metadata` section.
- ModifySet — adds or removes entries from a list, such as the arguments to a container.
- AssignImage — to change the `image` parameter of the resource.

You can read more about the available options in the gatekeeper documentation.

Availability of the module components

The module is on the critical path of the cluster: while its validating webhook is unavailable, the API server rejects the requests the webhook intercepts.

Why the validating webhook is a critical component

The `gatekeeper-controller-manager` deployment serves the ValidatingWebhookConfiguration named `d8-admission-policy-engine-config`. Its main webhook is configured with `failurePolicy: Fail`, which means that a request the API server cannot deliver to the webhook is rejected rather than admitted.

While the webhook is unavailable, no object bypasses the policies, but the objects the webhook intercepts cannot be created or changed during that time either.

While no replica of `gatekeeper-controller-manager` is available, the following stops working in the namespaces the webhook covers:

- Operations on the objects listed in Controller-level validation, including `d8 k exec` and `d8 k attach`, as well as `d8 k debug`
- Creation, modification and deletion of Role, RoleBinding and Gatekeeper constraints

The mutating webhook is configured differently: its `failurePolicy` is `Ignore`, and an unavailable deployment only means that mutations are not applied.

Disabling the module unblocks the cluster, but the control goes with it: no policy is enforced any more, and an object a policy used to forbid is created without hindrance. The FAQ describes what to do while the webhook is unavailable.

Which objects are excluded from validation

The exclusions define which objects can be created and changed while the webhook is unavailable.

The webhooks of the module do not validate the following:

- Objects in namespaces with the `heritage: deckhouse` label, which the main webhook excludes through `namespaceSelector`
- Objects with the `gatekeeper.sh/operation: webhook` label that Gatekeeper sets on its own pods, which the webhooks exclude through `objectSelector`
- Requests from service accounts of the `d8-virtualization` namespace

Namespaces that also carry the `security.deckhouse.io/enable-security-policy-check` label, including `d8-admission-policy-engine`, are validated by a separate webhook.

The exclusion by the `gatekeeper.sh/operation: webhook` label is required in the namespace of the module. Without this exclusion, the webhook could not recover from its own outage. Once the last replica is gone, the API server would reject the creation of a replacement pod, since no replica is available to validate it.

`d8 k exec` and `d8 k attach` are not covered by the exclusion by label. The object of such a request cannot have labels, and the API server never calls a webhook with `objectSelector` for it. These requests are intercepted by a separate webhook without `objectSelector`, which excludes the same namespaces as the main webhook. In the `d8-*` and `kube-*` namespaces they do not reach Gatekeeper at all.

Third-party components

List of third-party software used in the `admission-policy-engine` module:

- Gatekeeper 3.23.1

  License: Apache License 2.0

  Policy-based control for cloud native environments

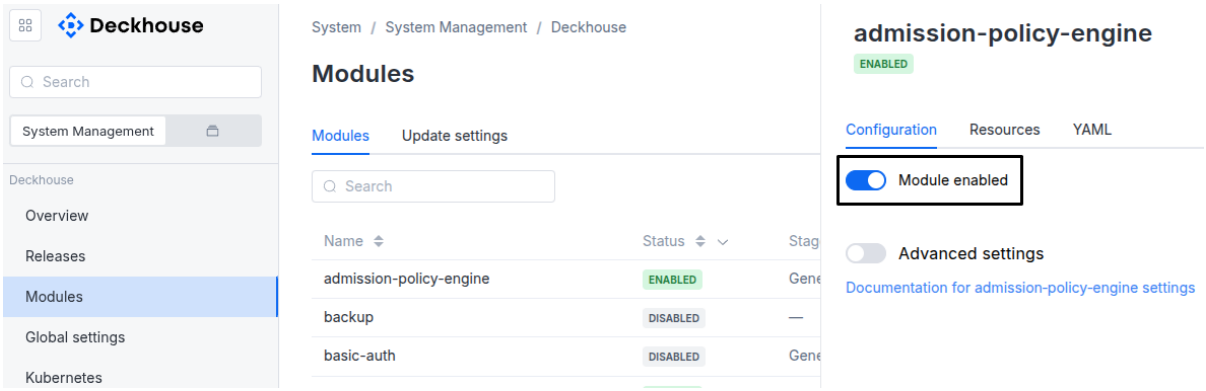
> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> **i** Available with limitations in: **Open/CE, Core, BE, SE, SE+**
>
> Available without limitations in: **Ultimate/EE**

> **i** Included in extensions: **Advanced Infrastructure Security**

> **i** The module lifecycle stage: General Availability



The module has 9 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `admission-policy-engine` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

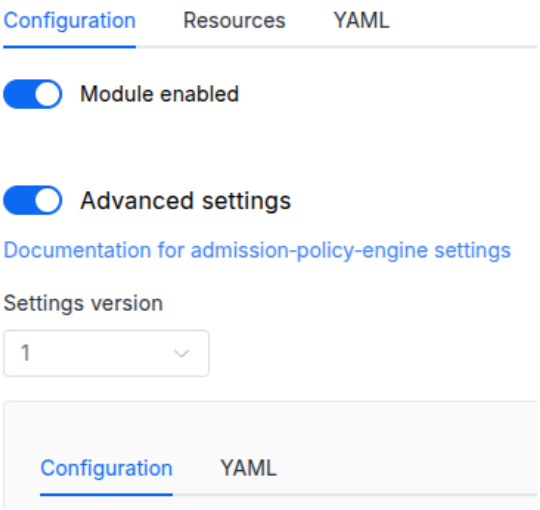
```
d8 system module enable admission-policy-engine
```

- **Using ModuleConfig `admission-policy-engine`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `admission-policy-engine` (create it if necessary);

  Example of a manifest to enable module `admission-policy-engine`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: admission-policy-engine
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `admission-policy-engine` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `admission-policy-engine` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `admission-policy-engine`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `admission-policy-engine` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc admission-policy-engine
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `admission-policy-engine` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `admission-policy-engine`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: admission-policy-engine
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.denyVulnerableImages**
    object

    Available in editions: Ultimate/EE

    Trivy provider settings.

    The Trivy provider prevents creation of the Pod, Deployment, StatefulSet, and DaemonSet resources with images containing vulnerabilities in namespaces labeled with `security.deckhouse.io/trivy-provider: ""`.

    Images of every container are checked, including init containers and ephemeral containers. As a result, attaching an ephemeral container with `kubectl debug` is denied if its image contains vulnerabilities of a disallowed severity level.

    Deprecated. These settings have been moved to the `operator-trivy` module. Migrate your

configuration.

- **settings.denyVulnerableImages.allowedSeverityLevels**
  array of strings

  List of allowed vulnerability severity levels.

  Images containing only vulnerabilities of the specified severity levels will not be blocked.

  - **Element of the array**
    string

    Allowed values: `UNKNOWN`, `LOW`, `MEDIUM`, `HIGH`, `CRITICAL`

- **settings.denyVulnerableImages.enabled**
  boolean

  Enable the Trivy provider.

  Default: `false`

- **settings.denyVulnerableImages.registrySecrets**
  array of objects

  List of additional Secrets for accessing private registries.

  By default, the `deckhouse-registry` Secret is used to download images for scanning.

  Default: `[]`

  - **settings.denyVulnerableImages.registrySecrets.name**
    string

    Required value

  - **settings.denyVulnerableImages.registrySecrets.namespace**
    string

    Required value

- **settings.denyVulnerableImages.storageClass**
  string

  Name of the StorageClass used by the Trivy provider.

  If the value is not specified, the StorageClass set in the global `settings.modules.storageClass` parameter is used instead.

  The global `settings.modules.storageClass` parameter is only applied when the module is enabled. Changing the global parameter while the module is enabled will not trigger disk re-provisioning.

  > **i** **Warning.** If you specify a value different from the current StorageClass used in the existing PersistentVolumeClaim, the disk will be re-provisioned, and all data will be deleted.

  If you set it to `false`, `emptyDir` will be forcibly used instead of a PVC.

  Examples:

  ```
  storageClass: ceph-ssd
  ```

  ```
  storageClass: 'false'
  ```

- **settings.imageSignatureVerification**
  object

  Available in editions: SE+, Ultimate/EE

  Settings of the image signature verification configured by the `verifyImageSignatures` policy of the SecurityPolicy resource.

  - **settings.imageSignatureVerification.registryCredentialsCacheTTLSeconds**
    integer

    Time in seconds for which the credentials of a private registry stay cached after being read from the `dockerCfg` field of a SecurityPolicy.

    After you change `dockerCfg`, the signature verification keeps using the previous credentials until the cache entry expires. A lower value applies the new credentials sooner, at the cost of more frequent reads of the Secret from the Kubernetes API.

Default: `300`

Allowed values: `30 <= X <= 43200`

Examples:

```
registryCredentialsCacheTTLSeconds: 300
```

```
registryCredentialsCacheTTLSeconds: 3600
```

- **settings.podSecurityStandards**
  object

  Pod Security Standards policy settings (PSS).

  - **settings.podSecurityStandards.controllerValidation**
    boolean

    Applies constraints to pod-creating controllers (Deployment, StatefulSet, DaemonSet, Job, CronJob, ReplicationController) in addition to Pods.

    Set to `true` (default) to validate both Pods and controllers, or to `false` to validate only Pods and leave controllers unchecked.

    How a violation in a controller is reported is set by controllerValidationEnforcement.

    The parameter is the default for every constraint that reads a pod spec, including the ones generated from OperationPolicy and SecurityPolicy resources. A policy overrides it with its own `spec.controllerValidation` section.

    Default: `true`

  - **settings.podSecurityStandards.controllerValidationEnforcement**
    string

    Action on a pod-creating controller that violates a policy with `enforcementAction: Deny`.

    - `Warn` — the controller is accepted with a warning, and the Pods it creates are denied. The value is the default for a transition period, while workloads are brought in line with the controller-level checks.
    - `Policy` — the controller is checked with the action of the policy, so a denying policy denies the controller as well. The value is to become the default after the transition period.

    A policy with another action keeps it for controllers: `Warn` warns and `Dryrun` only records the violation.

    The parameter applies to the Pod Security Standards and is the default for OperationPolicy and SecurityPolicy resources. A policy overrides it with `spec.controllerValidation.mode`. The parameter takes effect when controllerValidation is `true`.

    Default: `Warn`

    Allowed values: `Warn`, `Policy`

  - **settings.podSecurityStandards.controllerValidationExcludedPolicies**
    array of strings

    Pod Security Standards rules that are checked on Pods only.

    The rules are named as the SecurityPolicy parameters the standards are published with, in the `d8-pod-security-baseline` and `d8-pod-security-restricted` objects. An excluded rule is checked on Pods only in both standards. The parameter takes effect when controllerValidation is `true`.

    Some rules are checked by one constraint and are excluded together: listing any rule of a group checks the whole group on Pods only. The groups are `allowHostPID` with `allowHostIPC`, and `allowHostNetwork` with `allowedHostPorts`.

    Default: `[]`

    Example:

    ```
    controllerValidationExcludedPolicies:
    - allowPrivilegeEscalation
    - requiredDropCapabilities
    ```

    - **Element of the array**
      string

      Allowed values: `allowPrivileged`, `allowPrivilegeEscalation`, `allowHostPID`, `allowHostIPC`, `allowHostNetwork`, `allowedHostPorts`, `allowedAppArmor`,

`allowedCapabilities`, `requiredDropCapabilities`, `allowedHostPaths`, `allowedProcMount`, `seLinux`, `allowedUnsafeSysctls`, `seccompProfiles`, `allowedVolumes`, `runAsUser`

- **settings.podSecurityStandards.defaultPolicy**
  string

  Sets the default Pod Security Standards policy for all **non-system** namespaces:

  - `Privileged` — an unrestricted policy. Privilege escalation is possible with this policy;
  - `Baseline` — a policy with minimum restrictions that prevents privilege escalation;
  - `Restricted` — a policy with maximum restrictions that conforms to current best practices for securely running applications in a cluster.

  Default: `Baseline`

  Allowed values: `Privileged`, `Baseline`, `Restricted`

- **settings.podSecurityStandards.enforcementAction**
  string

  The enforcement action to control what to do with the result of the constraint.

  - `Deny` — Deny action.
  - `Dryrun` — No action. It is used when debugging. Information about the event can be viewed in the web-interface Deckhouse Platform or with `d8 k`.
  - `Warn` — Same as `Dryrun`. In addition to the event information, it provides some info on why that constraint would have been denied if you had set `Deny` instead of `Warn`.

  Applies to application namespaces. Namespaces named `d8-*` and `kube-*` are governed by the module itself: a violation is reported there and, unless the module that owns the namespace has opted it into enforcement, the workload still starts.

  Default: `Deny`

  Allowed values: `Warn`, `Deny`, `Dryrun`

- **settings.podSecurityStandards.policies**
  object

  Sets additional policy parameters.

  - **settings.podSecurityStandards.policies.hostPorts**
    object

    HostPort constraint settings.

    - **settings.podSecurityStandards.policies.hostPorts.knownRanges**
      array of objects

      Set the range of known ports which will be allowed in a hostPort binding.

      - **settings.podSecurityStandards.policies.hostPorts.knownRanges.max**
        integer
      - **settings.podSecurityStandards.policies.hostPorts.knownRanges.min**
        integer

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

Custom resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

OperationPolicy

Scope: Cluster
Version: v1alpha1

Describes an operation policy for a cluster.

Each CustomResource `OperationPolicy` describes rules for objects in a cluster.

- **spec**
  object

  Required value

  - **spec.controllerValidation**
    object

    Validation of the pod-creating controllers against the policy.

    The controllers are Deployment, StatefulSet, DaemonSet, Job, CronJob and ReplicationController. A controller is checked when it is created or updated, so a violation is reported before any Pod is created. Pods are checked in any case.

    The section overrides the module parameters podSecurityStandards.controllerValidation and podSecurityStandards.controllerValidationEnforcement for this policy.

    - **spec.controllerValidation.excludedPolicies**
      array of strings

      Rules of the policy that are checked on Pods only.

      Use it for a rule that a mutating webhook satisfies on the Pod but not in the controller's pod template, for example `requiredResources` with the Vertical Pod Autoscaler.

      Example:

      ```
      excludedPolicies:
      - requiredResources
      ```

      - **Element of the array**
        string

        Allowed values: `allowedRepos`, `requiredResources`, `disallowedImageTags`, `requiredProbes`, `imagePullPolicy`, `priorityClassNames`, `checkHostNetworkDNSPolicy`, `checkContainerDuplicates`, `disallowedTolerations`, `gpuResourceRestriction`

    - **spec.controllerValidation.mode**
      string

      Controller validation mode of the policy:

      - `Enforce` — controllers are checked against every rule of the policy except the ones listed in excludedPolicies, with the action of the policy;
      - `Warn` — controllers are checked in the same way, but a policy with `enforcementAction: Deny` only warns about a violation in a controller. The Pods the controller creates are denied;
      - `Disabled` — only Pods are checked.

      If the parameter is omitted, the module parameters podSecurityStandards.controllerValidation and podSecurityStandards.controllerValidationEnforcement are used.

      Allowed values: `Enforce`, `Warn`, `Disabled`

  - **spec.enforcementAction**
    string

    The enforcement action to control what to do with the result of the constraint.

    - `Deny` — Deny action.
    - `Dryrun` — No action. It is used when debugging. Information about the event can be viewed in Deckhouse Console.
    - `Warn` — Same as `Dryrun`. In addition to the event information, it provides some info on why that constraint would have been denied if you had set `Deny` instead of `Warn`.

    `Deny` holds in application namespaces. In a namespace named `d8-*` or `kube-*` the policy always warns, whatever action is set here.

    Default: `Deny`

    Allowed values: `Warn`, `Deny`, `Dryrun`

  - **spec.match**
    object

    Required value

    - **spec.match.labelSelector**
      object

      Specifies the label selector to filter Pods with.

You can get more into here.

- **spec.match.labelSelector.matchExpressions**
  array of objects

  List of label expressions for Pods.

  Example:

  ```
  matchExpressions:
  - key: tier
    operator: In
    values:
    - production
    - staging
  ```

  - **spec.match.labelSelector.matchExpressions.key**
    string

    Required value

  - **spec.match.labelSelector.matchExpressions.operator**
    string

    Required value

    Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

  - **spec.match.labelSelector.matchExpressions.values**
    array of strings
- **spec.match.labelSelector.matchLabels**
  object

  List of labels which Pod should have.

  Example:

  ```
  matchLabels:
    foo: bar
    baz: who
  ```

- **spec.match.namespaceSelector**
  object

  Specifies the namespace selector to filter objects with.

  - **spec.match.namespaceSelector.excludeNames**
    array of strings

    Include all namespaces except a particular set. Support glob pattern.

  - **spec.match.namespaceSelector.labelSelector**
    object

    Specifies the label selector to filter namespaces.

    You can get more info in the documentation.

    - **spec.match.namespaceSelector.labelSelector.matchExpressions**
      array of objects

      List of label expressions for namespaces.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      ```

      - **spec.match.namespaceSelector.labelSelector.matchExpressions.key**
        string

        Required value

      - **spec.match.namespaceSelector.labelSelector.matchExpressions.operator**
        string

Required value

Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.match.namespaceSelector.labelSelector.matchExpressions.values**
  array of strings
- **spec.match.namespaceSelector.labelSelector.matchLabels**
  object

  List of labels which a namespace should have.

  Example:

  ```
  matchLabels:
    foo: bar
    baz: who
  ```

- **spec.match.namespaceSelector.matchNames**
  array of strings

  Include only a particular set of namespaces. Supports glob pattern.

- **spec.policies**
  object

  Required value

  - **spec.policies.allowedRepos**
    array of strings

    The list of prefixes a container image is allowed to have.

    - **Element of the array**
      string

      Example:

      ```
      registry.deckhouse.io
      ```

  - **spec.policies.checkContainerDuplicates**
    boolean

    Check container names and env variables for duplicates.

  - **spec.policies.checkHostNetworkDNSPolicy**
    boolean

    Check `ClusterFirstWithHostNet` dnsPolicy is set for Pods with `hostNetwork: true`.

  - **spec.policies.disallowedImageTags**
    array of strings

    Requires container images to have an image tag different from the ones in the specified list.

    Example:

    ```
    disallowedImageTags: latest
    ```

  - **spec.policies.disallowedTolerations**
    array of objects

    Deny Pods that have tolerations from the ones in the specified list.

    See more in the Kubernetes documentation.

    Each item in the list is a toleration pattern matched against the `key`, `operator`, `value`, and `effect` fields. A partial match on these fields is enough to consider it a match.

    - **spec.policies.disallowedTolerations.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **spec.policies.disallowedTolerations.key**
      string
    - **spec.policies.disallowedTolerations.operator**
      string

      Allowed values: `Exists`, `Equal`

    - **spec.policies.disallowedTolerations.value**
      string

- **spec.policies.gpuResourceRestriction**
  object

  Restricts GPU resource usage in pods.

  Pods that request GPU resources are denied unless the namespace has the specified label. The same check runs on the pod-creating controllers, so a controller whose pod template requests GPU resources is denied on creation and update. Both `resources.requests` and `resources.limits` of every container, init container, and ephemeral container are inspected.

  The namespace label is read from the Gatekeeper cache. While the namespace is missing from that cache, for example when a namespace and a pod are applied together and the namespace has not been cached yet, the policy denies the pods that request GPU resources in that namespace.

  - **spec.policies.gpuResourceRestriction.gpuResourcePatterns**
    array of strings

    List of regular expressions matched against GPU resource names in pod specs.

    A resource name that matches any of these patterns is considered a GPU resource. Patterns are not anchored implicitly: `nvidia.com/gpu` also matches the `not-nvidia.com/gpu` resource name. Use `^` and `$` to match the whole resource name.

    Default: `["^nvidia\\.com/.*$"]`

    Example:

    ```
    gpuResourcePatterns:
    - "^nvidia\\.com/.*$"
    - "^amd\\.com/gpu$"
    - "^intel\\.com/gpu$"
    ```

  - **spec.policies.gpuResourceRestriction.namespaceLabel**
    object

    Label that must be present on the namespace to allow GPU resource usage.

    - **spec.policies.gpuResourceRestriction.namespaceLabel.key**
      string

      Label key that must be present on the namespace.

      Default: `gpu.deckhouse.io/enabled`

    - **spec.policies.gpuResourceRestriction.namespaceLabel.value**
      string

      Expected label value.

      Default: `true`

- **spec.policies.imagePullPolicy**
  string

  Required image pull policy for containers.

  Allowed values: `Always`, `IfNotPresent`

- **spec.policies.ingressClassNames**
  array of strings

  List of allowed ingress class names.

- **spec.policies.maxRevisionHistoryLimit**
  integer

  A maximum value for a revision history.

- **spec.policies.priorityClassNames**
  array of strings

  List of allowed priority class names.

- **spec.policies.replicaLimits**
  object

  A range of allowed replicas. Values are inclusive.

  - **spec.policies.replicaLimits.maxReplicas**
    integer

    The maximum number of replicas allowed, inclusive.

- **spec.policies.replicaLimits.minReplicas**
  integer

  The minimum number of replicas allowed, inclusive.

- **spec.policies.requiredAnnotations**
  object

  A list of annotations and values the object must specify.

  - **spec.policies.requiredAnnotations.annotations**
    array of objects
    - **spec.policies.requiredAnnotations.annotations.allowedRegex**
      string

      If specified, a regular expression, the annotation’s value must match. The value must contain at least one match for the regular expression.

    - **spec.policies.requiredAnnotations.annotations.key**
      string

      The required annotation.

  - **spec.policies.requiredAnnotations.watchKinds**
    array of strings

    The list of Kubernetes objects in the format `$apiGroup/$kind` to watch the annotations on.

    - **Element of the array**
      string

      Pattern: `^[a-z]*/[a-zA-Z]+$`

      Examples:

      ```
      apps/Deployment
      ```

      ```
      "/Pod"
      ```

      ```
      networking.k8s.io/Ingress
      ```

- **spec.policies.requiredLabels**
  object

  A list of labels and values the object must specify.

  - **spec.policies.requiredLabels.labels**
    array of objects
    - **spec.policies.requiredLabels.labels.allowedRegex**
      string

      If specified, a regular expression, the label’s value must match. The value must contain at least one match for the regular expression.

    - **spec.policies.requiredLabels.labels.key**
      string

      The required label.

  - **spec.policies.requiredLabels.watchKinds**
    array of strings

    The list of Kubernetes objects in the format `$apiGroup/$kind` to watch the labels on.

    - **Element of the array**
      string

      Pattern: `^[a-z]*/[a-zA-Z]+$`

      Examples:

      ```
      apps/Deployment
      ```

      ```
      "/Pod"
      ```

      ```
      networking.k8s.io/Ingress
      ```

- **spec.policies.requiredProbes**
  array of strings

The list of probes that are required (e.g. `readinessProbe` and `livenessProbe`)

Example:

```
requiredProbes:
- readinessProbe
- livenessProbe
```

- **Element of the array**
  string

  Allowed values: `livenessProbe`, `readinessProbe`, `startupProbe`

- **spec.policies.requiredResources**
  object

  Requires containers to have defined resources set.

  - **spec.policies.requiredResources.limits**
    array of strings

    A list of limits that should be enforced (CPU, memory, or both).

    - **Element of the array**
      string

      Allowed values: `cpu`, `memory`

  - **spec.policies.requiredResources.requests**
    array of strings

    A list of requests that should be enforced (CPU, memory, or both).

    - **Element of the array**
      string

      Allowed values: `cpu`, `memory`

- **spec.policies.storageClassNames**
  array of strings

  List of allowed storage class names.

SecurityPolicyException

Short names: spe

Scope: Namespaced
Version: v1alpha1

Describes exceptions to the cluster's security policies. Each SecurityPolicyException resource defines a set of specific allowances.

- **status**
  object
  - **status.deckhouse**
    object
    - **status.deckhouse.observed**
      object

      Contains last timestamp when the resource change was noted by the operator and its checksum.

      - **status.deckhouse.observed.checkSum**
        string

        The checksum of last observed resource.

