  tenantId: "<TENANT_ID>"
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **kind**
  string

  Required value

  Allowed values: `AzureClusterConfiguration`

- **layout**

string

Required value

The way resources are located in the cloud.

Read more about possible provider layouts.

Allowed values: `Standard`

- **masterNodeGroup**

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the AzureInstanceClass fields.

    - **masterNodeGroup.instanceClass.acceleratedNetworking**
      boolean

      Accelerated Networking provides up to 30Gbps in networking throughput.

      Default: `false`

    - **masterNodeGroup.instanceClass.additionalTags**
      object

      The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **masterNodeGroup.instanceClass.diskSizeGb**
      integer

      Instance root disk size in gibibytes.

      Example:

      ```
      diskSizeGb: 40
      ```

    - **masterNodeGroup.instanceClass.diskType**
      string

      The type of the volumes to create.

      You can view a list of available volume types using the Azure CLI:

      ```
      az vm list-skus -l westeurope --zone
      ```

      Example:

      ```
      diskType: StandardSSD_LRS
      ```

    - **masterNodeGroup.instanceClass.enableExternalIP**
      boolean

      Defines whether to enable external IP for an instance or not.

      Only available for the `Standard` layout.

      Default: `false`

      Allowed values: `true`, `false`

    - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
      integer

Etcd disk size in gibibytes.

Default: `20`

Example:

```
etcdDiskSizeGb: 20
```

- **masterNodeGroup.instanceClass.machineSize**
  string

  Required value

  The type of instances to provision.

  Getting a list of available types for the specific region using the Azure CLI:

  ```
  az vm list-sizes --location westeurope -o table
  ```

  Example:

  ```
  machineSize: Standard_F4
  ```

- **masterNodeGroup.instanceClass.urn**
  string

  Required value

  The VM image to use for an instance.

  More information about virtual machine images can be found in the official Azure documentation.

  Getting the `urn` via Azure CLI (column #4):

  ```
  az vm image list --location westeurope --publisher Canonical --all --sku 20_04-lts -o
  table
  az vm image list --location westeurope --publisher OpenLogic --all --sku 7.5 -o table
  ```

  By default, the image specified in `AzureCloudDiscoveryData` is used (the master of the cluster is based on this image).

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version you use).

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create.

  It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  A list of zones where master nodes can be created.

  You can browse a list of zones available for the selected instance type using the Azure CLI:

  ```
  az vm list-skus -l westeurope -o table
  ```

  Default: `[1,2,3]`

- **nameservers**
  object

  DNS server configuration for the Azure virtual network used by the cluster nodes.

  - **nameservers.addresses**
    array of strings

    A list of DNS servers.

    Example:

```
addresses:
- 8.8.8.8
- 8.8.4.4
```

- **Element of the array**
  string

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the AzureInstanceClass.

    - **nodeGroups.instanceClass.acceleratedNetworking**
      boolean

      Accelerated Networking provides up to 30Gbps in networking throughput.

      Default: `false`

    - **nodeGroups.instanceClass.additionalTags**
      object

      The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **nodeGroups.instanceClass.diskSizeGb**
      integer

      Instance root disk size in gibibytes.

      Example:

      ```
      diskSizeGb: 40
      ```

    - **nodeGroups.instanceClass.diskType**
      string

      The type of the volumes to create.

      You can view a list of available volume types using the Azure CLI:

      ```
      az vm list-skus -l westeurope --zone
      ```

      Example:

      ```
      diskType: StandardSSD_LRS
      ```

    - **nodeGroups.instanceClass.enableExternalIP**
      boolean

      Defines whether to enable external IP for an instance or not.

      Only available for the `Standard` layout.

      Default: `false`

      Allowed values: `true`, `false`

    - **nodeGroups.instanceClass.machineSize**
      string

      Required value

      The type of instances to provision.

Getting a list of available types for the specific region using the Azure CLI:

```
az vm list-sizes --location westeurope -o table
```

Example:

```
machineSize: Standard_F4
```

- **nodeGroups.instanceClass.urn**
  string

  Required value

  The VM image to use for an instance.

  More information about virtual machine images can be found in the official Azure documentation.

  Getting the `urn` via Azure CLI (column #4):

  ```
  az vm image list --location westeurope --publisher Canonical --all --sku 20_04-lts -o
  table
  az vm image list --location westeurope --publisher OpenLogic --all --sku 7.5 -o table
  ```

  By default, the image specified in `AzureCloudDiscoveryData` is used (the master of the cluster is based on this image).

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version you use).

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: "true"
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

    Format — `key: value`.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

        - **nodeGroups.nodeTemplate.taints.effect**
          string

          Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
        - **nodeGroups.nodeTemplate.taints.key**
          string
        - **nodeGroups.nodeTemplate.taints.value**
          string
    - **nodeGroups.replicas**
      integer

      Required value

      The number of nodes to create.
    - **nodeGroups.zones**
      array of strings

      A list of zones where static nodes can be created;

      You can browse a list of zones available for the selected instance type using the Azure CLI:

      ```
      az vm list-skus -l westeurope -o table
      ```

      Default: `[1,2,3]`
- **peeredVNets**
  array of objects

  An array of `VNets` to merge with the cluster network.

  The service account must have access to all the `VNets` listed above. You have to configure the peering connection manually if no access is available.
    - **peeredVNets.resourceGroupName**
      string

      Required value

      The name of the resource group with the VNet.
    - **peeredVNets.vnetName**
      string

      Required value

      The name of the VNet.
- **provider**
  object

  Required value

  Parameters for connecting to the Azure API.
    - **provider.clientId**
      string

      Required value

      The client ID.
    - **provider.clientSecret**
      string

      Required value

      The client’s secret.

      Keep in mind the expiration date of the secret. By default, it is valid for one year. Refer to the official documentation to create a service account with a longer secret expiration date.
    - **provider.location**
      string

      Required value

The name of the geo location to create all the resources. Getting available locations from Azure CLI:

```
az account list-locations -o table
```

- **provider.subscriptionId**
  string

  Required value

  The ID of the subscription.

- **provider.tenantId**
  string

  Required value

  The ID of the tenant.

- **serviceEndpoints**
  array of strings

  The list of Service endpoints to associate with the subnet.

  Virtual Network (VNet) service endpoint provides secure and direct connectivity to Azure services over an optimized route over the Azure backbone network. Endpoints allow you to secure your critical Azure service resources to only your virtual networks. Service Endpoints enables private IP addresses in the VNet to reach the endpoint of an Azure service without needing a public IP address on the VNet.

  More information about Service Endpoints can be found in the official documentation.

  - **Element of the array**
    string

    Allowed values: `Microsoft.AzureActiveDirectory`, `Microsoft.AzureCosmosDB`, `Microsoft.ContainerRegistry`, `Microsoft.CognitiveServices`, `Microsoft.EventHub`, `Microsoft.KeyVault`, `Microsoft.ServiceBus`, `Microsoft.Sql`, `Microsoft.Storage`, `Microsoft.Storage.Global`, `Microsoft.Web`

- **sshAllowList**
  array of strings

  A list of CIDR’s allowed to connect to nodes via SSH.

  By default, `*`.

- **sshPublicKey**
  string

  Required value

  Public key to access nodes as `azureuser`.

- **standard**
  object

  Settings for the `Standard` layout.

  - **standard.natGatewayPublicIpCount**
    integer

    The number of IP addresses for the NAT Gateway (pricing). `NAT Gateway` is not used if the value is `0`.

    Default: `0`

- **subnetCIDR**
  string

  Required value

  A subnet from the `vNetCIDR` address space for cluster nodes.

  A virtual network can be segmented into one or more subnets up to the limits.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  Example:

  ```
  subnetCIDR: 10.1.2.0/24
  ```

- **tags**
  object

  A list of tags in the `key: value` format to attach to all cluster resources.

You have to re-create all the machines to add new tags if tags were modified in the running cluster.

- **vNetCIDR**
  string

  Required value

  An address space of the virtual network in the CIDR format.

  A virtual network is a virtual, isolated portion of the Azure public network. Each virtual network is dedicated to your subscription.

  Warning. If you are setting up peering, using vpn or linking networks of other clusters, network address spaces should not overlap.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  Example:

  ```
  vNetCIDR: 10.0.0.0/16
  ```

- **zones**
  array of strings

  The globally restricted set of zones that this Cloud Provider works with.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

The module lifecycle stage: General Availability

To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

For more information, see the documentation.

The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:

- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

Only regions where `Availability Zones` are available are supported.

The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

⚠ Starting with DP version 1.77, Azure uses the `cilium` CNI by default for new clusters. Existing clusters keep the current CNI configuration.

New clusters require Linux kernel version 5.8 or newer on all nodes. Make sure firewalls or security groups allow inter-node UDP traffic for Cilium VXLAN. For more information about Cilium requirements, limitations, and behavior, see the installation requirements, Network interaction of the platform components, and the `cni-cilium` module documentation.

To rule the Microsoft Azure cloud, you need an account and at least a single Subscription connected to id.

You have to create a service account with Microsoft Azure so that Deckhouse Platform can manage cloud resources:

1. Install the Azure CLI, login and get Subscription ID:

   ```
   export SUBSCRIPTION_ID=$(az login | jq -r '.[0].id')
   ```

2. Create the service account:

   ```
   az ad sp create-for-rbac --role="Contributor" --scopes="/subscriptions/$SUBSCRIPTION_ID" --
   name "DeckhouseCANDI"
   ```

   Example output of the command:

   ```
   {
     "appId": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx",     <-- used in the clientId
   parameter of the AzureClusterConfiguration resource
     "displayName": "DeckhouseCANDI",
     "password": "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx", <-- used in the clientSecret
   parameter of the AzureClusterConfiguration resource
     "tenant": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"    <-- used in the tenantId
   parameter of the AzureClusterConfiguration resource
   }
   ```

   ℹ By default, service account will be created with a secret (used in the clientSecret parameter of the `AzureClusterConfiguration` resource) validity period of one year without automatic renewal. Refer to the official documentation to create a service account with a longer secret expiration date.

You have to be logged in for further work with the `az` tool. Use the service account username, password, and tenant to log in:

```
az login --service-principal -u <username> -p <password> --tenant <tenant>
```

ℹ **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

ℹ The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

ℹ The module lifecycle stage: General Availability

AzureInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of the Azure Instances used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.acceleratedNetworking**
    boolean

    Accelerated Networking provides up to 30Gbps in networking throughput.

    Default: `true`

  - **spec.additionalTags**
    object

    The additional tags to attach to the instances created.

  - **spec.capacity**
    Deprecated
    object

    Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

    Instance capacity for *non-standard* instance types (the `machineSize` parameter).

    Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

    The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`Standard_A1_v2`, `Standard_B16ms`, etc.) is embedded in Deckhouse.

    - **spec.capacity.cpu**
      integer or string

      Required value

      Node vCPU resources.

      Pattern: `^[0-9]+m?$`

      Example:

      ```
      cpu: 1000m
      ```

    - **spec.capacity.memory**
      integer or string

      Required value

      Node memory resources.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

      Example:

      ```
      memory: 1500Mi
      ```

  - **spec.diskSizeGb**
    integer

    Instance root disk size in gibibytes.

    Default: `50`

    Example:

    ```
    diskSizeGb: 40
    ```

  - **spec.diskType**
    string

    The type of the volume to create.

    You can view a list of available volume types using the Azure CLI:

    ```
    az vm list-skus -l westeurope --zone`
    ```

Default: `StandardSSD_LRS`

- **spec.machineSize**
  string

  Required value

  The type of instances to provision.

  You can view a list of available types for the specific region using the Azure CLI:

  ```
  az vm list-sizes --location westeurope -o table
  ```

  Example:

  ```
  machineSize: Standard_F4
  ```

- **spec.urn**
  string

  Not required value.

  The VM image to use for an instance.

  More information about virtual machine images can be found in the official documentation.

  You can get the latest version of an image using the Azure CLI:

  - `az vm image show --urn Canonical:UbuntuServer:18.04-LTS:latest --location westeurope`;
  - `az vm image show --urn Canonical:0001-com-ubuntu-server-focal:20_04-lts:latest --location westeurope`.

  By default, the image specified in `AzureCloudDiscoveryData` is used (the master of the cluster is based on this image).

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

  Example:

  ```
  urn: Canonical:UbuntuServer:18.04-LTS:18.04.202010140
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of the Azure Instances used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.acceleratedNetworking**
    boolean

    Accelerated Networking provides up to 30Gbps in networking throughput.

    Default: `true`

  - **spec.additionalTags**
    object

    The additional tags to attach to the instances created.

  - **spec.capacity**
    Deprecated
    object

    Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

    Instance capacity for *non-standard* instance types (the `machineSize` parameter).

    Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`Standard_A1_v2`, `Standard_B16ms`, etc.) is embedded in Deckhouse.

- **spec.capacity.cpu**
  integer or string

  Required value

  Node vCPU resources.

  Pattern: `^[0-9]+m?$`

  Example:

  ```
  cpu: 1000m
  ```

- **spec.capacity.memory**
  integer or string

  Required value

  Node memory resources.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

  ```
  memory: 1500Mi
  ```

- **spec.diskSizeGb**
  integer

  Instance root disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGb: 40
  ```

- **spec.diskType**
  string

  The type of the volume to create.

  You can view a list of available volume types using the Azure CLI:

  ```
  az vm list-skus -l westeurope --zone`
  ```

  Default: `StandardSSD_LRS`

- **spec.machineSize**
  string

  Required value

  The type of instances to provision.

  You can view a list of available types for the specific region using the Azure CLI:

  ```
  az vm list-sizes --location westeurope -o table
  ```

  Example:

  ```
  machineSize: Standard_F4
  ```

- **spec.urn**
  string

  Not required value.

  The VM image to use for an instance.

  More information about virtual machine images can be found in the official documentation.

  You can get the latest version of an image using the Azure CLI:

  - `az vm image show --urn Canonical:UbuntuServer:18.04-LTS:latest --location westeurope`;

- `az vm image show --urn Canonical:0001-com-ubuntu-server-focal:20_04-lts:latest --location westeurope`.

By default, the image specified in `AzureCloudDiscoveryData` is used (the master of the cluster is based on this image).

The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

Example:

```
urn: Canonical:UbuntuServer:18.04-LTS:18.04.202010140
```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

An example of the `AzureInstanceClass` custom resource

Below is a simple example of the `AzureInstanceClass` custom resource:

```
apiVersion: deckhouse.io/v1
kind: AzureInstanceClass
metadata:
  name: example
spec:
  machineSize: Standard_F4
```

Replacing the OS image

In this example, the nodes of a group are moved to a new OS image. The new image is set in the `urn` parameter of the instance class that the node group refers to:

```
apiVersion: deckhouse.io/v1
kind: AzureInstanceClass
metadata:
  name: example
spec:
  machineSize: Standard_F4
  urn: Canonical:ubuntu-24_04-lts:server:24.04.202602040
```

After the instance class is changed, Deckhouse Platform recreates the `CloudEphemeral` nodes from the new image. For `CloudPermanent` nodes and master nodes, the image is set in the `instanceClass` section of the AzureClusterConfiguration resource. The replacement procedure is described in “How do I replace the OS image in a cloud cluster?”.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Layouts

> i The module lifecycle stage: General Availability

> i **Caution!** Only regions where `Availability Zones` are available are supported.

Standard

- A separate resource group is created for the cluster.
- By default, one external IP address is dynamically allocated to each instance (it is used for Internet access only). Each IP has 64000 ports available for SNAT.
- The NAT Gateway (pricing) is supported. With it, you can use static public IP addresses for SNAT.
- Public IP addresses can be assigned to master nodes and nodes created by Terraform.
- If the master does not have a public IP, then an additional instance with a public IP (aka bastion host) is required for installation tasks and access to the cluster. In this case, you will also need to configure peering between the cluster's VNet and bastion's VNet.
- Peering can also be configured between the cluster VNet and other VNets.

When a cluster is created, the module creates a Network Security Group (NSG) named after the cluster prefix and associates it with the node subnet.

The following rules will be created:

- `AllowIcmp` — allow incoming traffic over the ICMP protocol from any source
- `AllowSsh` — allow incoming traffic over the TCP protocol on port `22` from CIDRs listed in `sshAllowList` (from any source if the list is not set)

You cannot attach a pre-created custom NSG to nodes through module parameters. Use `sshAllowList` to restrict SSH access.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: AzureClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>" # Required.
vNetCIDR: 10.50.0.0/16 # Required.

Cloud provider — Basis Dynamix

> **i** Included in extensions: **On-prem IaaS**

> ⚠ The module lifecycle stage: Preview

The `cloud-provider-dynamix` module integrates Deckhouse Platform with the Basis Dynamix platform. It allows the `node-manager` module to use Dynamix resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-dynamix` module:

- Managing Dynamix resources via `cloud-controller-manager`:
  - updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in Dynamix;
  - creates load balancers for Services of the LoadBalancer type. The Service must include annotations with the names of the internal and external networks.
- Provisioning disks via the Dynamix CSI driver (`dynamix.deckhouse.io`) so that PersistentVolumes can be requested from the cluster.
- Provisioning CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-decort`.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the DynamixInstanceClass resource.
- Registering with `node-manager` so that DynamixInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

> **i** The module is in the Preview stage.

Third-party components

List of third-party software used in the `cloud-provider-dynamix` module:

- Dynamix Terraform provider 4.12.2

  License: Apache License 2.0

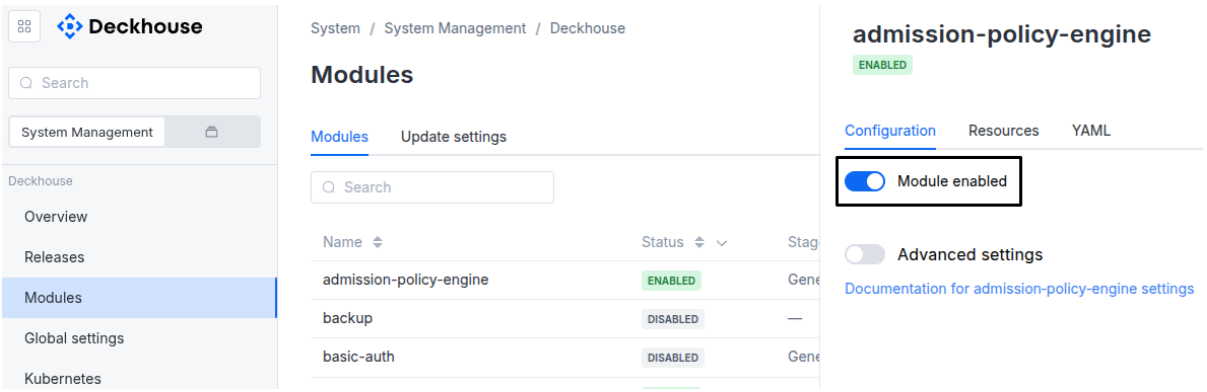
  Terraform provider for Dynamix (DECORT).

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> **i** Included in extensions: **On-prem IaaS**

> ⚠ The module lifecycle stage: Preview



The module is automatically enabled for all cloud clusters deployed in Basis Dynamix.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-dynamix` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

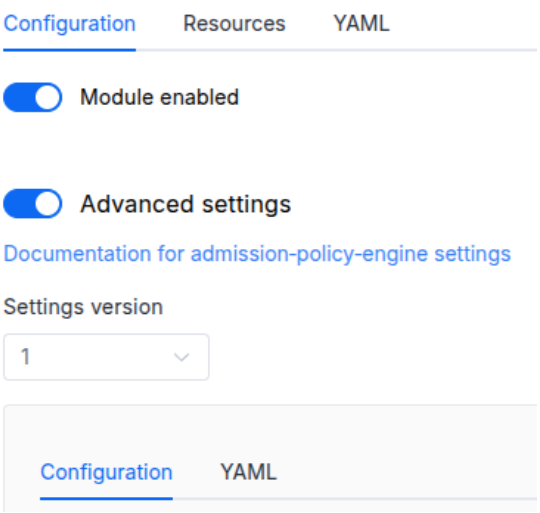
  ```
  d8 system module enable cloud-provider-dynamix
  ```

- **Using ModuleConfig `cloud-provider-dynamix`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-dynamix` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-dynamix`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-dynamix
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-dynamix` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-dynamix` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-dynamix`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

Edit the existing ModuleConfig `cloud-provider-dynamix` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc cloud-provider-dynamix
```

Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `cloud-provider-dynamix` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-dynamix`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-dynamix
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.storageClass**
    object

    The module automatically creates a StorageClass for every `ENABLED` storage policy available to the cluster account.

    - **settings.storageClass.default**
      Deprecated
      string

      The name of the StorageClass that the module marks as the default one among the StorageClasses it creates.

      The parameter applies only if the cluster has no default StorageClass and `global.defaultClusterStorageClass` isn’t set.

      If the parameter is omitted, the default StorageClass is either:

      - an arbitrary StorageClass present in the cluster that has the default annotation;
      - the first (in lexicographic order) StorageClass created by the module.

      > **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

      Example:

      ```
      default: storage-policy01
      ```

    - **settings.storageClass.exclude**
      array of strings

      A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

      Example:

      ```
      exclude:
      - ".*-hdd"
      - storage-policy01
      ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> ⚠ The module lifecycle stage: Preview

> If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-dynamix` module in the Deckhouse configuration. If the cluster control plane is hosted in a cloud, the cloud provider uses the DynamixClusterConfiguration structure for configuration.

DynamixClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in Dynamix.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: DynamixClusterConfiguration
layout: StandardWithInternalNetwork
sshPublicKey: ssh-rsa AAAA
location: dynamix
account: acc_user
storagePolicy: storage_policy01
nodeNetworkCIDR: 10.241.32.0/24
nameservers:
- 10.0.0.10
provider:
  controllerUrl: "<controller url>"
  oAuth2Url: "<oAuth2 url>"
  appId: "<app id>"
  appSecret: "<app secret>"
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    externalNetwork: "<external network>"
nodeGroups:
- name: worker
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    externalNetwork: "<external network>"
```

- **account**
  string

  Required value

  Account name.

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **kind**
  string

  Required value

  Allowed values: `DynamixClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **location**
  string

  Required value

  The name of the Basis Dynamix location where the cluster resource group is created.

- **masterNodeGroup**
  object

  Required value

The definition of the master’s NodeGroup.

> **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

- **masterNodeGroup.instanceClass**
  object

  Required value

  Partial contents of the fields of the DynamixInstanceClass.

  - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
    integer

    Etcd disk size in GiB.

    Default: `15`

    Example:

    ```
    etcdDiskSizeGb: 15
    ```

  - **masterNodeGroup.instanceClass.externalNetwork**
    string

    Required value

    External network name.

    Example:

    ```
    externalNetwork: extnet_vlan_1700
    ```

  - **masterNodeGroup.instanceClass.imageName**
    string

    Required value

    OS image name to use for VM deployment.

    Example:

    ```
    imageName: '1'
    ```

  - **masterNodeGroup.instanceClass.memory**
    integer

    Required value

    Memory in MiB to allocate to the VM.

    Allowed values: `1 <= X`

    Example:

    ```
    memory: 8192
    ```

  - **masterNodeGroup.instanceClass.numCPUs**
    integer

    Required value

    Number of vCPUs to allocate to the VM.

    Allowed values: `1 <= X`

    Example:

    ```
    numCPUs: 2
    ```

  - **masterNodeGroup.instanceClass.rootDiskSizeGb**
    integer

    Root disk size in GiB to use in Dynamix VirtualMachines.

    Default: `50`

    Example:

```
rootDiskSizeGb: 50
```

- **masterNodeGroup.instanceClass.storagePolicy**
  string

  The name of the storage policy for this node group instead of the cluster-wide `storagePolicy`.

  > **Warning.** A new value applies only to the nodes created after the change. Existing nodes aren't recreated.

  Example:

  ```
  storagePolicy: storage_policy01
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **nameservers**
  array of strings

  A list of IPv4 addresses of the DNS servers for the nodes.

  - In the `StandardWithInternalNetwork` layout, the nodes get these addresses through the ViNS.
  - In the `Standard` layout, the addresses are written into the cloud-init of every node. Specify them if the external network doesn't provide DNS server addresses to the nodes. Otherwise, the nodes can't resolve names.

  A new value applies only to the nodes created after the change.

  Default: `[]`

  - **Element of the array**
    string

    Pattern: `^[0-9.]+$`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the.

    - **nodeGroups.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in GiB.

      Default: `15`

      Example:

      ```
      etcdDiskSizeGb: 15
      ```

    - **nodeGroups.instanceClass.externalNetwork**
      string

      Required value

      External network name.

      Example:

      ```
      externalNetwork: extnet_vlan_1700
      ```

    - **nodeGroups.instanceClass.imageName**
      string

Required value

OS image name to use for VM deployment.

Example:

```
imageName: '1'
```

- **nodeGroups.instanceClass.memory**
  integer

  Required value

  Memory in MiB to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  memory: 8192
  ```

- **nodeGroups.instanceClass.numCPUs**
  integer

  Required value

  Number of vCPUs to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  numCPUs: 2
  ```

- **nodeGroups.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in Dynamix VirtualMachines.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **nodeGroups.instanceClass.storagePolicy**
  string

  The name of the storage policy for this node group instead of the cluster-wide `storagePolicy`.

  > **Warning.** A new value applies only to the nodes created after the change. Existing nodes aren’t recreated.

  Example:

  ```
  storagePolicy: storage_policy01
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

- **nodeGroups.nodeTemplate.labels**
  object

  A list of labels to attach to cluster resources.

  The same as the `metadata.labels` standard field.

  Example:

  ```
  labels:
    environment: production
    app: warp-drive-ai
  ```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeNetworkCIDR**
  string

  IP CIDR to be assigned to the internal segment of this ViNS.

- **provider**
  object

  Required value

  Parameters for connecting to the Dynamix.

  - **provider.appId**
    string

    Required value

    App ID.

  - **provider.appSecret**
    string

    Required value

    App Secret.

  - **provider.controllerUrl**
    string

    Required value

    The URL to the Dynamix API endpoint.

  - **provider.insecure**
    boolean

    Set to `true` if Dynamix has a self-signed certificate.

Default: `false`

- **provider.oAuth2Url**
  string

  Required value

  The URL to the SSO Dynamix API endpoint.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **storagePolicy**
  string

  Required value

  The name of the storage policy used by default for virtual machine disks.

  A storage policy defines the storage endpoints and pools available to the account, as well as an IOPS limit. Basis Dynamix chooses the exact placement of a disk within the policy. You can set a different storage policy for a node group in its instance class.

  > **Warning.** Changing the value recreates the nodes of the `CloudEphemeral` type in all node groups, including groups with their own storage policy. Master nodes and the nodes of `nodeGroups` aren't recreated.