      - **status.deckhouse.observed.lastTimestamp**
        string

        A timestamp of when the operator last noted a change to the resource.

    - **status.deckhouse.processed**
      object

      Contains last timestamp when the resource was applied in the cluster by the operator and its checksum.

      - **status.deckhouse.processed.checkSum**
        string

        The checksum of last applied resource.

        - **status.deckhouse.processed.lastTimestamp**
          string

          A timestamp of when the resource was last applied in the cluster.

      - **status.deckhouse.synced**
        string

        True if last observed version of the resource was successfully applied in the cluster.

- **spec**
  object

  Required value

  - **spec.network**
    object

    Exceptions for network-related parameters.

    - **spec.network.hostIPC**
      object

      Exceptions for the `hostIPC` parameter.

      - **spec.network.hostIPC.allowedValue**
        boolean

        Required value

        Allowed value for `hostIPC`.

        Default: `false`

      - **spec.network.hostIPC.metadata**
        object

        Metadata related to the exception.

    - **spec.network.hostNetwork**
      object

      Exceptions for the `hostNetwork` parameter. For pods with `hostNetwork: true`, an additional exception is performed on the ports specified in `containerPort`.

      - **spec.network.hostNetwork.allowedValue**
        boolean

        Required value

        Allowed value for `hostNetwork`.

        Default: `false`

      - **spec.network.hostNetwork.metadata**
        object

        Metadata related to the exception.

    - **spec.network.hostPID**
      object

      Exceptions for the `hostPID` parameter.

      - **spec.network.hostPID.allowedValue**
        boolean

        Required value

        Allowed value for `hostPID`.

        Default: `false`

      - **spec.network.hostPID.metadata**
        object

        Metadata related to the exception.

    - **spec.network.hostPorts**
      array of objects

      Exceptions for host ports.

      - **spec.network.hostPorts.metadata**
        object

Metadata related to the exception.

- **spec.network.hostPorts.port**
  integer

  Allowed host port.

- **spec.network.hostPorts.protocol**
  string

  Protocol for the host port.

  Allowed values: `TCP`, `UDP`

- **spec.securityContext**
  object

  Exceptions for parameters in the `securityContext` section.

  - **spec.securityContext.allowPrivilegeEscalation**
    object

    Exceptions for the `allowPrivilegeEscalation` parameter.

    - **spec.securityContext.allowPrivilegeEscalation.allowedValue**
      boolean

      Required value

      Allowed value for `allowPrivilegeEscalation`.

      Default: `false`

    - **spec.securityContext.allowPrivilegeEscalation.metadata**
      object

      Metadata related to the exception.

  - **spec.securityContext.appArmorProfile**
    object

    List of allowed AppArmor profile values for pods and containers.

    Supported formats:

    - Via annotations: `runtime/default`, `docker/default`, `unconfined`, `localhost/some-profile.json`. `localhost/*` allows any local profile.
    - Via `securityContext`: `RuntimeDefault`, `Unconfined`, `Localhost`. For `Localhost`, specify allowed profiles using the `allowedLocalhostFiles` parameter.

    Profile types:

    - `Unconfined`: No restrictions (not recommended for security reasons).
    - `RuntimeDefault`: The default profile provided by the container runtime (such as Docker or CRI-O).
    - `Localhost`: A custom profile defined on the host and tailored for the application.

    Using `*` allows all profiles. It's not necessary to specify both formats as they are automatically mapped to each other.

    - **spec.securityContext.appArmorProfile.allowedValues**
      array of strings

      Required value

      Allowed values:

      - `runtime/default`
      - `unconfined`
      - `localhost/*` (where `*` may be a profile name or a wildcard)
      - **Element of the array**
        string

        Pattern: `^(runtime\/default|unconfined|localhost\/.+)$`

    - **spec.securityContext.appArmorProfile.metadata**
      object

      Metadata related to the exception.

  - **spec.securityContext.capabilities**
    object

    Exceptions for the `capabilities` parameter.

    - **spec.securityContext.capabilities.allowedValues**

object

Required value

Allowed values for adding or dropping Linux capabilities.

- **spec.securityContext.capabilities.allowedValues.add**
  array of strings

  List of capabilities that are allowed to be added to the container.

  Default: `[]`

- **spec.securityContext.capabilities.allowedValues.drop**
  array of strings

  List of capabilities that are allowed to be dropped from the container.

  Default: `["all"]`

- **spec.securityContext.capabilities.metadata**
  object

  Metadata related to the exception.

- **spec.securityContext.privileged**
  object

  Exceptions for the `privileged` parameter.

  - **spec.securityContext.privileged.allowedValue**
    boolean

    Required value

    Allowed value for `privileged`.

    Default: `false`

  - **spec.securityContext.privileged.metadata**
    object

    Metadata related to the exception.

- **spec.securityContext.procMount**
  object

  Exceptions for the `procMount` parameter.

  - **spec.securityContext.procMount.allowedValues**
    array of strings

    Required value

    List of allowed `procMount` values.

    - **Element of the array**
      string

      Allowed values: `Default`, `Unmasked`

  - **spec.securityContext.procMount.metadata**
    object

    Metadata related to the exception.

- **spec.securityContext.readOnlyRootFilesystem**
  object

  Exceptions for the `readOnlyRootFilesystem` parameter.

  - **spec.securityContext.readOnlyRootFilesystem.allowedValue**
    boolean

    Required value

    Allowed value for `readOnlyRootFilesystem`.

    Default: `false`

  - **spec.securityContext.readOnlyRootFilesystem.metadata**
    object

    Metadata related to the exception.

- **spec.securityContext.runAsNonRoot**
  object

Exceptions for the `runAsNonRoot` parameter.

- **spec.securityContext.runAsNonRoot.allowedValue**
  boolean

  Required value

  Allowed value for `runAsNonRoot`.

  Default: `true`

- **spec.securityContext.runAsNonRoot.metadata**
  object

  Metadata related to the exception.

- **spec.securityContext.runAsUser**
  object

  Exceptions for the `runAsUser` parameter.

  - **spec.securityContext.runAsUser.allowedValues**
    array of integers

    Required value

    List of allowed user IDs (UIDs).

  - **spec.securityContext.runAsUser.metadata**
    object

    Metadata related to the exception.

- **spec.securityContext.seLinuxOptions**
  object

  Exceptions for the `seLinuxOptions` parameter.

  - **spec.securityContext.seLinuxOptions.allowedValues**
    array of objects

    Required value

    List of allowed SELinux configurations.

    - **spec.securityContext.seLinuxOptions.allowedValues.level**
      string

      SELinux level label.

    - **spec.securityContext.seLinuxOptions.allowedValues.role**
      string

      SELinux role label.

    - **spec.securityContext.seLinuxOptions.allowedValues.type**
      string

      SELinux type label.

    - **spec.securityContext.seLinuxOptions.allowedValues.user**
      string

      SELinux user label.

  - **spec.securityContext.seLinuxOptions.metadata**
    object

    Metadata related to the exception.

- **spec.securityContext.seccompProfile**
  object

  Exceptions for the `seccompProfile` parameter.

  - **spec.securityContext.seccompProfile.allowedValues**
    array of strings

    Required value

    List of allowed seccomp profiles.

    A value that ends with `*` allows every profile that starts with the part before `*`. For example, `localhost/profiles/*` allows `localhost/profiles/app.json` and `localhost/profiles/team/app.json`.

- **spec.securityContext.seccompProfile.metadata**
  object

  Metadata related to the exception.

- **spec.securityContext.sysctls**
  object

  Exceptions for the `sysctls` parameter.

  - **spec.securityContext.sysctls.allowedValues**
    array of objects

    Required value

    List of allowed `sysctl` settings.

    - **spec.securityContext.sysctls.allowedValues.name**
      string

      Name of the `sysctl` parameter.

      A name that ends with `*` allows every `sysctl` parameter that starts with the part before `*`. For example, `net.core.*` allows `net.core.rmem_max` and `net.core.somaxconn`.

    - **spec.securityContext.sysctls.allowedValues.value**
      string

      Allowed value for the specified `sysctl` parameter.

  - **spec.securityContext.sysctls.metadata**
    object

    Metadata related to the exception.

- **spec.volumes**
  object

  Exceptions for volume-related parameters.

  - **spec.volumes.hostPath**
    object

    Exceptions for `hostPath` volumes.

    - **spec.volumes.hostPath.allowedValues**
      array of objects

      Required value

      List of allowed `hostPath` configurations.

      - **spec.volumes.hostPath.allowedValues.metadata**
        object

        Metadata related to the exception.

        - **spec.volumes.hostPath.allowedValues.metadata.description**
          string

          Description of the exception.

      - **spec.volumes.hostPath.allowedValues.path**
        string

        Allowed `hostPath`.

      - **spec.volumes.hostPath.allowedValues.pathType**
        string

        How the path parameter is matched against the `hostPath` of a volume.

        The values follow the path types of an Ingress:

        - `Exact` — the exception allows only the exact path;
        - `Prefix` — the exception allows the path and every path nested under it. Paths are compared by their components, and trailing slashes are ignored. For example, `/var/lib` allows `/var/lib`, `/var/lib/` and `/var/lib/docker`, but does not allow `/var/libvirt` or `/var`.

        The readOnly parameter applies to nested paths the same way as to the path itself.

        Default: `Exact`

        Allowed values: `Exact`, `Prefix`

Example:

```
pathType: Prefix
```

- **spec.volumes.hostPath.allowedValues.readOnly**
  boolean

  A `readOnly` value for the `hostPath`.

  Default: `false`

- **spec.volumes.types**
  object

  Exceptions for volume types.

  - **spec.volumes.types.allowedValues**
    array of strings

    Required value

    List of allowed volume types.

  - **spec.volumes.types.metadata**
    object

    Metadata related to the exception.

SecurityPolicy

Scope: Cluster
Version: v1alpha1

Describes a security policy for a cluster.

Each `SecurityPolicy` custom resource describes rules for the objects in the cluster.

- **status**
  object
  - **status.deckhouse**
    object
    - **status.deckhouse.observed**
      object

      Contains last timestamp when the resource change was noted by the operator and its checksum.

      - **status.deckhouse.observed.checkSum**
        string

        The checksum of last observed resource.

      - **status.deckhouse.observed.lastTimestamp**
        string

        A timestamp of when the operator last noted a change to the resource.

    - **status.deckhouse.processed**
      object

      Contains last timestamp when the resource was applied in the cluster by the operator and its checksum.

      - **status.deckhouse.processed.checkSum**
        string

        The checksum of last applied resource.

      - **status.deckhouse.processed.lastTimestamp**
        string

        A timestamp of when the resource was last applied in the cluster.

    - **status.deckhouse.synced**
      string

      True if last observed version of the resource was successfully applied in the cluster.

- **spec**
  object

  Required value

  - **spec.controllerValidation**
    object

Validation of the pod-creating controllers against the policy.

The controllers are Deployment, StatefulSet, DaemonSet, Job, CronJob and ReplicationController. A controller is checked when it is created or updated, so a violation is reported before any Pod is created. Pods are checked in any case.

The section overrides the module parameters podSecurityStandards.controllerValidation and podSecurityStandards.controllerValidationEnforcement for this policy.

- **spec.controllerValidation.excludedPolicies**
  array of strings

  Rules of the policy that are checked on Pods only.

  Use it for a rule that a mutating webhook satisfies on the Pod but not in the controller's pod template, for example `requiredDropCapabilities` when the webhook adds `drop: [ALL]` to the containers.

  Some rules are checked by one constraint and are excluded together: listing any rule of a group checks the whole group on Pods only. The groups are:

  - `allowHostPID` and `allowHostIPC`;
  - `allowHostNetwork` and `allowedHostPorts`;
  - `fsGroup`, `runAsUser`, `runAsGroup` and `supplementalGroups`;
  - `allowedUnsafeSysctls` and `forbiddenSysctls`.

  `allowedCapabilities` and `requiredDropCapabilities` are excluded one by one.

  Example:

  ```
  excludedPolicies:
  - requiredDropCapabilities
  ```

  - **Element of the array**
    string

    Allowed values: `allowPrivileged`, `allowPrivilegeEscalation`, `allowHostPID`, `allowHostIPC`, `allowHostNetwork`, `allowedHostPorts`, `readOnlyRootFilesystem`, `automountServiceAccountToken`, `allowedFlexVolumes`, `allowedVolumes`, `allowedHostPaths`, `allowedCapabilities`, `requiredDropCapabilities`, `allowedAppArmor`, `allowedProcMount`, `fsGroup`, `runAsUser`, `runAsGroup`, `supplementalGroups`, `seLinux`, `allowedUnsafeSysctls`, `forbiddenSysctls`, `seccompProfiles`, `verifyImageSignatures`

- **spec.controllerValidation.mode**
  string

  Controller validation mode of the policy:

  - `Enforce` — controllers are checked against every rule of the policy except the ones listed in excludedPolicies, with the action of the policy;
  - `Warn` — controllers are checked in the same way, but a policy with `enforcementAction: Deny` only warns about a violation in a controller. The Pods the controller creates are denied;
  - `Disabled` — only Pods are checked.

  If the parameter is omitted, the module parameters podSecurityStandards.controllerValidation and podSecurityStandards.controllerValidationEnforcement are used.

  Allowed values: `Enforce`, `Warn`, `Disabled`

- **spec.enforcementAction**
  string

  An enforcement action as a result of the constraint:

  - `Deny` — Deny action.
  - `Dryrun` — No action. Used for debugging. Information about the event can be viewed in Deckhouse Console.
  - `Warn` — No action; similar to `Dryrun`. Provides information about the constraint that would result in a denial if the `Deny` action is used.

  `Deny` holds in application namespaces. In a namespace named `d8-*` or `kube-*` the policy always warns, whatever action is set here.

  Default: `Deny`

  Allowed values: `Warn`, `Deny`, `Dryrun`

- **spec.match**
  object

  Required value

Container filtering rules. Use selectors to specify the pods and containers to which you want to apply the policy.

- **spec.match.labelSelector**
  object

  Specifies the label selector to filter Pods with.

  You can get more into here.

  - **spec.match.labelSelector.matchExpressions**
    array of objects

    The list of label expressions for Pods.

    Example:

    ```
    matchExpressions:
    - key: tier
      operator: In
      values:
      - production
      - staging
    ```

    - **spec.match.labelSelector.matchExpressions.key**
      string

      Required value

    - **spec.match.labelSelector.matchExpressions.operator**
      string

      Required value

      Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

    - **spec.match.labelSelector.matchExpressions.values**
      array of strings
  - **spec.match.labelSelector.matchLabels**
    object

    The list of the labels that the Pod should have.

    Example:

    ```
    matchLabels:
      foo: bar
      baz: who
    ```

- **spec.match.namespaceSelector**
  object

  Specifies the Namespace selector to filter objects with.

  - **spec.match.namespaceSelector.excludeNames**
    array of strings

    Includes all namespaces except a particular set. Support glob pattern.

  - **spec.match.namespaceSelector.labelSelector**
    object

    Specifies the label selector to filter namespaces.

    You can get more info in the documentation.

    - **spec.match.namespaceSelector.labelSelector.matchExpressions**
      array of objects

      The list of label expressions for namespaces.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      ```

- **spec.match.namespaceSelector.labelSelector.matchExpressions.key**
  string

  Required value

- **spec.match.namespaceSelector.labelSelector.matchExpressions.operator**
  string

  Required value

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.match.namespaceSelector.labelSelector.matchExpressions.values**
  array of strings

- **spec.match.namespaceSelector.labelSelector.matchLabels**
  object

  The list of the labels that the namespace should have.

  Example:

  ```
  matchLabels:
    foo: bar
    baz: who
  ```

- **spec.match.namespaceSelector.matchNames**
  array of strings

  Includes only a particular set of namespaces. Supports glob pattern.

- **spec.policies**
  object

  Required value

  Policies that pods and containers must comply with.

  - **spec.policies.allowHostIPC**
    boolean

    Allows sharing the host’s IPC namespace with containers.

  - **spec.policies.allowHostNetwork**
    boolean

    Allows containers to use the host’s network.

  - **spec.policies.allowHostPID**
    boolean

    Allows sharing the host’s PID namespace with containers.

  - **spec.policies.allowPrivilegeEscalation**
    boolean

    Allows container processes to gain more privileges than its parent process.

    By default (if not specified) — `false`. This means that if the field is omitted or explicitly set to `false`, the container is denied any privilege escalation. If you want to allow elevated privileges, set this parameter to `true`.

  - **spec.policies.allowPrivileged**
    boolean

    Allows running containers in a privileged mode.

    By default (if not specified) — `false`. This means that if the field is omitted or explicitly set to `false`, the container is denied any privilege escalation. If you want to allow elevated privileges, set this parameter to `true`.

  - **spec.policies.allowRbacWildcards**
    boolean

    Allows using wildcards (`*`) in namespaced Role and RoleBinding resources.

    ClusterRole and ClusterRoleBinding are not validated by SecurityPolicy.

    By default (if not specified) — `true`. This means that if the field is omitted or explicitly set to `true`, using wildcards is allowed. If you want to deny wildcards, set this parameter to `false`.

    Default: `true`

  - **spec.policies.allowedAppArmor**
    array of strings

The list of AppArmor profiles the containers are permitted to use.

Example:

```
allowedAppArmor:
- runtime/default
- unconfined
```

- **Element of the array**
  string

  An AppArmor profile.

- **spec.policies.allowedCapabilities**
  array of strings

  The list of capabilities that the containers are permitted to use.

  To allow all capabilities, use `ALL`.

  Example:

  ```
  allowedCapabilities:
  - SETGID
  - SETUID
  - NET_BIND_SERVICE
  ```

  - **Element of the array**
    string

    A linux capability.

    Allowed values: `ALL`, `SETPCAP`, `SYS MODULE`, `SYS RAWIO`, `SYS PACCT`, `SYS ADMIN`, `SYS NICE`, `SYS RESOURCE`, `SYS TIME`, `SYS TTY CONFIG`, `MKNOD`, `AUDIT WRITE`, `AUDIT CONTROL`, `MAC OVERRIDE`, `MAC ADMIN`, `NET ADMIN`, `SYSLOG`, `CHOWN`, `NET_RAW`, `DAC_OVERRIDE`, `FOWNER`, `DAC_READ_SEARCH`, `FSETID`, `KILL`, `SETGID`, `SETUID`, `LINUX IMMUTABLE`, `NET BIND SERVICE`, `NET BROADCAST`, `IPC LOCK`, `IPC OWNER`, `SYS_CHROOT`, `SYS_PTRACE`, `SYS_BOOT`, `LEASE`, `SETFCAP`, `WAKE_ALARM`, `BLOCK_SUSPEND`

- **spec.policies.allowedClusterRoles**
  array of strings

  A list of allowed cluster roles to bind to users.

- **spec.policies.allowedFlexVolumes**
  array of objects

  The list of Flex Volume drivers the containers are permitted to use.

  - **spec.policies.allowedFlexVolumes.driver**
    string

    A driver name.

- **spec.policies.allowedHostPaths**
  array of objects

  The list of allowed path prefixes for `hostPath` mounts. An empty list (`[]`) forbids `hostPath` for all paths. If the field is omitted, no restrictions apply.

  Example:

  ```
  allowedHostPaths:
  - pathPrefix: "/dev"
    readOnly: true
  ```

  - **spec.policies.allowedHostPaths.pathPrefix**
    string

    Required value

    The path prefix to match against the host volume.

    It does not support the `*` mask. Trailing slashes are trimmed when validating the path prefix with a host path.

    For example, the `/foo` prefix allows `/foo`, `/foo/` and `/foo/bar` path, but doesn’t allow `/food` or `/etc/foo` path.

  - **spec.policies.allowedHostPaths.readOnly**
    boolean

When set to true, allows host volumes to be matched against the pathPrefix only if all the volume mounts are read-only.

Default: `false`

- **spec.policies.allowedHostPorts**
  array of objects

  The list of `hostPort` ranges allowed by the rule. For pods with `hostNetwork: true`, an additional check is performed on the ports specified in `containerPort`.

  - **spec.policies.allowedHostPorts.max**
    integer

    Max value for the `hostPort`.

  - **spec.policies.allowedHostPorts.min**
    integer

    Min value for the `hostPort`.

- **spec.policies.allowedProcMount**
  string

  Allows `/proc` mount type for containers.

  Allowed values: `Default`, `Unmasked`

  Example:

  ```
  allowedProcMount: Unmasked.
  ```

- **spec.policies.allowedServiceTypes**
  array of strings

  The list of allowed service types.

  Example:

  ```
  allowedServiceTypes:
  - LoadBalancer
  - ClusterIP
  ```

  - **Element of the array**
    string

    Allowed values: `ClusterIP`, `NodePort`, `LoadBalancer`, `ExternalName`

- **spec.policies.allowedUnsafeSysctls**
  array of strings

  The list of explicitly allowed unsafe sysctls.

  To allow all unsafe sysctls, use `*`.

  Example:

  ```
  allowedUnsafeSysctls:
  - kernel.msg*
  - net.core.somaxconn
  ```

- **spec.policies.allowedVolumes**
  array of strings

  The set of the permitted volume plugins.

  Example:

  ```
  allowedVolumes:
  - hostPath
  - persistentVolumeClaim
  ```

  - **Element of the array**
    string

    Allowed values: `*`, `none`, `awsElasticBlockStore`, `azureDisk`, `azureFile`, `cephFS`, `cinder`, `configMap`, `csi`, `downwardAPI`, `emptyDir`, `ephemeral`, `fc`, `flexVolume`, `flocker`, `gcePersistentDisk`, `gitRepo`, `glusterfs`, `hostPath`, `iscsi`, `nfs`, `persistentVolumeClaim`, `photonPersistentDisk`, `portworxVolume`, `projected`, `quobyte`, `rbd`, `scaleIO`, `secret`, `storageos`, `vsphereVolume`

- **spec.policies.automountServiceAccountToken**
  boolean

  Allows pods to run with `automountServiceAccountToken` enabled.

  When set to `false`, a pod is denied if it either sets `spec.automountServiceAccountToken: true` or mounts `/var/run/secrets/kubernetes.io/serviceaccount` in any container. The mount is checked regardless of the flag value, so explicitly projecting a service account token at that path is denied as well.

- **spec.policies.blockWildcardDomains**
  boolean

  Block creation of Ingress objects with `*` in DNS domains.

- **spec.policies.forbiddenSysctls**
  array of strings

  The list of forbidden sysctls.

  Takes precedence over allowed unsafe sysctls (allowedUnsafeSysctls).

  Example:

  ```
  forbiddenSysctls:
  - kernel.msg*
  - net.core.somaxconn
  ```

- **spec.policies.fsGroup**
  object

  Specifies which `fsGroup` values the security context is permitted to use.

  - **spec.policies.fsGroup.ranges**
    array of objects

    The list of `fsGroup` ID ranges that are allowed in `MustRunAs' mode.

    - **spec.policies.fsGroup.ranges.max**
      integer

      Max ID value.

    - **spec.policies.fsGroup.ranges.min**
      integer

      Min ID value.

  - **spec.policies.fsGroup.rule**
    string

    Required value

    Specifies the strategy of the `fsGroup` selection.

    Allowed values: `MustRunAs`, `MayRunAs`, `RunAsAny`

- **spec.policies.readOnlyRootFilesystem**
  boolean

  If set to true, only the pods with the read-only root filesystem across all containers will be permitted to run. See the Kubernetes documentation for more details.

- **spec.policies.requiredDropCapabilities**
  array of strings

  The list of capabilities that have to be dropped from the containers.

  To exclude all capabilities, use `ALL`'.

  Example:

  ```
  requiredDropCapabilities:
  - SETGID
  - SETUID
  - NET_BIND_SERVICE
  ```

  - **Element of the array**
    string

    A linux capability to drop from the containers' specs.