  Example:

  ```
  storagePolicy: storage_policy01
  ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> ⚠ The module lifecycle stage: Preview

Platform version

The module requires Basis Dynamix 4.6 or newer. Starting with version 4.6, Basis Dynamix creates disks and virtual machines only with a specified storage policy.

Before creating any resources in the cloud, `dhctl bootstrap` runs the `dynamix-storage-policy` preflight check. On Basis Dynamix earlier than 4.6, this check stops the installation.

Account permissions

The module works with Basis Dynamix through the user API (`/restmachine/cloudapi/*`). Use an account without platform administrator permissions (`/restmachine/cloudbroker/*`) for the module. With administrator permissions, the module gets access to the resources of other accounts, which breaks account isolation.

The account specified in the `provider` section of DynamixClusterConfiguration must be allowed to use the following user API groups:

Group	Component	Purpose
`account`, `locations`, `rg`	All components	Finding the account, the location, and the resource group by name
`extnet`, `vins`	Terraform, CAPD	External and internal networks
`image`	Terraform, CAPD	OS images for the nodes

Group	Component	Purpose
`storage_policy`	Terraform, CAPD, CSI, cloud-data-discoverer	Listing the storage policies available to the account, finding a policy by name, attaching policies to the cluster resource group
`disks`	Terraform, CSI	Disks of master nodes and PersistentVolumes
`compute`, `kvmx86`	Terraform, CCM, CAPD, CSI	Virtual machines and disk attachment
`lb`	CCM	Load balancers for Services of the LoadBalancer type

Storage policies in the cluster resource group

Basis Dynamix creates a virtual machine only if its storage policy is attached to the resource group. Therefore, when the module creates the cluster resource group, it attaches all `ENABLED` storage policies of the account to it.

The list of attached storage policies is updated when you run `dhctl converge` and when the `terraform-manager` module applies changes automatically. During the update, the module:

- Attaches the storage policies that have become available to the account.
- Detaches the storage policies that have become unavailable to the account or whose status has changed from `ENABLED` to another one.

Disable a storage policy only when the cluster nodes and volumes no longer use it. When a storage policy becomes unavailable to the account, the module deletes its StorageClass from the cluster. The volumes created in this policy are kept.

⚠ When the cluster is deleted or its installation is aborted, the module force-deletes the cluster resource group, bypassing the recycle bin. Everything still inside the group is deleted permanently with it, including volume disks, load balancers, and the virtual machines of node groups. The etcd disks of master nodes and the ViNS are also deleted bypassing the recycle bin. Move the data you need out of the cluster before deleting it.

Prepare an operating system image

Operating system vendors typically provide special cloud builds of their operating systems for use in virtualization environments. These builds typically contain virtual hardware drivers, cloud-init, virtualization guest agents, and are distributed as IMG or QCOW2 disk images. We recommend that you use these cloud images as the OS on the nodes in your clusters.

The cloud image of the operating system must be placed in the “Images” → “Template Images” section of the Basis Dynamix portal. Follow these steps to upload the OS image to the storage:

If the infrastructure does not have a DNS server, access to the Basis Dynamix portal from the cluster. Basis Dynamix portal from the cluster can be organized by adding the IP address and domains associated with the Basis Dynamix portal to the `cloud-init` template for generating the hosts file. This template is located in the `/etc/cloud/templates/` folder. The name of the template depends on the OS.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

⚠ After adding data to hosts and before creating the template from the virtual machine, you must run the `cloud-init clean` command.

Replacing the OS image

The OS image is set by the `imageName` parameter of the DynamixInstanceClass resource for `CloudEphemeral` nodes and in the `instanceClass` section of the DynamixClusterConfiguration resource for `CloudPermanent` nodes and master nodes.

The replacement procedure is described in “How do I replace the OS image in a cloud cluster?” .

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> ⚠ The module lifecycle stage: Preview

DynamixInstanceClass

Scope: Cluster
Version: v1

Parameters of a group of Dynamix VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.externalNetwork**
    string

    External network name.

    Example:

    ```
    externalNetwork: extnet_vlan_1700
    ```

  - **spec.imageName**
    string

    Required value

    Name of the OS image to base this VM on.

    Example:

    ```
    imageName: alt-p10-cloud-x86_64.img
    ```

  - **spec.memory**
    integer

    Required value

    Memory in MiB to allocate to Dynamix VirtualMachines.

    Example:

    ```
    memory: 8192
    ```

  - **spec.numCPUs**
    integer

    Required value

    Count of vCPUs to allocate to Dynamix VirtualMachines.

    Example:

    ```
    numCPUs: 2
    ```

  - **spec.rootDiskSizeGb**
    integer

Root disk size in GiB to use in Dynamix VirtualMachines.

The disk will be automatically resized if its size in the template differs from specified.

Default: `30`

Example:

```
rootDiskSizeGb: 30
```

- **spec.storagePolicy**
  string

  The name of the storage policy for the virtual machines of this instance class instead of the cluster-wide `storagePolicy`.

  > **Warning.** Changing the value recreates the nodes of the node groups that use this instance class.

  Example:

  ```
  storagePolicy: storage_policy01
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> ⚠ The module lifecycle stage: Preview

How to configure a LoadBalancer?

To configure a Service of the LoadBalancer type, add the following annotations to the Service manifest:

```
metadata:
  annotations:
    dynamix.cpi.flant.com/internal-network-name: <internal_name>
    dynamix.cpi.flant.com/external-network-name: <external_name>
```

Both annotations are required:

- `dynamix.cpi.flant.com/internal-network-name` — the name of the internal network in Basis Dynamix
- `dynamix.cpi.flant.com/external-network-name` — the name of the external network in Basis Dynamix

The terms “internal network” and “external network” are used in the context of Basis Dynamix. The external network does not have to be public and may use private IP addresses.

If one of the annotations is not specified, cloud-controller-manager will fail to process the Service.

Other ways to handle inbound traffic to the cluster, such as an external load balancer or MetalLB, are described in the Load balancing section.

How is the disk placement chosen?

The disk placement is defined by the storage policy. Its name is set in the following parameters:

- `storagePolicy` at the root of DynamixClusterConfiguration: The storage policy for all virtual machines in the cluster.
- `storagePolicy` in `masterNodeGroup.instanceClass`, `nodeGroups[].instanceClass`, or DynamixInstanceClass: The storage policy for a single node group instead of the cluster-wide one.

A storage policy sets the storage endpoint and pool pairs available to the account, as well as an IOPS limit. Basis Dynamix chooses the exact placement of a disk within the policy.

Which nodes are recreated when the storage policy changes?

The storage policy of a disk is set when the virtual machine is created and doesn’t change for an existing machine. Therefore, when the storage policy changes, the module recreates nodes of the `CloudEphemeral` type:

- When `storagePolicy` changes in a DynamixInstanceClass: The nodes of the groups that use this DynamixInstanceClass.
- When `storagePolicy` changes at the root of DynamixClusterConfiguration: The nodes of all groups, including groups with their own storage policy.

The module doesn’t recreate master nodes and the nodes of the `nodeGroups` groups. A new storage policy applies to such a node only when the node is created again.

Which StorageClasses does the module create?

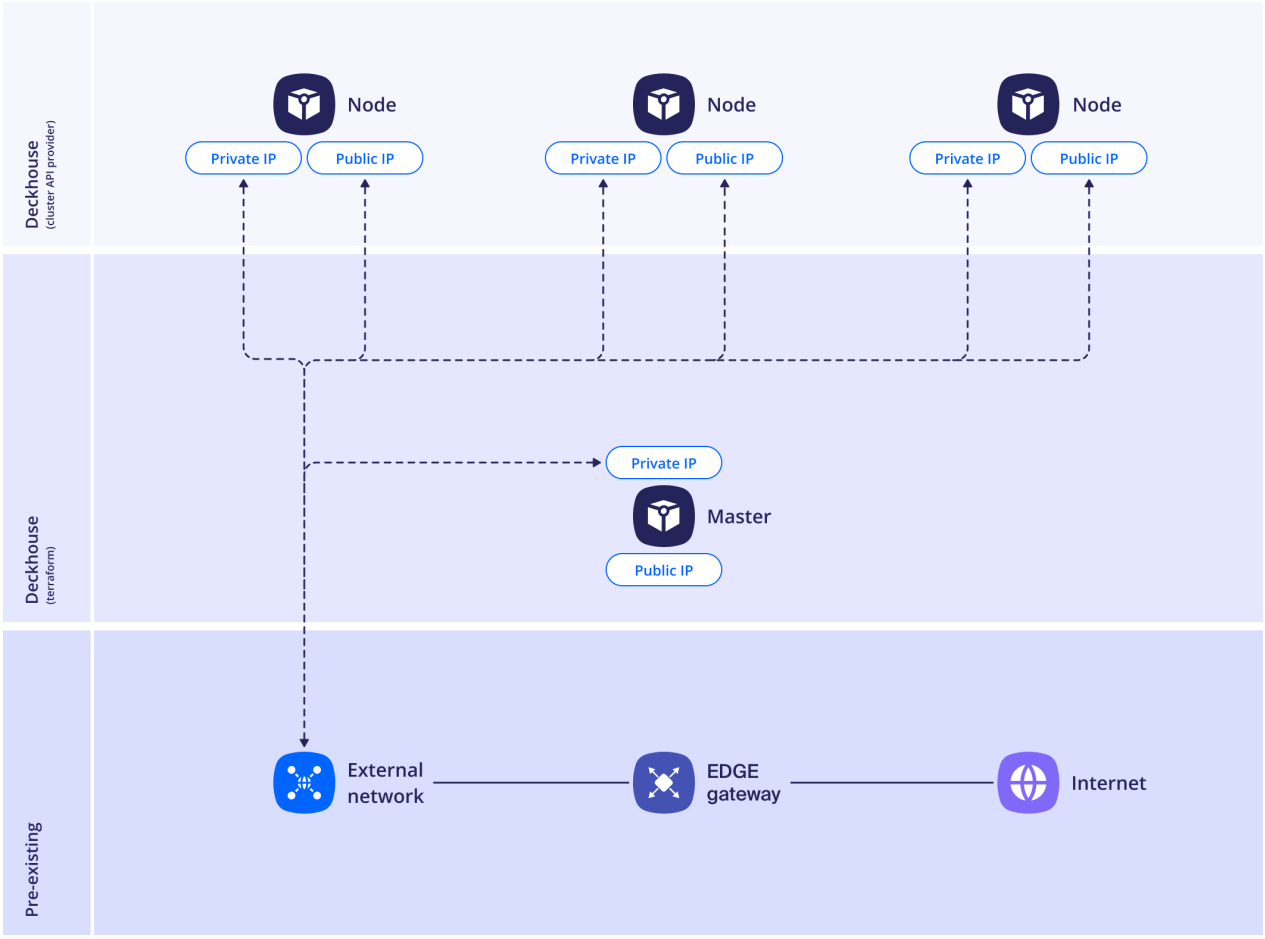
The module creates a StorageClass for every storage policy that is available to the cluster account and has the `ENABLED` status.

The module derives the StorageClass name from the storage policy name:

- Converts letters to lowercase
- Replaces spaces with `-`
- Removes the characters that a Kubernetes object name can’t contain, including `_`

For example, for the `storage_policy01` storage policy, the module creates the `storagepolicy01` StorageClass. If the names of several storage policies result in the same StorageClass name, the module creates the StorageClass for the policy whose name comes first when sorted.

To prevent the module from creating some StorageClasses, list their names or regular expressions in the `storageClass.exclude` parameter.



> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider - Basis Dynamix: Layouts

> ⚠ The module lifecycle stage: Preview

> ⚠ Changing `storagePolicy` recreates nodes of the `CloudEphemeral` type. The nodes that are recreated are listed in the module FAQ.

Standard

In this layout, the nodes are attached only to the external network. The nodes get DNS server addresses from the external network or from the `nameservers` parameter. If the external network doesn't provide DNS server addresses to the nodes, set them in `nameservers`. Otherwise, the nodes can't resolve names, and the installation stops at the preflight checks of the master node.

A new `nameservers` value applies only to the nodes created after the change.

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1
kind: DynamixClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
location: dynamix
account: acc_user
storagePolicy: storage_policy01
# Required if the external network doesn't provide DNS server addresses to the nodes.
nameservers: ["10.0.0.10"]
provider:
  controllerUrl: "<controller url>"
  oAuth2Url: "<oAuth2 url>"
  appId: "<app id>"
  appSecret: "<app secret>"
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    externalNetwork: "<external network>"
```

StandardWithInternalNetwork

In this layout, the nodes get DNS server addresses from the `nameservers` parameter through the ViNS.

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1
kind: DynamixClusterConfiguration
layout: StandardWithInternalNetwork
sshPublicKey: "<SSH_PUBLIC_KEY>"
location: dynamix
account: acc_user
storagePolicy: storage_policy01
nodeNetworkCIDR: "10.241.32.0/24"
nameservers: ["10.0.0.10"]
provider:
  controllerUrl: "<controller url>"
  oAuth2Url: "<oAuth2 url>"
  appId: "<app id>"
  appSecret: "<app secret>"
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    externalNetwork: "<external network>"
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — GCP

The module lifecycle stage: General Availability

The `cloud-provider-gcp` module integrates Deckhouse Platform with Google Cloud Platform (GCP). It allows the `node-manager` module to use GCP resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-gcp` module:

- Managing GCP resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the GCP side;
  - creates load balancers for Services of the LoadBalancer type;
  - updates cluster node metadata and removes from Kubernetes nodes that no longer exist in GCP.
- Provisioning disks via the Persistent Disk CSI driver (`pd.csi.storage.gke.io`) and creating StorageClasses for GCP disk types so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-google`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM). Virtual machine parameters are set in the GCPInstanceClass resource.
- Registering with `node-manager` so that GCPInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Third-party components

List of third-party software used in the `cloud-provider-gcp` module:

- Google Cloud Platform Cloud provider ccm/v33.4.0, ccm/v34.2.0, ccm/v35.0.5, ccm/v35.0.5, ccm/v35.0.5

  License: Apache License 2.0

  Cloud Controller Manager for Google Cloud Platform.

- Google Cloud Platform CSI driver v1.15.4, v1.15.4, v1.15.4, v1.15.4, v1.27.0

  License: Apache License 2.0

  CSI driver for Google Compute Engine persistent disks.

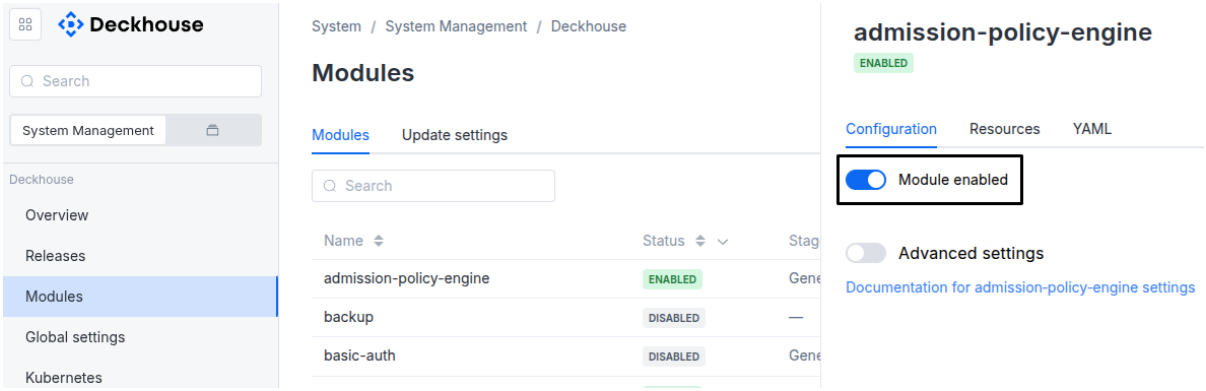
- Google Cloud Platform Terraform provider 4.85.0

  License: Mozilla Public License 2.0

  Terraform provider for Google Cloud Platform.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> The module lifecycle stage: General Availability

The module is configured automatically based on the chosen placement strategy defined in the GCPClusterConfiguration struct. In most cases, you do not have to configure the module manually.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-gcp` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

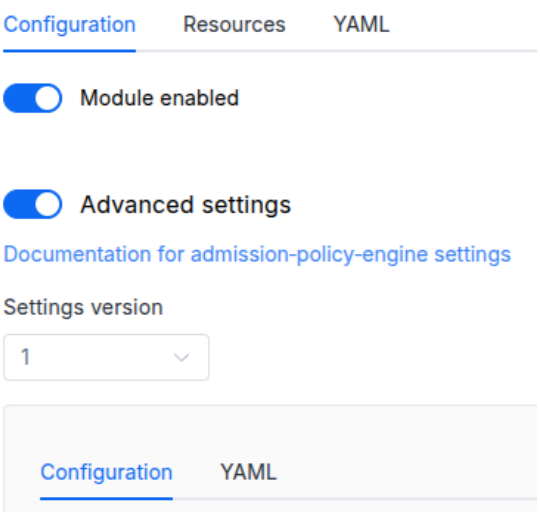
```
d8 system module enable cloud-provider-gcp
```

- **Using ModuleConfig `cloud-provider-gcp`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-gcp` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-gcp`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-gcp
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-gcp` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `cloud-provider-gcp` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-gcp`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-gcp` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-gcp
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-gcp` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-gcp`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-gcp
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

You can configure the number and parameters of provisioning machines in the cloud via the `NodeGroup` custom resource of the node-manager module. Also, in this custom resource, you can specify the instance class’s name for the above group of nodes (the `cloudInstances.ClassReference` parameter of NodeGroup). In the case of the GCP cloud provider, the instance class is the `GCPInstanceClass` custom resource that stores specific parameters of the machines.

The module automatically creates StorageClasses that cover all the available disk types in GCP:

Type	Replication	StorageClass Name
standard	none	pd-standard-not-replicated
standard	regional	pd-standard-replicated
balanced	none	pd-balanced-not-replicated
balanced	regional	pd-balanced-replicated
ssd	none	pd-ssd-not-replicated
ssd	regional	pd-ssd-replicated

Also, it can filter out the unnecessary StorageClasses (you can do this via the `exclude` parameter).

Parameters

Schema version: 1

- **settings**
  object
  - **settings.storageClass**
    object
    - **settings.storageClass.default**
      Deprecated
      string

      The name of StorageClass that will be used in the cluster by default.

      If the parameter is omitted, the default StorageClass is either:

      - existing StorageClass present in the cluster that has the default annotation;
      - the first (in lexicographic order) StorageClass created by the module (in accordance with the order listed in the table above).

      > **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

      Example:

      ```
      default: pd-ssd-not-replicated
      ```

    - **settings.storageClass.exclude**
      array of strings

      A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster;

      Example:

      ```
      exclude:
      - pd-standard.*
      - pd-ssd-replicated
      ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> The module lifecycle stage: General Availability

GCPClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in GCP.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: GCPClusterConfiguration
layout: WithoutNAT
sshKey: "<SSH_PUBLIC_KEY>"
subnetworkCIDR: 10.36.0.0/24
masterNodeGroup:
  replicas: 1
  zones:
  - europe-west3-b
  instanceClass:
    machineType: n1-standard-4
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
    diskSizeGb: 50
nodeGroups:
- name: static
  replicas: 1
  zones:
  - europe-west3-b
  instanceClass:
    machineType: n1-standard-4
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
    diskSizeGb: 50
    additionalNetworkTags:
    - tag1
    additionalLabels:
      kube-node: static
provider:
  region: europe-west3
  serviceAccountJSON: "<SERVICE_ACCOUNT_JSON>"
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **kind**
  string

  Required value

  Allowed values: `GCPClusterConfiguration`

- **labels**
  object

  A list of labels to attach to cluster resources.

  Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

  You can learn more about the labels in the official documentation.

  Format — `key: value`.

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  `Standard` - set Cloud NAT mode. More info...

  `WithoutNAT` - a dedicated VPC is created for the cluster. All cluster nodes have public IP addresses. More info...

  Allowed values: `Standard`, `WithoutNAT`

- **masterNodeGroup**
  object

  Required value

  Parameters of the master’s NodeGroup.

> **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

- **masterNodeGroup.instanceClass**
  object

  Required value

  Partial contents of the GCPInstanceClass fields.

  - **masterNodeGroup.instanceClass.additionalLabels**
    object

    Additional labels.

    For details on labels, refer to the Google Cloud documentation.

    Example:

    ```
    project: cms-production
    severity: critical
    ```

  - **masterNodeGroup.instanceClass.additionalNetworkTags**
    array of strings

    The list of additional network tags.

    You can use network tags to apply firewall rules to instances. The detailed description of network tags is available in the Google Cloud documentation.

  - **masterNodeGroup.instanceClass.disableExternalIP**
    boolean

    Defines whether to disable external IP for an instance or not.

    This parameter is only available for the `Standard` layout.

    True means that nodes do not have public addresses and connect to the Internet over `CloudNAT`;

    False means that static public addresses are created for nodes, they are also used for One-to-one NAT.;

    Default: `true`

    Allowed values: `true`, `false`

  - **masterNodeGroup.instanceClass.diskSizeGb**
    integer

    Instance disk size in gibibytes.

    Example:

    ```
    diskSizeGb: 50
    ```

  - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
    integer

    Etcd disk size in gibibytes.

    Default: `20`

    Example:

    ```
    etcdDiskSizeGb: 20
    ```

  - **masterNodeGroup.instanceClass.image**
    string

    Required value

    Image to use while provisioning GCP servers.

    You can find a list of available images in the provider documentation.

    The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

    Example:

```
image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
```

- **masterNodeGroup.instanceClass.machineType**
  string

  Required value

  Machine type of GCP instance.

  > **i** **Caution!** Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

  ```
  machineType: n1-standard-4
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create.

  It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the GCPInstanceClass fields.

    - **nodeGroups.instanceClass.additionalLabels**
      object

      Additional labels.

      For details on labels, refer to the Google Cloud documentation.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **nodeGroups.instanceClass.additionalNetworkTags**
      array of strings

      The list of additional network tags.

      You can use network tags to apply firewall rules to instances. The detailed description of network tags is available in the Google Cloud documentation.

    - **nodeGroups.instanceClass.disableExternalIP**
      boolean

      Defines whether to disable external IP for an instance or not.

      This parameter is only available for the `Standard` layout.

      True means that nodes do not have public addresses and connect to the Internet over

`CloudNAT`;

False means that static public addresses are created for nodes, they are also used for One-to-one NAT.;

Default: `true`

Allowed values: `true`, `false`

- **nodeGroups.instanceClass.diskSizeGb**
  integer

  Instance disk size in gibibytes.

  Example:

  ```
  diskSizeGb: 50
  ```

- **nodeGroups.instanceClass.image**
  string

  Required value

  Image to use while provisioning GCP servers.

  You can find a list of available images in the provider documentation.

  The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

  Example:

  ```
  image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
  ```

- **nodeGroups.instanceClass.machineType**
  string

  Required value

  Machine type of GCP instance.

  > **Caution!** Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

  ```
  machineType: n1-standard-4
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**
  object

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` (https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.25/#objectmeta-v1-meta).

  - **nodeGroups.nodeTemplate.labels**
    object

    The same as the `metadata.labels` standard (https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.25/#objectmeta-v1-meta).

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object(https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.25/#taint-v1-core).

> **i** Available fields: `effect`, `key`, and `values`.

- **nodeGroups.nodeTemplate.taints.effect**
  string

  Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
- **nodeGroups.nodeTemplate.taints.key**
  string
- **nodeGroups.nodeTemplate.taints.value**
  string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeGroups.zones**
  array of strings

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **peeredVPCs**
  array of strings

  A list of GCP VPC networks to peer with the cluster network.

  The service account must have access to all the VPCs listed. You have to configure the peering connection manually if no access is available.

- **provider**
  object

  Required value

  Parameters for connecting to the GCP API.

  - **provider.region**
    string

    Required value

    The name of the region where instances will be provisioned.

  - **provider.serviceAccountJSON**
    string

    Required value

    A key to the Service Account with Project Admin privileges (`service account key`) in the JSON format.

    How to create it a `service account key`.

- **sshAllowList**
  array of strings

  A list of CIDR’s allowed to connect to nodes via SSH.

  By default, from any.

- **sshKey**
  string

  Required value

  A public key to access nodes as `user`.

- **standard**
  object

  Settings for the `Standard` layout.

  - **standard.cloudNATAddresses**
    array of strings

    A list of public static IP addresses for `Cloud NAT`.

- **subnetworkCIDR**
  string

  A subnet to use for cluster nodes.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **withoutNAT**
  object

  Settings for the `WithoutNAT` layout.

- **zones**
  array of strings

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> **i** The module lifecycle stage: General Availability

> ⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:
>
> - Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
> - `CgroupsV2` support.
> - Systemd version `244` or newer.
> - `erofs` kernel module support.
>
> For more information, see the documentation.

> ⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:
>
> - `cloud-config.service`;
> - `cloud-final.service`;
> - `cloud-init.service`.

You need to create a service account so that Deckhouse Platform can manage resources in the Google Cloud. Below is a brief sequence of steps to create a service account. If you need detailed instructions, you can find them in the provider's documentation.

> ⚠ The created `service account key` cannot be restored, you can only delete and create a new one.

> ⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

⚠ Starting with DP version 1.77, GCP uses the `cilium` CNI by default for new clusters. Existing clusters keep the current CNI configuration.

New clusters require Linux kernel version `5.8` or newer on all nodes. Make sure firewalls or security groups allow inter-node UDP traffic for Cilium VXLAN. For more information about Cilium requirements, limitations, and behavior, see the installation requirements, Network interaction of the platform components, and the `cni-cilium` module documentation.

Setup using Google Cloud Console

Follow this link, select your project and create a new service account or select an existing one.

The account must be assigned several necessary roles:

```
Compute Admin
Service Account User
Network Management Admin
```

You can add roles when creating a service account or edit them here.

To create a `service account key` in JSON format, click on three vertical dots in the Actions column and select `Manage keys`. Next, click on `Add key` -> `Create new key` -> `Key type` -> `JSON`.

Setup using gcloud CLI

To configure via the command line interface, follow these steps:

1. Export environment variables:

   ```
   export PROJECT_ID=sandbox
   export SERVICE_ACCOUNT_NAME=deckhouse
   ```

2. Select a project:

   ```
   gcloud config set project $PROJECT_ID
   ```

3. Create a service account:

   ```
   gcloud iam service-accounts create $SERVICE_ACCOUNT_NAME
   ```

4. Connect roles to the service account:

   ```
   for role in roles/compute.admin roles/iam.serviceAccountUser roles/networkmanagement.admin;
   do gcloud projects add-iam-policy-binding ${PROJECT_ID} --
   member=serviceAccount:${SERVICE_ACCOUNT_NAME}@${PROJECT_ID}.iam.gserviceaccount.com \
      --role=${role}; done
   ```

   List of roles required:

   ```
   roles/compute.admin
   roles/iam.serviceAccountUser
   roles/networkmanagement.admin
   ```

5. Verify service account roles:

   ```
   gcloud projects get-iam-policy ${PROJECT_ID} --flatten="bindings[].members" --
   format='table(bindings.role)' \
        --
   filter="bindings.members:${SERVICE_ACCOUNT_NAME}@${PROJECT_ID}.iam.gserviceaccount.com"
   ```

6. Create a `service account key`:

   ```
   gcloud iam service-accounts keys create --iam-account
   ${SERVICE_ACCOUNT_NAME}@${PROJECT_ID}.iam.gserviceaccount.com \
        ~/service-account-key-${PROJECT_ID}-${SERVICE_ACCOUNT_NAME}.json
   ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

GCPInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of GCP Instances used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalDisks**
    array of objects

    A list of additional disks to attach to the instance.

    Useful for storage workloads such as LINSTOR, Ceph, NFS, and similar.

    Example:

    ```
    additionalDisks:
    - size: 100
      type: pd-ssd
    ```

    - **spec.additionalDisks.autoDelete**
      boolean

      Automatically delete the disk when the instance is deleted.

      Default: `true`

    - **spec.additionalDisks.provisionedIops**
      integer

      Provisioned IOPS for the disk.

      Required for `pd-extreme` and `hyperdisk-extreme` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.provisionedThroughput**
      integer

      Provisioned throughput in MiB/s for the disk.

      Applicable for `hyperdisk-balanced` and `hyperdisk-throughput` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.size**
      integer

      Required value

      Disk size in gigabytes (GB).

      Allowed values: `1 <= X`

Example:

```
size: 100
```

- **spec.additionalDisks.type**
  string

  Required value

  Disk type.

  - `pd-standard` — standard Persistent Disk (HDD).
  - `pd-balanced` — balanced Persistent Disk (SSD).
  - `pd-ssd` — SSD Persistent Disk.
  - `pd-extreme` — extreme Persistent Disk; requires `provisionedIops`.
  - `hyperdisk-balanced` — Hyperdisk with balanced performance.
  - `hyperdisk-throughput` — Hyperdisk optimized for throughput.
  - `hyperdisk-extreme` — Hyperdisk with maximum performance; requires `provisionedIops`.

  Allowed values: `pd-standard`, `pd-balanced`, `pd-ssd`, `pd-extreme`, `hyperdisk-balanced`, `hyperdisk-throughput`, `hyperdisk-extreme`

  Example:

  ```
  type: pd-ssd
  ```

- **spec.additionalLabels**
  object

  Additional labels.

  More info...

  Example:

  ```
  additionalLabels:
    project: cms-production
    severity: critical
  ```

- **spec.additionalNetworkTags**
  array of strings

  The list of additional tags.

  For example, you can use tags to apply firewall rules to instances. The detailed description of network tags is available in the official documentation.

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `machineType` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`a2-highgpu-8g`, `c2-standard-8`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

Node memory resources.

Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

Example:

```
memory: 1500Mi
```

- **spec.disableExternalIP**
  boolean

  Defines whether to disable external ip for an instance or not. True means that an instance is created without external ip

- **spec.diskSizeGb**
  integer

  Instance’s root disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGb: 20
  ```

- **spec.diskType**
  string

  Instance’s disk type.

  Default: `pd-standard`

  Allowed values: `pd-standard`, `pd-ssd`

  Example:

  ```
  diskType: pd-ssd
  ```

- **spec.enableNestedVirtualization**
  boolean

  Enables nested virtualization on the instance.

  Required for running virtual machine workloads (e.g., KVM-based VMs) inside GCP instances.

  Warning. Only supported on specific machine types. See the GCP documentation for the list of compatible types.

  Default: `false`

- **spec.image**
  string

  Not required value.

  Image to use while provisioning GCP servers.

  You can find a list of available images in the provider documentation.

  The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

  Example:

  ```
  image: https://www.googleapis.com/compute/v1/projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
  ```

- **spec.machineType**
  string

  Required value

  Machine type of GCP instance.

  Caution! Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

```
machineType: n1-standard-4
```

  - **spec.preemptible**
    boolean

    Order preemptible virtual machines (preemptible instances).

    Google Cloud can interrupt such a machine at any time.

    For more information about preemptible virtual machines, see the provider documentation.

    Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of GCP Instances used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalDisks**
    array of objects

    A list of additional disks to attach to the instance.

    Useful for storage workloads such as LINSTOR, Ceph, NFS, and similar.

    Example:

```
additionalDisks:
- size: 100
  type: pd-ssd
```

    - **spec.additionalDisks.autoDelete**
      boolean

      Automatically delete the disk when the instance is deleted.

      Default: `true`

    - **spec.additionalDisks.provisionedIops**
      integer

      Provisioned IOPS for the disk.

      Required for `pd-extreme` and `hyperdisk-extreme` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.provisionedThroughput**
      integer

      Provisioned throughput in MiB/s for the disk.

      Applicable for `hyperdisk-balanced` and `hyperdisk-throughput` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.size**
      integer

      Required value

      Disk size in gigabytes (GB).

      Allowed values: `1 <= X`

      Example:

```
size: 100
```

    - **spec.additionalDisks.type**
      string

      Required value

Disk type.

- `pd-standard` — standard Persistent Disk (HDD).
- `pd-balanced` — balanced Persistent Disk (SSD).
- `pd-ssd` — SSD Persistent Disk.
- `pd-extreme` — extreme Persistent Disk; requires `provisionedIops`.
- `hyperdisk-balanced` — Hyperdisk with balanced performance.
- `hyperdisk-throughput` — Hyperdisk optimized for throughput.
- `hyperdisk-extreme` — Hyperdisk with maximum performance; requires `provisionedIops`.

Allowed values: `pd-standard`, `pd-balanced`, `pd-ssd`, `pd-extreme`, `hyperdisk-balanced`, `hyperdisk-throughput`, `hyperdisk-extreme`

Example:

```
type: pd-ssd
```

- **spec.additionalLabels**
  object

  Additional labels.

  More info...

  Example:

  ```
  additionalLabels:
    project: cms-production
    severity: critical
  ```

- **spec.additionalNetworkTags**
  array of strings

  The list of additional tags.

  For example, you can use tags to apply firewall rules to instances. The detailed description of network tags is available in the official documentation.

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `machineType` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`a2-highgpu-8g`, `c2-standard-8`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

    Node memory resources.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    memory: 1500Mi
    ```

- **spec.disableExternalIP**
  boolean

  Defines whether to disable external ip for an instance or not. True means that an instance is created without external ip

- **spec.diskSizeGb**
  integer

  Instance’s root disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGb: 20
  ```

- **spec.diskType**
  string

  Instance’s disk type.

  Default: `pd-standard`

  Allowed values: `pd-standard`, `pd-ssd`

  Example:

  ```
  diskType: pd-ssd
  ```

- **spec.enableNestedVirtualization**
  boolean

  Enables nested virtualization on the instance.

  Required for running virtual machine workloads (e.g., KVM-based VMs) inside GCP instances.

  Warning. Only supported on specific machine types. See the GCP documentation for the list of compatible types.

  Default: `false`

- **spec.image**
  string

  Not required value.

  Image to use while provisioning GCP servers.

  You can find a list of available images in the provider documentation.

  The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

  Example:

  ```
  image: https://www.googleapis.com/compute/v1/projects/ubuntu-os-
  cloud/global/images/ubuntu-2404-noble-amd64-v20260128
  ```

- **spec.machineType**
  string

  Required value

  Machine type of GCP instance.

  Caution! Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

  ```
  machineType: n1-standard-4
  ```

- **spec.preemptible**
  boolean

  Order preemptible virtual machines (preemptible instances).

  Google Cloud can interrupt such a machine at any time.

For more information about preemptible virtual machines, see the provider documentation.

Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

How do I create a cluster?

1. Set up a cloud environment.
2. Enable the module or pass the `--extra-config-map-data base64_encoding_of_custom_config` flag with the module parameters to the `install.sh` script.
3. Create one or more GCPInstanceClass custom resources.
4. Create one or more NodeGroup custom resources for managing the number and the process of provisioning machines in the cloud.

Adding CloudStatic nodes to a cluster

For the VMs, you want to add to a cluster as nodes, add a `Network Tag` similar to the cluster prefix.

You can find out `prefix` using the command:

```
d8 k get mc global -o jsonpath='{.spec.settings.prefix}{"\n"}'
```

If the value is empty, get it from the deprecated `cloud.prefix` parameter of ClusterConfiguration (the prefix has moved to the ModuleConfig `global`):

```
d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r '.data."cluster-
configuration.yaml"' \
  | base64 -d | grep prefix
```

How to create preemptible nodes in GCP?

Preemptible virtual machines in Google Cloud are called preemptible instances. To make a node group order them, set the `preemptible` parameter of the GCPInstanceClass resource to `true`.

Example:

```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: worker-preempt
spec:
  machineType: n1-standard-4
  diskSizeGb: 30
  preemptible: true
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker-preempt
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    classReference:
      kind: GCPInstanceClass
      name: worker-preempt
    minPerZone: 2
    maxPerZone: 4
    zones:
      - europe-west4-a
```

Along with this parameter, Deckhouse Platform (DP) disables the automatic restart of the virtual machine and makes it stop during host maintenance.

Limitations of preemptible nodes in GCP

Consider the following limitations:

- The `preemptible` parameter applies only to CloudEphemeral node groups, because GCPInstanceClass applies only to them.
- DP does not track Google Cloud notices about an upcoming preemption and does not drain the node in advance. When Google Cloud stops the instance, the node switches to the `NotReady` state, and the group orders a new node in place of the lost one. Until then, the pods of the stopped node may appear in the Kubernetes API with the `Running` status even though they are no longer available.
- Place only the workload that tolerates a sudden node loss on preemptible nodes.

⚠ Changing the `preemptible` parameter in an existing GCPInstanceClass causes all nodes of the corresponding group to be recreated.

How do I replace the OS image on the nodes?

The OS image is set by the `image` parameter of the GCPInstanceClass resource for `CloudEphemeral` nodes and in the `instanceClass` section of the GCPClusterConfiguration resource for `CloudPermanent` nodes and master nodes.

The replacement procedure is described in “How do I replace the OS image in a cloud cluster?” .

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

i The module lifecycle stage: General Availability

An example of the `GCPInstanceClass` custom resource

Below is a simple example of custom resource `GCPInstanceClass` configuration:

```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: test
spec:
  machineType: n1-standard-1
```

Enabling nested virtualization

To run virtual machine workloads (e.g., KVM-based VMs) inside GCP instances, enable nested virtualization.

> **i** Only specific machine types support nested virtualization. See the GCP documentation for the list of compatible types.

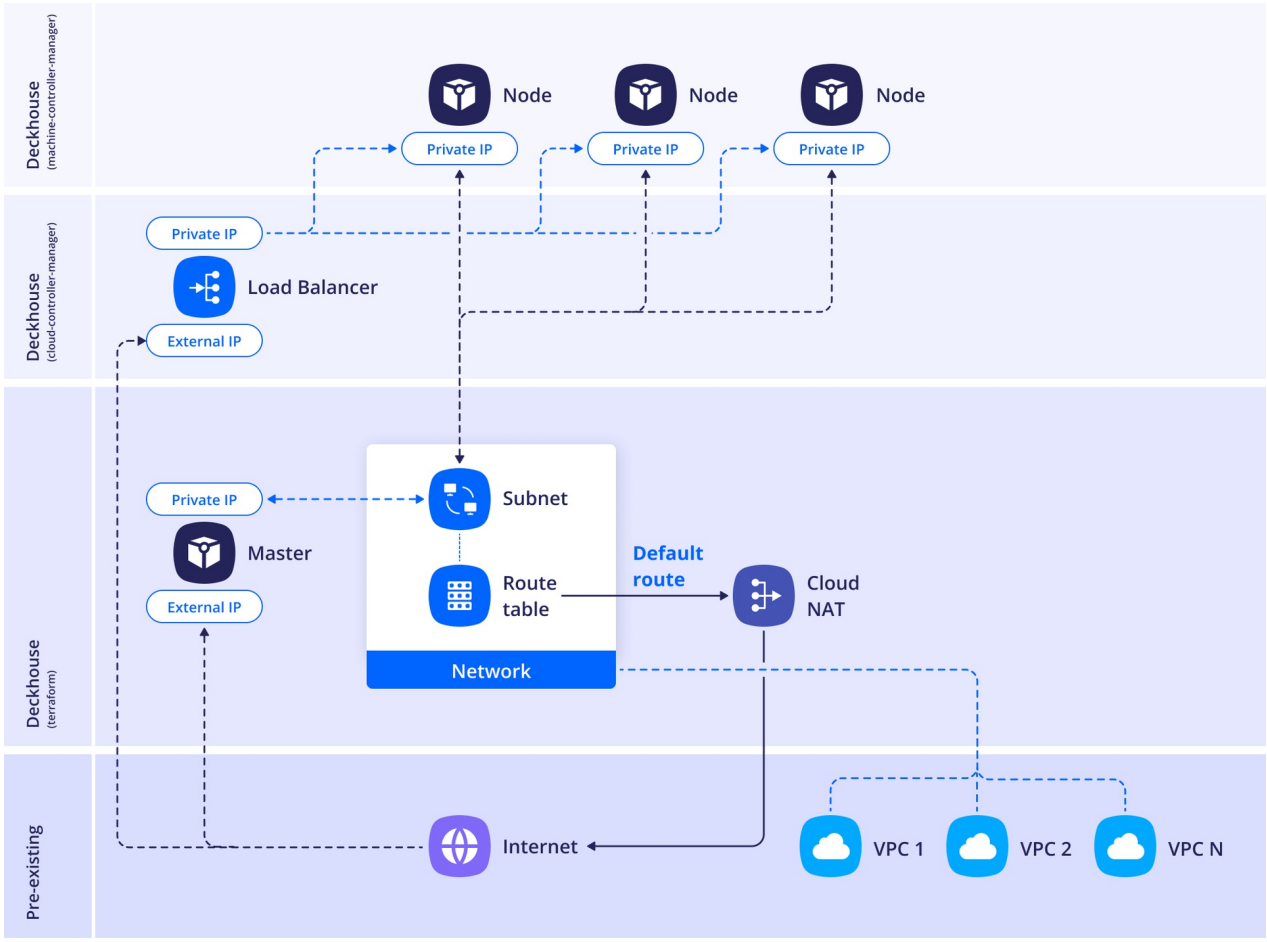
```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: vm-nodes
spec:
  machineType: n2-standard-8
  enableNestedVirtualization: true
```

Adding additional disks

To attach additional disks to instances (for example, for LINSTOR, Ceph, NFS storage nodes, and similar solutions), specify them in the `additionalDisks` parameter:

```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: storage-nodes
spec:
  machineType: n1-standard-8
  additionalDisks:
  - size: 200
    type: pd-ssd
  - size: 500
    type: pd-standard
    autoDelete: true
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.



Layouts

> The module lifecycle stage: General Availability

Two layouts are supported. Below is more information about each of them.

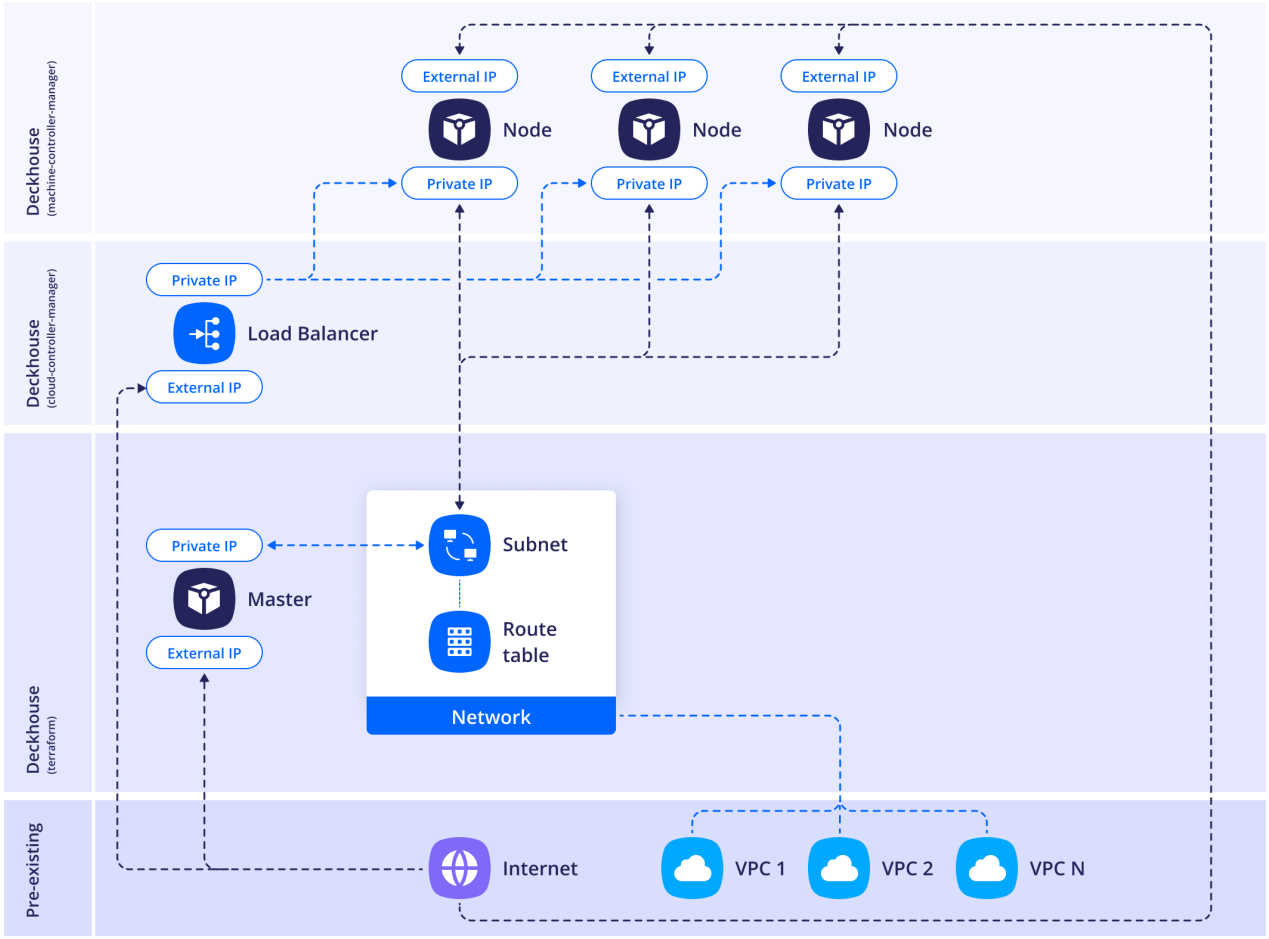
Standard

- A separate VPC with Cloud NAT is created for the cluster.
- Nodes in the cluster do not have public IP addresses.
- Public IP addresses can be allocated to master and static nodes:
  - In this case, one-to-one NAT is used to translate the public IP address to the node's IP address (note that CloudNAT is not used in such a case).
- If the master does not have a public IP, then an additional instance with a public IP (aka bastion host) is required for installation tasks and accessing the cluster.
- Peering can also be configured between the cluster VPC and other VPCs.

When a cluster is created, the module creates the following firewall rules in the cluster VPC:

- `<CLUSTER PREFIX>-ssh-and-ping` — allow incoming traffic over the ICMP and TCP (port `22`) protocols to nodes with the `<CLUSTER PREFIX>` network tag from CIDRs listed in `sshAllowList` (default `0.0.0.0/0`)
- `<CLUSTER_PREFIX>-intercommunication` — allow any traffic between nodes with the `<CLUSTER_PREFIX>` network tag, and from the pod subnet (`podSubnetCIDR`)

Apply custom firewall rules to nodes via additional network tags (`additionalNetworkTags`):



- for master nodes — in the `masterNodeGroup.instanceClass.additionalNetworkTags` parameter of the GCPClusterConfiguration resource
- for static nodes — in the `nodeGroups[].instanceClass.additionalNetworkTags` parameter of the GCPClusterConfiguration resource
- for ephemeral nodes — in the `spec.additionalNetworkTags` parameter of the GCPInstanceClass resource

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: GCPClusterConfiguration
layout: Standard
standard:
  # Optional, compute address names from this list are used as addresses for Cloud NAT.
  cloudNATAddresses:
  - example-address-1
  - example-address-2
subnetworkCIDR: 10.0.0.0/24       # Required.
peeredVPCs:
# Optional, list of GCP VPC Networks with which Kubernetes VPC Network will be peered.
- default
sshKey: "<SSH_PUBLIC_KEY>"  # Required.
labels:
  kube: example
masterNodeGroup:
  replicas: 1
  zones:                       # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128 # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    disableExternalIP: false       # Optional, by default master has externalIP.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:            # Optional.
      kube-node: master
nodeGroups:
- name: static
  replicas: 1
  zones:                       # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128 # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    disableExternalIP: true        # Optional, by default nodes do not have externalIP.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:            # Optional.
      kube-node: static
provider:
  region: europe-west4           # Required.
  serviceAccountJSON: |          # Required.
    {
      "type": "service_account",
      "project_id": "sandbox",
      "private_key_id": "98sdcj5e8c7asd98j4j3n9csakn",
      "private_key": "-----BEGIN PRIVATE KEY-----",
      "client_id": "342975658279248",
      "auth_uri": "https://accounts.google.com/o/oauth2/auth",
      "token_uri": "https://oauth2.googleapis.com/token",
      "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
      "client_x509_cert_url": "https://www.googleapis.com/robot/v1/metadata/x509/k8s-
test%40sandbox.iam.gserviceaccount.com"
    }
```

WithoutNAT

- A dedicated VPC is created for the cluster; all cluster nodes have public IP addresses.
- Peering can be configured between the cluster VPC and other VPCs.

When a cluster is created, the module creates the following firewall rules in the cluster VPC:

- `<CLUSTER_PREFIX>-ssh-and-ping` — allow incoming traffic over the ICMP and TCP (port `22`) protocols to nodes with the `<CLUSTER_PREFIX>` network tag from CIDRs listed in `sshAllowList` (default `0.0.0.0/0`)
- `<CLUSTER_PREFIX>-intercommunication` — allow any traffic between nodes with the `<CLUSTER_PREFIX>` network tag, and from the pod subnet (`podSubnetCIDR`)

Apply custom firewall rules to nodes via additional network tags (`additionalNetworkTags`):

- for master nodes — in the `masterNodeGroup.instanceClass.additionalNetworkTags` parameter of the GCPClusterConfiguration resource
- for static nodes — in the `nodeGroups[].instanceClass.additionalNetworkTags` parameter of the GCPClusterConfiguration resource
- for ephemeral nodes — in the `spec.additionalNetworkTags` parameter of the GCPInstanceClass resource

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: GCPClusterConfiguration
layout: WithoutNAT
subnetworkCIDR: 10.0.0.0/24       # Required.
# Optional, list of GCP VPC Networks with which Kubernetes VPC Network will be peered.
peeredVPCs:
- default
labels:
  kube: example
masterNodeGroup:
  replicas: 1
  zones:                        # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128  # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:             # Optional.
      kube-node: master
nodeGroups:
- name: static
  replicas: 1
  zones:                        # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128  # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:             # Optional.
      kube-node: static
provider:
  region: europe-west4            # Required.
  serviceAccountJSON: |           # Required.
    {
      "type": "service_account",
      "project_id": "sandbox",

Cloud provider — Huawei Cloud

> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability

The `cloud-provider-huaweicloud` module integrates Deckhouse Platform with Huawei Cloud. It allows the `node-manager` module to use Huawei Cloud resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-huaweicloud` module:

- Managing Huawei Cloud resources via `cloud-controller-manager`:
  - updates instance and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in the cloud;
  - creates load balancers (ELB) for Services of the LoadBalancer type.

- Provisioning disks via the EVS CSI driver (`evs.csi.huaweicloud.com`) so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-huaweicloud`.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the HuaweiCloudInstanceClass resource.
- Registering with `node-manager` so that HuaweiCloudInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Third-party components

List of third-party software used in the `cloud-provider-huaweicloud` module:

- Huawei Cloud provider v0.26.9

  License: Apache License 2.0

  Cloud Controller Manager for Huawei Cloud.

- Huawei CSI driver evs-0.1.11

  License: Apache License 2.0

  CSI driver for Huawei Cloud EVS and SFS.

- Huawei Terraform provider 1.69.0

  License: Mozilla Public License 2.0

  Terraform provider for Huawei Cloud.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in Huawei Cloud.

List of required Huawei Cloud services

A list of services required for Deckhouse Platform to work in Huawei Cloud:

Service	API version
Identity	v3
Compute	v2.1
Network (VPC)	v1/v2
Network (OpenStack Neutron API)	v2.0
Block Storage	v3
Load Balancing (ELB) *	v3

* Required if load balancers need to be provisioned in the cluster.

The module has 1 alert.

The module does not have any settings.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> The module lifecycle stage: General Availability

HuaweiCloudClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in Huawei Cloud.

Used by the cloud provider if a cluster's control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

Example:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
zones:
- eu-3a
standard:
  externalNetworkName: external-network
provider:
  domainName: "<DOMAIN_NAME>"
  region: eu-3
  accessKey: "<USERNAME>"
  secretKey: "<PASSWORD>"
masterNodeGroup:
  replicas: 1
  instanceClass:
    flavorName: m1.large
    rootDiskSize: 50
    imageName: debian-11-genericcloud-amd64-20220911-1135
  volumeTypeMap:
    eu-1a: fast-eu-1a
    eu-1b: fast-eu-1b
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.large
    imageName: debian-11-genericcloud-amd64-20220911-1135
    rootDiskSize: 50
  volumeTypeMap:
    eu-1a: fast-eu-1a
    eu-1b: fast-eu-1b
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **kind**
  string

  Required value

  Allowed values: `HuaweiCloudClusterConfiguration`

- **layout**
  string

  Required value

  The layout name.

  For details about possible provider layouts, refer to Layouts.

- **masterNodeGroup**

  Required value

  The definition of a NodeGroup for master nodes.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**

object

Required value

Partial contents of the fields of the HuaweiCloudInstanceClass.

- **masterNodeGroup.instanceClass.etcdDiskSizeGb**
  integer

  Etcd disk size in gigabytes.

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **masterNodeGroup.instanceClass.flavorName**
  string

  Required value

  The flavor of Huawei Cloud servers.

- **masterNodeGroup.instanceClass.imageName**
  string

  Required value

  The image to use while provisioning Huawei Cloud servers.

  For the list of operating systems and specific versions supported by Deckhouse, refer to Supported Kubernetes and OS versions (take into account the Deckhouse version you use).

- **masterNodeGroup.instanceClass.rootDiskSize**
  integer

  The size of a root disk in gigabytes.

  This parameter also affects the type of a root disk.

  Default: `50`

  Example:

  ```
  rootDiskSize: 50
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.serverGroup**
  object

  The ServerGroup object groups instances together. The instances in the group are placed on the same hypervisor (affinity) or different hypervisors (anti-affinity). This allows you to increase the fault tolerance of the cluster.

  - **masterNodeGroup.serverGroup.policy**
    string

    Required value

    The policy that determines how instances are distributed among hypervisors.

    - `AntiAffinity`: Instances are placed on different hypervisors. This policy is managed by Deckhouse.

    Allowed values: `AntiAffinity`

- **masterNodeGroup.volumeTypeMap**
  object

  Required value

  A dictionary of disk types for storing etcd data and Kubernetes configuration files.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <DISK TYPE>` (see the example).

  If the `rootDiskSize` parameter is specified, the same disk type will be used for the VM's boot drive.

  We recommend using the fastest disks provided by the provider in all cases.

  If the value specified in `replicas` exceeds the number of elements in the dictionary, the master nodes whose number exceeds the length of the dictionary get the values starting from the beginning of the dictionary. For example, if `replicas: 5`, then master-0, master-2, master-4 will have the `fast-eu-1a` disk type, while master-1, master-3 will have the `fast-eu-1b` disk type.

Example:

```
volumeTypeMap:
  eu-1a: fast-eu-1a
  eu-1b: fast-eu-1b
```

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields.

    - **nodeGroups.instanceClass.additionalNetworks**
      array of strings

      Not required value.

      List of network IDs (subnets) for secondary NICs.

    - **nodeGroups.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in gigabytes.

      Default: `10`

      Example:

      ```
      etcdDiskSizeGb: 10
      ```

    - **nodeGroups.instanceClass.flavorName**
      string

      Required value

      The flavor of Huawei Cloud servers.

    - **nodeGroups.instanceClass.imageName**
      string

      Required value

      The image to use while provisioning Huawei Cloud servers.

      For the list of operating systems and specific versions supported by Deckhouse, refer to Supported Kubernetes and OS versions (take into account the Deckhouse version you use).

    - **nodeGroups.instanceClass.mainNetwork**
      string

      Not required value.

      Primary network ID for the VM’s main NIC. **By default**, the value from ‘HuaweiCloudDiscoverData’ is used.

    - **nodeGroups.instanceClass.rootDiskSize**
      integer

      The size of a root disk in gigabytes.

      This parameter also affects the type of a root disk.

      Default: `50`

      Example:

      ```
      rootDiskSize: 50
      ```

  - **nodeGroups.name**
    string

    Required value

    The name of the NodeGroup to use for generating node names.

  - **nodeGroups.nodeTemplate**

    Parameters of Node objects in Kubernetes to add after registering the node.

    - **nodeGroups.nodeTemplate.annotations**
      object

      The same as the `metadata.annotations` standard field.

      Example:

```
annotations:
  ai.fleet.com/discombobulate: 'true'
```

- **nodeGroups.nodeTemplate.labels**
  object

  A list of labels to attach to all cluster resources, if they support it.

  The same as the `metadata.labels` standard field.

  If you change a label on a running cluster, recreate all virtual machines after the changes come into effect.

  Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeGroups.volumeTypeMap**
  object

  A dictionary mapping availability zones to disk types for the group's worker nodes.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <DISK TYPE>` (see the example).

  If the `rootDiskSize` parameter is specified, the same disk type is used for the VM's boot disk.

  We recommend using the fastest disk type offered by the provider whenever possible.

  If `volumeTypeMap` is not specified for a node group, the `masterNodeGroup`'s `volumeTypeMap` is used as a fallback for that group.

  If the replicas value exceeds the number of entries in the dictionary, assignment wraps around from the beginning. For example, if `replicas: 5` for the `front` group and the dictionary lists `fast-eu-1a` first and `fast-eu-1b` second, then front-0, front-2, front-4 will use `fast-eu-1a`, while front-1, front-3 will use `fast-eu-1b`.

  Example:

```
volumeTypeMap:
  eu-1a: fast-eu-1a
  eu-1b: fast-eu-1b
```

- **provider**
  object

  Required value

  Huawei Cloud API connection settings.

  These settings match the ones in the `connection` field of the cloud-provider-huaweicloud module.

  - **provider.accessKey**
    string

Required value

The Huawei Cloud access key.

- **provider.authURL**
  string

  The identity authentication URL.

- **provider.cloud**
  string

  Required value

  The endpoint of the cloud provider.

- **provider.domainName**
  string

  The account name of IAM to scope to.

- **provider.enterpriseProjectID**
  string

  The enterprise project ID.

- **provider.insecure**
  boolean

  Trust self-signed SSL certificates.

- **provider.projectID**
  string

  The project ID.

- **provider.region**
  string

  Required value

  The Huawei Cloud region where the cluster will be deployed.

- **provider.secretKey**
  string

  Required value

  The Huawei Cloud secret key.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **standard**
  object

  Settings for the `Standard` layout.

  - **standard.enableEIP**
    boolean

    Enable Elastic IP for the master nodes.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **standard.internalNetworkCIDR**
    string

    Required value

    Routing for the internal cluster node network.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **standard.internalNetworkDNSServers**
    array of strings

    A list of addresses of the recursive DNSs for the internal cluster node network.

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

  - **standard.internalNetworkSecurity**
    boolean

Defines whether SecurityGroups must be configured for the internal network ports.

When enabled, DP creates a security group named after the cluster `prefix` with the following default inbound rules:

- TCP/22 (SSH) from `0.0.0.0/0` by default
- ICMP from `0.0.0.0/0`
- TCP NodePorts `30000-32767` from `0.0.0.0/0`

For details, see Huawei Cloud: Layouts.

Default: `true`

- **vpcPeering**
  object

  Settings for the `VpcPeering` layout.

  - **vpcPeering.internalNetworkCIDR**
    string

    Required value

    Routing for the internal cluster node network.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`
  - **vpcPeering.internalNetworkDNSServers**
    array of strings

    A list of addresses of the recursive DNSs for the internal cluster node network.

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`
  - **vpcPeering.internalNetworkSecurity**

    Defines whether SecurityGroups must be configured for the internal network ports.
  - **vpcPeering.subnet**
    string

    The name of the subnet in the VPC.

- **zones**
  array of strings

  Not required value.

  The globally restricted set of zones that this cloud provider works with.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> **i** The module lifecycle stage: General Availability

> ⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:
>
> - Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
> - `CgroupsV2` support.
> - Systemd version `244` or newer.
> - `erofs` kernel module support.
>
> For more information, see the documentation.

> ⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:
>
> - `cloud-config.service`;
> - `cloud-final.service`;
> - `cloud-init.service`.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Deckhouse Platform components interact with Huawei Cloud resources through the Huawei Cloud API. To configure this connection, you need to create a user in the Huawei Cloud IAM service and provide it with the necessary permissions.

Configuring IAM via the web interface

To configure IAM via the web interface, first create a new user group and assign the necessary permissions. Follow these steps:

1. Go to the “Identity and Access Management (IAM)” section.
2. Open the “User Groups” page and click “Create User Group”.
3. In the “Name” field, enter the group name (e.g., `deckhouse`).
4. Click “OK” to create the group.
5. Select the newly created group from the list.
6. On the “Permissions” tab, click “Authorize”.
7. Assign the following policies: “ECS Admin”, “VPC Administrator”, “NAT Admin”, “ELB FullAccess”, “DEW KeypairFullAccess”.
8. Click “Next”, then “OK”, and complete the setup by clicking “Finish”.

Then add a new user. Follow these steps:

1. Go to the “Users” page in the IAM section and click “Create User”.
2. In the “Username” field, enter the username (e.g., `deckhouse`).
3. Set “Access type” to “Programmatic access” and make sure “Management console access” is disabled.
4. Select “Access key” as the “Credential Type”.
5. Click “Next”.
6. Select the previously created user group.
7. Click “Create” to complete the user creation process.
8. Click “OK” to download the `Access Key ID` and `Secret Access Key`. Make sure to save these credentials in a secure location, as they will be needed to access the API.

JSON policies

Below are the contents of the policies in JSON format:

ECS Admin policy

```
{
"Version": "1.1",
"Statement": [
{
    "Action": [
    "ecs:*:*",
    "evs:*:get",

                "ecs:*:list",
                "elb:*:get",
                "elb:*:list"
            ],
            "Effect": "Allow"
        }
    ]
}
```

NAT Admin policy

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Action": [
                "nat:*:*",
                "vpc:*:*"
            ],
            "Effect": "Allow"
        }
    ]
}
```

DEW KeypairFullAccess policy

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Action": [
                "kps:domainKeypairs:*",
                "ecs:serverKeypairs:*"
            ],
            "Effect": "Allow"
        }
    ]
}
```

ELB FullAccess policy

```
{
  "Version": "1.1",
  "Statement": [
      {
          "Action": [
              "elb:*:*",
              "vpc:*:get*",
              "vpc:*:list*",
              "ecs:*:get*",
              "ecs:*:list*"
          ],
          "Effect": "Allow"
      }
  ]
}
```

Replacing the OS image

The OS image is set by the `imageName` parameter of the HuaweiCloudInstanceClass resource for `CloudEphemeral` nodes and in the `instanceClass` section of the HuaweiCloudClusterConfiguration resource for `CloudPermanent` nodes and master nodes.

The replacement procedure is described in “How do I replace the OS image in a cloud cluster?”.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> **i** The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

HuaweiCloudInstanceClass

Scope: Cluster

Version: v1

Huawei Cloud server group parameters used by `machine-controller-manager` (the node-manager module).

The CloudInstanceClass resource of the `node-manager` module refers to this resource.

Example:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudInstanceClass
metadata:
  name: worker
spec:
  imageName: alt-p11
  flavorName: s7n.xlarge.2
  rootDiskSize: 50
  rootDiskType: SSD
```

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Not required value.