    Allowed values: `ALL`, `SETPCAP`, `SYS_MODULE`, `SYS_RAWIO`, `SYS_PACCT`, `SYS_ADMIN`,

`SYS_NICE`, `SYS_RESOURCE`, `SYS_TIME`, `SYS_TTY_CONFIG`, `MKNOD`, `AUDIT_WRITE`, `AUDIT_CONTROL`, `MAC_OVERRIDE`, `MAC_ADMIN`, `NET_ADMIN`, `SYSLOG`, `CHOWN`, `NET_RAW`, `DAC_OVERRIDE`, `FOWNER`, `DAC_READ_SEARCH`, `FSETID`, `KILL`, `SETGID`, `SETUID`, `LINUX_IMMUTABLE`, `NET_BIND_SERVICE`, `NET_BROADCAST`, `IPC_LOCK`, `IPC_OWNER`, `SYS_CHROOT`, `SYS_PTRACE`, `SYS_BOOT`, `LEASE`, `SETFCAP`, `WAKE_ALARM`, `BLOCK_SUSPEND`

- **spec.policies.runAsGroup**
  object

  Specifies which `runAsGroup` values the security context is permitted to use.

  - **spec.policies.runAsGroup.ranges**
    array of objects

    The list of group ID ranges that are allowed in `MustRunAs' mode.

    - **spec.policies.runAsGroup.ranges.max**
      integer

      Max ID value.

    - **spec.policies.runAsGroup.ranges.min**
      integer

      Min ID value.

  - **spec.policies.runAsGroup.rule**
    string

    Required value

    Specifies the strategy of the group ID selection.

    Allowed values: `MustRunAs`, `MayRunAs`, `RunAsAny`

- **spec.policies.runAsUser**
  object

  Specifies which `runAsUser` values the security context is permitted to use.

  - **spec.policies.runAsUser.ranges**
    array of objects

    The list of user ID ranges that are allowed in `MustRunAs' mode.

    - **spec.policies.runAsUser.ranges.max**
      integer

      Max ID value.

    - **spec.policies.runAsUser.ranges.min**
      integer

      Min ID value.

  - **spec.policies.runAsUser.rule**
    string

    Required value

    Specifies the strategy of the user ID selection.

    Allowed values: `MustRunAs`, `MustRunAsNonRoot`, `RunAsAny`

- **spec.policies.seLinux**
  array of objects

  Specifies which SELinux labels the security context is permitted to use.

  The `seLinuxOptions` of a pod or a container are allowed if they match at least one entry. A field left unset or empty in `seLinuxOptions` always matches. A field set in `seLinuxOptions` must equal the same field of the entry, so an entry that omits `user`, `role` or `type` forbids setting it. The `level` field is the exception: an entry that omits it allows any level.

  - **spec.policies.seLinux.level**
    string

    A SELinux level label that applies to the container.

  - **spec.policies.seLinux.role**
    string

    A SELinux role label that applies to the container.

  - **spec.policies.seLinux.type**
    string

A SELinux type label that applies to the container.

- **spec.policies.seLinux.user**
  string

  A SELinux user label that applies to the container.

- **spec.policies.seccompProfiles**
  object

  Specifies the list of allowed profiles that can be set for the Pod or container's seccomp annotations.

  - **spec.policies.seccompProfiles.allowedLocalhostFiles**
    array of strings

    Defines the local seccomp profiles (in JSON format) that can be used if `Localhost` is set in the `allowedProfiles` parameter.

    An empty list prohibits the use of any local profiles.

  - **spec.policies.seccompProfiles.allowedProfiles**
    array of strings

    The list of allowed profile values for seccomp on Pods/containers.

    Both formats are supported:

    - Via annotations: `runtime/default`, `docker/default`, `unconfined`, `localhost/some-profile.json`. `localhost/*` allows any local profile.
    - Via securityContext: `RuntimeDefault`, `Unconfined`, `Localhost`. For `Localhost`, specify the allowed profiles using the `allowedLocalhostFiles` parameter.

    Profile types:

    - `Unconfined` — no restrictions (not recommended for security reasons).
    - `RuntimeDefault` — the default profile provided by the container runtime (e.g., Docker, CRI-O).
    - `Localhost` — a custom profile defined on the host (flexible and tailored to the application).

    Using `*` allows all profiles. It's not necessary to specify both formats — they are automatically mapped to each other.

- **spec.policies.supplementalGroups**
  object

  Specifies what supplemental groups are allowed to be used by the security context.

  - **spec.policies.supplementalGroups.ranges**
    array of objects

    The list of supplemental group ID ranges that are allowed in `MustRunAs' mode.

    - **spec.policies.supplementalGroups.ranges.max**
      integer

      Max ID value.

    - **spec.policies.supplementalGroups.ranges.min**
      integer

      Min ID value.

  - **spec.policies.supplementalGroups.rule**
    string

    Required value

    Specifies the strategy of the supplemental group ID selection.

    Allowed values: `MustRunAs`, `MayRunAs`, `RunAsAny`

- **spec.policies.verifyImageSignatures**
  array of objects

  Available in editions: SE+, Ultimate/EE

  List of policies to verify container images signatures.

  Container images must be signed using Cosign.

  Example:

```
verifyImageSignatures:
- reference: docker.io/myrepo/*
  publicKeys:
  - |-
    -----BEGIN PUBLIC KEY-----
    .....
    -----END PUBLIC KEY-----
- reference: company.registry.com/*
  dockerCfg: "<Base64_dockerCfg>"
  publicKeys:
  - |-
    -----BEGIN PUBLIC KEY-----
    .....
    -----END PUBLIC KEY-----
```

- **spec.policies.verifyImageSignatures.ca**
  string

  A custom certificate authority to use when connecting to the container image repository.

- **spec.policies.verifyImageSignatures.dockerCfg**
  string

  A string in Base64 with authentication data for the container image repository.

  If the container images are available anonymously, it is not specified.

- **spec.policies.verifyImageSignatures.publicKeys**
  array of strings

  Required value

  The list of Cosign compliant public keys.

- **spec.policies.verifyImageSignatures.reference**
  string

  Required value

  Absolute address or template for container images.

  If it contains the `*` symbol, it is considered a template for container image addresses. The `*` symbol can only appear once and only at the end. For example, for the value `company.registry.com/*`, any container images from the repository `company.registry.com` will be checked with the specified keys and access parameters.

  If it does not contain the `*` symbol, it is considered an absolute address for a container image. For example, for the value `company.registry.com/nginx`, only the nginx image from the repository `company.registry.com` will be checked with the specified keys and access parameters.

  Pattern: `^[a-z0-9\.\-:@\/]*\*?$`

  Examples:

  ```
  reference: docker.io/myuser/*
  ```

  ```
  reference: "*"
  ```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources (by Gatekeeper)

The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

Mutation Custom Resources

> **i** The `reinvocationPolicy: IfNeeded` is used in MutatingWebhookConfiguration. More details in the Kubernetes documentation.

Reference

Provide a configurable set of policies for modifying Kubernetes resources at the time they are deployed.

AssignMetadata

Reference

Allows you to modify the `Metadata` section of a resource. At the moment, Gatekeeper only allows **adding** `labels` and `annotations` objects. Modification of existing objects is not provided.

> **i** Using `*` in `spec.match.kinds` is not allowed. If `*` is specified, the mutation will not be applied. Instead, you must explicitly list the target resources (`kinds`) along with their corresponding `apiGroups`.

Example 1. Adding the `owner` label with the value `admin` to all namespaces:

```
apiVersion: mutations.gatekeeper.sh/v1
kind: AssignMetadata
metadata:
  name: demo-annotation-owner
spec:
  match:
    scope: Namespaced
  location: "metadata.labels.owner"
  parameters:
    assign:
      value: "admin"
```

Example 2. Adding a label in a specific namespace and only to selected resources:

```
apiVersion: mutations.gatekeeper.sh/v1
kind: AssignMetadata
metadata:
  name: set-labels-<your_namespace>
spec:
  match:
    scope: Namespaced
    namespaces: ["<your_namespace>"]
    kinds:
    - apiGroups: [""]
      kinds: ["Pod"] # The use of "*" is not allowed.
  location: "metadata.labels.<your_label_name>"
  parameters:
    assign:
      value: <your_label_value>
```

Assign

Allows you to modify fields outside the `Metadata` section.

An example of setting `imagePullPolicy` for all containers to `Always` in all namespaces except the `system` namespace:

```
apiVersion: mutations.gatekeeper.sh/v1
kind: Assign
metadata:
  name: demo-image-pull-policy
spec:
  applyTo:
  - groups: [""]
    kinds: ["Pod"]
    versions: ["v1"]
  match:
    scope: Namespaced
    kinds:
    - apiGroups: ["*"]
      kinds: ["Pod"]
    excludedNamespaces: ["system"]
  location: "spec.containers[name:*].imagePullPolicy"
  parameters:
    assign:
      value: Always
```

ModifySet

Reference

Allows you to add and remove items from a list, such as arguments for running a container. New values are added to the end of the list.

An example of removing the `--alsologtostderr` argument from all containers in a pod:

```
apiVersion: mutations.gatekeeper.sh/v1
kind: ModifySet
metadata:
  name: remove-err-logging
spec:
  applyTo:
  - groups: [""]
    kinds: ["Pod"]
    versions: ["v1"]
  location: "spec.containers[name: *].args"
  parameters:
    operation: prune
    values:
      fromList:
        - --alsologtostderr
```

AssignImage

Reference

Allows you to make changes to the `image` parameter of a resource.

An example of changing the `image` parameter to the value `my.registry.io/repo/app@sha256:abcde67890123456789abc345678901a`:

```
apiVersion: mutations.gatekeeper.sh/v1alpha1
kind: AssignImage
metadata:
  name: assign-container-image
spec:
  applyTo:
  - groups: [ "" ]
    kinds: [ "Pod" ]
    versions: [ "v1" ]
  location: "spec.containers[name:*].image"
  parameters:
    assignDomain: "my.registry.io"
    assignPath: "repo/app"
    assignTag: "@sha256:abcde67890123456789abc345678901a"
  match:
    source: "All"
    scope: Namespaced
    kinds:
    - apiGroups: [ "*" ]
      kinds: [ "Pod" ]
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

The module lifecycle stage: General Availability

How do I configure alternative security policy management solutions?

For DP to work correctly, extended privileges are required to run and operate system component payloads. If you are using some alternative security policy management solution (e.g., Kyverno) instead of the admission-policy-engine module, you have to configure exceptions for the following namespaces:

- `kube-system`;
- all namespaces with the `d8-*` prefix (e.g., `d8-system`).

How do I configure policy selectors?

In `OperationPolicy` and `SecurityPolicy`, the `spec.match` field determines which specific objects (pods) in the cluster the policy will apply to. It must be present in the configuration. Filtering is performed by combining two main criteria: a pod selector (`labelSelector`) and a namespace selector (`namespaceSelector`).

If both selectors are specified, the policy is applied only to those pods that simultaneously:

- satisfy the pod selection conditions.
- are located in namespaces that passed the filtering.

If either selector is omitted, the corresponding check is not performed (all pods or namespaces will be used).

- `spec.match.labelSelector` – pod selection

The `labelSelector` is used to set criteria for selecting pods by their labels. Two mutually exclusive methods are supported:

- `matchLabels` – a simple check for an exact label match (key-value). The pod must have all the specified labels.
- `matchExpressions` – flexible expressions with operators. Each expression is defined by an object with the following fields:
  - `key` (string, required) – the label name.
  - `operator` (string, required) – one of the values: `In`, `NotIn`, `Exists`, `DoesNotExist`.
  - `values` (array of strings) – a list of values for the `In` / `NotIn` operators; not specified for `Exists` / `DoesNotExist`.

All elements in the `matchExpressions` list are combined with a logical AND – the pod must satisfy every expression.

Examples:

```
spec:
  match:
    labelSelector:
      matchLabels:
        app: nginx
        role: frontend
```

```
spec:
  match:
    labelSelector:
      matchExpressions:
        - key: tier
          operator: In
          values:
            - production
            - staging
        - key: monitoring
          operator: Exists
```

- `spec.match.namespaceSelector` – namespace selection

Allows limiting the namespaces in which the policy is active. You can use a combination of three filters:

- `matchNames` – an explicit list of allowed namespaces. If specified, the policy only applies to the listed namespaces.
- `excludeNames` – a list of excluded namespaces. The policy will apply to all namespaces except those specified.
- `labelSelector` – a selector based on the labels of the Namespace object itself.

If multiple fields are set, they are combined with logical AND:

1. Start with the set from `matchNames` (or all namespaces if `matchNames` is omitted).
2. Apply `labelSelector` (if set).
3. Subtract `excludeNames`.

Formula:

`result = (base_from_matchNames ∩ selected_by_labelSelector) \ excludeNames`

It is recommended not to mix `matchNames`, `excludeNames`, and `labelSelector` without a clear need.

When to use `labelSelector`

Use `labelSelector` when the policy should automatically apply to a group of namespaces by attribute rather than by fixed names.

For example:

- “all namespaces with label `env=prod`”;
- “all `team=backend` namespaces” (with the corresponding label);
- “all namespaces with `security.deckhouse.io/pod-policy=restricted`”.

`labelSelector` is especially useful when namespaces are created/deleted dynamically: it is enough to automatically set a label on the namespace when it is created, and the policy will apply without editing the policy.

`labelSelector` is not required if you have a small static list of namespaces — in that case, using `matchNames` is simpler and easier to read.

Can `matchNames` and `labelSelector` be used together?

Yes, technically they are not mutually exclusive: you can specify both, and then their intersection applies.

But in practice this often hurts readability and complicates maintenance. Therefore, it is recommended to choose one primary selection method:

- either `matchNames + excludeNames`;
- or `labelSelector + excludeNames`.

This makes it easier to understand why a particular namespace is included in or excluded from the policy.

Typical scenarios

1. Static environments list → `matchNames + excludeNames`.
2. Dynamic environments/teams → `labelSelector + excludeNames`.

3. `matchNames + labelSelector` combination — only when you really need the intersection of two independent conditions.

Examples:

Static namespace list (`matchNames + excludeNames`)

```
spec:
  match:
    namespaceSelector:
      matchNames:
        - production
        - staging
      excludeNames:
        - staging
```

Result: the policy applies only in the `production` namespace.

Dynamic label-based selection (`labelSelector + excludeNames`)

```
spec:
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          team: backend
          environment: production
      excludeNames:
        - backend-sandbox
```

Result: all namespaces with labels `team=backend` and `environment=production`, except `backend-sandbox`.

Flexible filtering with expressions (`labelSelector.matchExpressions`)

```
spec:
  match:
    namespaceSelector:
      labelSelector:
        matchExpressions:
          - key: compliance
            operator: In
            values:
              - pci
              - sox
          - key: lifecycle
            operator: NotIn
            values:
              - deprecated
```

Result: only namespaces with labels `compliance=pci` or `compliance=sox` and without label `lifecycle=deprecated`.

`matchNames` and `labelSelector` combination (intersection, use carefully)

```
spec:
  match:
    namespaceSelector:
      matchNames:
        - production
        - staging
        - qa
      labelSelector:
        matchLabels:
          team: backend
```

Result: applies only to namespaces that simultaneously:

- are in the list `production|staging|qa`;
- have label `team=backend`.

For example, if `qa` does not have `team=backend`, it will not be matched.

How do I extend Pod Security Standards policies?

> **i** Pod Security Standards respond to the `security.deckhouse.io/pod-policy: restricted` or `security.deckhouse.io/pod-policy: baseline` label.

To extend the Pod Security Standards policy by adding your checks to existing checks, you need to:

- Create a constraint template for the check (`ConstraintTemplate`).
- Bind it to the `restricted` or `baseline` policy.

Example of the `ConstraintTemplate` for checking a repository URL of a container image:

```
apiVersion: templates.gatekeeper.sh/v1
kind: ConstraintTemplate
metadata:
  name: k8sallowedrepos
spec:
  crd:
    spec:
      names:
        kind: K8sAllowedRepos
      validation:
        openAPIV3Schema:
          type: object
          properties:
            repos:
              type: array
              items:
                type: string
  targets:
    - target: admission.k8s.gatekeeper.sh
      rego: |
        package d8.pod_security_standards.extended

        violation[{"msg": msg}] {
          container := input.review.object.spec.containers[_]
          satisfied := [good | repo = input.parameters.repos[_] ; good =
startswith(container.image, repo)]
          not any(satisfied)
          msg := sprintf("container <%v> has an invalid image repo <%v>, allowed repos are
%v", [container.name, container.image, input.parameters.repos])
        }

        violation[{"msg": msg}] {
          container := input.review.object.spec.initContainers[_]
          satisfied := [good | repo = input.parameters.repos[_] ; good =
startswith(container.image, repo)]
          not any(satisfied)
          msg := sprintf("container <%v> has an invalid image repo <%v>, allowed repos are
%v", [container.name, container.image, input.parameters.repos])
        }
```

Example of binding a check to the `restricted` policy:

```
apiVersion: constraints.gatekeeper.sh/v1beta1
kind: K8sAllowedRepos
metadata:
  name: prod-repo
spec:
  match:
    kinds:
      - apiGroups: [""]
        kinds: ["Pod"]
    namespaceSelector:
      matchLabels:
        security.deckhouse.io/pod-policy: restricted
  parameters:
    repos:
      - "mycompany.registry.com"
```

The example demonstrates the configuration of checking the repository address in the `image` field for all Pods created in the namespace having the `security.deckhouse.io/pod-policy: restricted` label. A Pod will not be created if the address in the `image` field of the Pod does not start with `mycompany.registry.com`.

For more information about templates and the policy language, see the Gatekeeper documentation.

More examples of checks for policy extension are available in the Gatekeeper Library.

How to allow some Pod Security Standards policies without disabling whole list?

To apply only the required security policies without turning off the entire built-in set:

1. Add the `security.deckhouse.io/pod-policy: privileged` label to your namespace in order to disable built-in policies.
2. Create a SecurityPolicy that matches the baseline or restricted policy while also editing the list of `policies` elements as you see fit. Take the rules from the `d8-pod-security-baseline` or `d8-pod-security-restricted` object the module publishes the standards as, see Rules of the standards.
3. Add a label to your namespace that matches the `namespaceSelector` in the SecurityPolicy. In the examples below, the label is `security-policy.deckhouse.io/baseline-enabled: "true"` or `security-policy.deckhouse.io/restricted-enabled: "true"`.

> **i** The `allowedHostPaths` field defines the list of allowed path prefixes for `hostPath` mounts. An empty list (`[]`) forbids `hostPath` for all paths. If the field is omitted, no restrictions apply.

SecurityPolicy that matches baseline:

```
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicy
metadata:
  name: baseline
spec:
  enforcementAction: Deny
  policies:
    allowHostIPC: false
    allowHostNetwork: false
    allowHostPID: false
    allowPrivilegeEscalation: true
    allowPrivileged: false
    allowedAppArmor:
      - runtime/default
      - localhost/*
    allowedCapabilities:
      - AUDIT_WRITE
      - CHOWN
      - DAC_OVERRIDE
      - FOWNER
      - FSETID
      - KILL
      - MKNOD
      - NET_BIND_SERVICE
      - SETFCAP
      - SETGID
      - SETPCAP
      - SETUID
      - SYS_CHROOT
    allowedHostPaths: []
    allowedHostPorts:
      - max: 0
        min: 0
    allowedProcMount: Default
    allowedUnsafeSysctls:
      - kernel.shm_rmid_forced
      - net.ipv4.ip_local_port_range
      - net.ipv4.ip_unprivileged_port_start
      - net.ipv4.tcp_syncookies
      - net.ipv4.ping_group_range
      - net.ipv4.ip_local_reserved_ports
      - net.ipv4.tcp_keepalive_time
      - net.ipv4.tcp_fin_timeout
      - net.ipv4.tcp_keepalive_intvl
      - net.ipv4.tcp_keepalive_probes
    seLinux:
      - type: ""
      - type: container_t
      - type: container_init_t
      - type: container_kvm_t
      - type: container_engine_t
    seccompProfiles:
      allowedProfiles:
        - RuntimeDefault
        - Localhost
        - undefined
        - ''
      allowedLocalhostFiles:
        - '*'
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          security-policy.deckhouse.io/baseline-enabled: "true"
```

SecurityPolicy that matches restricted:

```
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicy
metadata:
  name: restricted
spec:
  enforcementAction: Deny
  policies:
    allowHostIPC: false
    allowHostNetwork: false
    allowHostPID: false
    allowPrivilegeEscalation: false
    allowPrivileged: false
    allowedAppArmor:
      - runtime/default
      - localhost/*
    allowedCapabilities:
      - NET_BIND_SERVICE
    allowedHostPaths: []
    allowedHostPorts:
      - max: 0
        min: 0
    allowedProcMount: Default
    allowedUnsafeSysctls:
      - kernel.shm_rmid_forced
      - net.ipv4.ip_local_port_range
      - net.ipv4.ip_unprivileged_port_start
      - net.ipv4.tcp_syncookies
      - net.ipv4.ping_group_range
      - net.ipv4.ip_local_reserved_ports
      - net.ipv4.tcp_keepalive_time
      - net.ipv4.tcp_fin_timeout
      - net.ipv4.tcp_keepalive_intvl
      - net.ipv4.tcp_keepalive_probes
    allowedVolumes:
      - configMap
      - csi
      - downwardAPI
      - emptyDir
      - ephemeral
      - persistentVolumeClaim
      - projected
      - secret
    requiredDropCapabilities:
      - ALL
    runAsUser:
      rule: MustRunAsNonRoot
    seLinux:
      - type: ""
      - type: container_t
      - type: container_init_t
      - type: container_kvm_t
      - type: container_engine_t
    seccompProfiles:
      allowedProfiles:
        - RuntimeDefault
        - Localhost
      allowedLocalhostFiles:
        - '*'
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          security-policy.deckhouse.io/restricted-enabled: "true"
```

What if there are multiple policies (operational or security) that are applied to the same object?

In that case the object's specification has to fulfill all the requirements imposed by the policies.

For example, consider the following two security policies:

```
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicy
metadata:
  name: foo
spec:
  enforcementAction: Deny
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          name: test
  policies:
    readOnlyRootFilesystem: true
    requiredDropCapabilities:
    - MKNOD
---
apiVersion: deckhouse.io/v1alpha1
kind: SecurityPolicy
metadata:
  name: bar
spec:
  enforcementAction: Deny
  match:
    namespaceSelector:
      labelSelector:
        matchLabels:
          name: test
  policies:
    requiredDropCapabilities:
    - NET_BIND_SERVICE
```

Then, in order to fulfill the requirements of the above security policies, the following settings must be set in a container specification:

```
    securityContext:
      capabilities:
        drop:
          - MKNOD
          - NET_BIND_SERVICE
      readOnlyRootFilesystem: true
```

Why is an Assign or AssignMetadata mutation rejected or silently ignored?

The `Assign`, `AssignMetadata`, `ModifySet`, and `AssignImage` CRDs are imported from Gatekeeper without modification (see Mutation Custom Resources). However, the Gatekeeper mutation webhook enforces content restrictions that go beyond the CRD schema. The `admission-policy-engine` module enforces the checkable restrictions with built-in ValidatingAdmissionPolicies. As a result, `kubectl apply` rejects an invalid resource immediately instead of silently ignoring it or having Gatekeeper reject it later with an unclear parser error.

The module enforces the following restrictions:

- `deny-invalid-assign-location.deckhouse.io` — the `spec.location` field of `Assign` cannot target the `metadata` field (`metadata.name`, `.namespace`, `.labels`, `.annotations`). Use `AssignMetadata` to add labels or annotations.
- `deny-invalid-assignmetadata-location.deckhouse.io` — the `spec.location` field of `AssignMetadata` must be exactly `metadata.labels.<KEY>` or `metadata.annotations.<KEY>`. If `<KEY>` contains characters other than letters, digits, `_`, or `-` (for example, a domain-prefixed key such as `app.kubernetes.io/name`), wrap it in quotes: `metadata.annotations."app.kubernetes.io/name"`.
- `deny-invalid-assignmetadata-value.deckhouse.io` — the `spec.parameters.assign.value` field of `AssignMetadata` must be a string, because Kubernetes label and annotation values are strings.
- `deny-invalid-mutator-frommetadata-field.deckhouse.io` — the `spec.parameters.assign.fromMetadata.field` field (in `Assign` and `AssignMetadata`) is mandatory once `fromMetadata` is set, and accepts only `namespace` or `name`.
- `deny-invalid-assignmetadata-externaldata-datasource.deckhouse.io` — the `spec.parameters.assign.externalData.dataSource` field of `AssignMetadata` supports only `Username`. This field defaults to `ValueAtLocation` when omitted, and that default is rejected too — set `dataSource: Username` explicitly. Unlike `Assign`, `AssignMetadata` doesn't support `ValueAtLocation`, because a

metadata mutation has no source value at `location` to read.
- `deny-mutator-without-match-kinds.deckhouse.io` — the `spec.match.kinds` field is required and must not be empty in `Assign`, `AssignMetadata`, `ModifySet`, and `AssignImage` resources, and every entry in it must set non-empty `apiGroups` and `kinds` without a `*` kind. This restriction is specific to Deckhouse: the `d8-admission-policy-engine-config` MutatingWebhookConfiguration rules are generated only from the `match.kinds` field across all resources of these kinds, resolving `apiGroups`/`kinds` through the Kubernetes REST mapper. A resource with an entry that doesn't resolve to a concrete resource type never triggers a mutation, even though Gatekeeper itself would still treat it as valid.

How to apply a mutation only when a resource is created?

Use the `spec.applyTo[].operations` field of `Assign`, `ModifySet`, or `AssignImage` to choose the admission operations that trigger the mutation. The field accepts `CREATE`, `UPDATE`, and `*`. If the field is omitted or contains `*`, the mutation runs on both `CREATE` and `UPDATE`.

The following example sets `imagePullPolicy` only when a pod is created and leaves updates of the pod unchanged:

```
apiVersion: mutations.gatekeeper.sh/v1
kind: Assign
metadata:
  name: always-pull-on-create
spec:
  applyTo:
    - groups: [""]
      kinds: ["Pod"]
      versions: ["v1"]
      operations: ["CREATE"]
  match:
    scope: Namespaced
    kinds:
      - apiGroups: [""]
        kinds: ["Pod"]
  location: "spec.containers[name:*].imagePullPolicy"
  parameters:
    assign:
      value: Always
```

The module builds the rules of the `d8-admission-policy-engine-config` MutatingWebhookConfiguration from these operations. A resource is sent to Gatekeeper only for the operations that at least one of its mutations requests. `AssignMetadata` has no `applyTo` field and always runs on `CREATE` and `UPDATE`.

Verification of image signatures

The module implements a function for verifying signatures of container images signed using Cosign. For more details on signing and verifying container images, see the DP documentation.

Signature verification caches the credentials of a private registry read from the `dockerCfg` field of a SecurityPolicy. After you change `dockerCfg`, the new credentials take effect once the cache entry expires. To set the cache lifetime, use the `imageSignatureVerification.registryCredentialsCacheTTLSeconds` parameter. The default is 300 seconds.

How to block deleting a node without a label

> **i** DELETE operations are handled by Gatekeeper by default.

You can create your own Gatekeeper policy to block Node deletion unless a special label is present. The example below uses `oldObject` to check labels on the Node being deleted:

```
apiVersion: templates.gatekeeper.sh/v1
kind: ConstraintTemplate
metadata:
  name: d8customnodedeleteguard
spec:
  crd:
    spec:
      names:
        kind: D8CustomNodeDeleteGuard
      validation:
        openAPIV3Schema:
          type: object
          properties:
            requiredLabelKey:
              type: string
            requiredLabelValue:
              type: string
  targets:
    - target: admission.k8s.gatekeeper.sh
      rego: |
        package d8.custom

        is_delete { input.review.operation == "DELETE" }
        is_node { input.review.kind.kind == "Node" }

        has_required_label {
          key := input.parameters.requiredLabelKey
          val := input.parameters.requiredLabelValue
          obj := input.review.oldObject
          obj.metadata.labels[key] == val
        }

        violation[{"msg": msg}] {
          is_delete
          is_node
          not has_required_label
          msg := sprintf("Node deletion is blocked. Add label %q=%q to proceed.",
[input.parameters.requiredLabelKey, input.parameters.requiredLabelValue])
        }
---
apiVersion: constraints.gatekeeper.sh/v1beta1
kind: D8CustomNodeDeleteGuard
metadata:
  name: require-node-delete-label
spec:
  enforcementAction: warn
  match:
    kinds:
      - apiGroups: [""]
        kinds: ["Node"]
  parameters:
    requiredLabelKey: "admission.deckhouse.io/allow-delete"
    requiredLabelValue: "true"
```

How to deny kubectl exec and kubectl attach to specific Pods?

The `admission-policy-engine` module webhook routes `CONNECT` requests for `pods/exec` and `pods/attach` in namespaces other than `d8-*` and `kube-*` through Gatekeeper. This allows creating custom policies to allow or deny `kubectl exec` and `kubectl attach` operations.

The `deckhouse` module denies the following operations into pods of system components labeled `heritage: deckhouse` for all users, but the Deckhouse Platform system users:

- `kubectl exec`
- `kubectl attach`
- `kubectl cp`
- `kubectl port-forward`
- `kubectl debug`

The operations are denied regardless of whether the `admission-policy-engine` module is enabled in the

cluster. For details, refer to the FAQ of the `deckhouse` module.

Built-in policy for finalizers

To protect objects managed by DP controllers, the `admission-policy-engine` module includes a built-in ValidatingAdmissionPolicy `deny-deckhouse-finalizers.deckhouse.io` that forbids removing finalizers containing the `deckhouse.io` substring on any cluster objects.

This policy doesn't apply to the following users who are allowed to remove such finalizers:

- Kubernetes system controllers (`system:kube-controller-manager`, `system:kube-scheduler`, etc.);
- `system:sudouser`, `dhctl`, `observability`;
- service accounts from `d8-*` namespaces (`system:serviceaccount:d8-*`);
- service accounts from `kube-*` namespaces (`system:serviceaccount:kube-*`).

Custom policy example

You can create your own Gatekeeper policy to deny `kubectl exec` and `kubectl attach` operations in specific namespaces. The example below uses `input.review.operation` and `input.review.resource.resource` to check for `CONNECT` operations:

```
apiVersion: templates.gatekeeper.sh/v1
kind: ConstraintTemplate
metadata:
  name: d8customdenyexec
spec:
  crd:
    spec:
      names:
        kind: D8CustomDenyExec
      validation:
        openAPIV3Schema:
          type: object
          properties:
            forbiddenNamespaces:
              type: array
              items:
                type: string
  targets:
    - target: admission.k8s.gatekeeper.sh
      rego: |
        package d8.custom

        is_connect {
          input.review.operation == "CONNECT"
        }

        # requestSubResource is preferred, but fall back to subResource for older APIs
        subresource_is(sub) {
          sr := object.get(input.review, "requestSubResource", input.review.subResource)
          sr == sub
        }

        is_exec_or_attach {
          input.review.resource.resource == "pods"
          subresource_is("exec")
        }

        is_exec_or_attach {
          input.review.resource.resource == "pods"
          subresource_is("attach")
        }

        is_forbidden_namespace {
          ns := input.review.namespace
          ns == input.parameters.forbiddenNamespaces[_]
        }

        violation[{"msg": msg}] {
          is_connect
          is_exec_or_attach
```

```
        is_forbidden_namespace
        msg := sprintf("Exec/attach is forbidden in namespace %q", [input.review.namespace])
      }
---
apiVersion: constraints.gatekeeper.sh/v1beta1
kind: D8CustomDenyExec
metadata:
  name: deny-exec-in-namespaces
spec:
  enforcementAction: deny
  match:
    kinds:
      - apiGroups: ["*"]
        kinds: ["*"]
    scope: Namespaced
  parameters:
    forbiddenNamespaces:
      - production
      - staging
```

Key data and checks available when validating `CONNECT` operations:

- Use `input.review.operation == "CONNECT"` to check for `CONNECT` operations.
- User information is available in `input.review.userInfo.username` and `input.review.userInfo.groups`.
- The namespace is available in `input.review.namespace`.

How do I restrict GPU resource usage in namespaces?

The `gpuResourceRestriction` policy in OperationPolicy denies the workloads that request GPU resources when the namespace has no label allowing GPU usage. The check runs on creation and update of a pod, including when an ephemeral container is added, and on creation and update of the controllers that create pods. Both `resources.requests` and `resources.limits` of every container, init container, and ephemeral container are inspected. A resource with a quantity of `0` is not treated as a GPU request.

To set up GPU resource restriction:

1. Create an OperationPolicy with the `gpuResourceRestriction` setting.

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: OperationPolicy
   metadata:
     name: gpu-restriction
   spec:
     enforcementAction: Deny
     match:
       namespaceSelector:
         labelSelector:
           matchLabels:
             operation-policy.deckhouse.io/enabled: "true"
     policies:
       gpuResourceRestriction:
         namespaceLabel:
           key: "gpu.deckhouse.io/enabled"
           value: "true"
         gpuResourcePatterns:
           - '^nvidia\.com/.*$'
           - '^amd\.com/gpu$'
   ```

   The `namespaceLabel` parameter defines the label key and value that must be present on the namespace. The `gpuResourcePatterns` parameter lists the regular expressions matched against GPU resource names. Patterns are not anchored implicitly, so use `^` and `$` to match the whole resource name.

2. Add the policy label to the namespaces where the policy must be enforced.

   ```
   d8 k label ns my-namespace operation-policy.deckhouse.io/enabled=true
   ```

3. Add the GPU label to the namespaces where GPU usage is allowed.

   ```
   d8 k label ns my-gpu-namespace gpu.deckhouse.io/enabled=true
   ```

After that, the pods that request GPU resources are allowed only in the namespaces with the `gpu.deckhouse.io/enabled: "true"` label.

⚠ The policy is applied to pods and to the pod-creating controllers, so a Deployment whose pod template requests GPU resources is denied on creation. To check this rule on Pods only, add `gpuResourceRestriction` to the `spec.controllerValidation.excludedPolicies` parameter of the policy.

The namespace label is read from the Gatekeeper cache. While a namespace is missing from that cache, for example when the namespace and the pod are applied together and the namespace has not been cached yet, the policy denies the pods that request GPU resources in that namespace.

The devices requested through Dynamic Resource Allocation in the `spec.resourceClaims` field are not extended resources, and the policy does not check them.

What to do if the validating webhook is unavailable?

While the `gatekeeper-controller-manager` Deployment has no available replicas, the API server rejects every request its webhook intercepts, and the cluster cannot create or delete workloads. The `D8AdmissionPolicyEngineWebhookUnavailable` alert reports this state. Read why the component is critical for the list of what stops working.

Confirm that the Deployment is the cause and collect the reason:

```
d8 k -n d8-admission-policy-engine get deploy gatekeeper-controller-manager
d8 k -n d8-admission-policy-engine get pods -l app=gatekeeper,control-plane=controller-manager -o wide
d8 k -n d8-admission-policy-engine describe pods -l app=gatekeeper,control-plane=controller-manager
d8 k -n d8-admission-policy-engine logs deploy/gatekeeper-controller-manager -c manager --all-pods=true --
tail=200
```

The pods of this Deployment are excluded from validation by their `gatekeeper.sh/operation: webhook` label, so the ReplicaSet creates a replacement pod even while the webhook is down. To get a fresh pod, delete the current one:

```
d8 k -n d8-admission-policy-engine delete pod -l app=gatekeeper,control-plane=controller-manager
```

Restarting the Deployment with `d8 k rollout restart` does not work here. The same label is guarded by the `deny-gatekeeper-webhook-operation-label-controllers` ValidatingAdmissionPolicy, which rejects a change to a pod template carrying it unless the request comes from a service account of a `d8-*` or `kube-*` namespace, or from `system:sudouser`.

Look for the cause first. Disabling the module unblocks the cluster, but it also removes every policy the cluster relies on, so treat it as a last resort rather than as the first step:

```
d8 platform module disable admission-policy-engine
```

Deckhouse Platform keeps the objects of the module removed while it is disabled, so the cluster stays unblocked for as long as the module is off. Return the module as soon as the cause is fixed, since no policy is enforced while it is disabled:

```
d8 platform module enable admission-policy-engine
```

ℹ **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The cert-manager module

ℹ Included in extensions: **Cluster Union**

ℹ The module lifecycle stage: General Availability

This module installs the reliable and highly available cert-manager release 1.21.2.

The installation process automatically takes into account cluster aspects:

- the component (webhook) that the `kube-apiserver` is accessing is installed on master nodes;
- if the webhook is unavailable, the `apiservice` is temporary deleted so that the unavailability of *cert-manager* does not block regular cluster operation.

The module itself is updated automatically (including the migration of cert-manager resources).

Features of the cert-manager module (with the changes made)

The module has all the features of the original cert-manager, including:

- Provisioning certificates of all the supported CA such as *Let's Encrypt*, *HashiCorp Vault*, *Venafi*;
- Issuing self-signed certificates;
- Keeping certificates up-to-date, reissuing them automatically, etc.

Changes to the original cert-manager were made so that the `cm-acme-http-solver` Pods could run on master and dedicated nodes.

Restricting ClusterIssuers for projects

When the `multitenancy-manager` module is enabled, `cert-manager` registers ClusterIssuer as a cluster-wide resource whose use from project namespaces can be restricted. The registration is the `clusterissuers` GrantableClusterResourceDefinition. It applies to the following references:

- the `.spec.issuerRef.name` field of a Certificate if `.spec.issuerRef.kind` is set to ClusterIssuer;
- the `cert-manager.io/cluster-issuer` annotation of an Ingress.

By default, every ClusterIssuer is available to every project. To limit the list or set the ClusterIssuer used by default, create a ClusterResourceGrantPolicy with `resourceName: clusterissuers`.

Monitoring

The module can expose metrics in the Prometheus format, allowing you to monitor:

- certificate validity;
- correctness of the certificate reissue.

Module roles

The module has several well-thought-out roles for managing resources:

- `User` – has read-only access to Certificate & Issuers resources in the permitted namespaces and to the global clusterIssues;
- `Editor` – manages Certificate and Issuer resources in the permitted namespaces;
- `ClusterEditor` – manages Certificate & Issuer resources in all namespaces;
- `SuperAdmin` – manages internal service objects.

Third-party components

List of third-party software used in the `cert-manager` module:

- cert-manager 1.21.2

  License: Apache License 2.0

  A Kubernetes add-on to automate the management and issuance of TLS certificates from various issuing sources.

- cert-manager-webhook-yandex 1a7dd500a97e9206fa5cfebb102decd3889e3544

  License: Apache License 2.0

  ACME DNS-01 webhook for Yandex Cloud DNS.

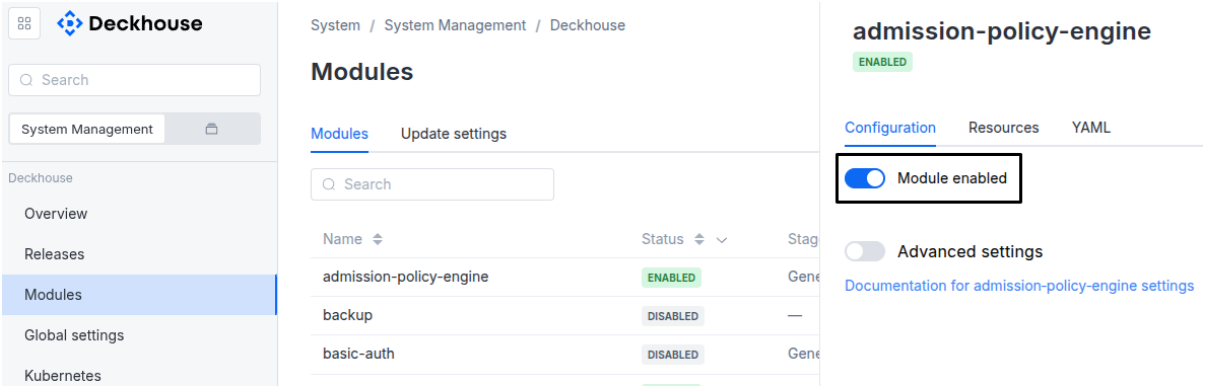
> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Included in extensions: **Cluster Union**

> **i** The module lifecycle stage: General Availability

The module does not have any mandatory parameters.



The module has 6 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cert-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

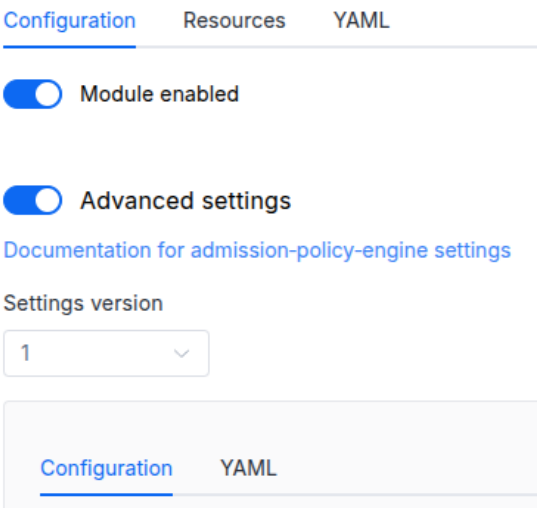
```
d8 system module enable cert-manager
```

- **Using ModuleConfig `cert-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cert-manager` (create it if necessary);

  Example of a manifest to enable module `cert-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cert-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cert-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cert-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cert-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cert-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cert-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cert-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cert-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cert-manager
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.certificateRequestMaximumBackoffDuration**
    string

    Maximum delay between attempts to issue a certificate after a failed CertificateRequest.

    The delay starts at one hour and doubles after each consecutive failure, but does not exceed this value. A lower value makes cert-manager retry sooner once the issuer is available again, for example after maintenance of the CA. Specify the value in the `<HOURS>h` or `<HOURS>h<MINUTES>m` format, for example `6h` or `1h30m`. The number of hours is from 1 to 9999, the number of minutes is from 0 to 59. Other notations of the same duration, such as `90m` or `1h30m0s`, are not accepted.

    If the parameter is not set, the cert-manager default of 32 hours applies.

    Pattern: `^[1-9][0-9]{0,3}h([0-5]?[0-9]m)?$`

    Examples:

```
certificateRequestMaximumBackoffDuration: 6h
```

```
certificateRequestMaximumBackoffDuration: 1h30m
```

- **settings.cleanupOrphanSecrets**
  boolean

  Delete a secret with a certificate automatically if the corresponding Certificate resource was deleted from the cluster.

  Default: `false`

  Examples:

  ```
  cleanupOrphanSecrets: true
  ```

  ```
  cleanupOrphanSecrets: false
  ```

- **settings.cloudDNSServiceAccount**
  string

  The Service Account for Google Cloud for the same project that has the DNS Administrator role.

  Example:

  ```
  cloudDNSServiceAccount:
  eyJzYSI6ICJhYmNkZWZnaEBzZXJ2aWNlYWNjb3VudC5jb20iLCAicHJvamVjdF9pZCI6ImFhYWFhIn0=
  ```

- **settings.cloudflareAPIToken**
  string

  API Tokens allow application-scoped keys bound to specific DNS zones.

  API Tokens are recommended for higher security, since they have more restrictive permissions and are more easily revocable.

  It allows you to verify that domains specified in the Certificate resource are managed by `cert-manager` and kept by the Cloudflare DNS provider. Verification is performed by adding special TXT records for the ACME DNS01 Challenge Provider domain.

  Example:

  ```
  cloudflareAPIToken: token
  ```

- **settings.cloudflareEmail**
  string

  The email used for accessing the Cloudflare platform.

  Example:

  ```
  cloudflareEmail: example@example.com
  ```

- **settings.cloudflareGlobalAPIKey**
  string

  The Cloudflare Global API key for managing DNS records

  It allows you to verify that domains specified in the Certificate resource are managed by `cert-manager` and kept by the Cloudflare DNS provider.

  Verification is performed by adding special TXT records for the ACME DNS01 Challenge Provider domain.

  Example:

  ```
  cloudflareGlobalAPIKey: key
  ```

- **settings.digitalOceanCredentials**
  string

  The Access Token for the Digital Ocean API (you can create it in the `API` section).

  Example:

  ```
  digitalOceanCredentials: creds
  ```

- **settings.disableLetsencrypt**
  boolean

  Disable `letsencrypt` and `letsencrypt-staging` ClusterIssuer objects (if set to `true`).

  Examples:

  ```
  disableLetsencrypt: true
  ```

  ```
  disableLetsencrypt: false
  ```

- **settings.email**
  string

  The email used for sending notifications by LetsEncrypt.

  Example:

  ```
  email: example@example.com
  ```

- **settings.enableACMERenewalInfo**
  boolean

  Enable ACME Renewal Information (ARI, RFC 9773) by turning on the `ACMEUseARI` feature gate.

  With ARI, cert-manager asks the ACME server, for example Let’s Encrypt, for the renewal window of every certificate it issued. If the server returns a window, cert-manager renews the certificate at a random moment inside it and ignores `renewBefore` and `renewBeforePercentage` of the Certificate resource. The renewal can therefore happen later than `renewBefore` requires. `spec.renewal` of the Certificate still applies on top of the window. If the server does not support ARI or the request fails, `renewBefore` applies as usual.

  The parameter affects every ACME Issuer and ClusterIssuer in the cluster, not only the ones of the module. The feature is in the alpha stage in cert-manager.

  Default: `false`

  Examples:

  ```
  enableACMERenewalInfo: true
  ```

  ```
  enableACMERenewalInfo: false
  ```

- **settings.enableCAInjector**
  boolean

  Manually enable CAInjector. By default, CAInjector is enabled automatically when resources with CA injection annotations are detected (`cert-manager.io/inject-ca-from`, `cert-manager.io/inject-ca-from-secret`, `cert-manager.io/inject-apiserver-ca`).

  Default: `false`

  Examples:

  ```
  enableCAInjector: true
  ```

  ```
  enableCAInjector: false
  ```

- **settings.enableListenerSet**
  boolean

  Enable ListenerSet support in cert-manager by turning on the `ListenerSets` feature gate.

  Additionally, when Gateway API integration is enabled, this flag also enables ListenerSet integration for Gateway API if the ListenerSet CRD is installed in the cluster and serves the `v1` version.

  Gateway API integration is enabled automatically when the Gateway and HTTPRoute CRDs are installed in the cluster and serve the `v1` version.

  Default: `false`

  Examples:

  ```
  enableListenerSet: true
  ```

```
enableListenerSet: false
```

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

  Examples:

  ```
  highAvailability: true
  ```

  ```
  highAvailability: false
  ```

- **settings.http01WaitInsteadOfSelfCheck**
  string

  Time to wait instead of the self-check before asking the ACME server to validate an HTTP-01 challenge.

  Applies to the `letsencrypt` and `letsencrypt-staging` ClusterIssuers, including their Gateway API variants. Before asking the ACME server, cert-manager checks that the challenge is reachable from inside the cluster. This self-check fails when the cluster cannot reach its own public address, for example behind NAT without hairpinning (when you cannot access your external IP address from inside the cluster) or with split-horizon DNS (when the same domain resolves to different IP addresses depending on where the DNS request originated: from inside the cluster or from outside), although the ACME server could validate the challenge. If the parameter is set, cert-manager skips the self-check and waits for the specified time instead. The value `0` asks the ACME server to validate right away and relies on its own retries.

  By default, the self-check is performed.

  Pattern: `^(0|[0-9]{1,4}h([0-9]{1,4}m)?([0-9]{1,4}s)?|[0-9]{1,4}m([0-9]{1,4}s)?|[0-9]{1,4}s)$`

  Examples:

  ```
  http01WaitInsteadOfSelfCheck: 30s
  ```

  ```
  http01WaitInsteadOfSelfCheck: 2m
  ```

- **settings.ingressClassHttp01**
  string

  The name of the `ingressClass` used to confirm ownership of domain using the ACME HTTP-01 challenges method. If the parameter is omitted, the default `ingressClass` is used.

  Example:

  ```
  ingressClassHttp01: nginx
  ```

- **settings.letsencrypt**
  object

  Settings for the `letsencrypt` ClusterIssuer.

  - **settings.letsencrypt.resources**
    object

    Resource requests and limits (CPU and memory) for the workload using the `letsencrypt` ClusterIssuer.