    List of networks IDs (subnets) for secondary NICs.

  - **spec.flavorName**
    string

    Required value

    Flavor of Huawei Cloud servers.

    To get a list of all available flavors, run the following command: `cloud ECS ListFlavors`.

    For all non-master nodes, it’s recommended that you use a flavor that includes a local disk. If the cloud provider supports local disks, they’re usually faster and cheaper. The disadvantage of using such a flavor is the inability to migrate nodes between hypervisors.

    Example:

    ```
    flavorName: m1.medium
    ```

  - **spec.imageName**
    string

    Not required value.

    Image to use while provisioning HuaweiCloud servers.

    Use this command to get a list of available images: `cloud IMS ListImages`.

    For the list of operating systems and specific versions supported by Deckhouse, refer to Supported Kubernetes and OS versions (take into account the Deckhouse version you use).

    By default, either the `HuaweiCloudDiscoveryData` value or `instances.imageName` is used.

    Example:

    ```
    imageName: ubuntu-18-04-cloud-amd64
    ```

  - **spec.mainNetwork**
    string

    Not required value.

    ID of the primary network for the VM’s main NIC.

    By default, the value from ‘HuaweiCloudDiscoverData’ is used.

  - **spec.rootDiskSize**
    integer

    Not required value.

    The size of a root disk in gigabytes.

    This parameter also affects the type of a root disk.

    Example:

    ```
    rootDiskSize: 20
    ```

- **spec.rootDiskType**
  string

  Not required value.

  The type of a root disk.

  The parameter is used to specify the type of a volume that will be used for the root disk.

  By default, the value from `HuaweiCloudDiscoveryData` is used.

  Example:

  ```
  rootDiskType: GPSSD
  ```

- **spec.securityGroups**
  array of strings

  Not required value.

  Security groups that will be applied to VM’s network ports in addition to security groups set in a cloud provider configuration.

  These security groups allow you to set firewall rules for provisioned instances.

  The `SecurityGroups` group may not be supported by the cloud provider.

  Example:

  ```
  securityGroups:
  - security-group-1
  - security-group-2
  ```

- **spec.serverGroupID**
  string

  Not required value.

  The server group to assign the machine to.

  Example:

  ```
  serverGroupID: server-group-1
  ```

- **spec.subnets**
  Deprecated
  array of strings

  Not required value.

  > **i** Use the additionalNetworks field instead.

  Paths to networks that the secondary VirtualMachines NICs will connect to.

  Example:

  ```
  subnets:
  - BGP-network-VLAN-3894
  - External-VLAN-3699
  ```

- **spec.vipAddress**
  string

  Not required value.

  If filled, enables Virtual IP for all nodes in this instance class.

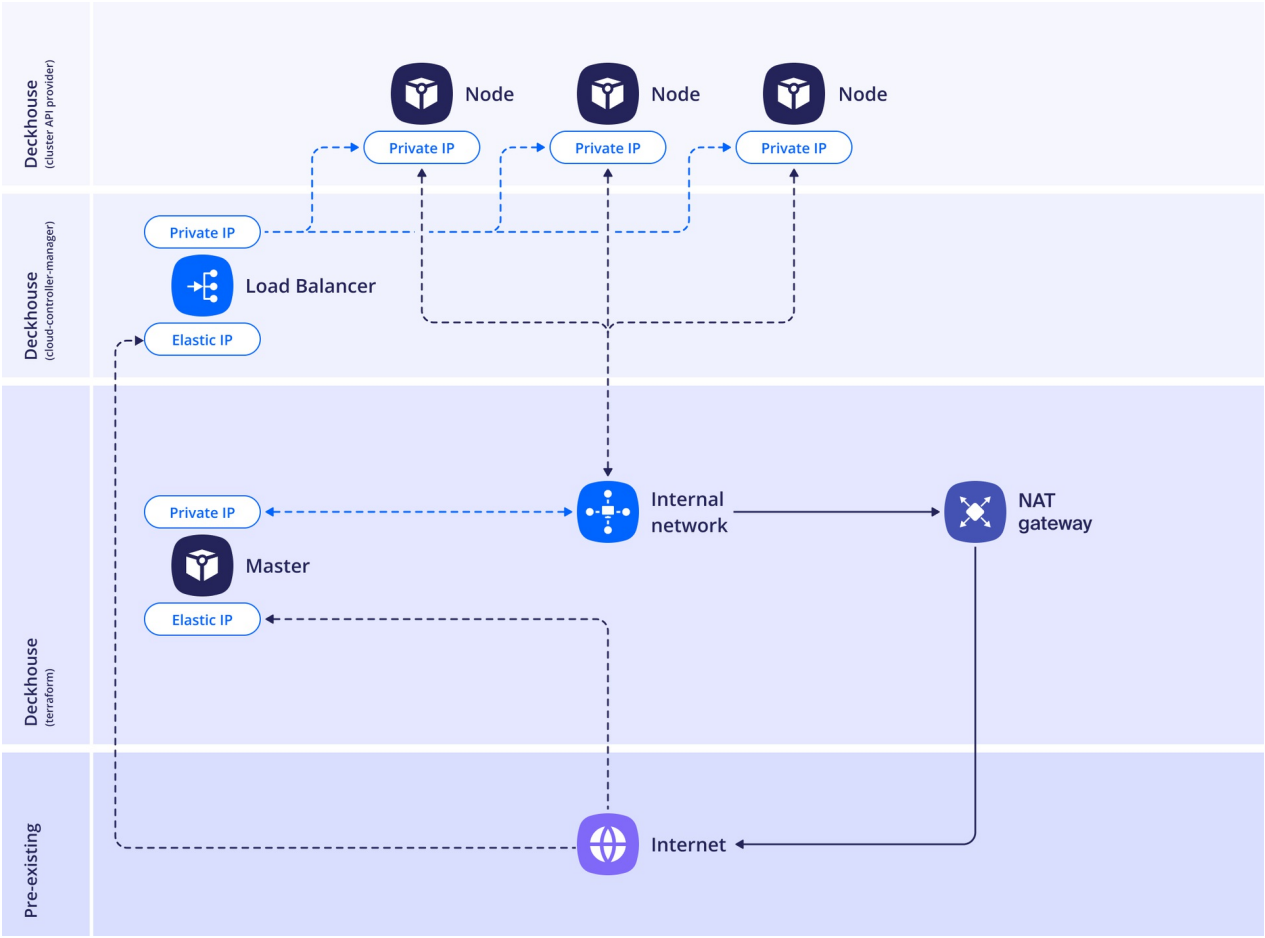
  `Auto` or IPv4 address are expected.

  Pattern: `^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$|^Auto$`

  Example:

  ```
  vipAddress: Auto
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings



> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider - HuaweiCloud: Layouts

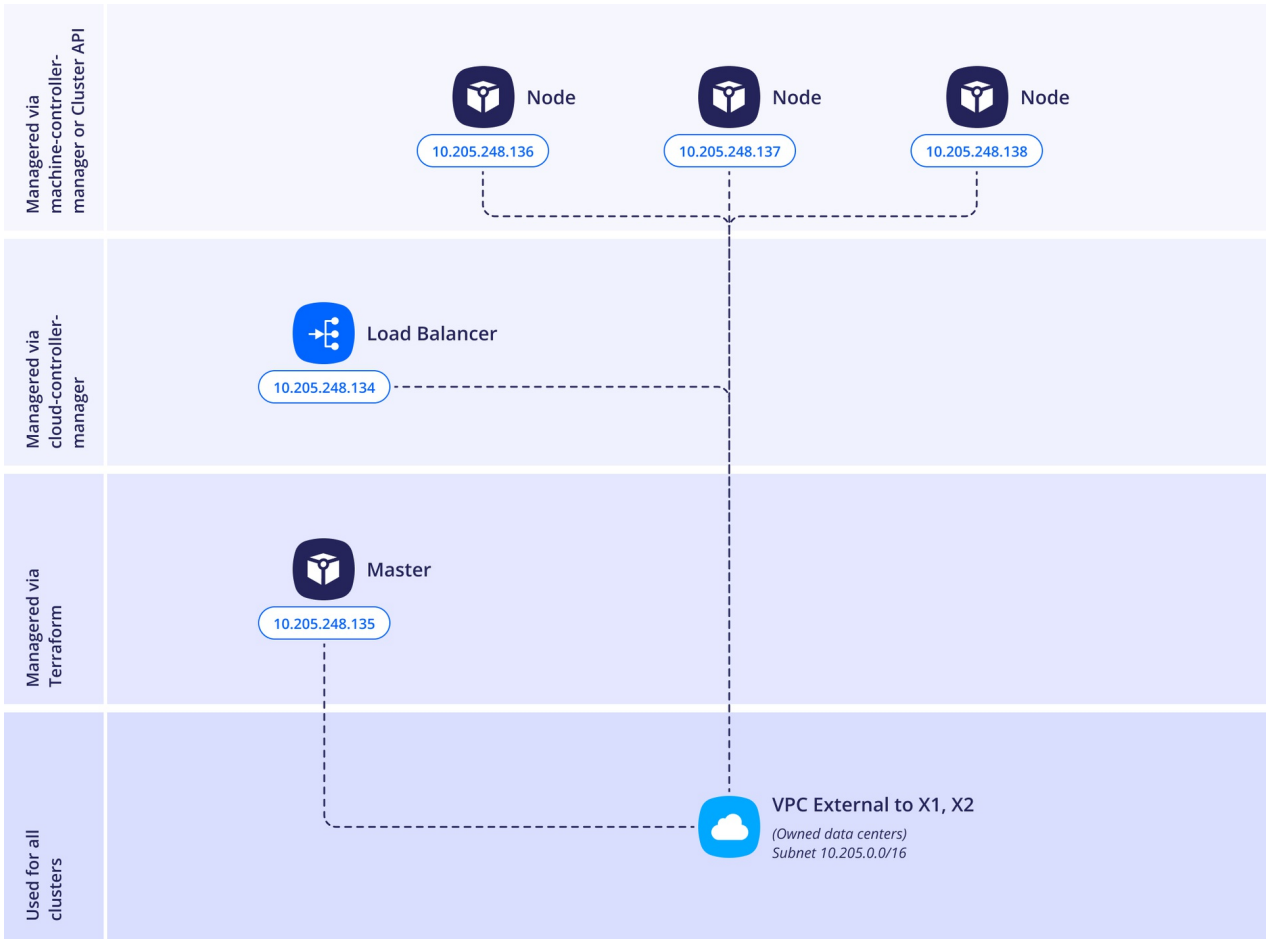
> The module lifecycle stage: General Availability

Standard

- An internal cluster network is created with a gateway to the public network.
- The elastic IP can be assigned to the master node.
- Nodes managed by the Cluster API do not have public IP addresses.

The `internalNetworkSecurity` parameter (default `true`) enables the creation of a security group (SecurityGroup) when a cluster is created. The module creates the group named after the cluster prefix and assigns it to the nodes.

The following inbound rules will be created:



- allow incoming traffic over the TCP protocol on port `22` from `0.0.0.0/0`
- allow incoming traffic over the ICMP protocol from `0.0.0.0/0`
- allow incoming traffic over the TCP protocol on ports `30000` – `32767` for services of the `NodePort` type. Inbound UDP traffic to `NodePort` ports is not allowed by default

Attach custom security groups for CloudEphemeral nodes in the HuaweiCloudInstanceClass resource via `spec.securityGroups`. They are applied together with the group created by the module.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
standard:
  internalNetworkDNSServers:
    - 8.8.8.8
  internalNetworkCIDR: 192.168.199.0/24
  internalNetworkSecurity: true
  enableEIP: true
provider:
  cloud: hc.sbercloud.ru
  region: ru-moscow-1
  accessKey: "<Access key>"
  secretKey: "<Secret key>"
  projectID: "<Project ID>"
masterNodeGroup:
  replicas: 1
  instanceClass:
    imageName: alt-p11
    flavorName: s7n.xlarge.2
    rootDiskSize: 50
  serverGroup:
    policy: AntiAffinity
  volumeTypeMap:
    ru-moscow-1a: SSD
```

VpcPeering

The `internalNetworkSecurity` parameter (default `true`) enables the creation of a security group (SecurityGroup) when a cluster is created. The module creates the group named after the cluster prefix and assigns it to the nodes.

The following inbound rules will be created:

- allow incoming traffic over the TCP protocol on port `22` from `0.0.0.0/0`
- allow incoming traffic over the ICMP protocol from `0.0.0.0/0`
- allow incoming traffic over the TCP protocol on ports `30000`–`32767` for services of the `NodePort` type. Inbound UDP traffic to `NodePort` ports is not allowed by default

Attach custom security groups for CloudEphemeral nodes in the HuaweiCloudInstanceClass resource via `spec.securityGroups`. They are applied together with the group created by the module.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudClusterConfiguration
layout: VpcPeering
sshPublicKey: "<SSH_PUBLIC_KEY>"
vpcPeering:
  internalNetworkDNSServers:
    - 8.8.8.8
  internalNetworkCIDR: 10.221.128.0/24
  internalNetworkSecurity: true
  subnet: subnet-43b4
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — OpenStack

Included in extensions: **On-prem IaaS**

The module lifecycle stage: General Availability

The `cloud-provider-openstack` module integrates Deckhouse Platform with OpenStack-based clouds. It allows the `node-manager` module to use OpenStack resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-openstack` module:

- Managing OpenStack resources via `cloud-controller-manager`:
  - updates OpenStack server and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in OpenStack;
  - creates load balancers (Octavia) for Services of the LoadBalancer type.
- Provisioning block disks via the Cinder CSI driver (`cinder.csi.openstack.org`). Manila (filesystem) is not supported. The Cinder CSI driver supports re-authentication in OpenStack with service catalog refresh, which improves resilience for long-running pods with volumes.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-openstack`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM) or Cluster API (CAPI). Virtual machine parameters are set in the OpenStackInstanceClass resource.
- Registering with `node-manager` so that OpenStackInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used. The network mode depends on the `podNetworkMode` parameter.

⚠ The module is migrating CloudEphemeral node management from Machine Controller Manager (MCM) to Cluster API (CAPI). Existing NodeGroups continue to use MCM, while new ones are created with CAPI by default. For migrating existing groups, see How to migrate node groups to Cluster API (CAPI).

Third-party components

List of third-party software used in the `cloud-provider-openstack` module:

- OpenStack Cloud provider v1.33.1, v1.34.1, v1.35.0, v1.36.0, v1.36.0

  License: Apache License 2.0

  Cloud Controller Manager for OpenStack.

- OpenStack CSI driver v1.33.1, v1.34.1, v1.35.0, v1.36.0, v1.36.0

  License: Apache License 2.0

  CSI driver for OpenStack Cinder.

- OpenStack Terraform provider 1.54.1

  License: Mozilla Public License 2.0

  Terraform provider for OpenStack.

- OpenStack Cluster API provider v0.14.8

  License: Apache License 2.0

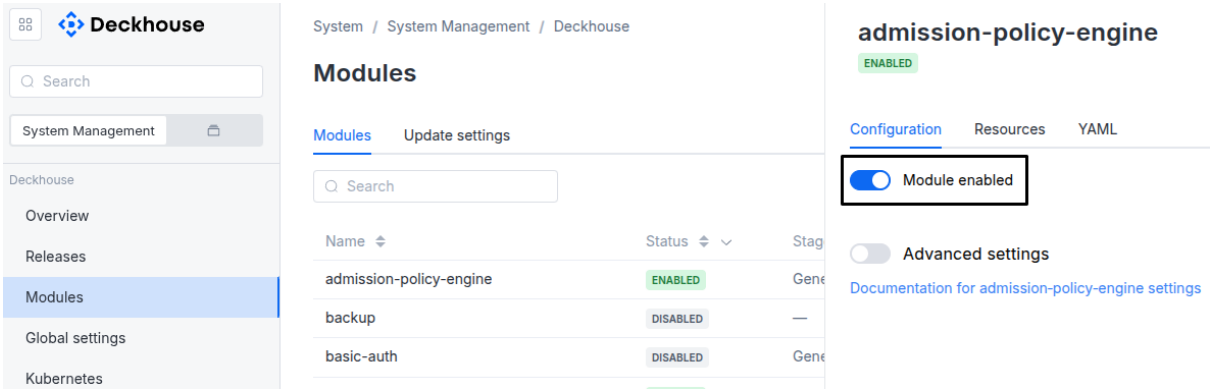
  Infrastructure provider for Kubernetes Cluster API in OpenStack.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability



The module is automatically enabled for all cloud clusters deployed in OpenStack.

The module has 1 alert.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-openstack` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

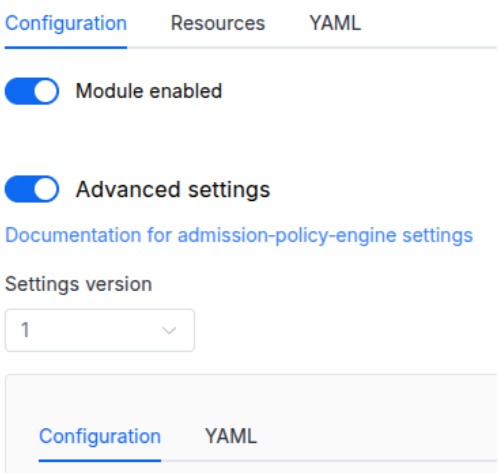
```
d8 system module enable cloud-provider-openstack
```

- **Using ModuleConfig `cloud-provider-openstack`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-openstack` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-openstack`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-openstack
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-openstack` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cloud-provider-openstack` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-openstack`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-openstack` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-openstack
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-openstack` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-openstack`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-openstack
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

You can configure the number and parameters of ordering machines in the cloud via the `NodeGroup` custom resource of the node-manager module. Also, in this custom resource, you can specify the instance class’s name for the above group of nodes (the `cloudInstances.ClassReference` NodeGroup parameter). In the case of the OpenStack-based cloud provider, the instance class is the `OpenStackInstanceClass` custom resource that stores specific parameters of the machines.

> **i** An OpenStack cluster is deployed in a single region (`provider.region` in OpenStackClusterConfiguration). Zones from other regions cannot be used. See How do I create NodeGroups in availability zones? .

The module settings are set automatically based on the placement strategy chosen. In most cases, you do not have to configure the module manually.

If you need to configure a module because, say, you have a bare metal cluster and you need to enable additional instances from vSphere, then refer to the How to configure a Hybrid cluster in vSphere section.

> **i** **Note!** If the parameters provided below are changed, the **existing `Machines` are NOT redeployed** (new `Machines` will be created with the updated parameters). Redeployment is only performed when `NodeGroup` and `OpenStackInstanceClass` parameters are changed. You can learn more in the node-manager module’s documentation. To authenticate using the `user-authn` module, you need to create a new `Generic` application in the project’s Crowd.

List of required OpenStack services

A list of services required for Deckhouse Platform to work in OpenStack:

Service	API Version
Identity (Keystone)	v3
Compute (Nova)	v2.1
Network (Neutron)	v2.0
Block Storage (Cinder)	v3
Load Balancing (Octavia) *	v2

* If you need to order a Load Balancer.

> **i** For Compute and Block Storage, the supported microversion depends on the installed OpenStack release. For Block Storage, microversion `3.0` is the minimum version and is used by default.

To ensure proper integration and functionality, the OpenStack user associated with the Deckhouse Platform should be granted the “member” role. This role assignment is essential to provide the necessary permissions for interacting with the listed services and managing resources within the OpenStack environment.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.additionalExternalNetworkNames**
    array of strings

    Specifies additional networks that can be connected to the VM. `cloud-controller-manager` uses them to insert `ExternalIP` to `.status.addresses` field in the Node API object.

    If you have instances in the cluster that use External Networks (other than those set out in the placement strategy), you must pass them via the `additionalExternalNetworkNames` parameter.

    Example:

    ```
    additionalExternalNetworkNames:
    - some-bgp-network
    ```

  - **settings.connection**
    object

    This section contains parameters required to connect to the cloud provider’s API.

    - **settings.connection.authURL**
      string

      An OpenStack Identity API URL.

    - **settings.connection.caCert**
      string

      Specify the CA x509 certificate used for signing if the OpenStack API has a self-signed certificate; The certificate must have a PEM format.

    - **settings.connection.domainName**
      string

      The domain name.

    - **settings.connection.password**
      string

      The user’s password.

    - **settings.connection.region**
      string

      The OpenStack region where the cluster will be deployed.

    - **settings.connection.tenantID**
      string

      The project ID. Cannot be used together with `tenantName`.

    - **settings.connection.tenantName**
      string

      The project name.

      Cannot be used together with `tenantID`.

    - **settings.connection.username**
      string

      The name of the user that has full project privileges.

- **settings.csiDriver**
  object

  Parameters for configuring the Cinder CSI Driver.

  - **settings.csiDriver.fsGroupPolicy**
    string

    Defines if the underlying volume supports changing ownership and permission of the volume before being mounted.

    - `ReadWriteOnceWithFSType`: Apply fsGroup only for ReadWriteOnce volumes (Kubernetes default behavior).
    - `File`: Always apply fsGroup. Use this for RWX volumes with Ceph backend.
    - `None`: Never change permissions.

    Default: `ReadWriteOnceWithFSType`

    Allowed values: `ReadWriteOnceWithFSType`, `File`, `None`

- **settings.externalNetworkNames**
  array of strings

  Additional networks that are connected to the VM. cloud-controller-manager uses them to insert ExternalIPs into `.status.addresses` in the Node API object.

  Example:

  ```
  externalNetworkNames:
  - KUBE-3
  - devops-internal
  ```

- **settings.ignoreVolumeMicroversion**
  boolean

  Setting for backwards compatibility. Enable if the cloud OpenStack version is less than 3.34 and you get error “Version 3.34 is not supported by the API. Minimum is 3.0 and maximum is 3.x” when ordering a PV. This will disable volumes online resize, but will restore ability to order new PVs. (original PR https://github.com/kubernetes/cloud-provider-openstack/pull/1986/)

  Default: `false`

- **settings.instances**
  object

  Instance parameters that are used when creating virtual machines.

  - **settings.instances.additionalNetworks**
    array of strings

    A list of networks to connect to the instance.

  - **settings.instances.imageName**
    string

    The name of the image.

  - **settings.instances.mainNetwork**
    string

    The path to the network that will serve as the primary network (the default gateway) for connecting to the VM.

  - **settings.instances.securityGroups**
    array of strings

    A list of securityGroups to assign to the provisioned instances. Defines firewall rules for the provisioned instances.

  - **settings.instances.sshKeyPairName**
    string

    The name of the OpenStack `keypair` resource; it is used for provisioning instances.

- **settings.internalNetworkNames**
  array of strings

  Additional networks that are connected to the VM. cloud-controller-manager uses them to insert InternalIPs into `.status.addresses` in the Node API object.

  Example:

  ```
  internalNetworkNames:
  - KUBE-3
  - devops-internal
  ```

- **settings.loadBalancer**
  object

Load Balancer parameters.

- **settings.loadBalancer.disabled**
  boolean

  Set to `true` to disable LoadBalancer support if the OpenStack cloud doesn't have Octavia (LBaaS) service available.

  Default: `false`

- **settings.loadBalancer.floatingNetworkID**
  string

  An ID of the external network for floating IPs.

- **settings.loadBalancer.subnetID**
  string

  An ID of the Neutron subnet to create the load balancer virtual IP in.

- **settings.podNetworkMode**
  string

  Sets the traffic mode for the network that the pods use to communicate with each other (usually, it is an internal network; however, there can be exceptions):

  - `DirectRouting` — means that there is a direct routing between the nodes.
  - `DirectRoutingWithPortSecurityEnabled` — direct routing is enabled between the nodes, but only if the range of addresses of the internal network is explicitly allowed in OpenStack for Ports.
    - **Caution!** Make sure that the `username` can edit AllowedAddressPairs on Ports connected to the `internalNetworkName` network. Generally, an OpenStack user doesn't have such a privilege if the network has the `shared` flag set.
  - `VXLAN` — direct routing between the nodes isn't available; VXLAN should be used.

  Allowed values: `DirectRouting`, `DirectRoutingWithPortSecurityEnabled`, `VXLAN`

- **settings.storageClass**
  object

  The module automatically creates StorageClasses that are available in OpenStack.

  - **settings.storageClass.default**
    Deprecated
    string

    The name of StorageClass that will be used in the cluster by default.

    If the parameter is omitted, the default StorageClass is either:

    - an arbitrary StorageClass present in the cluster that has the default annotation;
    - the first (in lexicographic order) StorageClass created by the module (in accordance with the order in OpenStack).

    > **i** **Parameter is deprecated**. Instead, use the global parameter global.defaultClusterStorageClass.

    Example:

    ```
    default: ceph-ssd
    ```

  - **settings.storageClass.exclude**
    array of strings

    A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

    Example:

    ```
    exclude:
    - ".*-hdd"
    - iscsi-fast
    ```

  - **settings.storageClass.topologyEnabled**
    boolean

    This feature enables driver to consider the topology constraints while creating the volume. It is used only during volume provisioning, existing PersistentVolumes are not affected.

    > **i** **Warning.** If it is set to `false` all-new PersistentVolumes are provisioned without topology constraints.

    Default: `true`

- **settings.tags**
  object

  A dictionary of tags that will be available on all provisioned instances.

- **settings.zones**
  array of strings

  The default list of zones for provisioning instances. Can be redefined for each NodeGroup individually.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> The module lifecycle stage: General Availability

OpenStackClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in OpenStack.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
zones:
- eu-3a
- eu-3b
standard:
  internalNetworkDNSServers:
  - 8.8.8.8
  internalNetworkCIDR: 192.168.195.0/24
  internalNetworkSecurity: false
  externalNetworkName: external-network
provider:
  authURL: "<AUTH_URL>"
  domainName: "<DOMAIN_NAME>"
  tenantID: "<TENANT_ID>"
  username: "<USERNAME>"
  password: "<PASSWORD>"
  region: eu-3
masterNodeGroup:
  replicas: 1
  instanceClass:
    rootDiskSize: 50
    flavorName: m1.large
    imageName: debian-11-genericcloud-amd64-20220911-1135
  volumeTypeMap:
    eu-3a: fast.eu-3a
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.large
    imageName: debian-11-genericcloud-amd64-20220911-1135
    rootDiskSize: 50
    configDrive: false
    floatingIPPools:
    - public
    - shared
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  zones:
  - eu-3a
  - eu-3b
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **kind**
  string

  Required value

  Allowed values: `OpenStackClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **masterNodeGroup**

  Required value

  The definition of the master’s NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

- **masterNodeGroup.instanceClass**
  object

  Required value

  Partial contents of the fields of the OpenStackInstanceClass.