    Example:

    ```
    resources:
      requests:
        cpu: 100m
        memory: 128Mi
      limits:
        cpu: 250m
        memory: 256Mi
    ```

    - **settings.letsencrypt.resources.limits**
      object
      - **settings.letsencrypt.resources.limits.cpu**

string

Required value

The same as in the pods' `spec.containers.resources.limits.cpu` parameter in Kubernetes.

Default: `50m`

Pattern: `^[0-9]+m?$`

- **settings.letsencrypt.resources.limits.memory**
  string or number

  Required value

  The same as in the pods' `spec.containers.resources.limits.memory` parameter in Kubernetes.

  Default: `64Mi`

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.letsencrypt.resources.requests**
  object

  Resource requests and limits (CPU and memory) for pods that create the `letsencrypt` ClusterIssuer for http01 challenges

  - **settings.letsencrypt.resources.requests.cpu**
    string

    Required value

    The same as in the pods' `spec.containers.resources.requests.cpu` parameter in Kubernetes.

    Default: `10m`

    Pattern: `^[0-9]+m?$`

  - **settings.letsencrypt.resources.requests.memory**
    string or number

    Required value

    The same as in the pods' `spec.containers.resources.requests.memory` parameter in Kubernetes.

    Default: `32Mi`

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.letsencryptStaging**
  object

  Settings for the `letsencrypt-staging` ClusterIssuer.

  - **settings.letsencryptStaging.resources**
    object

    Resource requests and limits (CPU and memory) for pods that create the `letsencrypt-staging` ClusterIssuer for http01 challenges.

    Example:

    ```
    resources:
      requests:
        cpu: 100m
        memory: 128Mi
      limits:
        cpu: 250m
        memory: 256Mi
    ```

    - **settings.letsencryptStaging.resources.limits**
      object
      - **settings.letsencryptStaging.resources.limits.cpu**
        string

        Required value

        The same as in the pods' `spec.containers.resources.limits.cpu` parameter in Kubernetes.

Default: `50m`

Pattern: `^[0-9]+m?$`

- **settings.letsencryptStaging.resources.limits.memory**
  string or number

  Required value

  The same as in the pods' `spec.containers.resources.limits.memory` parameter in Kubernetes.

  Default: `64Mi`

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.letsencryptStaging.resources.requests**
  object
  - **settings.letsencryptStaging.resources.requests.cpu**
    string

    Required value

    The same as in the pods' `spec.containers.resources.requests.cpu` parameter in Kubernetes.

    Default: `10m`

    Pattern: `^[0-9]+m?$`

  - **settings.letsencryptStaging.resources.requests.memory**
    string or number

    Required value

    The same as in the pods' `spec.containers.resources.requests.memory` parameter in Kubernetes.

    Default: `32Mi`

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.maxConcurrentChallenges**
  integer

  The maximum number of challenges that can be scheduled as 'processing' at once. (default 60)

  Allowed values: `0 <= X`

  Example:

  ```
  maxConcurrentChallenges: 25
  ```

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    has-gpu: 'true'
  ```

- **settings.recursiveSettings**
  object

  Parameters for using recursive DNS servers, which are used to check the existence of a DNS record, before initiating the domain ownership verification process using the ACME DNS-01 method.

  Example:

  ```
  recursiveSettings:
    nameservers:
    - 8.8.8.8:53
    - https://1.1.1.1
    useOnlyRecursive: true
  ```

  - **settings.recursiveSettings.nameservers**
    array of strings

List of recursive DNS servers (IP:port or HTTPS URLs).

- **Element of the array**
  string

  Pattern: `^(?:[0-9]{1,3}(?:\.[0-9]{1,3}){3}:\d{1,5}|https?://[^\s]+)$`

- **settings.recursiveSettings.useOnlyRecursive**
  boolean

  When set to true, only the specified recursive DNS servers will be used to check for the existence of a record in the DNS before starting the domain ownership verification process.

  Default: `false`

- **settings.route53AccessKeyID**
  string

  The Access Key ID of the user with the attached Amazon Route53 IAM Policy for managing domain records.

  Example:

  ```
  route53AccessKeyID: key_id
  ```

- **settings.route53SecretAccessKey**
  string

  The Secret Access Key of the user with privileges to manage domain records.

  Example:

  ```
  route53SecretAccessKey: secret
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: dedicated.deckhouse.io
    operator: Equal
    value: cert-manager
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

- **settings.yandexFolderID**
  string

  ID of the Yandex Cloud folder that contains the public DNS zone used for the ACME DNS-01 challenge.

  Must be set together with `yandexServiceAccountJSON`.

  Example:

  ```
  yandexFolderID: b1gabcdefghijklmnopq
  ```

- **settings.yandexServiceAccountJSON**
  string

  Base64-encoded authorized key JSON for a Yandex Cloud service account with the `dns.editor` role (or equivalent) on the folder with the DNS zone.

  Must be set together with `yandexFolderID`. Details are available in Issuing a DNS wildcard certificate using Yandex Cloud DNS.

  Example:

```
yandexServiceAccountJSON: eyJpZCI6ImFqZSIsInNlcnZpY2VfYWNjb3VudF9pZCI6ImFqZSJ9
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

The module uses the standard cert-manager Custom Resource called Certificate to request certificates.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Usage

> The module lifecycle stage: General Availability

An example of provisioning a certificate

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: example-com                     # the name of the certificate; you can use it to view
the cert's status
  namespace: default
spec:
  secretName: example-com-tls             # the name of the secret to store a private key and
a certificate
  issuerRef:
    kind: ClusterIssuer                  # the link to the certificate "issuer", see more
below
    name: letsencrypt
  commonName: example.com                 # the main certificate domain
  dnsNames:                              # additional domains (At least one DNS Name or IP
address is required)
  - www.example.com
  - admin.example.com
```

Here:

- a separate Ingress resource is created for the duration of the challenge (thus, authentication and whitelist of the primary Ingress will not interfere with the process),
- you can issue a single certificate for several Ingress resources (the deletion of the resource based on the `tls-acme` annotation won't affect it in any way),
- you can issue a certificate with multiple DNS names (as in the example above),
- you can validate different domains that are part of the same certificate using different Ingress controllers.

Read more in the cert-manager documentation.

Issuing a DNS wildcard certificate using Cloudflare

1. Get the `Global API Key` and `Email Address`:

- Go to https://dash.cloudflare.com/profile.
- You can find an active `Email Address` at the very top of the page.
- Click the `View` button at the bottom of the page next to the `Global API Key`.

You will see the key for interacting with the Cloudflare API (as well as the account email).

2. Edit the cert-manager module configuration and add the following parameters:

```
settings:
  cloudflareGlobalAPIKey: APIkey
  cloudflareEmail: some@mail.somedomain
```

or

```
settings:
  cloudflareAPIToken: some-token
  cloudflareEmail: some@mail.somedomain
```

After that, Deckhouse will automatically create ClusterIssuer and Secret for Cloudflare in the `d8-cert-manager` namespace.

- Configuration with APIToken is more secure and recommended for use.

3. Create a Certificate with validation via Cloudflare. Note that you must specify `cloudflareGlobalAPIKey` and `cloudflareEmail` in Deckhouse beforehand:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: domain-wildcard
  namespace: app-namespace
spec:
  secretName: tls-wildcard
  issuerRef:
    name: cloudflare
    kind: ClusterIssuer
  commonName: "*.domain.com"
  dnsNames:
  - "*.domain.com"
```

4. Create an Ingress:

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: domain-wildcard
  namespace: app-namespace
spec:
  ingressClassName: nginx
  rules:
  - host: "*.domain.com"
    http:
      paths:
      - backend:
          service:
            name: svc-web
            port:
              number: 80
        path: /
  tls:
  - hosts:
    - "*.domain.com"
    secretName: tls-wildcard
```

Issuing a DNS wildcard certificate using Route53

1. Create a user with the appropriate permissions.

- For this, go to the policy management page and create a policy as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "route53:GetChange",
            "Resource": "arn:aws:route53:::change/*"
        },
        {
            "Effect": "Allow",
            "Action": "route53:ChangeResourceRecordSets",
            "Resource": "arn:aws:route53:::hostedzone/*"
        },
        {
            "Effect": "Allow",
            "Action": "route53:ListHostedZonesByName",
            "Resource": "*"
        }
    ]
}
```

- Go to the user management page and create a user with the above policy.

2. Edit the cert-manager module configuration and add the following parameters:

```
settings:
  route53AccessKeyID: <ACCESS_KEY_ID>
  route53SecretAccessKey: <SECRET_ACCESS_KEY>
```

After that, Deckhouse will automatically create ClusterIssuer and Secret for route53 in the `d8-cert-manager` namespace.

3. Create a Certificate with validation via route53. Note that you must specify `route53AccessKeyID` and `route53SecretAccessKey` in Deckhouse beforehand:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: domain-wildcard
  namespace: app-namespace
spec:
  secretName: tls-wildcard
  issuerRef:
    name: route53
    kind: ClusterIssuer
  commonName: "*.domain.com"
  dnsNames:
  - "*.domain.com"
```

Issuing a DNS wildcard certificate using Google

1. Create a service account with the appropriate role:
   - Go to the policy management page.
   - Select your project.
   - Create a service account with the desired name (e.g., `dns01-solver`).
   - Switch to the service account created.
   - Add a key by clicking the “Add key” button.
   - The `.json` file with the key data will be saved to your computer.
   - Encode the resulting file using the **base64** algorithm:

     ```
     base64 project-209317-556c656b81c4.json
     ```

2. Use the resulting **base-64** string for setting the `cloudDNSServiceAccount` module parameter.

   After that, Deckhouse will automatically create ClusterIssuer and Secret for cloudDNS in the `d8-cert-manager` namespace.

3. Create a Certificate with validation via cloudDNS:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: domain-wildcard
  namespace: app-namespace
spec:
  secretName: tls-wildcard
  issuerRef:
    name: clouddns
    kind: ClusterIssuer
  dnsNames:
  - "*.domain.com"
```

Issuing a DNS wildcard certificate using Yandex Cloud DNS

To issue a wildcard certificate with DNS-01 validation in Yandex Cloud DNS, configure the module parameters and create a Certificate that references the `yandex` ClusterIssuer.

⚠ If you previously installed the upstream `cert-manager-webhook-yandex` Helm chart manually, uninstall that chart and delete the cluster-scoped APIService `v1alpha1.acme.cloud.yandex.com` before enabling the module settings below. The built-in webhook registers the same APIService name; leaving the manual install in place can break the whole `cert-manager` release or silently break renewals for an existing custom ClusterIssuer.

i The built-in `yandex` ClusterIssuer uses the production Let's Encrypt directory (same as Cloudflare, Route53, and CloudDNS issuers in this module). Confirm that the folder ID, service account role (`dns.editor`), and public DNS zone are correct before creating Certificates, so failed retries do not consume production rate limits. To validate the setup against staging first, create a temporary ClusterIssuer that points at `https://acme-staging-v02.api.letsencrypt.org/directory` and reuses the same webhook solver config.

1. Create a service account in Yandex Cloud and assign the `dns.editor` role (or equivalent) on the folder that contains the public DNS zone.
2. Create an authorized key for the service account and encode the resulting JSON file with **Base64**:

   ```
   base64 authorized_key.json
   ```

3. Set the module parameters:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: cert-manager
   spec:
     version: 1
     enabled: true
     settings:
       yandexFolderID: <FOLDER_ID>
       yandexServiceAccountJSON: <AUTHORIZED_KEY_JSON_BASE64>
   ```

   After that, Deckhouse Kubernetes Platform automatically deploys the Yandex Cloud DNS ACME webhook and creates a ClusterIssuer and Secret for Yandex in the `d8-cert-manager` namespace.

   Where:

   - `<FOLDER_ID>`: ID of the Yandex Cloud folder that contains the public DNS zone
   - `<AUTHORIZED_KEY_JSON_BASE64>`: Contents of `authorized_key.json` encoded in Base64

4. Create a Certificate with validation via Yandex Cloud DNS:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: domain-wildcard
  namespace: app-namespace
spec:
  secretName: tls-wildcard
  issuerRef:
    name: yandex
    kind: ClusterIssuer
  dnsNames:
  - "*.domain.com"
```

Issuing a self-signed certificate

In this case, the entire process is even more straightforward than that of LetsEncrypt. Simply replace the issuer name (`letsencrypt`) with `selfsigned`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: example-com                     # Name of the certificate; you can use it to view the
cert's status.
  namespace: default
spec:
  secretName: example-com-tls             # Name of the secret to store a private key and a
certificate.
  issuerRef:
    kind: ClusterIssuer                  # Link to the ClusterIssuer.
    name: selfsigned
  commonName: example.com                 # Main certificate domain.
  dnsNames:                             # Additional domain certificates. Requires at least a
duplicate commonName record.
  - www.example.com
  - admin.example.com
```

> An example of creating a self-signed certificate manually, without using the `cert-manager`, is available in FAQ.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

What types of certificates are supported?

The module installs the following ClusterIssuers:

- `letsencrypt`
- `letsencrypt-staging`
- `selfsigned`
- `selfsigned-no-trust`

If you need support for other types of certificates, you can add them yourself.

How to add an additional `ClusterIssuer`?

When is an additional `ClusterIssuer` required?

The standard delivery set includes `ClusterIssuer` that issues certificates from the trusted public certificate authority Let's Encrypt or issues self-signed certificates.

To issue certificates for a domain name via Let's Encrypt, the service requires that you verify domain ownership. The `cert-manager` supports several methods for verifying domain ownership when using `ACME` (Automated Certificate Management Environment):

- `HTTP-01` - when using this method `cert-manager` will create a temporary Pod in the cluster that will listen on a specific URL to verify domain ownership. For it to work, you must be able to direct external traffic to this Pod, usually via `Ingress`.
- `DNS-01` - when using this method `cert-manager` makes a TXT record in DNS to verify domain ownership. The `cert-manager` has built-in support for popular DNS providers: AWS Route53, Google Cloud DNS, Cloudflare, and others.

✖ The `HTTP-01` method does not support issuing wildcard certificates.

The `ClusterIssuers` in standard delivery set that issue certificates via Let's Encrypt are divided into two types:

1. `ClusterIssuer` specific to the cloud provider being used.

   Added automatically when filling in the module settings associated with the cloud provider.
   These `ClusterIssuers` support the `DNS-01` method.

   - `clouddns`
   - `cloudflare`
   - `digitalocean`
   - `route53`

2. `ClusterIssuers` using the `HTTP-01` method.

   Added automatically unless their creation is disabled in the module settings.

   - `letsencrypt`
   - `letsencrypt-staging`

In this way, an additional `ClusterIssuer` may be required in the following cases:

1. Certificates need to be issued in a CA other than Let's Encrypt (including a private one). Supported CAs are available in the `cert-manager` documentation
2. Certificates need to be issued via Let's Encrypt using the `DNS-01` method via a third-party provider.

How to add an additional `ClusterIssuer` using Let's Encrypt and `DNS-01` verification method?

To verify domain ownership via Let's Encrypt using the `DNS-01` method, you need to configure the ability to create TXT records in a public DNS.

`cert-manager` has support for mechanisms for creating TXT records in some popular DNS: `AzureDNS`, `Cloudflare`, `Google Cloud DNS`, etc.
The full list is available in the `cert-manager` documentation.

The module automatically creates `ClusterIssuer` of supported cloud providers when filling in the module settings related to the cloud used.
If necessary, you can create such `ClusterIssuer` yourself.

An example of using AWS Route53 is available in the section How to protect `cert-manager` credentials.
The list of all possible `ClusterIssuer`s that can be created is available in the module templates.

Built-in providers configured via module settings: Cloudflare, Amazon Route53, DigitalOcean, Google Cloud DNS, and Yandex Cloud DNS. For Yandex Cloud DNS, follow the steps in Issuing a DNS wildcard certificate using Yandex Cloud DNS.

Using other third-party DNS providers is implemented via the `webhook` method.

When cert-manager makes an `ACME` `DNS-01` call, it sends a request to the webhook server, which then performs the necessary operations to update the DNS record.
When using this method, you need to place a service that will process the hook and create a TXT record in the DNS provider, then create a `ClusterIssuer` with `dns01.webhook` solver settings according to the webhook documentation.

How to add an additional `Issuer` and `ClusterIssuer` using HashiCorp Vault to issue certificates?

You can use this manual for configuring certificate issuance using Vault.

After configuring PKI and enabling Kubernetes authorization, follow these steps:

- Create a `ServiceAccount`:

  ```
  d8 k create serviceaccount issuer
  ```

- Create a `Secret` with a token for this service account. Starting with Kubernetes 1.24, the secret for a `ServiceAccount` is not created automatically:

```
d8 k apply -f - <<EOF
apiVersion: v1
kind: Secret
metadata:
  name: issuer
  annotations:
    kubernetes.io/service-account.name: issuer
type: kubernetes.io/service-account-token
EOF
```

- Create an Issuer:

```
d8 k apply -f - <<EOF
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: vault-issuer
  namespace: default
spec:
  vault:
    # HashiCorp instruction has mistype here
    server: http://vault.default.svc.cluster.local:8200
    path: pki/sign/example-dot-com # configure in pki setup step
    auth:
      kubernetes:
        mountPath: /v1/auth/kubernetes
        role: issuer
        secretRef:
          name: issuer
          key: token
EOF
```

- Create a Certificate resource, to get a TLS certificate, which is issued by Vault CA:

```
d8 k apply -f - <<EOF
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: example-com
  namespace: default
spec:
  secretName: example-com-tls
  issuerRef:
    name: vault-issuer
  # domains are set on PKI setup
  commonName: www.example.com
  dnsNames:
  - www.example.com
EOF
```

How to add `ClusterIssuer` using its own or intermediate CA to to issue certificates?

Follow the steps below to use a custom or interim CA:

- Generate a certificate (if necessary):

```
openssl ecparam -name prime256v1 -genkey -out rootCAKey.pem
openssl req -x509 -sha256 -new -nodes -key rootCAKey.pem -days 3650 -out rootCACert.pem
```

- In the `d8-cert-manager` namespace, create a secret containing certificate file data.

  An example of creating a secret with d8 k:

```
d8 k create secret tls internal-ca-key-pair -n d8-cert-manager --key="rootCAKey.pem" --
cert="rootCACert.pem"
```

An example of creating a secret from a YAML file (the contents of the certificate files must be Base64-encoded):

```
apiVersion: v1
data:
  tls.crt: <OUTPUT OF `cat rootCACert.pem | base64 -w0`>
  tls.key: <OUTPUT OF `cat rootCAKey.pem | base64 -w0`>
kind: Secret
metadata:
  name: internal-ca-key-pair
  namespace: d8-cert-manager
type: Opaque
```

You can use any name you like for the secret.

- Create a `ClusterIssuer` using the secret you created earlier:

```
apiVersion: cert-manager.io/v1
kind: ClusterIssuer
metadata:
  name: inter-ca
spec:
  ca:
    secretName: internal-ca-key-pair   # Name of the secret you created earlier.
```

You can use any name as your `ClusterIssuer` name.

You can now use the created `ClusterIssuer` to issue certificates for all Deckhouse components or a particular component.

For example, to issue certificates for all Deckhouse components, specify the `ClusterIssuer` name in the ClusterIssuerName global parameter (`d8 k edit mc global`):

```
spec:
  settings:
    modules:
      https:
        certManager:
          clusterIssuerName: inter-ca
        mode: CertManager
      publicDomainTemplate: '%s.<public_domain_template>'
  version: 1
```

How does cert-manager work behind a proxy server?

`cert-manager` uses the cluster-wide proxy server set in the proxy parameter of the ClusterConfiguration resource. The proxy settings are passed to the `cert-manager` controller and to the Yandex Cloud DNS webhook. Requests to the ACME server, to HashiCorp Vault and to the HTTP APIs of DNS providers go through the proxy server.

The following requests go directly:

- requests to the cluster domain, to the pod and service subnets;
- requests of the controller to service names in the `<SERVICE>.<NAMESPACE>.svc` form;
- requests to the addresses listed in `noProxy`.

Node addresses and short service names, such as `<SERVICE>.<NAMESPACE>`, are not on this list. To reach an issuer inside the cluster directly, address it by the full `<SERVICE>.<NAMESPACE>.svc` name. To reach an issuer in the internal network directly, add its address to `noProxy`. Keep in mind that `noProxy` also applies to the other cluster components and to the nodes.

Before the `DNS-01` verification, the controller checks the TXT record over the DNS protocol, which a proxy server does not carry. If the cluster has no direct access to external DNS servers, set DNS over HTTPS in the recursiveSettings parameter:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cert-manager
spec:
  version: 1
  settings:
    recursiveSettings:
      nameservers: ["https://1.1.1.1/dns-query"]
      useOnlyRecursive: true
```

With `useOnlyRecursive: true`, the controller sends the checks only to the listed servers, and DNS over HTTPS requests go through the proxy server. A DNS server of the internal network that resolves external names works as well: specify it in the `IP:port` form.

Before the `HTTP-01` verification, the controller also requests the verification URL of the domain through the proxy server. If the proxy server cannot reach the public address of the cluster, add the domain to `noProxy`.

How to secure `cert-manager` credentials?

If you don’t want to store credentials in the Deckhouse configuration (security reasons, for example), feel free to create your own ClusterIssuer / Issuer. For example, you can create your own `ClusterIssuer` for a route53 service in this way:

- Create a Secret with credentials:

  ```
  d8 k apply -f - <<EOF
  apiVersion: v1
  kind: Secret
  type: Opaque
  metadata:
    name: route53
    namespace: default
  data:
    secret-access-key: MY-AWS-ACCESS-KEY-TOKEN
  EOF
  ```

- Create a simple `ClusterIssuer` with reference to that secret:

  ```
  d8 k apply -f - <<EOF
  apiVersion: cert-manager.io/v1
  kind: ClusterIssuer
  metadata:
    name: route53
    namespace: default
  spec:
    acme:
      server: https://acme-v02.api.letsencrypt.org/directory
      privateKeySecretRef:
        name: route53-tls-key
      solvers:
      - dns01:
          route53:
            region: us-east-1
            accessKeyID: MY-AWS-ACCESS-KEY-ID
            secretAccessKeySecretRef:
              name: route53
              key: secret-access-key
  EOF
  ```

- Order certificates as usual, using created `ClusterIssuer`:

```
d8 k apply -f - <<EOF
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: example-com
  namespace: default
spec:
  secretName: example-com-tls
  issuerRef:
    name: route53
  commonName: www.example.com
  dnsNames:
  - www.example.com
EOF
```

Does the tls-acme annotation work?

Yes, it works! The dedicated component (`cert-manager-ingress-shim`) automatically creates `Certificate` resources based on these annotations (in the same namespaces as those of Ingress resources with annotations).

i The Certificate for a particular annotation is linked to the existing Ingress resource. The additional records are put into the existing Ingress resource instead of creating a separate one. Thus, the process will fail if authentication or whitelist is set for the primary Ingress. In this case, you shouldn’t use the annotation; use the Certificate instead.

⚠ If you switched to the Certificate instead of annotation, delete the annotation-based Certificate. Otherwise, the same Secret will be updated for both Certificates, and this may lead to exceeding the Let’s Encrypt limits.

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  annotations:
    kubernetes.io/tls-acme: "true"         # The annotation.
  name: example-com
  namespace: default
spec:
  ingressClassName: nginx
  rules:
  - host: example.com
    http:
      paths:
      - backend:
          service:
            name: site
            port:
              number: 80
        path: /
        pathType: ImplementationSpecific
  - host: www.example.com                # The additional domain
    http:
      paths:
      - backend:
          service:
            name: site
            port:
              number: 80
        path: /
        pathType: ImplementationSpecific
  - host: admin.example.com               # Another additional domain
    http:
      paths:
      - backend:
          service:
            name: site
            port:
              number: 80
        path: /
        pathType: ImplementationSpecific
  tls:
  - hosts:
    - example.com
    - www.example.com                   # The additional domain
    - admin.example.com                  # Another additional domain
    secretName: example-com-tls           # The name of the certificate and secret
```

How do I check the certificate status?

```
d8 k -n default describe certificate example-com
...
Status:
  Acme:

```

How do I get a list of certificates?

```
d8 k get certificate --all-namespaces
NAMESPACE          NAME                         AGE
default            example-com                  13m
```

The “CAA record does not match issuer” error

Suppose `cert-manager` gets the following error when trying to provide a certificate:

```
CAA record does not match issuer
```

In this case, you have to check the `CAA (Certificate Authority Authorization)` DNS record of the domain for which the certificate is intended. For Let’s Encrypt certificates, the domain must have the `issue "letsencrypt.org"` CAA record. You can read more about CAA in the Let’s Encrypt documentation.

What to do if the HTTP-01 self-check never completes?

Before cert-manager asks Let’s Encrypt to validate an `HTTP-01` Challenge, it requests the challenge URL of the domain from inside the cluster. If the cluster cannot reach its own public address, this self-check never succeeds, and the Challenge stays pending, although Let’s Encrypt could validate it. It happens, for example, behind NAT without hairpinning (when you cannot access your external IP address from inside the cluster) or with split-horizon DNS (when the same domain resolves to different IP addresses depending on where the DNS request originated: from inside the cluster or from outside).

The Challenge then reports the self-check error. To see it, run the following command:

```
d8 k -n <NAMESPACE> describe challenges.acme.cert-manager.io
```

To skip the self-check for the `letsencrypt` and `letsencrypt-staging` ClusterIssuers, set the

`http01WaitInsteadOfSelfCheck` parameter. The following ModuleConfig makes cert-manager wait 30 seconds instead of the self-check:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cert-manager
spec:
  version: 1
  settings:
    http01WaitInsteadOfSelfCheck: 30s
```

After the ClusterIssuers are updated, a new Challenge no longer waits for the successful self-check. cert-manager asks Let's Encrypt to validate it 30 seconds after the challenge is presented.

Use the parameter only when the domain is reachable from the internet. Otherwise every validation attempt fails on the side of Let's Encrypt and counts against its rate limits.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The chrony module

> **i** The module lifecycle stage: General Availability

Provides time synchronization on all cluster nodes using the chrony utility.

How it works

The module starts `chrony` agents on all cluster nodes.

By default, the NTP server `pool.ntp.org` is used. The NTP server can be changed via the settings module.

To view the NTP servers used, you can use the command:

```
d8 k exec -it -n d8-chrony ds/chrony-master -- chronyc -N sources
```

Ouput example:

```
MS Name/IP address         Stratum Poll Reach LastRx Last sample
===============================================================================
^* pool.ntp.org.                 2  10   377   171   -502us[ -909us] +/- 5388us
^- pool.ntp.org.                 2  10   377   666  -5317us[-5698us] +/-  103ms
^+ pool.ntp.org.                 2  10   377   938   -201us[ -567us] +/- 5346us
^+ pool.ntp.org.                 2  10   377   843   -159us[ -530us] +/-   12ms
```

> **i** `^+` - combined NTP server (`chrony` combines information from `combined` servers to reduce inaccuracies);
> `^*` - current NTP server;
> `^-` - non-combinable NTP server.
> Extra flag `-v` adds information about meanings of the columns: `chronyc sources -v`.

`chrony` agents on master nodes and on other nodes have one main difference - on all nodes that are not masters, the list of NTP servers contains not only NTP servers from `module config`, but also the addresses of all master nodes of the cluster.

Thus, agents on master nodes synchronize time only from the list of hosts specified in `module config` (by default from `pool.ntp.org`). And agents on other nodes synchronize time with the list of NTP servers from `module config` plus with `chrony` agents on master nodes.

This is done so that in case of unavailability of NTP servers specified in `module config`, the time is synchronized with the master nodes.

Boot-time synchronization on master nodes

On master nodes, the module also sets the clock once during boot, before `kubelet` starts. This keeps control plane static Pods from starting with a wrong time taken from the real-time clock (RTC) or the hypervisor.

If most of the NTP servers that respond agree on the time within 1 second, `kubelet` starts right after the clock is set. If no NTP server responds, or the servers that respond disagree, `kubelet` starts with an unverified clock after up to 30 seconds. On nodes managed by bashible, the limit can be raised to 60 seconds using `earlyTimeSync.timeoutSeconds`. On nodes managed by bashible, the time spent waiting for the node network is not included. On these nodes, systemd waits for `nodelet.service` to report readiness after the check. The check runs in the main nodelet process. On Deckhouse Engine nodes, the wait starts when nodelet starts and can include the wait for the node network. Boot-time synchronization can be turned off with the `earlyTimeSync.enabled` parameter.

Boot-time synchronization uses the node network and the node DNS settings. Kubernetes DNS and NTP servers running inside the cluster are not available at this point.

If a master node with boot-time synchronization configured cannot reach the NTP servers, the check delays `kubelet` up to its limit. The alert fires once monitoring collects the failed check. This applies to an air-gapped cluster that keeps the default `pool.ntp.org` server. In that case, set `ntpServers` to NTP servers that the master nodes can reach, or disable boot-time synchronization.

Enabling boot-time synchronization or changing its parameters takes effect on the next boot. The clock on a running node is not changed immediately, because stepping it back on a live control plane can disrupt authentication and leader election. Disabling boot-time synchronization with `earlyTimeSync.enabled: false` takes effect as soon as the configuration is applied on the master nodes.

If the clock was not synchronized during boot, the `NodeTimeNotSynchronizedAtBoot` alert fires for the master node. The alert stays active until one of the following happens:

- The node boots again and the synchronization succeeds.
- Boot-time synchronization is disabled. On Deckhouse Engine nodes, the alert then clears on the next boot.
- You clear the alert as described in the alert description.

The alert works only when the `monitoring-kubernetes` module is enabled, because that module collects the result from the node.

Limitations

Boot-time synchronization has the following limitations:

- On Deckhouse Engine nodes, `earlyTimeSync.timeoutSeconds` does not apply: `kubelet` waits for 30 seconds at most. Only the first 16 host names and IPv4 addresses of `ntpServers` are used there. When a master node boots into a new OS image, this wait counts toward the 15 minutes the node has to confirm the image. If the NTP servers are unreachable, set reachable servers in `ntpServers` or disable boot-time synchronization.
- Values of `ntpServers` other than a host name or an IPv4 address, such as an IPv6 address or a value with a port, are skipped.
- It does not cover the first boot of a new master node, including the cluster bootstrap. The configuration reaches the node during that boot, after `kubelet` has already started.
- On nodes managed by bashible, disabling the module leaves the boot-time synchronization files on the nodes. Deckhouse Engine nodes stop the synchronization on their own from the next boot. Before disabling the module, set `earlyTimeSync.enabled` to `false` and wait until the configuration is applied on the master nodes. If the module is already disabled, remove the files with a NodeGroupConfiguration as shown in the FAQ.

Third-party components

List of third-party software used in the `chrony` module:

- Chrony

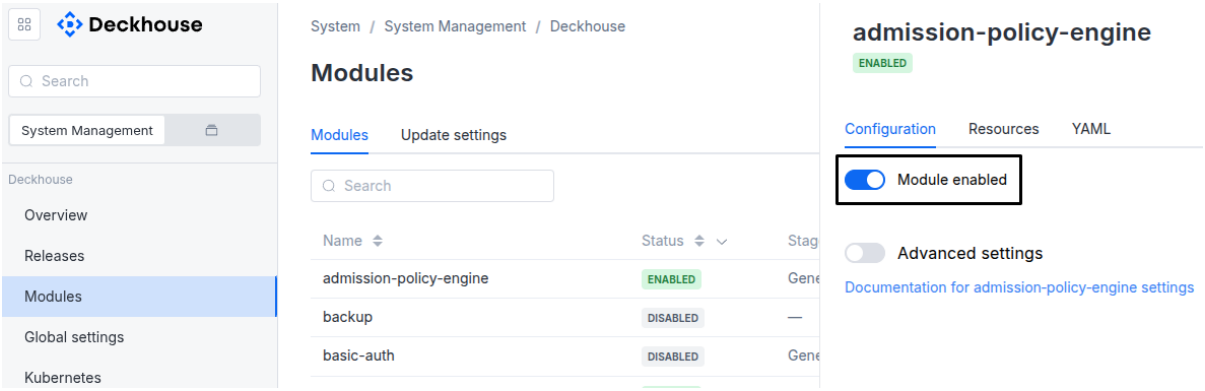
  License: GNU General Public License version 2

  chrony is a versatile implementation of the Network Time Protocol (NTP)

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> **i** The module lifecycle stage: General Availability



The module has 3 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `chrony` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

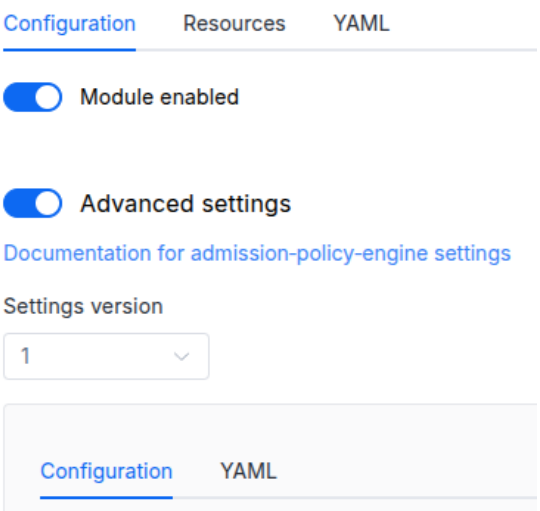
```
d8 system module enable chrony
```

- **Using ModuleConfig `chrony`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `chrony` (create it if necessary);

  Example of a manifest to enable module `chrony`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: chrony
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `chrony` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `chrony` on the “YAML” tab in the module settings window

("System" → "System Management" → "Deckhouse" → "Modules", open the module `chrony`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `chrony` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc chrony
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `chrony` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `chrony`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: chrony
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.earlyTimeSync**
    object

    Time synchronization on master nodes during boot, before kubelet starts.

    It prevents control plane static Pods from starting with an incorrect time received from the real-time clock (RTC) or the hypervisor. Enabling and changing the settings take effect on the next boot of the node. Disabling takes effect as soon as the configuration is applied.

    - **settings.earlyTimeSync.enabled**
      boolean

      Enables boot-time synchronization, before kubelet starts.

      Default: `true`

    - **settings.earlyTimeSync.timeoutSeconds**
      integer

      Maximum time to wait for synchronization before kubelet starts, in seconds.

      On nodes managed by bashible, the wait starts once the node network is available. If within this time no NTP server responds, or the servers that respond disagree, kubelet starts with an unverified clock. On Deckhouse Engine nodes, the parameter does not apply: the wait is at most 30 seconds.

      If a master node already configured for boot-time synchronization cannot reach the NTP servers, for example in an air-gapped cluster with the default `pool.ntp.org`, the check waits for the full time. Set reachable servers in ntpServers or disable boot-time synchronization.

      Default: `30`

      Allowed values: `30 <= X <= 60`

  - **settings.ntpServers**
    array of strings

    NTP servers used for time synchronization.

Each server is specified as a host name or an IPv4 address, without a port.

On master nodes, these servers are also used for boot-time synchronization, before kubelet starts. On Deckhouse Engine nodes, boot-time synchronization uses the first 16 of them. Boot-time synchronization is configured by earlyTimeSync. An empty list disables boot-time synchronization.

Default: `["pool.ntp.org"]`

Examples:

```
ntpServers:
- pool.ntp.org
```

```
ntpServers:
- pool.ntp.org
- ntp.ubuntu.com
- time.google.com
```

An example of the configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: chrony
spec:
  enabled: true
  settings:
    ntpServers:
      - pool.ntp.org
      - ntp.ubuntu.com
      - time.google.com
  version: 1
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

How do I disable chrony and use NTP daemon on nodes?

1. Disable usage of chrony module.
2. Create `NodeGroupConfiguration` custom step to enable use NTP daemon on nodes (example for `systemd-timesyncd`):

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: enable-ntp-on-node.sh
spec:
  weight: 100
  nodeGroups: ["*"]
  bundles: ["*"]
  content: |
    if [ -f /etc/systemd/system/kubelet.service.d/20-d8-early-time-sync.conf ] || [ -f
/etc/systemd/system/nodelet.service.d/20-d8-early-time-sync.conf ]; then
      rm -f /etc/systemd/system/kubelet.service.d/20-d8-early-time-sync.conf
      rm -f /etc/systemd/system/nodelet.service.d/20-d8-early-time-sync.conf
      systemctl daemon-reload
    fi
    rm -f /var/run/node-exporter-textfile/d8_early_time_sync.prom
    systemctl enable systemd-timesyncd
    systemctl start systemd-timesyncd
```

The script removes the boot-time synchronization drop-ins and metric file that remain after disabling the module.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The cilium-hubble module

The module lifecycle stage: General Availability

The module has requirements for installation

Web interfaces associated with the module: hubble

The `cilium-hubble` module provides visualization of the cluster network stack if the cilium CNI is enabled.

Requirements

The following is required for the `cilium-hubble` module:

- Linux kernel version >= 5.8 with eBPF support.
- BPF Type Format (BTF) support enabled. You can verify it as follows:
  - Run `ls -lah /sys/kernel/btf/vmlinux` — if the file exists, BTF is supported.
  - Run `grep -E "CONFIG_DEBUG_INFO_BTF=(y|m)" /boot/config-*` — if the parameter is enabled, BTF is supported.

Third-party components

List of third-party software used in the `cilium-hubble` module:

- Hubble UI 0.13.5

  License: Apache License 2.0

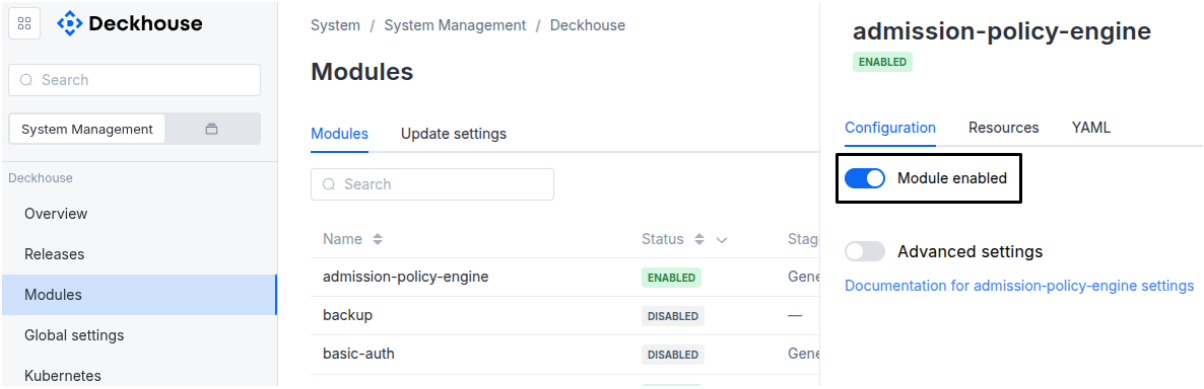
  Hubble UI is an open-source user interface for Cilium Hubble.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> **i** The module lifecycle stage: General Availability
>
> The module has requirements for installation



The module is not enabled by default in any bundles.

If the `cni-cilium` module is disabled, the `ciliumHubbleEnabled:` parameter will not affect the enabling of the `cilium-hubble` module.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cilium-hubble` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

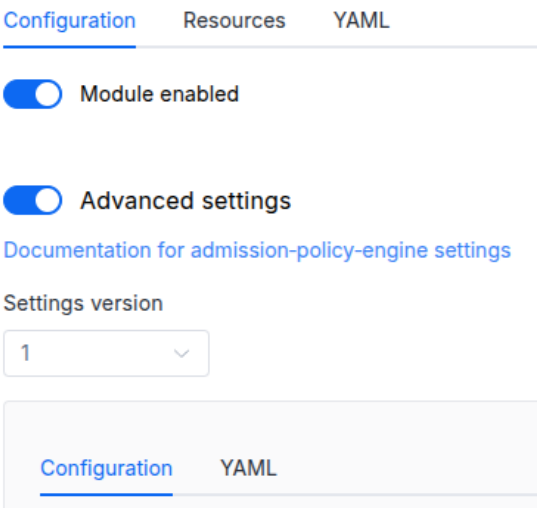
```
d8 system module enable cilium-hubble
```

- **Using ModuleConfig `cilium-hubble`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cilium-hubble` (create it if necessary);

  Example of a manifest to enable module `cilium-hubble`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cilium-hubble
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cilium-hubble` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cilium-hubble` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cilium-hubble`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cilium-hubble` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cilium-hubble
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cilium-hubble` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cilium-hubble`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cilium-hubble
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `cni-cilium`: any version.

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Conversion description is missing.

  Actions performed by the conversion (jq syntax)...

  - `del(.auth.password) | if .auth == {} then del(.auth) end`

Parameters

Schema version: 2

- **settings**
  object
  - **settings.auth**
    object

    Options related to authentication or authorization in the Hubble web UI.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module's public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

      An array of user groups that can access Hubble web UI.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

      Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

    - **settings.auth.externalAuthentication**
      object

      Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

      > **i** External authentication is enabled automatically if the user-authn module is enabled.

      - **settings.auth.externalAuthentication.authSignInURL**
        string

        The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

        Example:

        ```
        authSignInURL: https://example.com/dex/sign_in
        ```

      - **settings.auth.externalAuthentication.authURL**
        string

        The URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

        Example:

        ```
        authURL: https://example.com/dex/auth
        ```

    - **settings.auth.whitelistSourceRanges**
      array of strings

      An array if CIDRs that are allowed to authenticate in Hubble web UI.

      Example:

      ```
      whitelistSourceRanges:
      - 1.1.1.1/32
      ```

  - **settings.debugLogging**
    boolean

    Enabled debug logging for Cilium Hubble component.

    Default: `false`

  - **settings.https**
    object

    What certificate type to use.

This parameter completely overrides the `global.modules.https` settings.

Examples:

```
https:
  mode: Disabled
```

```
https:
  mode: OnlyInURI
```

```
https:
  mode: CustomCertificate
  customCertificate:
    secretName: foobar
```

```
https:
  mode: CertManager
  certManager:
    clusterIssuerName: letsencrypt
```

- **settings.https.certManager**
  object

  Parameters for certmanager.

  - **settings.https.certManager.clusterIssuerName**
    string

    What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

    Default: `letsencrypt`

    Examples:

    ```
    clusterIssuerName: letsencrypt
    ```

    ```
    clusterIssuerName: letsencrypt-staging
    ```

    ```
    clusterIssuerName: selfsigned
    ```

- **settings.https.customCertificate**
  object

  Parameters for custom certificate usage.

  - **settings.https.customCertificate.secretName**
    string

    The name of the secret in the `d8-system` namespace to use with the Hubble web UI.

    This secret must have the kubernetes.io/tls format.

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager` — the web UI is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter;
  - `CustomCertificate` — the web UI is accessed over HTTPS using a certificate from the `d8-system` namespace;
  - `Disabled` — in this mode, the documentation web UI can only be accessed over HTTP;
  - `OnlyInURI` — the documentation web UI will work over HTTP (thinking that there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

  Default: `CertManager`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for Hubble.

Optional. By default, the `modules.ingressClass` global value is used.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.nodeSelector**
  object

  The same as the `spec.nodeSelector` pod parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.tolerations**
  array of objects

  The same as `spec.tolerations` for the Kubernetes Pod.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

Authentication

user-authn module provides authentication by default. Also, externalAuthentication can be configured. If these options are disabled, the module will use basic auth with the auto-generated password.

To view the generated password, run the command:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values cilium-hubble -o json | jq '.ciliumHubble.internal.auth.password'
```

To generate a new password, delete the Secret:

```
d8 k -n d8-cni-cilium delete secret/hubble-basic-auth
```

> **i** The `auth.password` parameter is deprecated.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — AWS

> **i** The module lifecycle stage: General Availability

The `cloud-provider-aws` module integrates Deckhouse Platform with Amazon AWS. It allows the `node-manager` module to use AWS resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-aws` module:

- Managing AWS resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the AWS side;
  - creates load balancers for Services of the LoadBalancer type;
  - updates cluster node metadata and removes from Kubernetes nodes that no longer exist in AWS.
- Provisioning disks via the EBS CSI driver (`ebs.csi.aws.com`) and creating StorageClasses for AWS volume types so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-aws`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM). Virtual machine parameters are set in the AWSInstanceClass resource.
- Registering with `node-manager` so that AWSInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Third-party components

List of third-party software used in the `cloud-provider-aws` module:

- Amazon Web Services Cloud provider v1.33.4, v1.34.3, v1.35.2, v1.36.0, v1.37.0

  License: Apache License 2.0

  Cloud Controller Manager for Amazon Web Services.

- Amazon Web Services CSI driver v1.54.0, v1.54.0, v1.54.0, v1.54.0, v1.66.0

  License: Apache License 2.0

  CSI driver for Amazon EBS.

- Amazon Web Services Terraform provider 6.69.1

  License: Mozilla Public License 2.0

  Terraform provider for Amazon Web Services.

- Amazon Web Services Node termination handler v1.25.6

  License: Apache License 2.0

  Gracefully handle instance shutdown within Kubernetes for Amazon EC2.

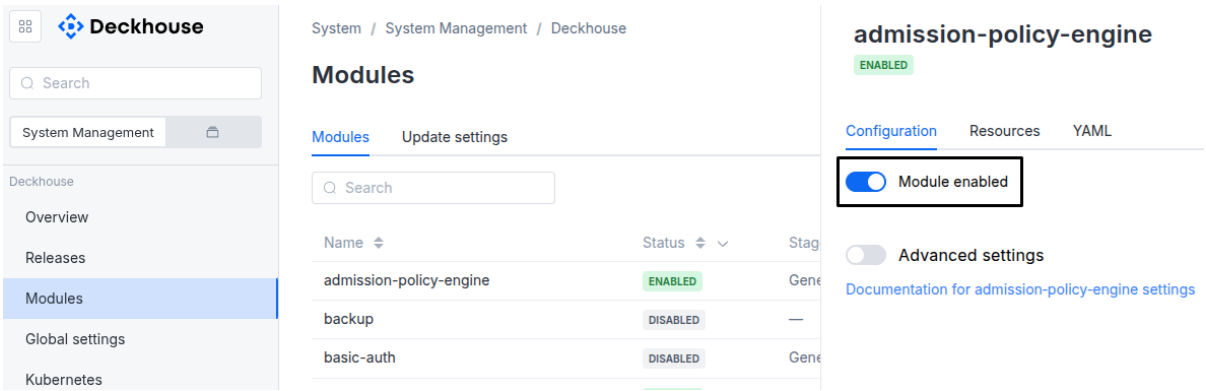
> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability

The module is configured automatically based on the chosen placement strategy (the AWSClusterConfiguration custom resource). In most cases, you do not have to configure the module manually.

You can configure the number and parameters of provisioning machines in the cloud via the `NodeGroup` custom resource of the node-manager module. Also, in this custom resource, you can specify the instance class's name for the above group of nodes (the `cloudInstances.ClassReference` NodeGroup parameter). In the case of the AWS cloud provider, the instance class is the `AWSInstanceClass` custom resource that stores specific parameters of the machines.



The module automatically creates StorageClasses that are available in AWS: `gp3`, `gp2`, `sc1`, and `st1`. It lets you configure disks with the required IOPS. Also, it can filter out the unnecessary StorageClasses (you can do this via the `exclude` parameter).

The module has 1 alert.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `cloud-provider-aws` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

Example of enabling the module:

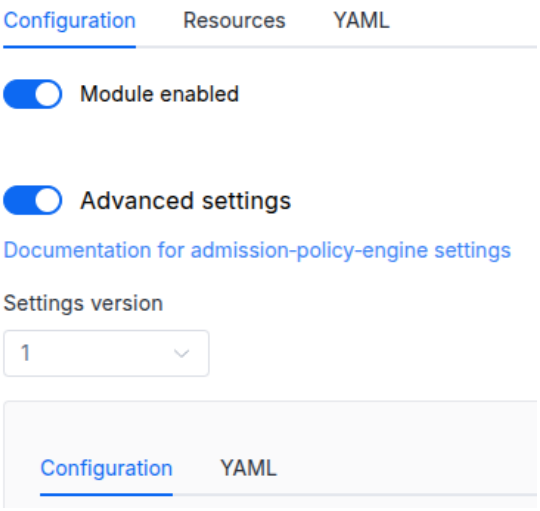
```
d8 system module enable cloud-provider-aws
```

- **Using ModuleConfig `cloud-provider-aws`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-aws` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-aws`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-aws
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-aws` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-aws` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-aws`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-aws` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc cloud-provider-aws
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-aws` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-aws`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-aws
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.storageClass**
    object
    - **settings.storageClass.default**
      Deprecated
      string

      The name of StorageClass that will be used in the cluster by default.

      If the parameter is omitted, the default StorageClass is either:

      - an arbitrary StorageClass present in the cluster that has the default annotation;
      - the first (in lexicographic order) StorageClass created by the module.

      > **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

      Example:

      ```
      default: gp3
      ```

    - **settings.storageClass.exclude**
      array of strings

      A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

      Example:

      ```
      exclude:
      - sc.*
      - st1
      ```

    - **settings.storageClass.provision**
      array of objects

      Defines additional StorageClasses or override the parameters of created by default.

      - **settings.storageClass.provision.iops**
        string

        I/O operations per second for `gp3` volume type:

        - Allowed values: from `3000` to `16000`.
        - If empty, it will set to 3000 as documented here.
        - Changing doesn't apply to existing volumes. You can modify them manually through AWS Console.
      - **settings.storageClass.provision.iopsPerGB**
        string

        The number of I/O operations per second per GB for `io1` and `io2` volume types (this parameter is `3` for `gp2` volumes):

        - **Caution!** If the iopsPerGB value multiplied by the target volume's size is less than 100 or more than 64000, the creation of such a volume will fail.
        - You can find a detailed description of the volume types and their IOPS in the official documentation.
      - **settings.storageClass.provision.name**
        string

Required value

The name of the class to create.

- **settings.storageClass.provision.throughput**
  string

  Throughput in MiB/s for `gp3` volume type:

  - Allowed values: from `125` to `1000`.
  - If empty, it will set to 125 as documented here.
  - Changing doesn't apply to existing volumes. You can modify them manually through AWS Console.
- **settings.storageClass.provision.type**
  string

  Required value

  The volume type.

  Allowed values: `gp3`, `gp2`, `sc1`, `st1`, `io1`, `io2`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> The module lifecycle stage: General Availability

AWSClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in AWS.

Used by the cloud provider if a cluster's control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: AWSClusterConfiguration
layout: WithoutNAT
sshPublicKey: "<SSH_PUBLIC_KEY>"
nodeNetworkCIDR: 172.16.0.0/22
vpcNetworkCIDR: 172.16.0.0/16
masterNodeGroup:
  replicas: 1
  instanceClass:
    instanceType: m5.xlarge
    ami: ami-08b6d44b4f6f7b279
    diskType: gp3

```

- **additionalRolePolicies**
  array of strings

  A list containing additional policy actions for IAM roles.