  - **masterNodeGroup.instanceClass.additionalSecurityGroups**
    array of strings

    Security groups that will be applied to VM’s network ports. Default group should also be added to this list.

    They allow you to set firewall rules for provisioned instances.

    The `SecurityGroups` may not be supported by the cloud provider.

  - **masterNodeGroup.instanceClass.additionalTags**
    object

    The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

    Example:

    ```
    additionalTags:
      project: cms-production
      severity: critical
    ```

  - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
    integer

    Etcd disk size in gigabytes.

    Default: `10`

    Example:

    ```
    etcdDiskSizeGb: 10
    ```

  - **masterNodeGroup.instanceClass.flavorName**
    string

    Required value

    Flavor of OpenStack servers.

    To get a list of all available flavors, run the command: `openstack flavor list`.

    For all non-master nodes it is advisable to use flavor’s with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

    Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

  - **masterNodeGroup.instanceClass.imageName**
    string

    Required value

    Image to use while provisioning OpenStack servers.

    Use this command to get a list of available images: `openstack image list`.

    The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

  - **masterNodeGroup.instanceClass.rootDiskSize**
    integer

    The size of a root disk (in gigabytes).

    This parameter also has influence on type of volume that will be used for root disk; the “How to use rootDiskSize and when it is preferred” section describes how to use it.

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.serverGroup**
  object

  Object groups instances together. The instances in the group are placed on the same hypervisor (affinity) or different hypervisors (anti-affinity). This allows you to increase the fault tolerance of the cluster.

  - **masterNodeGroup.serverGroup.manuallyManaged**
    object

        - **masterNodeGroup.serverGroup.manuallyManaged.id**
          string

          Required value

          The id of the existing `ServerGroup` object managed outside of Deckhouse.

      - **masterNodeGroup.serverGroup.policy**
        string

        Required value

        The policy that determines how instances are distributed among hypervisors.

        - `AntiAffinity` — instances are placed on different hypervisors. This policy is managed by Deckhouse.
        - `ManuallyManaged` — instances are placed on different hypervisors. This policy is managed outside of Deckhouse.

        Allowed values: `AntiAffinity`, `ManuallyManaged`

    - **masterNodeGroup.volumeTypeMap**
      object

      Required value

      A dictionary of disk types for storing etcd data and Kubernetes configuration files.

      Format of dictionary elements: `<AVAILABILITY ZONE>: <VOLUME TYPE>` (see the example).

      If the `rootDiskSize` parameter is specified, the same disk type will be used for the VM's boot drive.

      We recommend using the fastest disks provided by the provider in all cases.

      If the value specified in `replicas` exceeds the number of elements in the dictionary, the master nodes whose number exceeds the length of the dictionary get the values starting from the beginning of the dictionary. For example, if `replicas: 5`, then master-0, master-2, master-4 will have the `fast-eu-1a` disk type, while master-1, master-3 will have the `fast-eu-1b` disk type.

      Master nodes will be created in zones specified at this param following by alphabetical order. Based on the example below, `master-0` will be created in zone `eu-1a`, `master-1` will be created in zone `eu-1b`, and `master-2` will be created in zone `eu-1a`.

      Useful commands:

      - `openstack availability zone list` — get list of availability zones.
      - `openstack volume type list` — get list of volume types.

      Example:

      ```
      volumeTypeMap:
        eu-1a: fast-eu-1a
        eu-1b: fast-eu-1b
      ```

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating CloudPermanent nodes (for example, dedicated front nodes or gateways).

  For CloudEphemeral nodes, use a separate NodeGroup resource and an OpenStackInstanceClass.

  - **nodeGroups.instanceClass**
    object

    Partial contents of the fields of the OpenStackInstanceClass.

    - **nodeGroups.instanceClass.additionalNetworks**
      array of strings

      Paths to networks that VirtualMachines secondary NICs will connect to. To get a list of all available networks, run the command: `openstack network list`.

      Example:

      ```
      additionalNetworks:
      - BGP-network-VLAN-3894
      - External-VLAN-3699
      ```

    - **nodeGroups.instanceClass.additionalSecurityGroups**
      array of strings

      Security groups that will be applied to VM's network ports. Default group should also be added to this list.

      They allow you to set firewall rules for provisioned instances.

      The `SecurityGroups` may not be supported by the cloud provider.

    - **nodeGroups.instanceClass.additionalTags**
      object

The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

Example:

```
additionalTags:
  project: cms-production
  severity: critical
```

- **nodeGroups.instanceClass.configDrive**
  boolean

  Not required value.

  Specifies whether an additional disk containing the bootstrapping configuration will be mounted to the node.

  You must set it if DHCP is disabled in the `mainNetwork`.

  Default: `false`

- **nodeGroups.instanceClass.flavorName**
  string

  Required value

  Flavor of OpenStack servers.

  To get a list of all available flavors, run the command: `openstack flavor list`.

  For all non-master nodes it is advisable to use flavor's with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

  Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

- **nodeGroups.instanceClass.floatingIPPools**
  array of strings

  A list of networks to assign Floating IPs to nodes.

- **nodeGroups.instanceClass.imageName**
  string

  Required value

  Image to use while provisioning OpenStack servers.

  Use this command to get a list of available images: `openstack image list`.

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

- **nodeGroups.instanceClass.mainNetwork**
  string

  Required value

  Path to the network that VirtualMachines primary NICs will connect to (default gateway). To get a list of all available networks, run the command: `openstack network list`.

- **nodeGroups.instanceClass.networksWithSecurityDisabled**
  array of strings

  A list of `mainNetwork` and `additionalNetworks` in which `SecurityGroups` and `AllowedAddressPairs` on ports **cannot be configured**.

- **nodeGroups.instanceClass.rootDiskSize**
  integer

  The size of a root disk (in gigabytes).

  This parameter also has influence on type of volume that will be used for root disk; the "How to use rootDiskSize and when it is preferred" section describes how to use it.

- **nodeGroups.name**
  string

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

```
annotations:
  ai.fleet.com/discombobulate: 'true'
```

- **nodeGroups.nodeTemplate.labels**
  object

  A list of labels to attach to cluster resources.

  The same as the `metadata.labels` standard field.

  Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

  Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  The number of nodes to create.

- **nodeGroups.volumeTypeMap**
  object

  A dictionary of disk types for root drive.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <VOLUME TYPE>` (see the example).

  If the value specified in `replicas` exceeds the number of elements in the dictionary, the nodes whose number exceeds the length of the dictionary get the values starting from the beginning of the dictionary. For example, if `replicas: 5`, then worker-0, worker-2, worker-4 will have the `fast-eu-1a` disk type, while worker-1, worker-3 will have the `fast-eu-1b` disk type.

  > **i** **Caution.** Limits by availability zones works only when using the `zones` parameter (`nodeGroups.zones`). If `zones` parameter is not specified, all availability zones will be used.

  Useful commands:

  - `openstack availability zone list` — get list of availability zones.
  - `openstack volume type list` — get list of volume types.

  Example:

```
volumeTypeMap:
  eu-1a: fast-eu-1a
  eu-1b: fast-eu-1b
```

- **nodeGroups.zones**
  array of strings

  Not required value.

  A limited set of zones in which nodes can be created.

  The zones must belong to the `provider.region` region. If the `zones` parameter is set, only zones from that

parameter can be used.

- **provider**
  object

  Required value

  Contains settings to connect to the OpenStack API.

  These settings are the same as those in the `connection` field of the cloud-provider-openstack module.

  - **provider.authURL**
    string

    An OpenStack Identity API URL.

  - **provider.caCert**
    string

    Specify the CA x509 certificate used for signing if the OpenStack API has a self-signed certificate. Certificate should be passed in PEM format as multiline string.

    Example:

    ```
    caCert: |
      -----BEGIN CERTIFICATE-----
      MIIFyDCCBLCgAwIBAgIQBwDIWH1asdaKNaALUa4NUzANBgkqhkiG9w0BAQsFADBc
      ...
      -----END CERTIFICATE-----
    ```

  - **provider.domainName**
    string

    The domain name.

    `OS_USER_DOMAIN_NAME` variable from the openrc file.

  - **provider.password**
    string

    The user’s password.

  - **provider.region**
    string

    The OpenStack region where the cluster will be deployed.

    The cluster runs in a single region. Master nodes, as well as CloudPermanent and CloudEphemeral nodes, can be created only in zones of this region.

  - **provider.tenantID**
    string

    The project id.

    Cannot be used together with `tenantName`.

  - **provider.tenantName**
    string

    The project name.

    Cannot be used together with `tenantID`.

  - **provider.username**
    string

    The name of the user that has full project privileges.

- **simple**
  object

  Settings for the `Simple` layout.

  - **simple.externalNetworkDHCP**
    boolean

    This parameter defines if DHCP is enabled in the external network.

    Default: `true`

  - **simple.externalNetworkName**
    string

    Required value

    The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

  - **simple.podNetworkMode**
    string

Sets the traffic mode for the network that the pods use to communicate with each other (usually, it is an internal network; however, there can be exceptions):

- `DirectRouting` — nodes are directly routed (SecurityGroups are disabled in this mode).
- `VXLAN` — direct routing does NOT work between nodes, VXLAN must be used (SecurityGroups are disabled in this mode).

> **Caution.** After changing this parameter, you need to run `dhctl converge` command for the changes to take effect.

> **Caution.** All cluster nodes must be rebooted after switching work mode from/to VXLAN.

Default: `VXLAN`

Allowed values: `VXLAN`, `DirectRouting`

- **simpleWithInternalNetwork**
  object

  Settings for the `SimpleWithInternalNetwork` layout.

  - **simpleWithInternalNetwork.externalNetworkDHCP**
    boolean

    This parameter defines if DHCP is enabled in the external network.

    Default: `true`

  - **simpleWithInternalNetwork.externalNetworkName**
    string

    The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

  - **simpleWithInternalNetwork.internalSubnetID**
    string

    The UUID of the subnet in which the cluster nodes will run.

    Set either this parameter or `internalSubnetName`.

    Use the UUID when the subnet has no meaningful name. For example, in Selectel the subnet name is generated automatically, and in the web interface of some providers it is not shown at all. The UUID is visible in the `Subnets` column of the `openstack network list` output and in the `ID` column of the `openstack subnet list` output.

    Pattern: `^[0-9a-fA-F]{8}-[0-9a-fA-F]{4}-[0-9a-fA-F]{4}-[0-9a-fA-F]{4}-[0-9a-fA-F]{12}$`

  - **simpleWithInternalNetwork.internalSubnetName**
    string

    The name of the subnet in which the cluster nodes will run.

    Set either this parameter or `internalSubnetID`.

    Specify a subnet, not a network. A network can have several subnets, and the subnet name does not have to match the network name. The `openstack subnet list -c ID -c Name -c Network` command lists the subnets with their names and networks.

  - **simpleWithInternalNetwork.masterWithExternalFloatingIP**
    boolean

    Defines if Floating IP must be assigned to master nodes.

    Default: `true`

  - **simpleWithInternalNetwork.podNetworkMode**
    string

    Sets the traffic mode for the network that the pods use to communicate with each other (usually, it is an internal network; however, there can be exceptions):

    - `DirectRouting` — nodes are directly routed (SecurityGroups are disabled in this mode).
    - `DirectRoutingWithPortSecurityEnabled` — direct routing is enabled between the nodes, but only if the range of addresses of the internal network is explicitly allowed in OpenStack for Ports:
      - **Caution.** Make sure that the `username` can edit `AllowedAddressPairs` on Ports connected to the `internalNetworkName` network. Usually, an OpenStack user doesn't have such a privilege if the network has the `shared` flag set.
    - `VXLAN` — direct routing does NOT work between nodes, VXLAN must be used (`SecurityGroups` are disabled in this mode).

    > **Caution.** After changing this parameter, you need to run `dhctl converge` command for the changes to take effect.

> **Caution.** All cluster nodes must be rebooted after switching work mode from/to VXLAN.

Default: `DirectRoutingWithPortSecurityEnabled`

Allowed values: `VXLAN`, `DirectRouting`, `DirectRoutingWithPortSecurityEnabled`

- **sshAllowList**
  array of strings

  A list of CIDR's allowed to connect to nodes via SSH.

  By default, `0.0.0.0/0`.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **standard**
  object

  Settings for the `Standard` layout.

  - **standard.bastion**
    object

    The definition of the bastion instance.

    - **standard.bastion.instanceClass**
      object

      Partial contents of the fields of the OpenStackInstanceClass.

      - **standard.bastion.instanceClass.additionalTags**
        object

        The additional tags to attach to the instance created (in addition to those specified in the cloud provider configuration).

        Example:

        ```
        additionalTags:
          project: cms-production
          severity: critical
        ```

      - **standard.bastion.instanceClass.flavorName**
        string

        Required value

        Flavor of OpenStack servers.

        To get a list of all available flavors, run the command: `openstack flavor list`.

      - **standard.bastion.instanceClass.imageName**
        string

        Required value

        Image to use while provisioning OpenStack servers.

        Use this command to get a list of available images: `openstack image list`.

        The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

      - **standard.bastion.instanceClass.rootDiskSize**
        integer

        The size of a root disk (in gigabytes).

        This parameter also has influence on type of volume that will be used for root disk; the "How to use rootDiskSize and when it is preferred" section describes how to use it.

        Default: `50`

    - **standard.bastion.volumeType**
      string

      Root disk type.

    - **standard.bastion.zone**
      string

      The zone to create an instance for the bastion node.

  - **standard.externalNetworkName**

string

Required value

The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

- **standard.internalNetworkCIDR**
  string

  Required value

  Routing for the internal cluster network.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **standard.internalNetworkDNSServers**
  array of strings

  Required value

  A list of addresses of the recursive DNSs of the internal cluster network.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **standard.internalNetworkSecurity**
  boolean

  Defines whether SecurityGroups and AllowedAddressPairs must be configured for ports of the internal network.

  When enabled, DP creates a security group named after the cluster `prefix` with the following default inbound rules:

  - TCP/22 (SSH) from CIDRs in `sshAllowList` (default `0.0.0.0/0`)
  - ICMP from `0.0.0.0/0`
  - TCP NodePorts `30000–32767` from `0.0.0.0/0`
  - all inbound traffic from members of the same security group

  For details, see OpenStack: Layouts.

  Default: `true`

- **standardWithNoRouter**
  object

  Settings for the `StandardWithNoRouter` layout.

  - **standardWithNoRouter.externalNetworkDHCP**
    boolean

    This parameter defines if DHCP is enabled in the external network.

    Default: `true`

  - **standardWithNoRouter.externalNetworkName**
    string

    Required value

    The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

  - **standardWithNoRouter.internalNetworkCIDR**
    string

    Required value

    Routing for the internal cluster network.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **standardWithNoRouter.internalNetworkSecurity**
    boolean

    Defines whether SecurityGroups and AllowedAddressPairs must be configured for ports of the internal network.

    When enabled, DP creates a security group named after the cluster `prefix` with the following default inbound rules:

    - TCP/22 (SSH) from CIDRs in `sshAllowList` (default `0.0.0.0/0`)
    - ICMP from `0.0.0.0/0`
    - TCP NodePorts `30000–32767` from `0.0.0.0/0`
    - all inbound traffic from members of the same security group

    For details, see OpenStack: Layouts.

    Default: `true`

- **tags**
  object

  Not required value.

  A dictionary of tags to create on all resources that support this feature.

  You have to re-create all the machines to add new tags if tags were modified in the running cluster.

- **zones**
  array of strings

  Not required value.

  The globally restricted set of availability zones that this cloud provider works with.

  Specify only zones of the `provider.region` region. The cluster is deployed in a single OpenStack region — zones from other regions cannot be used.

  To get the list of zones in the region, run: `openstack availability zone list --compute`.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> The module lifecycle stage: General Availability

> To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:
>
> - Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
> - `CgroupsV2` support.
> - Systemd version `244` or newer.
> - `erofs` kernel module support.
>
> For more information, see the documentation.

> The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:
>
> - `cloud-config.service`;
> - `cloud-final.service`;
> - `cloud-init.service`.

> The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

To manage resources in an OpenStack cloud, Deckhouse connects to the OpenStack API.
The list of OpenStack API services that need to be accessed for deployment is available in the settings section.
The user credentials required to connect to the OpenStack API are located in the openrc file (OpenStack RC file).

You can read the OpenStack documentation to get information about getting and using an openrc file with the standard OpenStack web interface.

The interface for getting an openrc file may differ if you use an OpenStack API of a cloud provider.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

OpenStackInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of OpenStack servers used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines' secondary NICs will connect to.

    By default: the value from `OpenStackCloudDiscoveryData` is used.

    Example:

    ```
    additionalNetworks:
    - BGP-network-VLAN-3894
    - External-VLAN-3699
    ```

  - **spec.additionalSecurityGroups**
    array of strings

    Security groups that will be applied to VM's network ports. Default group should also be added to this list.

    They allow you to set firewall rules for provisioned instances.

    The `SecurityGroups` may not be supported by the cloud provider.

    Example:

    ```
    additionalSecurityGroups:
    - security-group-1
    - security-group-2
    ```

  - **spec.additionalTags**
    object

    The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

    Example:

    ```
    additionalTags:
      project: cms-production
      severity: critical
    ```

  - **spec.capacity**
    Deprecated
    object

    Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

    Instance capacity for *non-standard* instance types (the `flavorName` parameter).

    Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

    The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`m1.medium`, `m1.large`, etc.) is embedded in Deckhouse.

    - **spec.capacity.cpu**
      integer or string

      Required value

      Node vCPU resources.

      Pattern: `^[0-9]+m?$`

      Example:

      ```
      cpu: 1000m
      ```

    - **spec.capacity.memory**
      integer or string

Required value

Node memory resources.

Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

Example:

```
memory: 1500Mi
```

- **spec.flavorName**
  string

  Required value

  Flavor of OpenStack servers.

  Get a list of all available flavors: `openstack flavor list`.

  For all non-master nodes it is advisable to use flavor's with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

  Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

  Example:

  ```
  flavorName: m1.medium
  ```

- **spec.imageName**
  string

  Not required value.

  Image to use while provisioning OpenStack servers.

  Use this command to get a list of available images: `openstack image list`.

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

  By default: either `OpenStackCloudDiscoveryData` value or `instances.imageName` is used.

  Example:

  ```
  imageName: ubuntu-18-04-cloud-amd64
  ```

- **spec.mainNetwork**
  string

  Not required value.

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  By default: the value from `OpenStackCloudDiscoveryData` is used.

  Example:

  ```
  mainNetwork: k8s-msk-178
  ```

- **spec.preemptible**
  boolean

  Order preemptible virtual machines.

  The cloud can interrupt such a machine at any time.

  The parameter applies in Selectel and only to CloudEphemeral node groups managed by Cluster API (CAPI). In another OpenStack cloud, or when the node group is managed by Machine Controller Manager (MCM), the platform creates regular virtual machines and fires the `OpenStackPreemptibleUnsupported` alert.

  Default: `false`

  Example:

  ```
  preemptible: true
  ```

- **spec.rootDiskSize**
  integer

  Not required value.

  The size of a root disk (in gigabytes). This parameter also has influence on type of volume that will be used for root disk; the "How to use rootDiskSize and when it is preferred" section describes how to use it.

  Example:

```
rootDiskSize: 20
```

- **spec.volumeTypeMap**
  object

  Root disk volume types in different availability zones.

  Dictionary elements use the `<AVAILABILITY_ZONE>: <VOLUME_TYPE>` format.

  Warning. Changing the parameter recreates the nodes of every group that references this OpenStackInstanceClass.

  Set this parameter if volume types in your cloud are bound to availability zones. In such a cloud, Cinder creates the root disk with the default volume type, which is bound to a single zone, so provisioning a node in another zone fails with the `HTTP 400 Availability zone '…' is invalid` error.

  For a zone listed in the dictionary, the platform creates the root disk of the specified type in the same zone where the node is provisioned. For the other zones, Cinder picks the volume type.

  The parameter takes effect only together with `rootDiskSize`, because without it the root disk is local and Cinder is not involved. The parameter only works in node groups running on the CAPI engine. The MCM engine ignores it.

  The `openstack availability zone list` command lists availability zones. The `openstack volume type list` command lists volume types.

  Example:

  ```
  volumeTypeMap:
    ru-3a: fast.ru-3a
    ru-3b: fast.ru-3b
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of OpenStack servers used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines’ secondary NICs will connect to.

    By default: the value from `OpenStackCloudDiscoveryData` is used.

    Example:

    ```
    additionalNetworks:
    - BGP-network-VLAN-3894
    - External-VLAN-3699
    ```

  - **spec.additionalSecurityGroups**
    array of strings

    Security groups that will be applied to VM’s network ports. Default group should also be added to this list.

    They allow you to set firewall rules for provisioned instances.

    The `SecurityGroups` may not be supported by the cloud provider.

    Example:

    ```
    additionalSecurityGroups:
    - security-group-1
    - security-group-2
    ```

  - **spec.additionalTags**
    object

    The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

    Example:

    ```
    additionalTags:
      project: cms-production
      severity: critical
    ```

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `flavorName` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`m1.medium`, `m1.large`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

    Node memory resources.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    memory: 1500Mi
    ```

- **spec.flavorName**
  string

  Required value

  Flavor of OpenStack servers.

  Get a list of all available flavors: `openstack flavor list`.

  For all non-master nodes it is advisable to use flavor's with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

  Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

  Example:

  ```
  flavorName: m1.medium
  ```

- **spec.imageName**
  string

  Not required value.

  Image to use while provisioning OpenStack servers.

  Use this command to get a list of available images: `openstack image list`.

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

  By default: either `OpenStackCloudDiscoveryData` value or `instances.imageName` is used.

  Example:

  ```
  imageName: ubuntu-18-04-cloud-amd64
  ```

- **spec.mainNetwork**
  string

  Not required value.

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  By default: the value from `OpenStackCloudDiscoveryData` is used.

  Example:

```
mainNetwork: k8s-msk-178
```

- **spec.preemptible**
  boolean

  Order preemptible virtual machines.

  The cloud can interrupt such a machine at any time.

  The parameter applies in Selectel and only to CloudEphemeral node groups managed by Cluster API (CAPI). In another OpenStack cloud, or when the node group is managed by Machine Controller Manager (MCM), the platform creates regular virtual machines and fires the `OpenStackPreemptibleUnsupported` alert.

  Default: `false`

  Example:

  ```
  preemptible: true
  ```

- **spec.rootDiskSize**
  integer

  Not required value.

  The size of a root disk (in gigabytes). This parameter also has influence on type of volume that will be used for root disk; the “How to use rootDiskSize and when it is preferred” section describes how to use it.

  Example:

  ```
  rootDiskSize: 20
  ```

- **spec.volumeTypeMap**
  object

  Root disk volume types in different availability zones.

  Dictionary elements use the `<AVAILABILITY_ZONE>: <VOLUME_TYPE>` format.

  Warning. Changing the parameter recreates the nodes of every group that references this OpenStackInstanceClass.

  Set this parameter if volume types in your cloud are bound to availability zones. In such a cloud, Cinder creates the root disk with the default volume type, which is bound to a single zone, so provisioning a node in another zone fails with the `HTTP 400 Availability zone '…' is invalid` error.

  For a zone listed in the dictionary, the platform creates the root disk of the specified type in the same zone where the node is provisioned. For the other zones, Cinder picks the volume type.

  The parameter takes effect only together with `rootDiskSize`, because without it the root disk is local and Cinder is not involved. The parameter only works in node groups running on the CAPI engine. The MCM engine ignores it.

  The `openstack availability zone list` command lists availability zones. The `openstack volume type list` command lists volume types.

  Example:

  ```
  volumeTypeMap:
    ru-3a: fast.ru-3a
    ru-3b: fast.ru-3b
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

FAQ

> The module lifecycle stage: General Availability

How do I set up LoadBalancer?

> ⚠ To correctly determine the client IP address, use a LoadBalancer with Proxy Protocol support.

It is recommended to limit the list of nodes added to the load balancer pool using the `loadbalancer.openstack.org/node-selector` annotation.

Without a `node-selector` restriction, cloud-controller-manager may use all suitable cluster nodes as load balancer targets. As a result, adding or removing nodes that are not related to the workload served by the load balancer may trigger an update of the load balancer pool membership. In large or frequently changing clusters, such updates may occur regularly and, in some configurations, may cause brief disruptions to existing connections.

The `annotations` field of the corresponding inlet configuration in the IngressNginxController resource supports the following annotations:

- `loadbalancer.openstack.org/node-selector`: Selects the nodes that will be used as LoadBalancer targets.
- `loadbalancer.openstack.deckhouse.io/load-balancer-id`: Instructs OpenStack CCM to use a pre-created Octavia load balancer.
- `loadbalancer.openstack.deckhouse.io/load-balancer-address`: Instructs OpenStack CCM to associate a pre-allocated floating IP with the load balancer it creates.

DP automatically adds the specified annotations to the generated Service object of type LoadBalancer.

When using the `loadbalancer.openstack.deckhouse.io/load-balancer-id` annotation, the load balancer must meet the following requirements:

- reside in the cluster subnet
- be in the `ACTIVE` state

If `loadbalancer.openstack.deckhouse.io/load-balancer-id` is used to reference a pre-created load balancer with a custom name, associate the floating IP with its VIP port before creating the cluster. In this case, do not specify the `loadbalancer.openstack.deckhouse.io/load-balancer-address` annotation.

When using only `loadbalancer.openstack.deckhouse.io/load-balancer-address`, the floating IP must meet the following requirements:

- not be associated with any port
- reside in the floating network configured for OpenStack CCM

If the specified floating IP is unavailable, OpenStack CCM will not be able to assign an external IP address to the Service object.

Do not add the `loadbalancer.openstack.deckhouse.io/load-balancer-id` or `loadbalancer.openstack.deckhouse.io/load-balancer-address` annotations to application Ingress resources. Specify them only in the IngressNginxController configuration. DP will add them to the generated Service object, which is processed by `openstack-cloud-controller-manager`.

IngressNginxController with a pre-created load balancer

In the example below:

- Ingress controller pods are scheduled on frontend nodes.
- `loadbalancer.openstack.org/node-selector` limits the load balancer target pool to those frontend nodes.
- `loadbalancer.openstack.deckhouse.io/load-balancer-id` references a pre-created Octavia load balancer whose VIP port already has a floating IP associated with it.

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: LoadBalancerWithProxyProtocol
  loadBalancerWithProxyProtocol:
    annotations:
      loadbalancer.openstack.deckhouse.io/load-balancer-id: "df7c6f73-8c68-4a11-a3e2-6268a655ce9b"
      loadbalancer.openstack.org/node-selector: "node-role.deckhouse.io/frontend="
      loadbalancer.openstack.org/proxy-protocol: "true"
      loadbalancer.openstack.org/timeout-member-connect: "2000"
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
  - effect: NoExecute
    key: dedicated.deckhouse.io
    operator: Equal
    value: frontend
```

IngressNginxController with a pre-allocated floating IP

In the example below, OpenStack CCM creates a load balancer and associates the specified unassigned floating IP with it:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: LoadBalancerWithProxyProtocol
  loadBalancerWithProxyProtocol:
    annotations:
      loadbalancer.openstack.deckhouse.io/load-balancer-address: "203.0.113.10"
      loadbalancer.openstack.org/node-selector: "node-role.deckhouse.io/frontend="
      loadbalancer.openstack.org/proxy-protocol: "true"
      loadbalancer.openstack.org/timeout-member-connect: "2000"
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
  - effect: NoExecute
    key: dedicated.deckhouse.io
    operator: Equal
    value: frontend
```

How do I create NodeGroups in availability zones?

An OpenStack cluster is deployed in a single region, which is set by the `provider.region` parameter of the OpenStackClusterConfiguration resource. Nodes can be created only in availability zones of this region. Using zones from other regions is not supported.

To get the list of availability zones in the region, run:

```
openstack --os-region-name <REGION> availability zone list --compute
```

CloudPermanent node groups are defined in the `nodeGroups` section of the OpenStackClusterConfiguration resource. To limit availability zones, use the `nodeGroups[].zones` parameter.

CloudEphemeral nodes are created with a separate NodeGroup resource with `nodeType: CloudEphemeral`. Availability zones for them are set in the `spec.cloudInstances.zones` parameter. If the `zones` parameter is specified in OpenStackClusterConfiguration, the required zones must also be added to it.

> **i** If the admission webhook returns the `unknown zone` error when creating a NodeGroup, make sure that the specified zone belongs to the `provider.region` region and, when using the `zones` parameter, is included in the OpenStackClusterConfiguration zones list.

Nodes from another region can be added to the cluster only manually as Static nodes. The `cloud-provider-openstack` module does not create such nodes.

> **⚠** After changing OpenStackClusterConfiguration, run the `dhctl converge` command. For details, see Adding and managing cloud nodes.

Example NodeGroup for CloudEphemeral nodes:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: workers
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    classReference:
      kind: OpenStackInstanceClass
      name: workers
    minPerZone: 1
    maxPerZone: 1
    zones:
    - eu-3a
    - eu-3b
```

If the instance class of the group sets the `rootDiskSize` parameter, the root disk is created in Cinder. In clouds where volume types are bound to availability zones, set the volume type for each zone in the `volumeTypeMap` parameter of the OpenStackInstanceClass resource. Otherwise, provisioning a node in a zone where the default volume type is unavailable fails with the `HTTP 400 Availability zone '…' is invalid` error.

How do I create a hybrid cluster?

A hybrid cluster combines bare metal and OpenStack nodes. To create such a cluster, you need an L2 network between all nodes of the cluster.

> **i** The Deckhouse Platform allows to set a prefix for the names of CloudEphemeral nodes added to a hybrid cluster with Static master nodes. To do this, use the `instancePrefix` parameter of the `node-manager` module. The prefix specified in the parameter will be added to the name of all CloudEphemeral nodes added to the cluster. It is not possible to set a prefix for a specific NodeGroup.

To set up a hybrid cluster, follow these steps:

1. Delete flannel from kube-system: `d8 k -n kube-system delete ds flannel-ds`.
2. Enable and configure the module.
3. Create one or more OpenStackInstanceClass custom resources.
4. Create one or more NodeManager custom resources for specifying the number of machines and managing the provisioning process in the cloud.

> **i** **Caution!** Cloud-controller-manager synchronizes OpenStack and Kubernetes states by deleting Kubernetes nodes that are not in OpenStack. In a hybrid cluster, such behavior does not always make sense. That is why cloud-controller-manager automatically skips Kubernetes nodes that do not have the `--cloud-provider=external` parameter (Deckhouse inserts `static://` into nodes in `.spec.providerID`, and cloud-controller-manager ignores them).

Attaching storage devices to instances in a hybrid cluster

To use PersistentVolumes on OpenStack nodes, you must create StorageClass with the appropriate OpenStack volume type. The `openstack volume type list` command lists all available types.

Here is the example config for the `ceph-ssd` volume type:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: ceph-ssd
provisioner: csi-cinderplugin # have to be like this
parameters:
  type: ceph-ssd
volumeBindingMode: WaitForFirstConsumer
```

How do I create an image in OpenStack?

1. Download the latest stable Ubuntu 18.04 image:

   ```
   curl -L https://cloud-images.ubuntu.com/bionic/current/bionic-server-cloudimg-amd64.img --output ~/ubuntu-18-04-cloud-amd64
   ```

2. Prepare an OpenStack RC (openrc) file containing credentials for accessing the OpenStack API:

   > **i** The interface for getting an openrc file may differ depending on the OpenStack provider. If the provider has a standard interface for OpenStack, you can download the openrc file using the following instruction.

3. Otherwise, install the OpenStack client using this instruction.

   Also, you can run the container and mount an openrc file and a downloaded Ubuntu image in it:

   ```
   docker run -ti --rm -v ~/ubuntu-18-04-cloud-amd64:/ubuntu-18-04-cloud-amd64 -v ~/.openrc:/openrc jmcvea/openstack-client
   ```

4. Initialize the environment variables from the openrc file:

   ```
   source /openrc
   ```

5. Get a list of available disk types:

```
/ # openstack volume type list
+--------------------------------------+--------------+-----------+
| ID                                   | Name         | Is Public |
+--------------------------------------+--------------+-----------+
| 8d39c9db-0293-48c0-8d44-015a2f6788ff | ko1-high-iops | True      |
| bf800b7c-9ae0-4cda-b9c5-fae283b3e9fd | dp1-high-iops | True      |
| 74101409-a462-4f03-872a-7de727a178b8 | ko1-ssd       | True      |
| eadd8860-f5a4-45e1-ae27-8c58094257e0 | dp1-ssd       | True      |
| 48372c05-c842-4f6e-89ca-09af3868b2c4 | ssd           | True      |
| a75c3502-4de6-4876-a457-a6c4594c067a | ms1           | True      |
| ebf5922e-42af-4f97-8f23-716340290de2 | dp1           | True      |
| a6e853c1-78ad-4c18-93f9-2bba317a1d13 | ceph          | True      |
+--------------------------------------+--------------+-----------+
```

6. Create an image, pass the disk format to use (if OpenStack does not support local disks or these disks don’t fit):

```
openstack image create --private --disk-format qcow2 --container-format bare \
  --file /ubuntu-18-04-cloud-amd64 --property cinder_img_volume_type=dp1-high-iops ubuntu-18-04-cloud-amd64
```

7. Check that the image was created successfully:

```
/ # openstack image show ubuntu-18-04-cloud-amd64
+------------------+------------------------------------
```

This behavior is especially important for clusters where `cinder-csi-plugin` pods run for a long time without restart, while the OpenStack service catalog may change between the initial authentication and subsequent API requests.

How to check whether the provider supports SecurityGroups?

Run the following command: `openstack security group list`. If there are no errors in the output, then Security Groups are supported.

How to set up online disk resize

The OpenStack API states that the resize is completed successfully. However, Nova does not get any information about the resize from Cinder. As a result, the size of the disk in the guest OS remains the same.

To get rid of this problem, you need to insert the Nova API access parameters into the `cinder.conf` file, e.g., as follows:

```
[nova]
interface = admin
insecure = {{ keystone_service_internaluri_insecure | bool }}
auth_type = {{ cinder_keystone_auth_plugin }}
auth_url = {{ keystone_service_internaluri }}/v3
password = {{ nova_service_password }}
project_domain_id = default
project_name = service
region_name = {{ nova_service_region }}
user_domain_id = default
username = {{ nova_service_user_name }}
```

Source...

How to use `rootDiskSize` and when it is preferred?

Disks in OpenStack

The node disk can be local or network. A local disk in OpenStack, is an ephemeral disk, and a network disk is a persistent disk (cinder storage). Nodes with local disks cannot migrate between hypervisors.

- A network disk is preferred for the master node so that the node can migrate between hypervisors.
- A local disk is preffered for the ephemeral node to save on cost. Not all cloud providers support the use of local disks. If local disks are not supported, you have to use network disks for ephemeral nodes.

Local disk (ephemeral)	Network disk (persistent)
Cheaper	More expensive
Suitable for ephemeral nodes	Suitable for master nodes

The `rootDiskSize` parameter

The `OpenStackInstanceClass` has a `rootDiskSize` parameter, and OpenStack flavor has a disk size parameter. Which disk will be ordered depending on the combination of parameters is shown in the table:

	flavor disk size = 0	**flavor disk size > 0**
`rootDiskSize` is not specified	*You need to set the size*. Without specifying the size, there will be an error creating a VM.	Local disk with size according to the flavor
`rootDiskSize` is specified	Network disk with the `rootDiskSize` size	Network disk (rootDiskSize) and local disk (according to the flavor). Avoid using this option, as the cloud provider will charge for both disks.

> **i** Please note, that to create a node with the `CloudEphemeral` type in a zone other than zone A, you must first create a flavor with a disk of the required size. The rootDiskSize parameter does not need to be specified.

Network disk is recommended for master nodes and bastion host

- Use flavor with a zero disk size.
- Set the `rootDiskSize` in the `OpenStackInstanceClass`.
- Check the disk type. The disk type will be taken from the OS image if it is set. If it is not set, the disk type will be taken from volumeTypeMap.

Local disk is recommended for ephemeral nodes

- Use flavor with the specified disk size.

- Do not use the `rootDiskSize` parameter in the `OpenStackInstanceClass`.
- Check the disk type. The disk type will be taken from the OS image if it is set. If it is not set, the default disk type of the cloud provider will be used.

How do I check the disk volume in a flavor?

```
# openstack flavor show m1.medium-50g -c disk
+-------+-------+
| Field | Value |
+-------+-------+
| disk  | 50    |
+-------+-------+
```

How to override a default volume type of cloud provider?

If there are several types of disks in a *cloud provider*, you can set a default disk type for the image in order to select a specific VM's disk type. To do this, specify the name of a disk type in the image metadata.

Also, you may need to create a custom OpenStack image; the "How do I create an image in OpenStack" section describes how to do it

Example:

```
openstack volume type list
openstack image set ubuntu-18-04-cloud-amd64 --property cinder_img_volume_type=VOLUME_NAME
```

OFFLINE disk resize

Some cloud providers may not support ONLINE disk resizing. If you get the following error, then you need to reduce the number of StatefulSet replicas to 0, wait for disk resizing and return the number of replicas that was before the start of the operation.

```
Warning  VolumeResizeFailed     5s (x11 over 41s)  external-resizer cinder.csi.openstack.org
resize volume "pvc-555555-ab66-4f8d-947c-296520bae4c1" by resizer "cinder.csi.openstack.org" failed:
rpc error: code = Internal desc = Could not resize volume "bb5a275b-3f30-4916-9480-9efe4b6dfba5" to size 2:
Expected HTTP response code [202] when accessing
[POST https://public.infra.myfavourite-cloud-provider.ru:8776/v3/555555555555/volumes/bb5a275b-3f30-4916-9480-
9efe4b6dfba5/action], but got 406 instead
{"computeFault": {"message": "Version 3.42 is not supported by the API. Minimum is 3.0 and maximum is 3.27.", "code": 406}}
```

How to create preemptible nodes in Selectel?

Selectel triggers preemption on the presence of the raw Nova tag `preemptible`. Set the `preemptible` parameter of the OpenStackInstanceClass to `true` — the tag is then attached to the instance automatically.

Example:

```
apiVersion: deckhouse.io/v1
kind: OpenStackInstanceClass
metadata:
  name: worker-preempt
spec:
  flavorName: SL1.4-8192
  imageName: Ubuntu 24.04 LTS 64-bit
  rootDiskSize: 30
  preemptible: true
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker-preempt
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    classReference:
      kind: OpenStackInstanceClass
      name: worker-preempt
    minPerZone: 2
    maxPerZone: 4
    zones: [ru-3a]
```

Limitations:

- The `preemptible` tag is a Selectel-specific mechanism, and the CAPI provider template emits it only when the cluster's `connection.authURL` points at Selectel (`selcloud.ru` / `selectel`). On other OpenStack providers the tag is silently dropped: the node is still created, but as a regular (non-preemptible) VM.
- Supported only for CloudEphemeral NodeGroups running on the CAPI engine. If an OpenStackInstanceClass with

`preemptible: true` is used by a NodeGroup running on the MCM engine, the field is silently ignored — no MCM MachineClass field maps to a raw Nova tag. Nodes are created as regular VMs.
- Both situations above raise the **OpenStackPreemptibleUnsupported** Prometheus alert (with `reason=mcm` or `reason=non-selectel`) so the operator learns about the silent drop instead of discovering it weeks later from an unchanged billing line. The alert description carries the exact commands to fix each case.
- The management engine is selected per NodeGroup. If the same OpenStackInstanceClass with `preemptible: true` is used simultaneously by NodeGroups running on CAPI and MCM, the MCM NodeGroup keeps firing the alert — use separate OpenStackInstanceClass resources for different engines when the preemptibility contract differs.

⚠ Changing the `preemptible` parameter in an existing OpenStackInstanceClass changes the OpenStackMachineTemplate and causes all nodes in the corresponding NodeGroup to be recreated.

If a preemptible instance is terminated without a `graceful shutdown`, the corresponding node transitions to the `NotReady` state. After the missing instance is detected, CAPO and MachineHealthCheck initiate the creation of a new Machine and virtual machine. Until recovery is complete, pods on the lost node may still appear in the Kubernetes API with the `Running` status even though they are no longer actually available.

What to do if switching to nodes in lower-priority groups takes a long time?

If switching to nodes in lower-priority groups takes a long time, follow the instructions.

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

i The module lifecycle stage: General Availability

Below are two simple examples of OpenStack cloud provider configuration.

Example 1

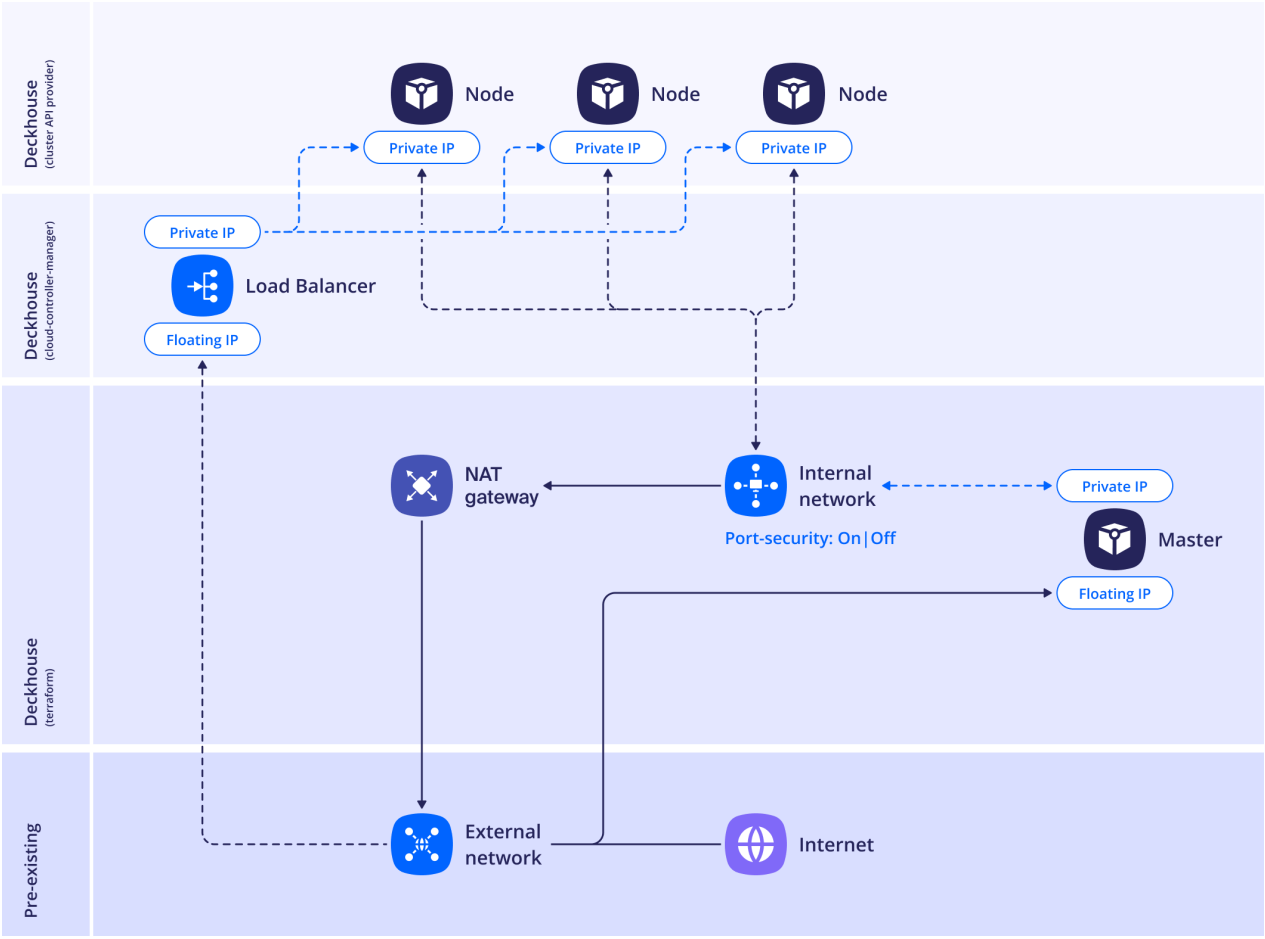
```
apiVersion: deckhouse.io/v1
kind: OpenStackInstanceClass
metadata:
  name: test
spec:
  flavorName: m1.large
```

Example 2

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-openstack
spec:
  version: 1
  enabled: true
  settings:
    connection:
      authURL: https://test.tests.com:5000/v3/
      domainName: default
      tenantName: default
      username: jamie
      password: nein
      region: SomeRegion
    externalNetworkNames:
    - public
    internalNetworkNames:
    - kube
    instances:
      sshKeyPairName: my-ssh-keypair
      securityGroups:
      - default
      - allow-ssh-and-icmp
    zones:
    - zone-a
    - zone-b
    tags:
      project: cms
      owner: default
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.



Cloud provider - OpenStack: Layouts

The module lifecycle stage: General Availability

Four layouts are supported. Below is more information about each of them.

Standard

In this scheme, an internal cluster network is created with a gateway to the public network; the nodes do not have public IP addresses. Note that the floating IP is assigned to the master node.

Caution! If the provider does not support SecurityGroups, all applications running on nodes with Floating IPs assigned will be available at a public IP. For example, `kube-apiserver` on master nodes will be available on port 6443. To avoid this, we recommend using the SimpleWithInternalNetwork placement strategy or Standard strategy with bastion host.

The `internalNetworkSecurity` parameter (default `true`) enables the creation of a security group (SecurityGroup) when a cluster is created. The module creates the group named after the cluster prefix (`prefix`) and assigns it to the nodes.

The following inbound rules will be created:

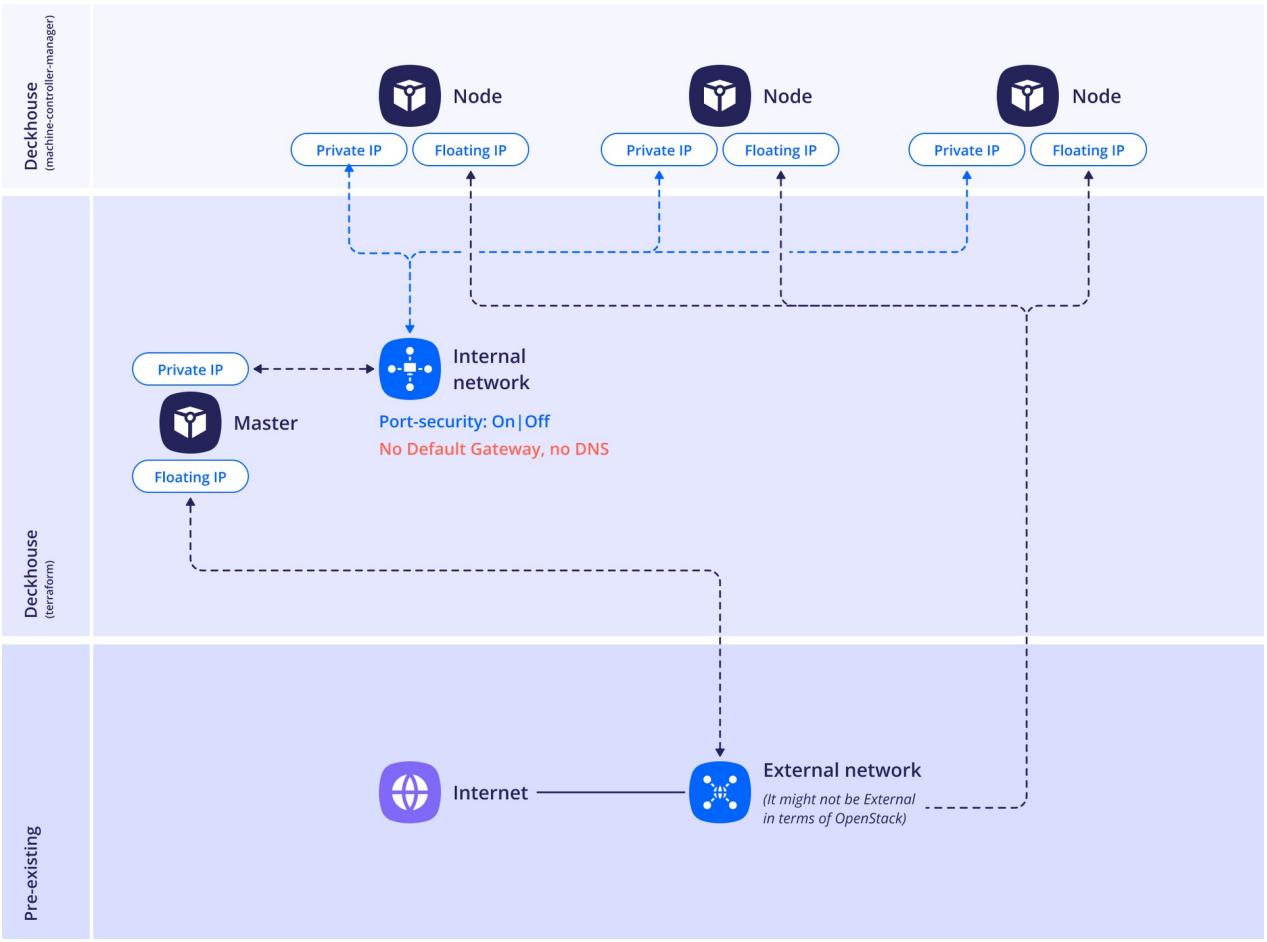
- allow incoming traffic over the TCP protocol on port `22` from CIDRs listed in `sshAllowList` (default `0.0.0.0/0`)
- allow incoming traffic over the ICMP protocol from `0.0.0.0/0`
- allow incoming traffic over the TCP protocol on ports `30000-32767` for services of the `NodePort` type. Inbound UDP traffic to `NodePort` ports is not allowed by default
- allow any incoming traffic from nodes in the same security group

In addition to the group created by the module, you can attach your own security groups. Prepare them in the cloud beforehand by following the OpenStack documentation and specify them in `additionalSecurityGroups`:

- for master nodes — in the `masterNodeGroup.instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource
- for static nodes — in the `nodeGroups[].instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource
- for ephemeral nodes — in the `spec.additionalSecurityGroups` parameter of the OpenStackInstanceClass resource

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: Standard
standard:
  internalNetworkCIDR: 192.168.199.0/24       # Required.
  internalNetworkDNSServers:                # Required.
  - 8.8.8.8
  - 4.2.2.2
  internalNetworkSecurity: true|false         # Optional, default true.
  externalNetworkName: shared               # Required.
  bastion:
    zone: ru2-b                           # Optional.
    volumeType: fast-ru-2b                  # Optional.
    instanceClass:
      flavorName: m1.large                  # Required.
```



```
     imageName: ubuntu-20-04-cloud-amd64     # Required.
     rootDiskSize: 50                       # Optional, default 50 gigabytes.
     additionalTags:
       severity: critical                   # Optional.
       environment: production              # Optional.
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
    additionalTags:
      severity: critical
      environment: production
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    ru-1a: fast-ru-1a
    ru-1b: fast-ru-1b
    ru-1c: fast-ru-1c
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                    # Required.

    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive is
    # required during vm bootstrap process. It's needed if there
    # is no dhcp in network that is used as default gateway.
    configDrive: false
    # Required, the gateway of the network will be used as the default gateway.
    # Matches the prefix parameter in the global ModuleConfig.
    mainNetwork: kube
    additionalNetworks:                     # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  zones:
  - ru-1a
  - ru-1b
sshPublicKey: "<SSH_PUBLIC_KEY>"
tags:
  project: cms
  owner: default
provider:
  ...
```

StandardWithNoRouter

An internal cluster network is created that does not have access to the public network. All nodes (including master ones) have two interfaces: the first one to the public network, the second one to the internal network. This layout should be used if you want all nodes in the cluster to be directly accessible.

Caution! This strategy does not support a LoadBalancer since a Floating IP is not available for the router-less network. Thus, you cannot provision a load balancer with the Floating IP. An internal load balancer with the virtual IP in the public network is only accessible to cluster nodes.

Caution! In this strategy, it is necessary to explicitly specify the name of the internal network in `additionalNetworks` when creating an `OpenStackInstanceClass` in the cluster.

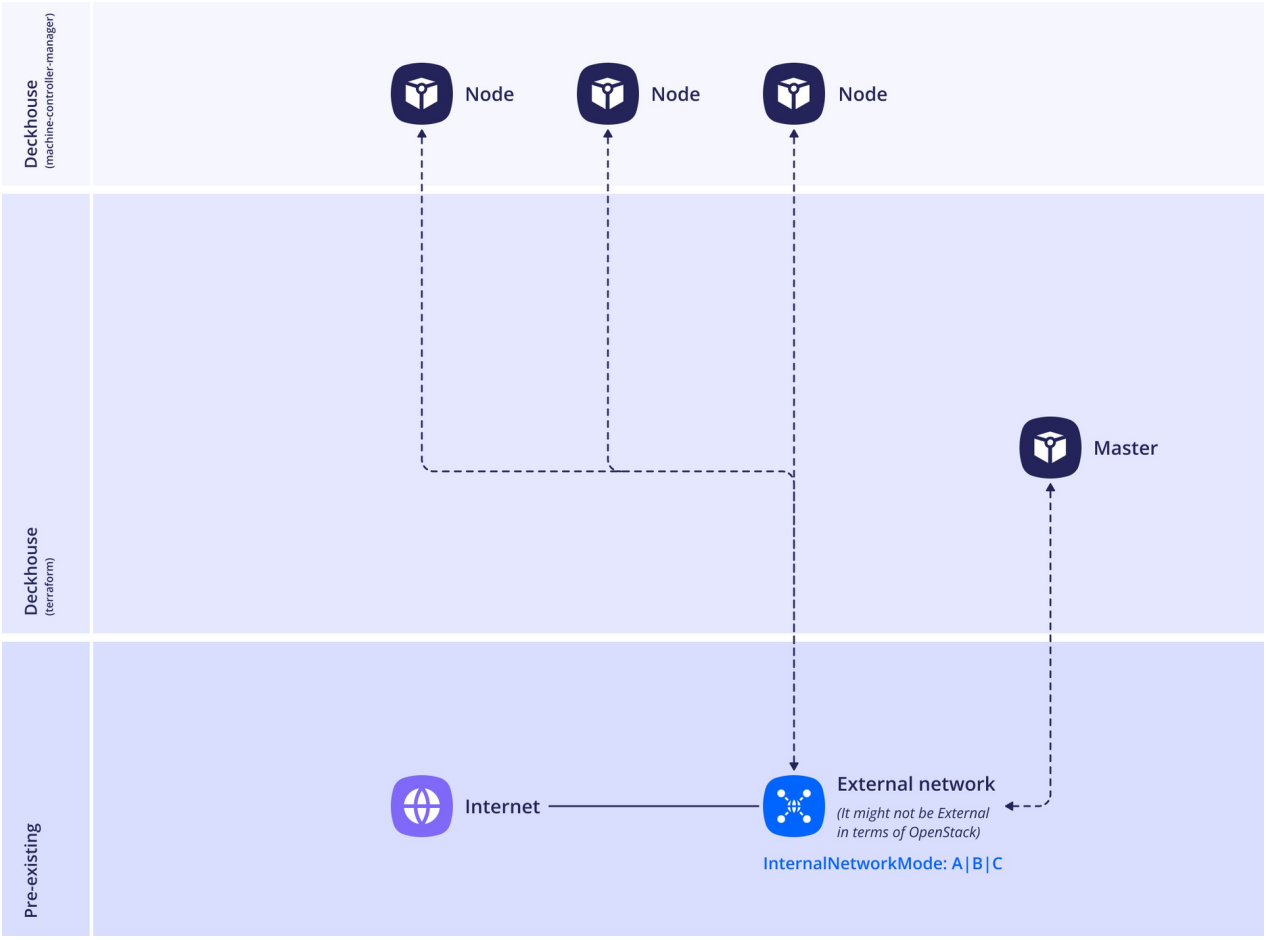
The `internalNetworkSecurity` parameter (default `true`) enables the creation of a security group (SecurityGroup) when a cluster is created. The module creates the group named after the cluster prefix (`prefix`) and assigns it to the nodes.

The following inbound rules will be created:

- allow incoming traffic over the TCP protocol on port `22` from CIDRs listed in `sshAllowList` (default `0.0.0.0/0`)
- allow incoming traffic over the ICMP protocol from `0.0.0.0/0`
- allow incoming traffic over the TCP protocol on ports `30000`–`32767` for services of the `NodePort` type. Inbound UDP traffic to `NodePort` ports is not allowed by default
- allow any incoming traffic from nodes in the same security group

In addition to the group created by the module, you can attach your own security groups. Prepare them in the cloud beforehand by following the OpenStack documentation and specify them in `additionalSecurityGroups`:

- for master nodes — in the `masterNodeGroup.instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource
- for static nodes — in the `nodeGroups[].instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource
- for ephemeral nodes — in the `spec.additionalSecurityGroups` parameter of the OpenStackInstanceClass resource



Example of the layout configuration:

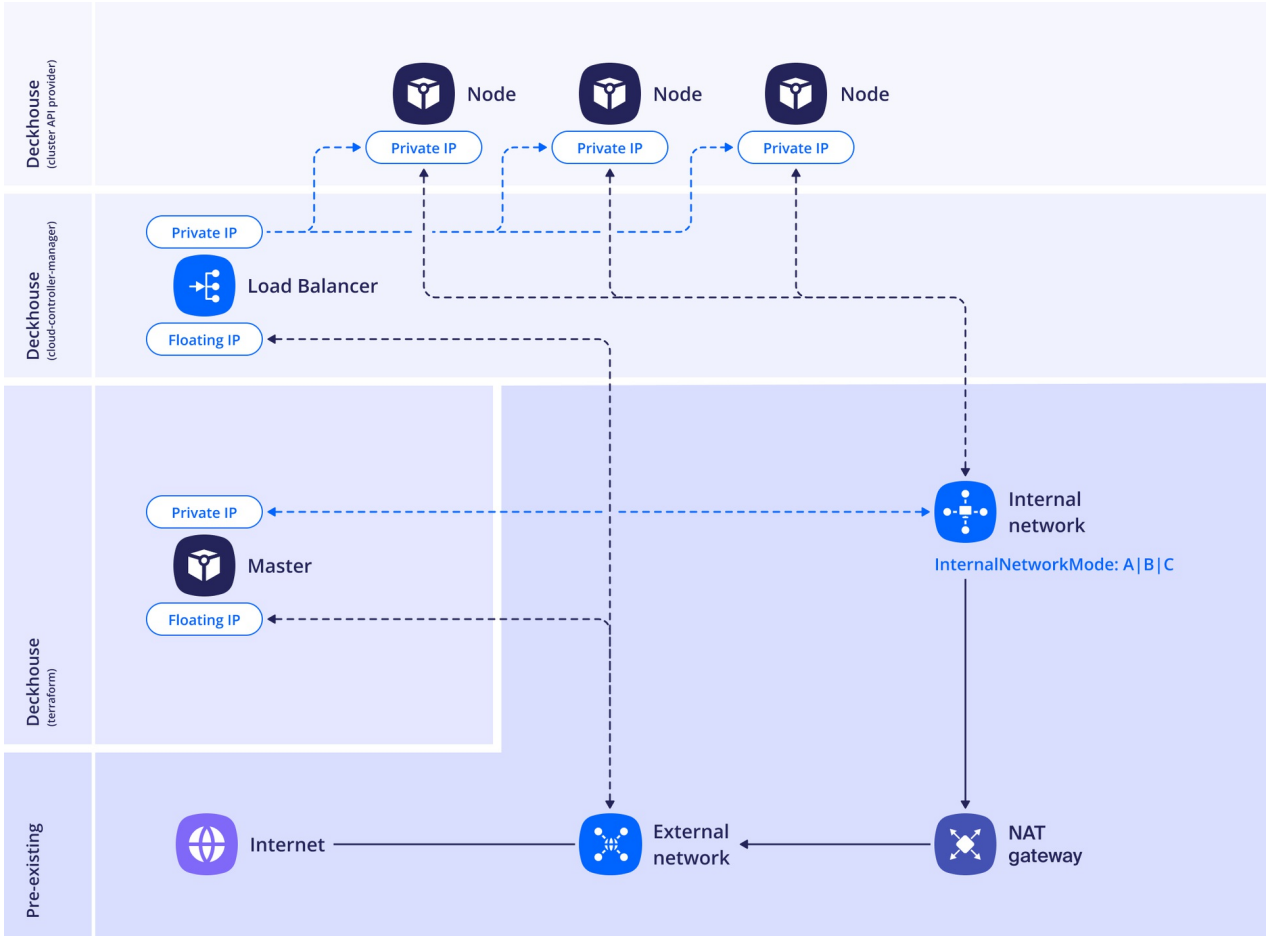
```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: StandardWithNoRouter
standardWithNoRouter:
  internalNetworkCIDR: 192.168.199.0/24        # Required.
  externalNetworkName: ext-net                # Required.
  # Optional, whether dhcp is enabled in specified external
  # network (default true).
  externalNetworkDHCP: false
  internalNetworkSecurity: true|false          # Optional, default true.
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                     # Required.
    imageName: ubuntu-18-04-cloud-amd64        # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    nova: ceph-ssd
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                     # Required.
    imageName: ubuntu-18-04-cloud-amd64        # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive
    # is required during vm bootstrap process. It's needed
    # if there is no dhcp in network that is used as default
    # gateway.
    configDrive: false
    # Required, the gateway of the network will be used as the default gateway.
    # Matches the prefix parameter in the global ModuleConfig.
    mainNetwork: kube
    additionalNetworks:                      # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required if rootDiskSize is specified. Volume type map for node's root volume
  volumeTypeMap:
    nova: ceph-ssd
sshPublicKey: "<SSH_PUBLIC_KEY>"
provider:
  ...
```

Simple

The master node and cluster nodes are connected to the existing network. This placement strategy might come in handy if you need to merge a Kubernetes cluster with existing VMs.

> **Caution!** This strategy does not support a LoadBalancer since a Floating IP is not available for the router-less network. Thus, you cannot provision a load balancer with the Floating IP. An internal load balancer with the virtual IP in the public network is only accessible to cluster nodes.

In this layout, the module does not create security groups. Prepare them in the cloud beforehand by following the OpenStack documentation and attach them to the nodes via `additionalSecurityGroups`:



- For master nodes, in the `masterNodeGroup.instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource.
- For static nodes, in the `nodeGroups[].instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource.
- For ephemeral nodes, in the `spec.additionalSecurityGroups` parameter of the OpenStackInstanceClass resource.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: Simple
simple:
  externalNetworkName: ext-net              # Required.
  externalNetworkDHCP: false                # Optional, default true.
  # Optional, by default VXLAN, may also be DirectRouting
  # or DirectRoutingWithPortSecurityEnabled.
  podNetworkMode: VXLAN
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    nova: ceph-ssd
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive
    # is required during vm bootstrap process. It's needed
    # if there is no dhcp in network that is used as default
    # gateway.
    configDrive: false
    # Required, network will be used as default gateway.
    # Matches the name of the pre-created network.
    mainNetwork: kube
    additionalNetworks:                     # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
sshPublicKey: "<SSH_PUBLIC_KEY>"
provider:
  ...
```

SimpleWithInternalNetwork

The master node and cluster nodes are connected to the existing network. This placement strategy might come in handy if you need to merge a Kubernetes cluster with existing VMs.

In this layout, the module does not create security groups. Prepare them in the cloud beforehand by following the OpenStack documentation and attach them to the nodes via `additionalSecurityGroups`:

- For master nodes, in the `masterNodeGroup.instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource.
- For static nodes, in the `nodeGroups[].instanceClass.additionalSecurityGroups` parameter of the OpenStackClusterConfiguration resource.
- For ephemeral nodes, in the `spec.additionalSecurityGroups` parameter of the OpenStackInstanceClass resource.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: SimpleWithInternalNetwork
simpleWithInternalNetwork:
  # All cluster nodes have to be in the same subnet. Set either the subnet name
  # in internalSubnetName or its UUID in internalSubnetID.
  internalSubnetName: pivot-standard
  # Optional, by default DirectRoutingWithPortSecurityEnabled,
  # may also be DirectRouting or VXLAN.
  podNetworkMode: DirectRoutingWithPortSecurityEnabled
  # Optional, if set will be used for load balancer default
  # configuration and ordering master floating IP.
  externalNetworkName: ext-net
  # Optional, default value is true.
  masterWithExternalFloatingIP: false
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    nova: ceph-ssd
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive
    # is required during vm bootstrap process. It's needed
    # if there is no dhcp in network that is used as default
    # gateway.
    configDrive: false
    # Required, network will be used as default gateway.
    # Matches the name of the pre-created network.
    mainNetwork: kube
    additionalNetworks:                     # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
sshPublicKey: "<SSH_PUBLIC_KEY>"
provider:
  ...
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — VMware Cloud Director

> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability

The `cloud-provider-vcd` module integrates Deckhouse Platform with VMware Cloud Director. It allows the `node-manager` module to use VCD resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-vcd` module:

- Managing VCD resources via `cloud-controller-manager`:
  - updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in VCD;
  - creates load balancers for Services of the LoadBalancer type. This uses VMware NSX Advanced Load Balancer (Avi); support is available with NSX-T.
- Provisioning disks via the Named Disk CSI driver (`named-disk.csi.cloud-director.vmware.com`) so that PersistentVolumes can be requested from the cluster.
- Provisioning CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-vcd`. Base infrastructure is provisioned depending on the layout.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the VCDInstanceClass resource.
- Registering with `node-manager` so that VCDInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

> For VCD API versions earlier than 37.2, the module uses compatibility mode (legacy components).

Third-party components

List of third-party software used in the `cloud-provider-vcd` module:

- VMware Cloud Director Cluster API provider v1.3.2, v1.2.0

  License: Apache License 2.0

  Cluster API provider for VMware Cloud Director.

- VMware Cloud Director Cloud provider 1.5.0, 1.6.1

  License: Apache License 2.0

  Cloud Controller Manager for VMware Cloud Director.

- VMware Cloud Director CSI driver 1.4.1, 1.6.0

  License: Apache License 2.0

  CSI driver for VMware Cloud Director Named Disks.

- VMware Cloud Director Terraform provider 3.10.0, 3.14.1

  License: Mozilla Public License 2.0

  Terraform provider for VMware Cloud Director.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

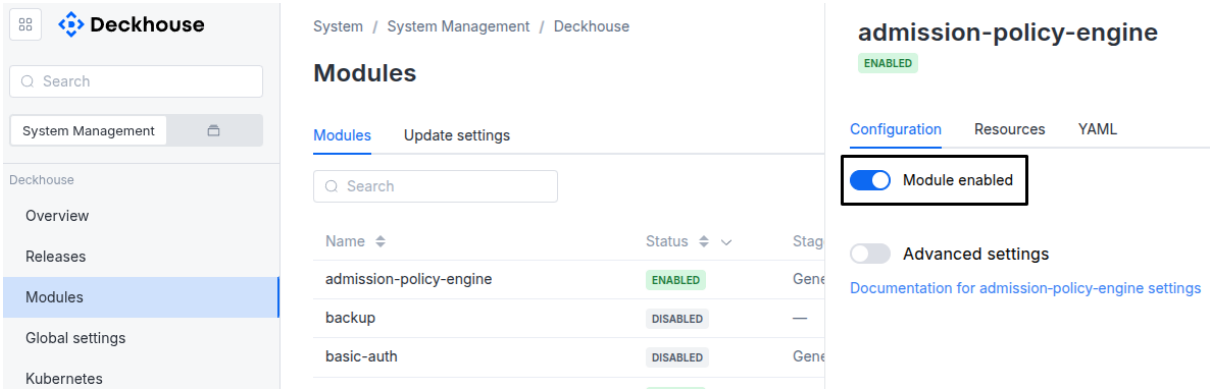
> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in VMware Cloud Director.

List of required VMware Cloud Director services

The following VMware Cloud Director service must be available for Deckhouse Platform to operate:



Service	API version
VMware Cloud Director API	`37.2` and later

> For VMware Cloud Director API versions earlier than `37.2`, compatibility mode for legacy API versions is used.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vcd` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

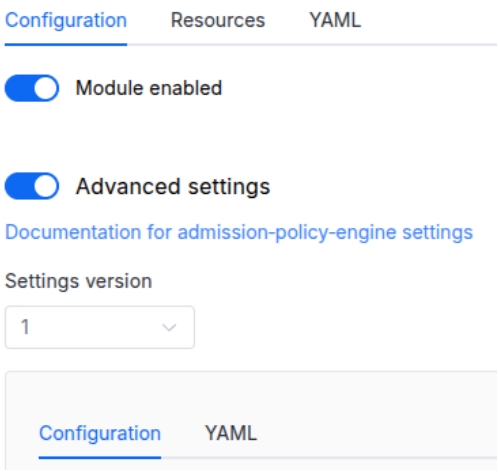
```
d8 system module enable cloud-provider-vcd
```

- **Using ModuleConfig `cloud-provider-vcd`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-vcd` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-vcd`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vcd
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vcd` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cloud-provider-vcd` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-vcd`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-vcd` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-vcd
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-vcd` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-vcd`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-vcd
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.mainNetwork**
    string

    Path to the network to which the primary network interfaces of virtual machines will be connected..

    Example:

    ```
    mainNetwork: internal
    ```
  - **settings.metadata**
    object

    Custom metadata entries that will be stored in cluster objects, such as virtual machines, disks, and networks.

    > **i** Changing metadata will cause CloudEphemeral nodes to be recreated.
  - **settings.organization**
    string

    Name of the Organization in VCD.

- **settings.provider**
  object

  Parameters for connecting to the VCD API.

  - **settings.provider.apiToken**
    string

    Token for authentication in VCD.

    > **i** When using the `apiToken` parameter, the `username` and `password` parameters must be empty.

  - **settings.provider.insecure**
    boolean

    Set to `true` if VCD has a self-signed certificate.

    Default: `false`

  - **settings.provider.password**
    string

    VCD user password.

  - **settings.provider.server**
    string

    VCD server host or IP address.

  - **settings.provider.username**
    string

    VCD user name with full permissions for the project.

- **settings.sshPublicKey**
  string

  Public SSH key for accessing the nodes.

- **settings.storageClass**
  object

  The module automatically creates StorageClasses that are available in VCD (VMware Cloud Director).

  - **settings.storageClass.default**
    Deprecated
    string

    The name of StorageClass that will be used in the cluster by default.

    If the parameter is omitted, the default StorageClass is either:

    - an arbitrary StorageClass present in the cluster that has the default annotation;
    - StorageClass for `default StorageProfile`;
    - the first (in lexicographic order) StorageClass created by the module.

    > **i** **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

    Example:

    ```
    default: ceph-ssd
    ```

  - **settings.storageClass.exclude**
    array of strings

    A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

    Example:

    ```
    exclude:
    - ".*-hdd"
    - iscsi-fast
    ```

- **settings.virtualApplicationName**
  string

  Name of the Virtual Application in VCD that belongs to the specified Virtual Data Center.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **settings.virtualDataCenter**
  string

  Name of the Virtual Data Center in VCD that belongs to the specified Organization.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> The module lifecycle stage: General Availability

> If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-vcd` module in the Deckhouse configuration. Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the VCDClusterConfiguration structure for configuration.

VCDClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in VCD.

Used by the cloud provider if a cluster's control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: VCDClusterConfiguration
sshPublicKey: "<SSH_PUBLIC_KEY>"
organization: My_Org
virtualDataCenter: My_Org
virtualApplicationName: Cloud
mainNetwork: internal
layout: Standard
internalNetworkCIDR: 172.16.2.0/24
masterNodeGroup:
  replicas: 1
  instanceClass:
    template: Templates/ubuntu-focal-20.04
    sizingPolicy: 4cpu8ram
    rootDiskSizeGb: 20
    etcdDiskSizeGb: 20
    storageProfile: nvme
nodeGroups:
- name: worker
  replicas: 1
  instanceClass:
    template: Org/Templates/ubuntu-focal-20.04
    sizingPolicy: 16cpu32ram
    storageProfile: ssd
provider:
  server: "<SERVER>"
  username: "<USERNAME>"
  password: "<PASSWORD>"
  insecure: true
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **bastion**
  object

  Parameters for the bastion host, which is used to access the cluster's nodes.

- **bastion.instanceClass**
  object

  Required value

  Partial contents of the fields of the VCDInstanceClass.

  - **bastion.instanceClass.additionalMetadata**
    object

    Custom string key-value pairs to be stored in the Metadata of the bastion, useful for organizing and categorizing your virtualization inventory.

    The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the spec. This field will take precedence over the existing metadata in cases of duplicate keys.

  - **bastion.instanceClass.mainNetworkIPAddress**
    string

    The IP address of the bastion host in the `mainNetwork`. If not set, the DHCP client will be enabled.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **bastion.instanceClass.placementPolicy**
    string

    Placement policy to be used on this machine.

    If no placement policy is specified, the default placement policy will be used to create the bastion host.

    Length: `1..128`

  - **bastion.instanceClass.rootDiskSizeGb**
    integer

    Root disk size in gigabytes.

    Default: `50`

    Allowed values: `0 <= X`

    Example:

    ```
    rootDiskSizeGb: 50
    ```

  - **bastion.instanceClass.sizingPolicy**
    string

    Required value

    Sizing policy to be used on this machine.

    If no sizing policy is specified, the default sizing policy will be used to create the bastion host.

    Length: `1..128`

  - **bastion.instanceClass.storageProfile**
    string

    Required value

    Storage profile to be used on this machine.

    Length: `1..128`

  - **bastion.instanceClass.template**

    Required value

    Path of the template OVA that is to be used.

    Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

    If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

    You can find the template identifier in the URL when you open the template in the VCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

    Length: `1..128`

- **createDefaultFirewallRules**
  boolean

  If enabled, configures the following default firewall rules for the cluster’s main network (mainNetwork):

  - Allows all outgoing connections from mainNetwork.
  - Allows all incoming ICMP packets to mainNetwork.
  - Allows all incoming TCP connections to mainNetwork on port 22 (SSH).

  - Allows all incoming TCP and UDP connections to mainNetwork for NodePorts in the range 30000–32767.

Attention! Using this option together with an Edge Gateway of type NSX-T implies that only one cluster should be deployed per Edge Gateway, because in this case all existing firewall rules will be overwritten.

Default: `false`

- **edgeGateway**
  object

  VMware Cloud Director Edge Gateway parameters (belongs to Virtual Data Center).

  - **edgeGateway.NSX-V**
    object

    Additional parameters required if `type` is NSX-V.

    - **edgeGateway.NSX-V.externalNetworkName**
      string

      External network name for build DNAT rule for master node. The external network is the one connected to the Edge Gateway in `Gateway Interface` and has an external IP address.

      Length: `1..128`

    - **edgeGateway.NSX-V.externalNetworkType**
      string

      External network type for build DNAT rule for master node (one of “org” or “ext”).

      Allowed values: `org`, `ext`

  - **edgeGateway.externalIP**
    string

    Required value

    The IP address accessible from external networks through which incoming SSH connections are forwarded to the master node using DNAT.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **edgeGateway.externalPort**
    integer

    The external port mapped by the DNAT rule to forward incoming SSH connections to the master node.

    Default: `22`

    Allowed values: `1 <= X <= 65535`

    Example:

    ```
    externalPort: 22
    ```

  - **edgeGateway.name**
    string

    Required value

    VMware Cloud Director Edge Gateway name.

    Length: `1..128`

  - **edgeGateway.type**
    string

    Required value

    Network virtualization platform type providing the VMware Cloud Director Edge Gateway (one of “NSX-V” or “NSX-T”). The type can be obtained from your administrator.

    Allowed values: `NSX-V`, `NSX-T`

- **internalNetworkCIDR**
  string

  Subnet for master nodes in the internal network.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **internalNetworkDHCPPoolStartAddress**
  integer

  Specifies the starting address number in the internal network from which the DHCP address pool will begin. Addresses below this number will not be assigned automatically by DHCP and are available for manual allocation. If not set, the default start address is 30.

  For example, in a network 192.168.100.128/27, a value of 10 means the DHCP pool will start with the IP address 192.168.100.138. The pool will end at the address immediately before the broadcast address (192.168.100.159), i.e., the last assignable host address.

Allowed values: `2 <= X`

- **internalNetworkDNSServers**
  array of strings

  A list of addresses of the recursive DNSs servers.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **kind**
  string

  Required value

  Allowed values: `VCDClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **legacyMode**
  boolean

  Support for outdated versions of the VCD API.

  If set to `true`, the API version below `37.2` will be used.

  The parameter has an effect only when installing a cluster. In the working cluster, the need to enable the support for outdated versions of the VCD API is determined automatically.

  Default: `false`

- **mainNetwork**
  string

  Required value

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  Example:

  ```
  mainNetwork: internal
  ```

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the VCDInstanceClass.

    - **masterNodeGroup.instanceClass.additionalMetadata**
      object

      Custom string key-value pairs to be stored in the Metadata of every master node VM, useful for organizing and categorizing your virtualization inventory.

      The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the spec. This field will take precedence over the existing metadata in cases of duplicate keys.

    - **masterNodeGroup.instanceClass.affinityRule**
      object

      Specifies the affinity rule applied to virtual machines of the master nodes within the cluster. Affinity rules determine how nodes are scheduled in relation to each other at the hypervisor level, which can help improve fault tolerance, and control the distribution of workloads. If not specified, no affinity rule will be applied by default.

      - **masterNodeGroup.instanceClass.affinityRule.polarity**
        string

        Required value

The polarity of the affinity rule. Must be either `Affinity` or `AntiAffinity`. `Affinity` means that nodes should be placed on the same host, while `AntiAffinity` means they should be placed on different hosts.

Allowed values: `Affinity`, `AntiAffinity`

- **masterNodeGroup.instanceClass.affinityRule.required**
  boolean

  Indicates whether the affinity rule is mandatory (`true`) or only preferred (`false`). If set to `true`, the rule must be enforced; if `false`, the rule is applied if possible but not strictly required.

  Default: `false`

- **masterNodeGroup.instanceClass.etcdDiskSizeGb**
  integer

  Etcd disk size in gigabytes.

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **masterNodeGroup.instanceClass.mainNetworkIPAddresses**
  array of strings

  A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

  By default, the DHCP client is enabled.

  Example:

  ```
  mainNetworkIPAddresses:
  - 10.1.14.20
  - 10.1.4.21
  ```

  - **Element of the array**
    string

    An IP address with a CIDR prefix.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **masterNodeGroup.instanceClass.placementPolicy**
  string

  PlacementPolicy is the placement policy to be used on this machine.

  If no placement policy is specified, default placement policy will be used to create the nodes.

  Example:

  ```
  placementPolicy: Hypervisor1
  ```

- **masterNodeGroup.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in gigabytes.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **masterNodeGroup.instanceClass.sizingPolicy**
  string

  Required value

  SizingPolicy is the sizing policy to be used on this machine.

  If no sizing policy is specified, default sizing policy will be used to create the nodes.

  Example:

  ```
  sizingPolicy: 4Cpu8Memory
  ```

- **masterNodeGroup.instanceClass.storageProfile**
  string

  Required value

  StorageProfile is the storage profile to be used on this machine.

  Example:

```
storageProfile: ssd
```

- **masterNodeGroup.instanceClass.template**
  string

  Required value

  Path of the template OVA that is to be used.

  Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

  If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

  You can find the template identifier in the URL when you open the template in the VCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

  Examples:

  ```
  template: Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: MyOrg/Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

  ```
  template: MyOrg/Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **metadata**
  object

  Custom metadata entries to be stored in cluster objects such as virtual machines, disks and network.

  Clearing the `metadata` and `additionalMetadata` fields, if they contain any keys, will result in all metadata no longer being tracked except for nodes of the CloudEphemeral type. This means that if you need to remove metadata entirely, you will have to do it manually.

  > **Warning.** Changing the metadata will cause the recreation of CloudEphemeral nodes.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the VCDInstanceClass.

    - **nodeGroups.instanceClass.additionalMetadata**
      object

      Custom string key-value pairs to be stored in the Metadata of every node VM, useful for organizing and categorizing your virtualization inventory.

      The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the spec. This field will take precedence over the existing metadata in cases of duplicate keys.

    - **nodeGroups.instanceClass.affinityRule**
      object

      Specifies the affinity rule applied to virtual machines of nodes of the NodeGroup within the cluster. Affinity rules determine how nodes are scheduled in relation to each other at the hypervisor level, which can help improve fault tolerance, and control the distribution of workloads. If not specified, no affinity rule will be applied by default.

      - **nodeGroups.instanceClass.affinityRule.polarity**
        string

        Required value

        The polarity of the affinity rule. Must be either `Affinity` or `AntiAffinity`. `Affinity` means that

nodes should be placed on the same host, while `AntiAffinity` means they should be placed on different hosts.

Allowed values: `Affinity`, `AntiAffinity`

- **nodeGroups.instanceClass.affinityRule.required**
  boolean

  Indicates whether the affinity rule is mandatory (`true`) or only preferred (`false`). If set to `true`, the rule must be enforced; if `false`, the rule is applied if possible but not strictly required.

  Default: `false`

- **nodeGroups.instanceClass.mainNetworkIPAddresses**
  array of strings

  A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

  By default, the DHCP client is enabled.

  Example:

  ```
  mainNetworkIPAddresses:
  - 10.1.14.20
  - 10.1.4.21
  ```

  - **Element of the array**
    string

    An IP address with a CIDR prefix.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **nodeGroups.instanceClass.placementPolicy**
  string

  PlacementPolicy is the placement policy to be used on this machine.

  If no placement policy is specified, default placement policy will be used to create the nodes.

  Example:

  ```
  placementPolicy: Hypervisor1
  ```

- **nodeGroups.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in gigabytes.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **nodeGroups.instanceClass.sizingPolicy**
  string

  Required value

  SizingPolicy is the sizing policy to be used on this machine.

  If no sizing policy is specified, default sizing policy will be used to create the nodes.

  Example:

  ```
  sizingPolicy: 4Cpu8Memory
  ```

- **nodeGroups.instanceClass.storageProfile**
  string

  Required value

  StorageProfile is the storage profile to be used on this machine.

  Example:

  ```
  storageProfile: ssd
  ```

- **nodeGroups.instanceClass.template**
  string

  Required value

  Path of the template OVA that is to be used.

  Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

You can find the template identifier in the URL when you open the template in the VCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

Examples:

```
template: Linux/ubuntu2204-cloud-ova
```

```
template: MyOrg/Linux/ubuntu2204-cloud-ova
```

```
template: Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
```

```
template: MyOrg/Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **nodeGroups.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **nodeGroups.nodeTemplate.taints.key**
      string
    - **nodeGroups.nodeTemplate.taints.value**
      string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **organization**
  string

  Required value

  VMware Cloud Director Organization name.

- **provider**
  object

  Required value

  Parameters for connecting to the VCD.

  - **provider.apiToken**
    string

    The token for authentication.

    > **Caution!** When using `apiToken`, leave `username` and `password` empty.

  - **provider.insecure**
    boolean

    Set to `true` if VCD has a self-signed certificate.

    Default: `false`

  - **provider.password**
    string

    The user's password.

  - **provider.server**
    string

    Required value

    The host or the IP address of the VCD server.

  - **provider.username**
    string

    The login ID.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **virtualApplicationName**
  string

  Required value

  VMware Cloud Director Virtual Application name (belongs to Virtual Data Center).

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **virtualDataCenter**
  string

  Required value

  VMware Cloud Director Virtual Data Center name (belongs to Organization).

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> The module lifecycle stage: General Availability

List of required VCD resources

- Organization
- VirtualDataCenter
- vApp
- StoragePolicy
- SizingPolicy

- Network
- EdgeRouter
- Catalog

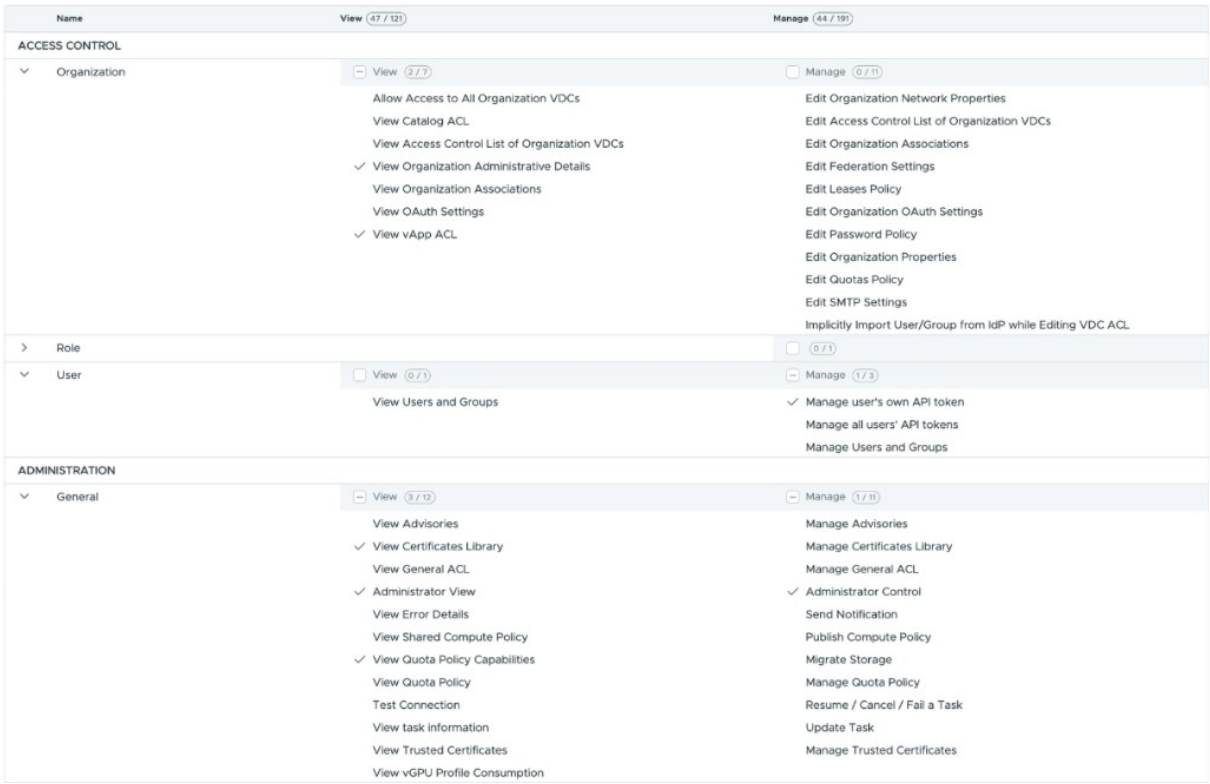
The Organization, VirtualDataCenter, StoragePolicy, SizingPolicy, EdgeRouter, and Catalog resources must be provided by your VMware Cloud Director service provider.

> ⚠ Each VDC (Virtual Data Center) must have an Edge Gateway configured, and the cluster network must be connected to it.

Network (internal network) can be configured either by your VMware Cloud Director service provider or manually by you. If you choose the `WithNAT` placement scheme, the network will be created automatically. The following section describes how to configure the internal network manually.

User permissions

For access to the VMware Cloud Director API, one of the following options is sufficient:

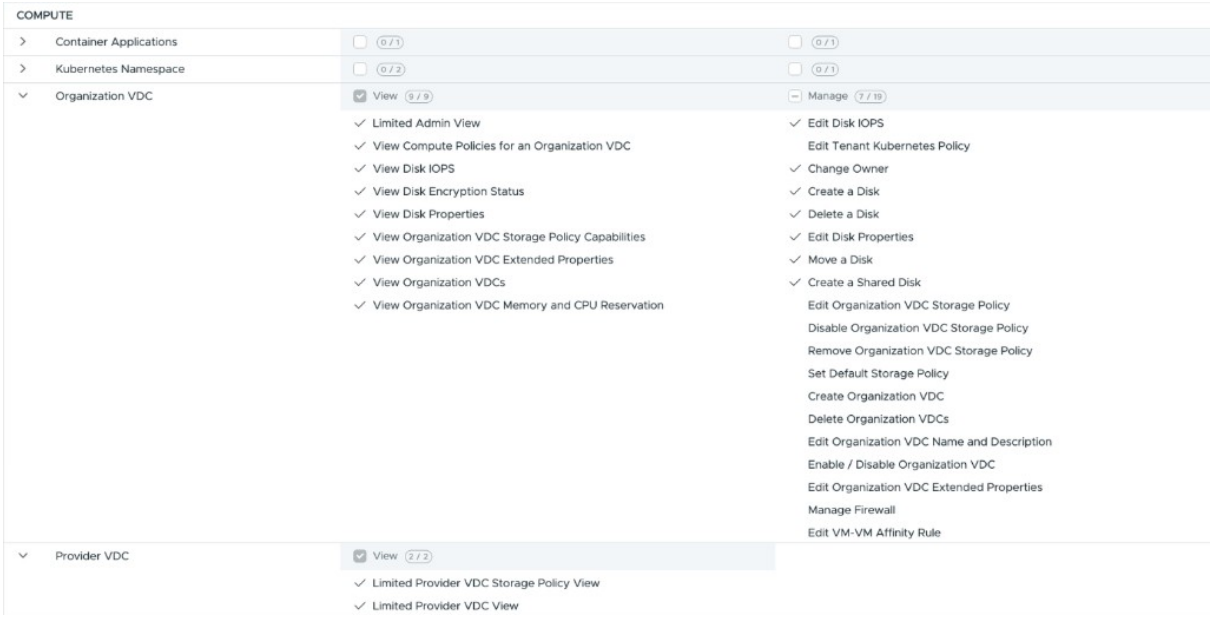


- The `Organization Administrator` role with the `Preserve All ExtraConfig Elements During OVF Import and Export` right. This option does not require configuring a separate role, but grants the user full administrative access to the organization.
- A custom role with the set of rights listed below. This set is sufficient to create a cluster, provision nodes (including CloudEphemeral with static addressing and DHCP), and work with CSI disks and StorageClass without granting additional administrative rights.

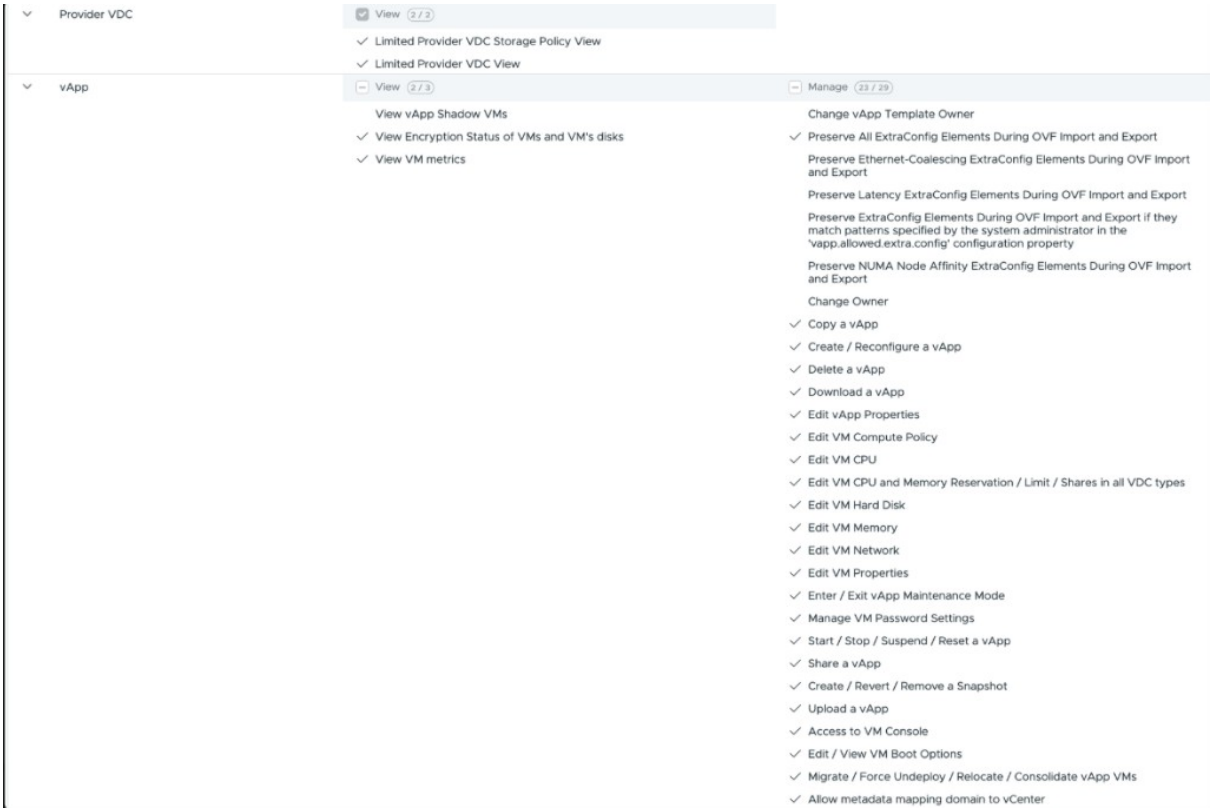
In VMware Cloud Director, user permissions come from the role and from a **Rights Bundle** — a set of rights published to the organization. Add the `Preserve All ExtraConfig Elements During OVF Import and Export` right both to the role and to the organization's Rights Bundle.

> ⚠ Without the `Preserve All ExtraConfig Elements During OVF Import and Export` right in both the role and the organization's Rights Bundle, `userdata` is not passed to the virtual machines of ephemeral nodes.

To create a custom role, enable the rights as shown below. Right names match the VCD UI.



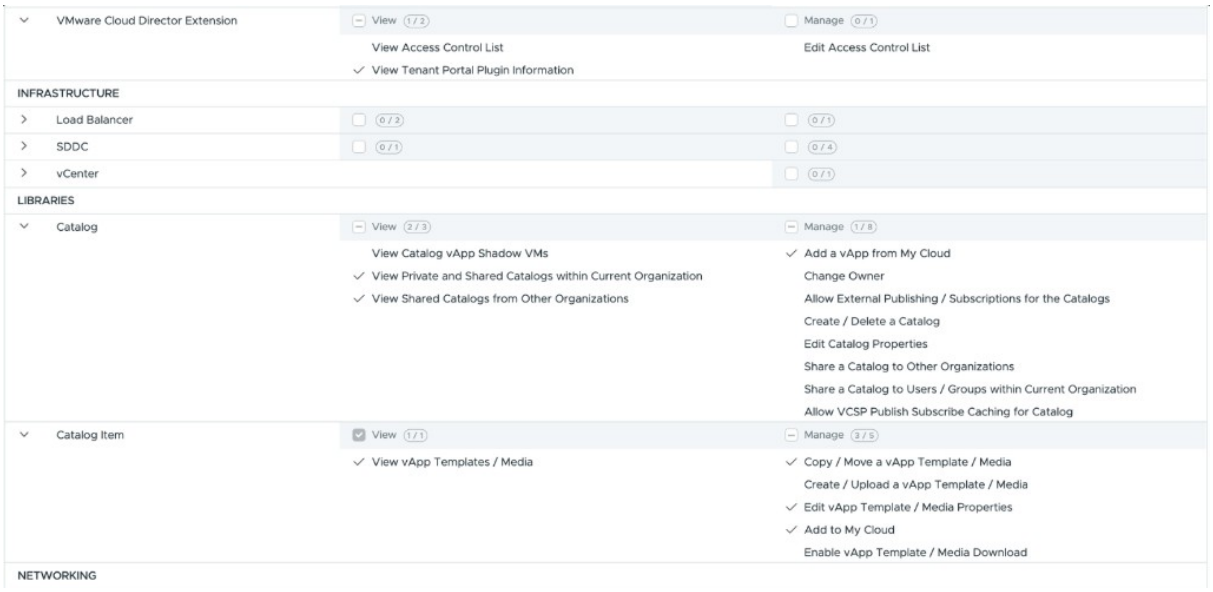
1. In the "ACCESS CONTROL" and "ADMINISTRATION" sections, enable the following rights:
   - Organization → View: `View Organization Administrative Details`, `View vApp ACL`
   - User → Manage: `Manage user's own API token`
   - General → View: `View Certificates Library`, `Administrator View`, `View Quota Policy Capabilities`
   - General → Manage: `Administrator Control`



2. In the "COMPUTE" → "Organization VDC" section, enable all View rights and the following Manage rights:
   - `Edit Disk IOPS`
   - `Edit Tenant Kubernetes Policy`
   - `Change Owner`
   - `Create a Disk`
   - `Delete a Disk`
   - `Edit Disk Properties`

- `Move a Disk`
- `Create a Shared Disk`

In the “Provider VDC” → View section, enable `Limited Provider VDC Storage Policy View` and `Limited Provider VDC View`:

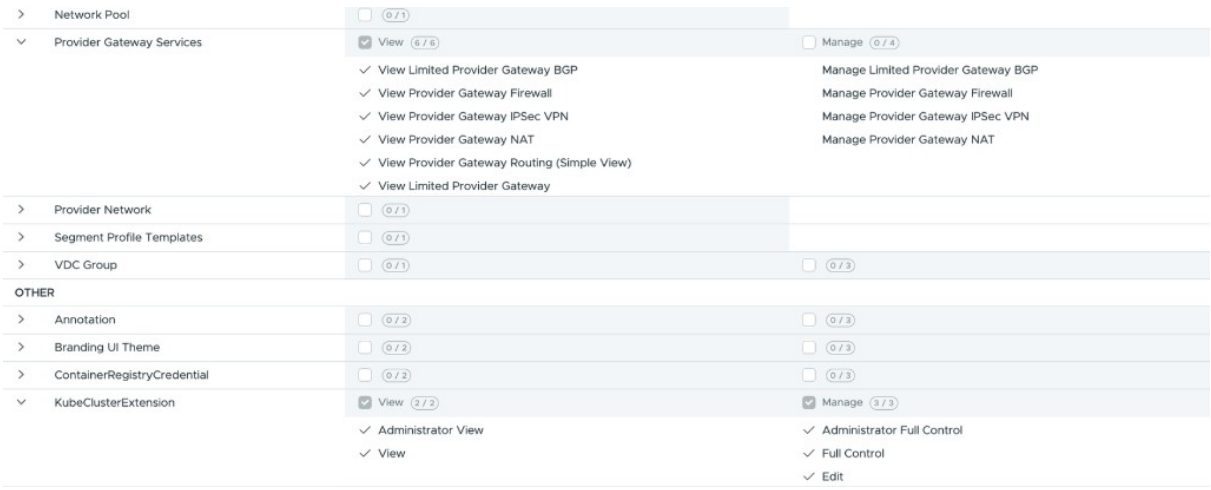


3. In the “COMPUTE” → “vApp” section, enable the rights as shown in the screenshot. Make sure that `Preserve All ExtraConfig Elements During OVF Import and Export` is enabled. In the verified role, View includes `View Encryption Status of VMs and VM's disks` and `View VM metrics`; `View vApp Shadow VMs` and the other Preserve ExtraConfig options are not enabled:

4. In the “LIBRARIES” section, enable the following rights:

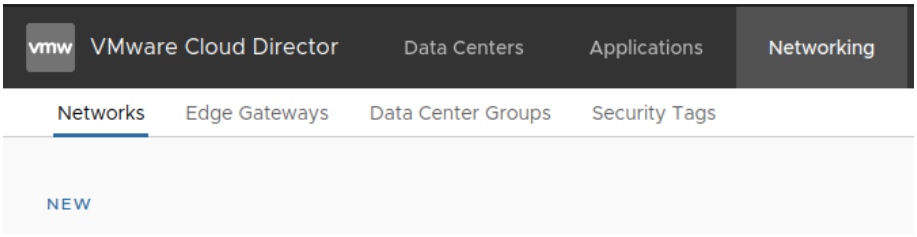
   - Catalog → View: `View Private and Shared Catalogs within Current Organization`, `View Shared Catalogs from Other Organizations` (to use images from shared catalogs)
   - Catalog → Manage: `Add a vApp from My Cloud`
   - Catalog Item → View: `View vApp Templates / Media`
   - Catalog Item → Manage: `Copy / Move a vApp Template / Media`, `Edit vApp Template / Media Properties`, `Add to My Cloud`

   In the “VMware Cloud Director Extension” → View section, enable `View Tenant Portal Plugin Information`:

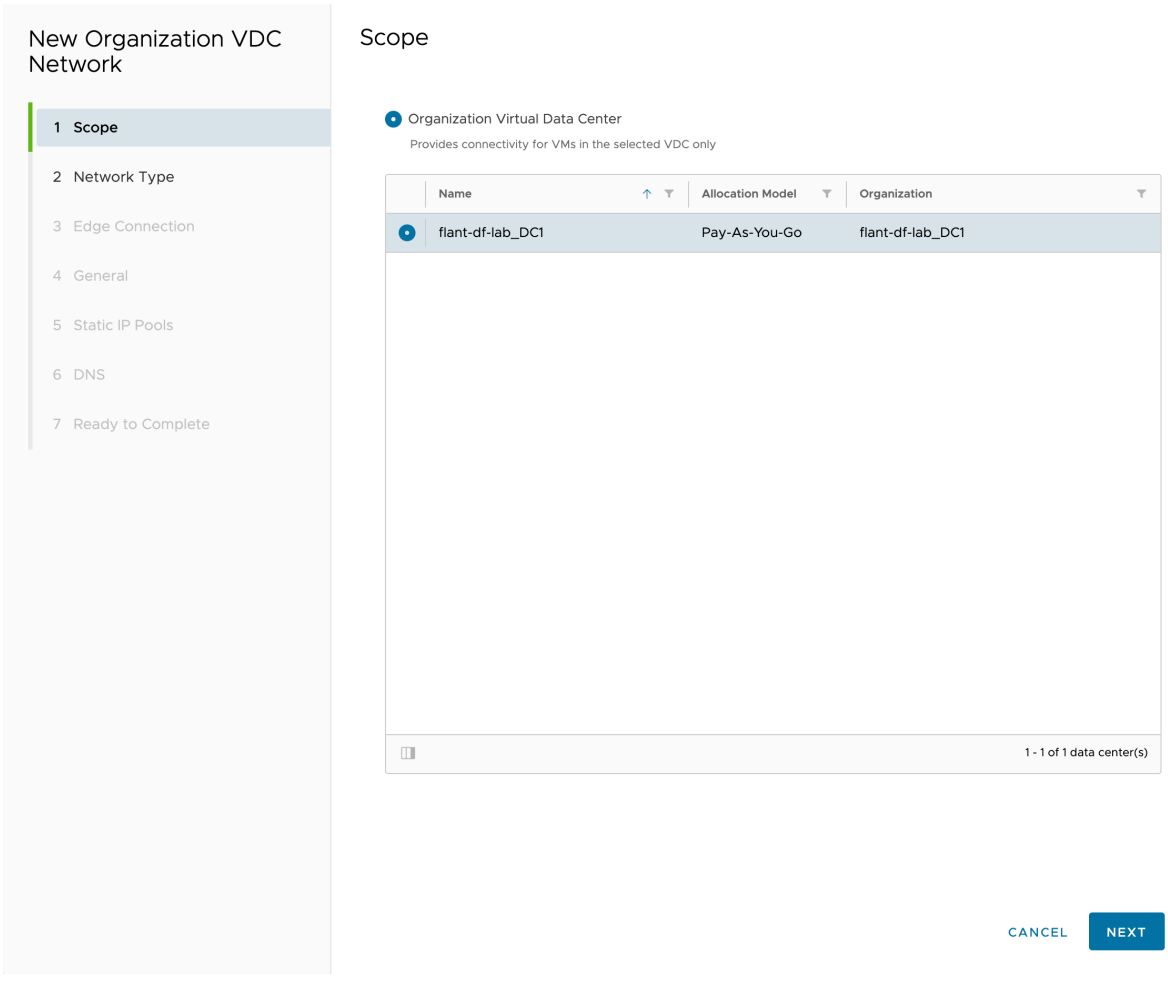


5. In the “NETWORKING” section, enable the following rights:

   - Edge Gateway → View: `View Gateway`
   - Edge Gateway Services → View: all items
   - Edge Gateway Services → Manage: `Load Balancer Configure`, `NAT Configure`
   - IP Spaces → View: `View IP Spaces`
   - IP Spaces → Manage: `Allocate IP Spaces`, `Manage IP Spaces`
   - Organization VDC Network → View: `View Properties`
   - Organization VDC Network → Manage: `Edit Properties` (required to create networks in the organization)

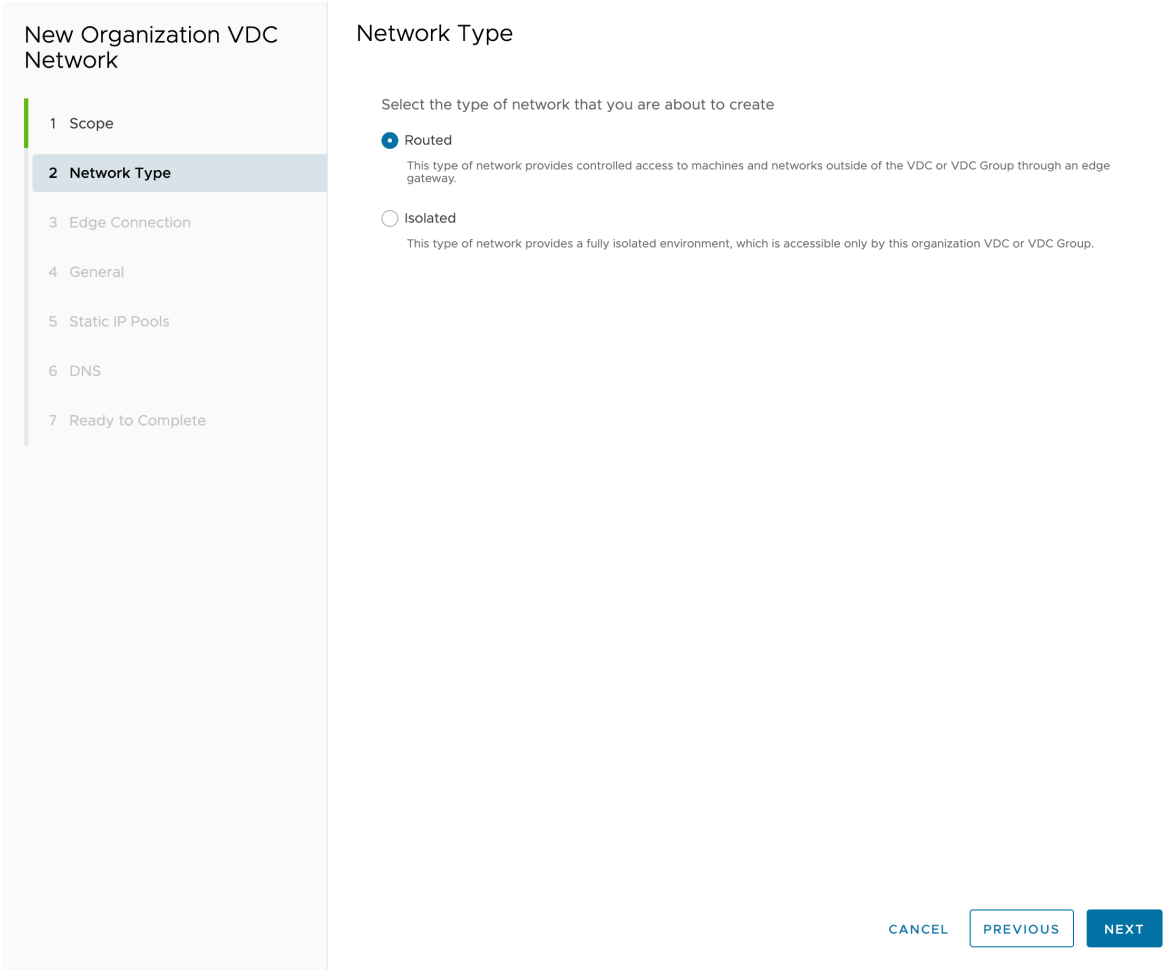


6. In the “Provider Gateway Services” section, enable all View rights. In the “KubeClusterExtension” section, enable all View and Manage rights:

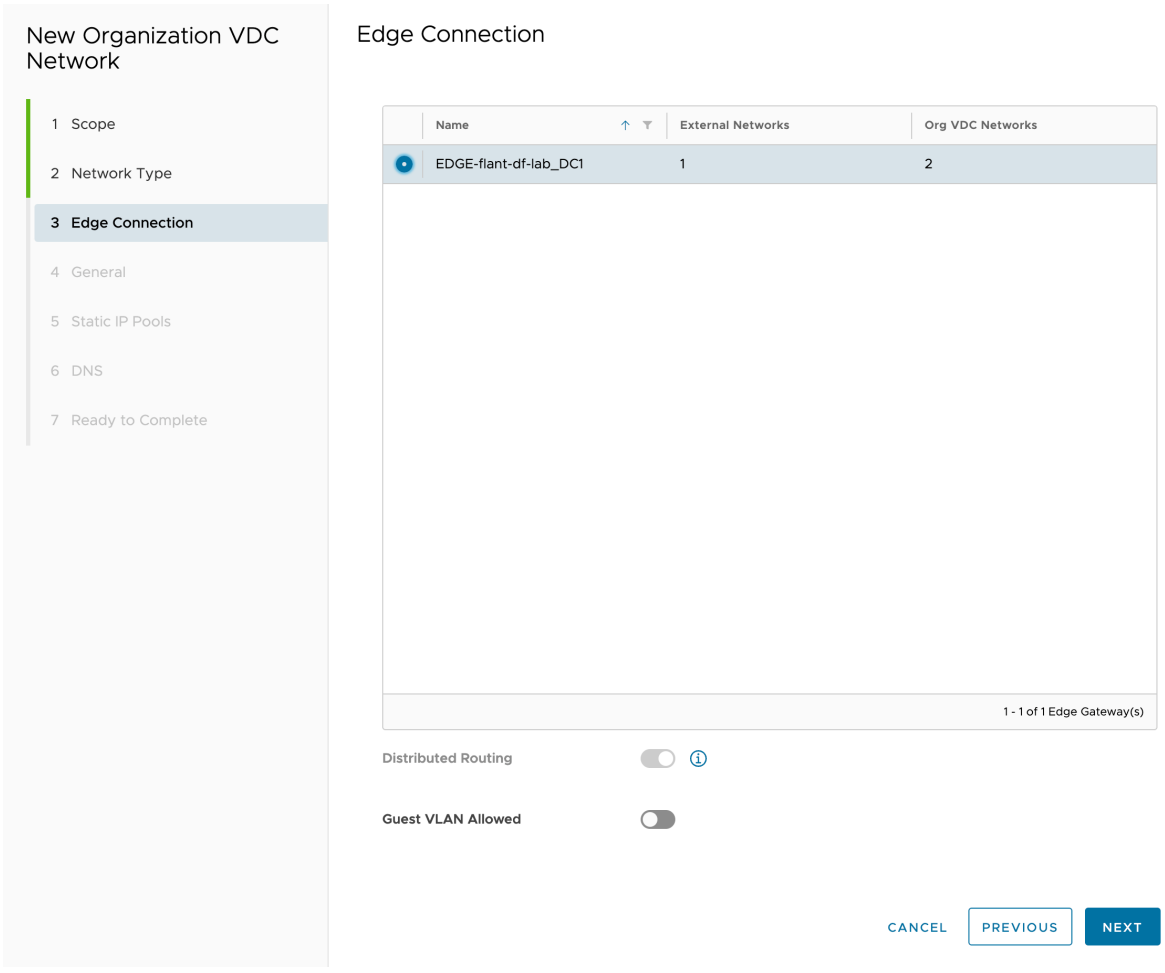


Adding a network

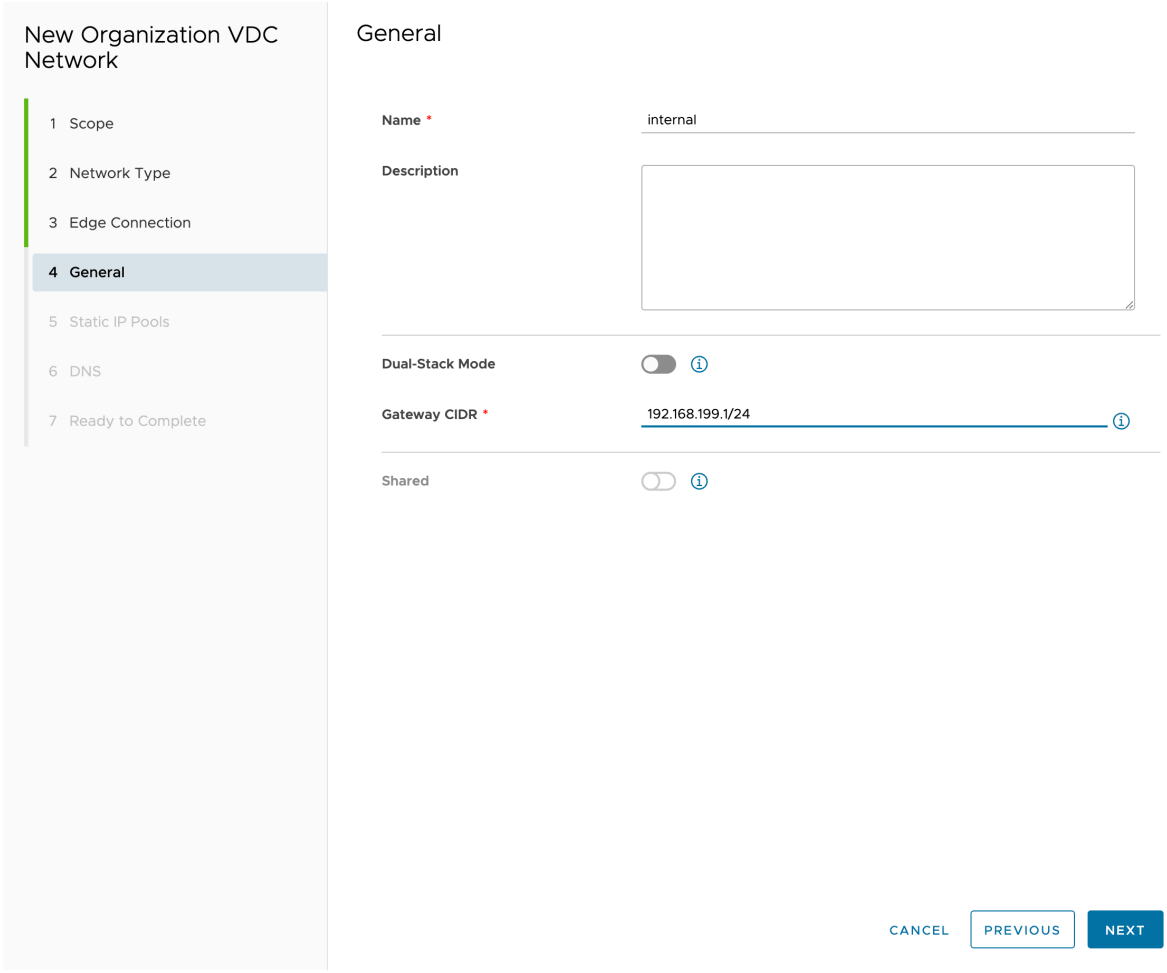
> **i** This instruction is applicable only for the `Standard` layout.