  - Additional policy actions would be attached to the default IAM role policy actions.
  - Parameter is optional. If omitted, only default IAM role policy actions are used.
  - Example of policy actions: `ecr:ListImages`, `s3:GetObject`, etc.

  Default IAM role policies actions contain the following roles:

  - `ec2:DescribeTags`
  - `ec2:DescribeInstances`
  - **Element of the array**
    string

    Pattern: `^([a-zA-Z0-9_\-]+):([a-zA-Z0-9_\-\*\?]+)$`

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **disableDefaultSecurityGroup**
  boolean

  If set to `true`, the default security group will not be created.

  Warning. When using `disableDefaultSecurityGroup: true`, you must manually create all required security groups to allow access to cluster nodes. Additionally, you must explicitly specify them in the following parameters:

  - `additionalSecurityGroups` in the `masterNodeGroup` section of the `AWSClusterConfiguration` resource
  - `additionalSecurityGroups` in the `AWSInstanceClass` resource
  - `additionalSecurityGroups` in the `nodeGroups.instanceClass` section

  To configure the security groups used by load balancers, specify them using the `service.beta.kubernetes.io/aws-load-balancer-security-groups` annotation.

  For details, see AWS: Layouts.

- **existingVPCID**
  string

ID of the existing VPC to use for deploying.

  - **A mandatory parameter** if the `vpcNetworkCIDR` is omitted.
  - **Caution!** If there is an Internet Gateway in the target VPC, the deployment of the basic infrastructure will fail with an error. Currently, an Internet Gateway cannot be adopted.
- **iamNodeRole**
string

The name of the IAM role that will be attached to all AWS instances of the cluster nodes.

DP always creates and assigns a special IAM role named `<PREFIX>-node` to each AWS instance of the cluster nodes (`<PREFIX>` is the value of the `prefix` parameter in the ModuleConfig `global`). You can specify your IAM-role with greater permissions in the `iamNodeRole` parameter, but it is important that it includes the IAM policies of the role created by DP (the `<PREFIX>-node` role).

More details about IAM roles for AWS EC2 can be found in the AWS documentation.

Pattern: `^[a-zA-Z0-9+=,.@\-_']{1,64}$`

- **imdsv2**
boolean

Enables mandatory use of IMDSv2 and disables IMDSv1 for EC2 instances in the cluster.

Using IMDSv2 is recommended. IMDSv2 requires a session token to access instance metadata, which reduces the risk of unauthorized access, including through SSRF (Server-Side Request Forgery) attacks.

For backward compatibility, the default value of the parameter is `false`. However, if the parameter is not specified in an existing configuration, DP does not change the current instance metadata service settings. Once the parameter is explicitly specified, the IMDS settings are managed by DP:

  - `false` — allows both IMDSv1 and IMDSv2
  - `true` — allows only IMDSv2 and requires a session token to access instance metadata

> **i** **Warning.** When IMDSv2 is enabled, DP sets the IMDS hop limit to `1`. If the AWS account defaults or the AMI provide a higher value, it is lowered to `1` on the next converge. As a result, the instance metadata service is unavailable from pods, even if the applications running in those pods support IMDSv2. This limitation does not affect DP components because they use the host network. Before enabling IMDSv2, make sure that applications requiring access to instance metadata support IMDSv2 and run using the host network.

To apply the change to master, static, and bastion nodes, run `dhctl converge`. CloudEphemeral nodes are recreated automatically.

Default: `false`

- **kind**
string

Required value

Allowed values: `AWSClusterConfiguration`

- **layout**
string

Required value

The way resources are located in the cloud.

Read more about possible provider layouts.

> **i** **Note,** that the `Standard` layout is deprecated.

Allowed values: `WithoutNAT`, `WithNAT`, `Standard`

- **masterNodeGroup**
object

Required value

Parameters of the master's NodeGroup.

> **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.additionalTags**
  object

The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

Example:

```
additionalTags:
  project: cms-production
  severity: critical
```

- **masterNodeGroup.instanceClass**
  object

  Required value

  Partial contents of the fields of the AWSInstanceClass.

  - **masterNodeGroup.instanceClass.additionalSecurityGroups**
    array of strings

    The additional security groups to add to provisioned instances of the specific InstanceClass.

  - **masterNodeGroup.instanceClass.ami**
    string

    Required value

    The Amazon Machine Image (AMI ID) to use in provisioned instances.

    Here is how you can find the required AMI (each region has its own set of AMIs):

    ```
    aws ec2 --region <REGION> describe-images \
    --filters 'Name=name,Values=ubuntu/images/hvm-ssd/ubuntu-bionic-18.04-amd64-server-2020*' | \
    jq '.Images[].ImageId'
    ```

    Example:

    ```
    ami: ami-040a1551f9c9d11ad
    ```

  - **masterNodeGroup.instanceClass.diskSizeGb**
    integer

    Instance disk size in gibibytes.

    Example:

    ```
    diskSizeGb: 50
    ```

  - **masterNodeGroup.instanceClass.diskType**
    string

    Instance EBS disk type.

    Allowed values: `gp3`, `gp2`, `io2`, `io1`, `st1`, `sc1`

    Example:

    ```
    diskType: gp2
    ```

  - **masterNodeGroup.instanceClass.etcdDisk**
    object

    Default: `{"sizeGb":20,"type":"gp3"}`

    - **masterNodeGroup.instanceClass.etcdDisk.sizeGb**
      integer

      Etcd disk size in gibibytes.

    - **masterNodeGroup.instanceClass.etcdDisk.type**
      string

      Etcd disk type.

  - **masterNodeGroup.instanceClass.instanceType**
    string

    Required value

Instance type of AWS instance.

Caution! Ensure that this type is present in all zones specified in the `zones` parameter.

Example:

```
instanceType: t3.large
```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create.

  It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  Not required value.

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.additionalTags**
    object

    The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

    Example:

    ```
    project: cms-production
    severity: critical
    ```

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the AWSInstanceClass.

    - **nodeGroups.instanceClass.additionalSecurityGroups**
      array of strings

      The additional security groups to add to provisioned instances of the specific InstanceClass.

    - **nodeGroups.instanceClass.ami**
      string

      Required value

      The Amazon Machine Image (AMI ID) to use in provisioned instances.

      Here is how you can find the required AMI (each region has its own set of AMIs):

      ```
      aws ec2 --region <REGION> describe-images \
      --filters 'Name=name,Values=ubuntu/images/hvm-ssd/ubuntu-bionic-18.04-amd64-
      server-2020*' | \
      jq '.Images[].ImageId'
      ```

      Example:

      ```
      ami: ami-040a1551f9c9d11ad
      ```

    - **nodeGroups.instanceClass.diskSizeGb**
      integer

      Instance disk size in gibibytes.

Example:

```
diskSizeGb: 50
```

- **nodeGroups.instanceClass.diskType**
  string

  Instance EBS disk type.

  Allowed values: `gp3`, `gp2`, `io2`, `io1`, `st1`, `sc1`

  Example:

  ```
  diskType: gp2
  ```

- **nodeGroups.instanceClass.instanceType**
  string

  Required value

  Instance type of AWS instance.

  Caution! Ensure that this type is present in all zones specified in the `zones` parameter.

  Example:

  ```
  instanceType: t3.large
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup. It is used to generate the node name.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: "true"
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

        - **nodeGroups.nodeTemplate.taints.effect**
          string

          Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
        - **nodeGroups.nodeTemplate.taints.key**
          string
        - **nodeGroups.nodeTemplate.taints.value**
          string
    - **nodeGroups.replicas**
      integer

      Required value

      The number of nodes.
    - **nodeGroups.zones**
      array of strings

      Not required value.

      A limited set of zones in which nodes can be created.

      The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **nodeNetworkCIDR**
  string

  A subnet to use for cluster nodes:

  - The IP range must overlap or match the VPC address range.
  - The IP range will be evenly split into subnets, one per Availability Zone in your region.
  - An optional but recommended parameter. By default, it corresponds to the whole range of VPC addresses.

  If a new VPC is created along with a new cluster and no `vpcNetworkCIDR` is provided, then the range from `nodeNetworkCIDR` is used for the VPC. Thus, the entire VPC is allocated for the cluster networks, and you will not be able to add other resources to this VPC.

  The `nodeNetworkCIDR` range is distributed between subnets depending on the number of availability zones in the selected region. For example, if `nodeNetworkCIDR: "10.241.1.0/20"` and there are three availability zones in the region, subnets will be created with the `/22` mask.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **peeredVPCs**
  array of strings

  A list of AWS VPC IDs to peer with the cluster network.

  The service account must have access to all the VPCs listed. You have to configure the peering connection manually if no access is available.

- **provider**
  object

  Required value

  Contains settings to connect to the AWS API.

  - **provider.providerAccessKeyId**
    string

    Required value

    Access key ID.
  - **provider.providerSecretAccessKey**
    string

    Required value

    Access key secret.

    - **provider.region**
      string

      Required value

      The name of the AWS region where instances will be provisioned.

- **publicNetworkAllowList**
  array of strings

  A list of CIDRs allowed to access public endpoints of the cluster.

  Caution. AWS limits the number of inbound and outbound rules per security group to 60 each. If you need to specify more CIDRs, request a quota increase via AWS Support.

  Default: `["0.0.0.0/0"]`

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **sshAllowList**
  array of strings

  A list of CIDR’s allowed to connect to nodes via SSH.

  By default, `0.0.0.0/0`.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **standard**
  Deprecated
  object

  Layout is **deprecated**.

- **tags**
  object

  Not required value.

  A dictionary of tags to create on all resources that support this feature.

  You have to re-create all the machines to add new tags if tags were modified in the running cluster.

- **vpcNetworkCIDR**
  string

  A subnet to use in the VPC being created.

  A mandatory parameter if the `existingVPCID` parameter is omitted.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **withNAT**
  object
    - **withNAT.bastionInstance**
      object
        - **withNAT.bastionInstance.instanceClass**
          object

          Required value

          Partial contents of the fields of the AWSInstanceClass.

            - **withNAT.bastionInstance.instanceClass.additionalSecurityGroups**
              array of strings

              The additional security groups to add to provisioned instance of the specific InstanceClass.

            - **withNAT.bastionInstance.instanceClass.ami**
              string

              Required value

              The Amazon Machine Image (AMI ID) to use in provisioned instance.

              Here is how you can find the required AMI (each region has its own set of AMIs):

```
aws ec2 --region <REGION> describe-images \
--filters 'Name=name,Values=ubuntu/images/hvm-ssd/ubuntu-bionic-18.04-amd64-server-2020*' | \
jq '.Images[].ImageId'
```

Example:

```
ami: ami-040a1551f9c9d11ad
```

- **withNAT.bastionInstance.instanceClass.diskSizeGb**
  integer

  Instance disk size in gibibytes.

  Example:

  ```
  diskSizeGb: 20
  ```

- **withNAT.bastionInstance.instanceClass.diskType**
  string

  Instance EBS disk type.

  Allowed values: `gp3`, `gp2`, `io2`, `io1`, `st1`, `sc1`

  Example:

  ```
  diskType: gp2
  ```

- **withNAT.bastionInstance.instanceClass.instanceType**
  string

  Required value

  Instance type of AWS instance.

  Caution! Ensure that this type is present in selected zone.

  Example:

  ```
  instanceType: t3.large
  ```

- **withNAT.bastionInstance.zone**
  string

  The zone in which the bastion instance will be created.

  By default, the first available zone in the region or the first from the list of the global parameter `zones` will be used.

- **withoutNAT**
  object
- **zones**
  array of strings

  The globally restricted set of zones that this cloud provider works with.

  Restricts only the **creation** of nodes in the cluster.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> The module lifecycle stage: General Availability

⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

For more information, see the documentation.

In Amazon AWS, Ubuntu distributions with a custom kernel without `erofs` are used. To bring the OS into compliance with the requirements and add the necessary modules, you can use the command `sudo apt install linux-modules-extra-aws`.

⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:

- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

To use the `cloud-provider` and `machine-controller-manager` modules, you must access the AWS API as an IAM user with a sufficient set of privileges.

⚠ Make sure that you have access to the desired regions and that you have the necessary quotas.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

JSON Policy

First, prepare a JSON file with the configuration of the necessary privileges:

                "elasticloadbalancing:CreateLoadBalancerPolicy",
                "elasticloadbalancing:CreateTargetGroup",
                "elasticloadbalancing:DeleteListener",
                "elasticloadbalancing:DeleteLoadBalancer",
                "elasticloadbalancing:DeleteLoadBalancerListeners",
```

```
                "elasticloadbalancing:DeleteTargetGroup",
                "elasticloadbalancing:DeregisterInstancesFromLoadBalancer",
                "elasticloadbalancing:DeregisterTargets",
                "elasticloadbalancing:DescribeListeners",
                "elasticloadbalancing:DescribeLoadBalancerAttributes",
                "elasticloadbalancing:DescribeLoadBalancerPolicies",
                "elasticloadbalancing:DescribeLoadBalancers",
                "elasticloadbalancing:DescribeTargetGroups",
                "elasticloadbalancing:DescribeTargetHealth",
                "elasticloadbalancing:DetachLoadBalancerFromSubnets",
                "elasticloadbalancing:ModifyListener",
                "elasticloadbalancing:ModifyLoadBalancerAttributes",
                "elasticloadbalancing:ModifyTargetGroup",
                "elasticloadbalancing:RegisterInstancesWithLoadBalancer",
                "elasticloadbalancing:RegisterTargets",
                "elasticloadbalancing:SetLoadBalancerPoliciesForBackendServer",
                "elasticloadbalancing:SetLoadBalancerPoliciesOfListener",
                "iam:AddRoleToInstanceProfile",
                "iam:CreateInstanceProfile",
                "iam:CreateRole",
                "iam:CreateServiceLinkedRole",
                "iam:DeleteInstanceProfile",
                "iam:DeleteRole",
                "iam:DeleteRolePolicy",
                "iam:GetInstanceProfile",
                "iam:GetRole",
                "iam:GetRolePolicy",
                "iam:ListInstanceProfilesForRole",
                "iam:ListRolePolicies",
                "iam:ListAttachedRolePolicies",
                "iam:PassRole",
                "iam:PutRolePolicy",
                "iam:RemoveRoleFromInstanceProfile",
                "iam:TagRole",
                "kms:DescribeKey",
                "sts:GetCallerIdentity"
            ],
            "Resource": "*"
        }
    ]
}
```

Below, you can find instructions on how to apply this policy.

Configuring IAM via the web interface

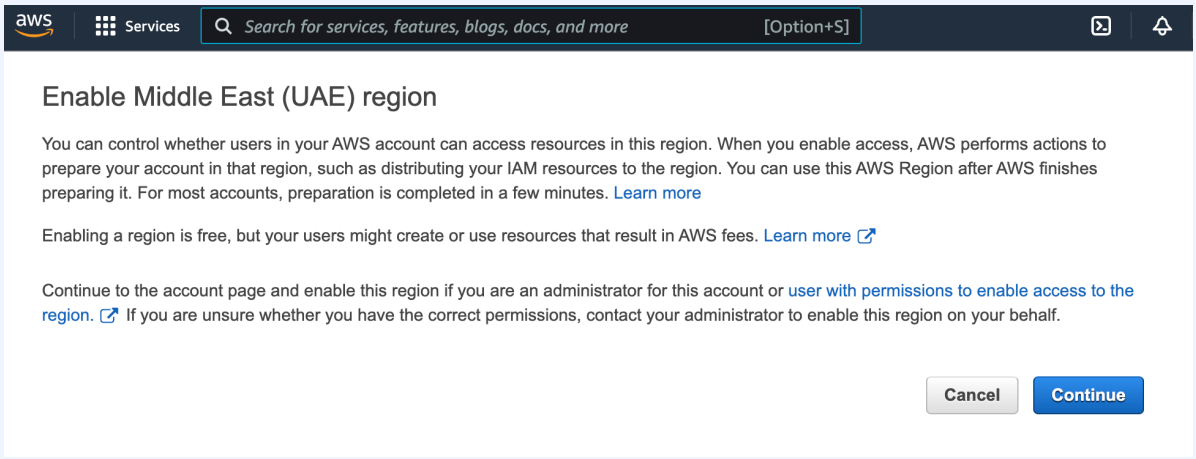
In order to configure IAM via the web interface, first create a new Policy and apply the previously created JSON file to it:

1. Open `Identity and Access Management (IAM)`.
2. Open the `Policies` page and click `Create Policy`.
3. Select the `JSON` tab and insert the policy.
4. Click `Next: Tags`, then `Next: Review`.
5. Enter a policy name in the `Name` field (e.g., `D8CloudProviderAWS`).
6. Click `Create Policy`.

Then add a new user:

1. Open the `Users` page of IAM and click `Add users`.
2. Enter a name in the `User name` field (e.g., `deckhouse`).

And apply the created Policy to it:



1. Select `Access key - Programmatic access` in the `Select AWS credential type` area.
2. Click `Next: Permissions`.
3. Select the `Attach existing policies directly` tab.
4. Search (use the `Filter policies` field) for the policy name entered above (e.g., `D8CloudProviderAWS`) and click the checkbox next to it.
5. Click `Next: Tags`, then `Next: Review`.
6. Click `Create user`.

Save credentials (`Access key ID` and `Secret access key`).

Make sure that you have access to the desired regions. Select the desired region from the dropdown list in the upper right corner.

If there is a switch to the selected region, then there is access to the region.

If there is no access to the region, then you will receive the following message (may differ):

In this case, click `Continue` to enable the region.

Configuring IAM via the CLI

Create the `JSON specification` using the following command.

```
cat > policy.json << EOF
<Policy JSON spec>
EOF
```

Create a new Policy based on the specification created above with `D8CloudProviderAWS` as a policy name and the ARN identifier:

```
aws iam create-policy --policy-name D8CloudProviderAWS --policy-document file://policy.json
```

You will see the following:

```
{
    "Policy": {
        "PolicyName": "D8CloudProviderAWS",
        "PolicyId": "AAA",
        "Arn": "arn:aws:iam::123:policy/D8CloudProviderAWS",
        "Path": "/",
        "DefaultVersionId": "v1",
        "AttachmentCount": 0,
        "PermissionsBoundaryUsageCount": 0,
        "IsAttachable": true,
        "CreateDate": "2020-08-27T02:52:06+00:00",
        "UpdateDate": "2020-08-27T02:52:06+00:00"
    }
}
```

Create a new user:

```
aws iam create-user --user-name deckhouse
```

You will see the following:

```
{
   "User": {
      "Path": "/",
      "UserName": "deckhouse",
      "UserId": "AAAXXX",
      "Arn": "arn:aws:iam::123:user/deckhouse",
      "CreateDate": "2020-08-27T03:05:42+00:00"
   }
}
```

You need to allow access to the API and remember your `AccessKeyId` + `SecretAccessKey` values:

```
aws iam create-access-key --user-name deckhouse
```

You will see the following:

```
{
   "AccessKey": {
      "UserName": "deckhouse",
      "AccessKeyId": "XXXYYY",
      "Status": "Active",
      "SecretAccessKey": "ZZZzzz",
      "CreateDate": "2020-08-27T03:06:22+00:00"
   }
}
```

Attach the specified `Policy` to the specified `User`:

```
aws iam attach-user-policy --user-name deckhouse --policy-arn arn:aws:iam::123:policy/D8CloudProviderAWS
```

Configuring IAM via Terraform

An example of configuring IAM via Terraform:

```
resource "aws_iam_user" "user" {
  name = "deckhouse"
}

resource "aws_iam_access_key" "user" {
  user = aws_iam_user.user.name
}

resource "aws_iam_policy" "policy" {
  name       = "D8CloudProviderAWS"
  path       = "/"
  description = "Deckhouse policy"

  policy = <<EOF
<JSON Policy>
EOF
}

resource "aws_iam_user_policy_attachment" "policy-attachment" {
  user      = aws_iam_user.user.name
  policy_arn = aws_iam_policy.policy.arn
}
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

Custom Resources

> **i** The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

AWSInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of the AWS instance used by `machine-controller-manager` (the node-manager modile).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalSecurityGroups**
    array of strings

    The additional security groups to add to provisioned instances of the specific InstanceClass.

  - **spec.additionalTags**
    object

    Extra AWS tags for instances in addition to `AWSClusterConfiguration.tags`.

  - **spec.ami**
    string

    The Amazon Machine Image (AMI ID) to use in provisioned instances.

    If omitted, the AMI defined in the masterNodeGroup.instanceClass.ami parameter of the `AWSClusterConfiguration` resource is used.

    Here is how you can find the required AMI (each region has its own set of AMIs):

    ```
    aws ec2 --region <REGION> describe-images \
    --filters 'Name=name,Values=ubuntu/images/hvm-ssd/ubuntu-bionic-18.04-amd64-server-2020*' | \
    jq '.Images[].ImageId'
    ```

    Example:

    ```
    ami: ami-040a1551f9c9d11ad
    ```

  - **spec.capacity**
    Deprecated
    object

    Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

    Instance capacity for *non-standard* instance types (the `instanceTypes` parameter).

    Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

    The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`t2.micro`, `m6a.12xlarge`, etc.) is embedded in Deckhouse.

    - **spec.capacity.cpu**
      integer or string

      Required value

      Node vCPU resources.

      Pattern: `^[0-9]+m?$`

      Example:

```
cpu: 1000m
```

- **spec.capacity.memory**
  integer or string

  Required value

  Node memory resources.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

```
memory: 1500Mi
```

- **spec.diskSizeGb**
  integer

  Instance root disk size in gibibytes.

  Default: `20`

  Example:

```
diskSizeGb: 20
```

- **spec.diskType**
  string

  Instance EBS disk type.

  Default: `gp2`

  Example:

```
diskType: gp2
```

- **spec.instanceType**
  string

  Required value

  Instance type of AWS instance.

  Caution! Ensure that this type is present in all zones specified in the `zones` parameter.

  Example:

```
instanceType: t3.large
```

- **spec.iops**
  string

  IOPS rate for io1 diskType

  Example:

```
iops: '500'
```

- **spec.spot**
  boolean

  Order preemptible virtual machines (Spot Instances).

  AWS can interrupt such a machine at any time.

  For more information about preemptible virtual machines, see the provider documentation.

  Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of the AWS instance used by `machine-controller-manager` (the node-manager modile).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**

object

Required value

- **spec.additionalSecurityGroups**
  array of strings

  The additional security groups to add to provisioned instances of the specific InstanceClass.

- **spec.additionalTags**
  object

  Extra AWS tags for instances in addition to `AWSClusterConfiguration.tags`.

- **spec.ami**
  string

  The Amazon Machine Image (AMI ID) to use in provisioned instances.

  If omitted, the AMI defined in the masterNodeGroup.instanceClass.ami parameter of the `AWSClusterConfiguration` resource is used.

  Here is how you can find the required AMI (each region has its own set of AMIs):

  ```
  aws ec2 --region <REGION> describe-images \
  --filters 'Name=name,Values=ubuntu/images/hvm-ssd/ubuntu-bionic-18.04-amd64-server-2020*' | \
  jq '.Images[].ImageId'
  ```

  Example:

  ```
  ami: ami-040a1551f9c9d11ad
  ```

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `instanceTypes` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`t2.micro`, `m6a.12xlarge`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

    Node memory resources.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    memory: 1500Mi
    ```

- **spec.diskSizeGb**
  integer

  Instance root disk size in gibibytes.

  Default: `20`

Example:

```
diskSizeGb: 20
```

- **spec.diskType**
  string

  Instance EBS disk type.

  Default: `gp2`

  Example:

  ```
  diskType: gp2
  ```

- **spec.instanceType**
  string

  Required value

  Instance type of AWS instance.

  Caution! Ensure that this type is present in all zones specified in the `zones` parameter.

  Example:

  ```
  instanceType: t3.large
  ```

- **spec.iops**
  string

  IOPS rate for io1 diskType

  Example:

  ```
  iops: '500'
  ```

- **spec.spot**
  boolean

  Order preemptible virtual machines (Spot Instances).

  AWS can interrupt such a machine at any time.

  For more information about preemptible virtual machines, see the provider documentation.

  Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

FAQ

> The module lifecycle stage: General Availability

How do I create a peering connection between VPCs?

Let’s, for example, create a peering connection between two VPCs, vpc-a and vpc-b.

> **Caution!** IPv4 CIDR must be unique for each VPC.

To configure, follow these steps:

1. Switch to the region where vpc-a is running.

2. Click `VPC` -> `VPC Peering Connections` -> `Create Peering Connection` and then configure a peering connection:
   - Name: `vpc-a-vpc-b`.
   - Fill in `Local` and `Another VPC` fields.
3. Switch to the region where vpc-b is running.
4. Click `VPC` -> `VPC Peering Connections`.
5. Select the newly created peering connection and click `Action "Accept Request"`.
6. Add routes to vpc-b's CIDR over a peering connection to the vpc-a's routing tables.
7. Add routes to vpc-a's CIDR over a peering connection to the vpc-b's routing tables.

How do I create a cluster in a new VPC with access over an existing bastion host?

1. Bootstrap the base-infrastructure of the cluster:

   ```
   dhctl bootstrap-phase base-infra --config config
   ```

2. Set up a peering connection using the instructions above.
3. Continue installing the cluster, enter `y` when asked about the Terraform cache:

   ```
   dhctl bootstrap --config config --ssh-...
   ```

How do I create a cluster in a new VPC and set up bastion host to access the nodes?

1. Bootstrap the base-infrastructure of the cluster:

   ```
   dhctl bootstrap-phase base-infra --config config
   ```

2. Manually set up the bastion host in the subnet -public-0.
3. Continue installing the cluster, enter `y` when asked about the Terraform cache:

   ```
   dhctl bootstrap --config config --ssh-...
   ```

Configuring a bastion host

There are two possible cases:

- A bastion host already exists in an external VPC; in this case, you need to:
  1. Create a basic infrastructure of the cluster: `dhctl bootstrap-phase base-infra`;
  2. Set up peering connection between an external and a newly created VPC;
  3. Continue the installation by specifying the bastion host: `dhctl bootstrap --ssh-bastion...`
- A bastion host needs to be deployed to a newly created VPC; in this case, you need to:
  1. Create a basic infrastructure of the cluster: `dhctl bootstrap-phase base-infra`;
  2. Manually run a bastion in the -public-0 subnet;
  3. Continue the installation by specifying the bastion host: `dhctl bootstrap --ssh-bastion...`

Adding CloudStatic nodes to a cluster

To add a pre-created VM as a node to a cluster, follow these steps:

1. Attach a security group `<prefix>-node` to the virtual machine.
2. Attach the IAM role `<prefix>-node` to the virtual machine.
3. Add the following tags to the virtual machine (so that `cloud-controller-manager` can find virtual machines in the cloud):

   ```
   "kubernetes.io/cluster/<cluster_uuid>" = "shared"
   "kubernetes.io/cluster/<prefix>" = "shared"
   ```

   - You can find out the `cluster_uuid` using the command:

     ```
     d8 k -n kube-system get cm d8-cluster-uuid -o json | jq -r '.data."cluster-uuid"'
     ```

   - You can find out `prefix` using the command:

     ```
     d8 k get mc global -o jsonpath='{.spec.settings.prefix}{"\n"}'
     ```

     If the value is empty, get it from the deprecated `cloud.prefix` parameter of ClusterConfiguration (the prefix has moved to the ModuleConfig `global`):

```
d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r '.data."cluster-
configuration.yaml"' \
  | base64 -d | grep prefix
```

How to increase the size of a volume?

Set the new size in the corresponding PersistentVolumeClaim resource, in the `spec.resources.requests.storage` parameter.

The operation is fully automatic and takes up to one minute. No further action is required.

The progress of the process can be observed in events using the command `d8 k describe pvc`.

> **i** After modifying a volume, you must wait at least six hours and ensure that the volume is in the `in-use` or `available` state before you can modify the same volume. This is sometimes referred to as a cooldown period. You can find details in the official documentation.

How do I configure access to Amazon ECR repository on cluster nodes?

1. Set permissions to read images in Repository policies. There must be an existing `Roles` object in `Principal`.

   ```
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "RepositoryRead",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::xxx:role/xxx-node"
         },
         "Action": [
           "ecr:BatchCheckLayerAvailability",
           "ecr:BatchGetImage",
           "ecr:DescribeImages",
           "ecr:DescribeRepositories",
           "ecr:GetAuthorizationToken",
           "ecr:GetDownloadUrlForLayer",
           "ecr:ListImages",
           "ecr:ListTagsForResource"
          ]
       }
     ]
   }
   ```

   Apply this policy in `Amazon ECR` > `Private registry` > `Repositories` > `` > `Permissions`.

2. Add `ecr:GetAuthorizationToken` to additionalRolePolicies.

How to create preemptible nodes in AWS?

Preemptible virtual machines in AWS are called Spot Instances. To make a node group order them, set the `spot` parameter of the AWSInstanceClass resource to `true`.

Example:

```
apiVersion: deckhouse.io/v1
kind: AWSInstanceClass
metadata:
  name: worker-spot
spec:
  instanceType: m5.large
  diskSizeGb: 30
  spot: true
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker-spot
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    classReference:
      kind: AWSInstanceClass
      name: worker-spot
    minPerZone: 2
    maxPerZone: 4
    zones:
      - eu-central-1a
```

Handling AWS notifications

When an EC2 Instance Rebalance Recommendation signals an elevated risk of Spot Instance interruption, the `node-termination-handler` component automatically applies the `aws-node-termination-handler/rebalance-recommendation` taint with `effect: NoSchedule` to the CloudEphemeral node. This taint prevents the scheduler from placing new workloads on the node unless they have a matching toleration.

The `aws-node-termination-handler/spot-itn` taint indicates a notice of an upcoming Spot Instance interruption.

If either taint is present, the `node-manager` module cordons and drains the node, then deletes it. If the node count in a zone falls below the `minPerZone` parameter value, the group provisions new nodes.

The recommendation allows node decommissioning to start before an interruption notice arrives. AWS may send both notifications at the same time.

Limitations of preemptible nodes in AWS

Consider the following limitations:

- The `spot` parameter applies only to CloudEphemeral node groups, because AWSInstanceClass applies only to them.
- The time between the interruption notice and the instance shutdown may be too short to drain the node. Place only the workload that tolerates a sudden node loss on preemptible nodes.

> ⚠ Changing the `spot` parameter in an existing AWSInstanceClass causes all nodes of the corresponding group to be recreated.

How do I replace the OS image on the nodes?

The OS image is set by the `ami` parameter of the AWSInstanceClass resource for `CloudEphemeral` nodes and in the `instanceClass` section of the AWSClusterConfiguration resource for `CloudPermanent` nodes and master nodes.

The replacement procedure is described in “How do I replace the OS image in a cloud cluster?” .

What to do if switching to nodes in lower-priority groups takes a long time?

If switching to nodes in lower-priority groups takes a long time (for example, when node groups with spot instances are set to the highest priority and, if such instances are unavailable, switching to nodes from other groups takes a very long time), follow the instructions.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

An example of the `AWSInstanceClass` custom resource

Below is a simple example of custom resource `AWSInstanceClass` configuration:

```
apiVersion: deckhouse.io/v1
kind: AWSInstanceClass
metadata:
  name: worker
spec:
  instanceType: t3.large
  ami: ami-040a1551f9c9d11ad
  diskSizeGb: 15
  diskType:  gp2
```

LoadBalancer

Service object Annotations

The following parameters are supported in addition to the existing upstream ones:

1. `service.beta.kubernetes.io/aws-load-balancer-type` — if it has the `none` value, then the target group will **only** be created (without any LoadBalancer).
2. `service.beta.kubernetes.io/aws-load-balancer-backend-protocol` — this parameter is used together with `service.beta.kubernetes.io/aws-load-balancer-type: none`:
   - Possible values:
     - `tcp` (default);
     - `tls`;
     - `http`;
     - `https`.
   - **Caution!** The `cloud-controller-manager` (CCM) will try to recreate the target group in response to changes in this field. If the target group has NLB or ALB attached to it, the CCM will fail to delete it and get stuck in this state forever. You have to manually disconnect NLB or ALB from the target group.

Configuring the load balancer if Ingress nodes are not available in all zones

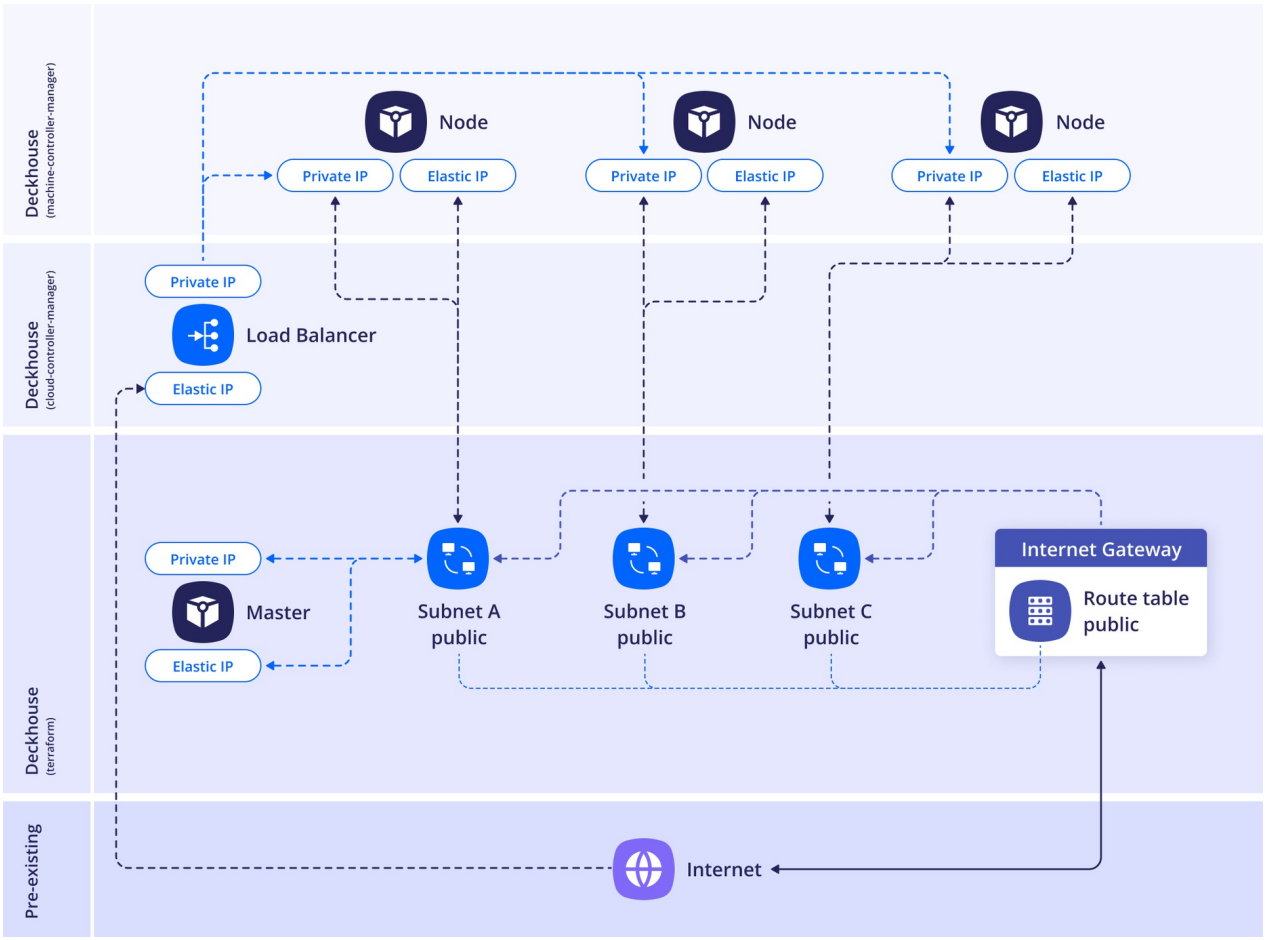
Set the following annotation for the Service object: `service.beta.kubernetes.io/aws-load-balancer-subnets: subnet-foo, subnet-bar`.

You can get current subnets for a particular installation as follows:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values cloud-provider-aws -o json \
| jq -r '.cloudProviderAws.internal.zoneToSubnetIdMap'
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Layouts



> The module lifecycle stage: General Availability

Two layouts are supported. Below is more information about each of them.

WithoutNAT

Recommended layout.

Under this placement strategy, each node gets a public IP (ElasticIP). NAT is not used at all.

When `disableDefaultSecurityGroup: false` is set, the module creates default security groups when a cluster is created.

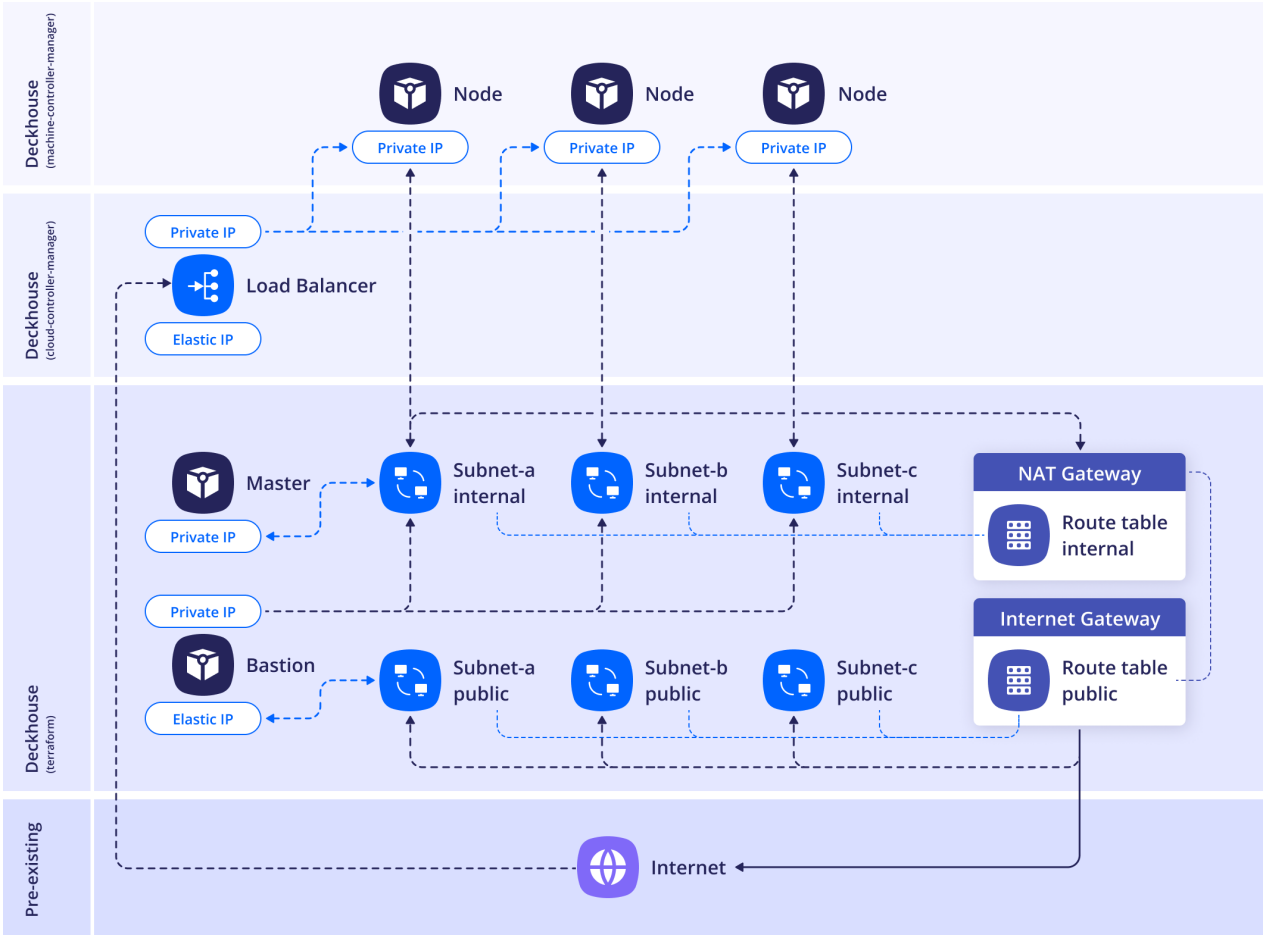
The following groups and rules will be created:

- `<CLUSTER_PREFIX>-node` — assigned to cluster nodes:
  - allow any outgoing traffic to `0.0.0.0/0`
  - allow any incoming traffic from the `<CLUSTER_PREFIX>-loadbalancer` group
  - allow any incoming traffic from nodes in the same `<CLUSTER_PREFIX>-node` group
  - allow incoming traffic over the ICMP protocol from CIDRs listed in `publicNetworkAllowList` (default `0.0.0.0/0`)
- `<CLUSTER_PREFIX>-loadbalancer` — used by load balancers:
  - allow any incoming traffic from CIDRs in `publicNetworkAllowList`
  - allow any outgoing traffic to the `<CLUSTER_PREFIX>-node` group
- `<CLUSTER_PREFIX>-ssh-accessible` — created when `sshAllowList` is set; allows incoming traffic over the TCP protocol on port `22` from the listed CIDRs (default `0.0.0.0/0`). Assigned to master nodes or to the bastion host in the `WithNAT` layout

⚠ When `disableDefaultSecurityGroup: true` is set, you must create all required security groups yourself and specify them in `additionalSecurityGroups`. For load balancers, set groups with the `service.beta.kubernetes.io/aws-load-balancer-security-groups` annotation.

Attach custom security groups (created in the cloud in advance) via `additionalSecurityGroups`:

- for master nodes — in the `masterNodeGroup.instanceClass.additionalSecurityGroups` parameter of the AWSClusterConfiguration resource
- for static nodes — in the `nodeGroups[].instanceClass.additionalSecurityGroups` parameter of the AWSClusterConfiguration resource
- for ephemeral nodes — in the `spec.additionalSecurityGroups` parameter of the AWSInstanceClass resource



Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: AWSClusterConfiguration
layout: WithoutNAT
vpcNetworkCIDR: "10.241.0.0/16"
nodeNetworkCIDR: "10.241.32.0/20"
sshPublicKey: <SSH_PUBLIC_KEY>
provider:
  providerAccessKeyId: '<AWS_ACCESS_KEY>'
  providerSecretAccessKey: '<AWS_SECRET_ACCESS_KEY>'
  region: eu-central-1
masterNodeGroup:
  replicas: 1
  instanceClass:
    # Type of the instance.
    instanceType: m5.xlarge
    # Amazon Machine Image ID
    # AMI Catalog in the AWS console: EC2 -> AMI Catalog
    ami: ami-0aad10862ade98f27
    # Master node VM disk size.
    diskSizeGb: 30
    # Master node VM disk type to use.
    diskType: gp3
nodeGroups:
  - name: mydb
    nodeTemplate:
      labels:

```

WithNAT

> **Caution!** A bastion host is required to access nodes (it can be created alongside the cluster by specifying the parameters in the section `withNAT.bastionInstance`).
>
> **Caution!** The NAT Gateway is always created in zone `a` in this layout. If cluster nodes are placed in other zones, then if there are problems in zone `a`, they will also be unavailable. In other words, when choosing the `WithNat` layout, the availability of the entire cluster will depend on the availability of zone `a`.

Virtual machines access the Internet using a NAT Gateway with a shared (and single) source IP.

When `disableDefaultSecurityGroup: false` is set, the module creates default security groups when a cluster is created.

The following groups and rules will be created:

- `<CLUSTER_PREFIX>-node` — assigned to cluster nodes:
  - allow any outgoing traffic to `0.0.0.0/0`
  - allow any incoming traffic from the `<CLUSTER_PREFIX>-loadbalancer` group
  - allow any incoming traffic from nodes in the same `<CLUSTER_PREFIX>-node` group
  - allow incoming traffic over the ICMP protocol from CIDRs listed in `publicNetworkAllowList` (default `0.0.0.0/0`)
- `<CLUSTER_PREFIX>-loadbalancer` — used by load balancers:
  - allow any incoming traffic from CIDRs in `publicNetworkAllowList`
  - allow any outgoing traffic to the `<CLUSTER_PREFIX>-node` group
- `<CLUSTER_PREFIX>-ssh-accessible` — created when `sshAllowList` is set; allows incoming traffic over the TCP protocol on port `22` from the listed CIDRs (default `0.0.0.0/0`). Assigned to master nodes or to the bastion host in the `WithNAT` layout

⚠ When `disableDefaultSecurityGroup: true` is set, you must create all required security groups yourself and specify them in `additionalSecurityGroups`. For load balancers, set groups with the `service.beta.kubernetes.io/aws-load-balancer-security-groups` annotation.

Attach custom security groups (created in the cloud in advance) via `additionalSecurityGroups`:

- for master nodes — in the `masterNodeGroup.instanceClass.additionalSecurityGroups` parameter of the AWSClusterConfiguration resource
- for static nodes — in the `nodeGroups[].instanceClass.additionalSecurityGroups` parameter of the AWSClusterConfiguration resource
- for ephemeral nodes — in the `spec.additionalSecurityGroups` parameter of the AWSInstanceClass resource

Example of the layout configuration:
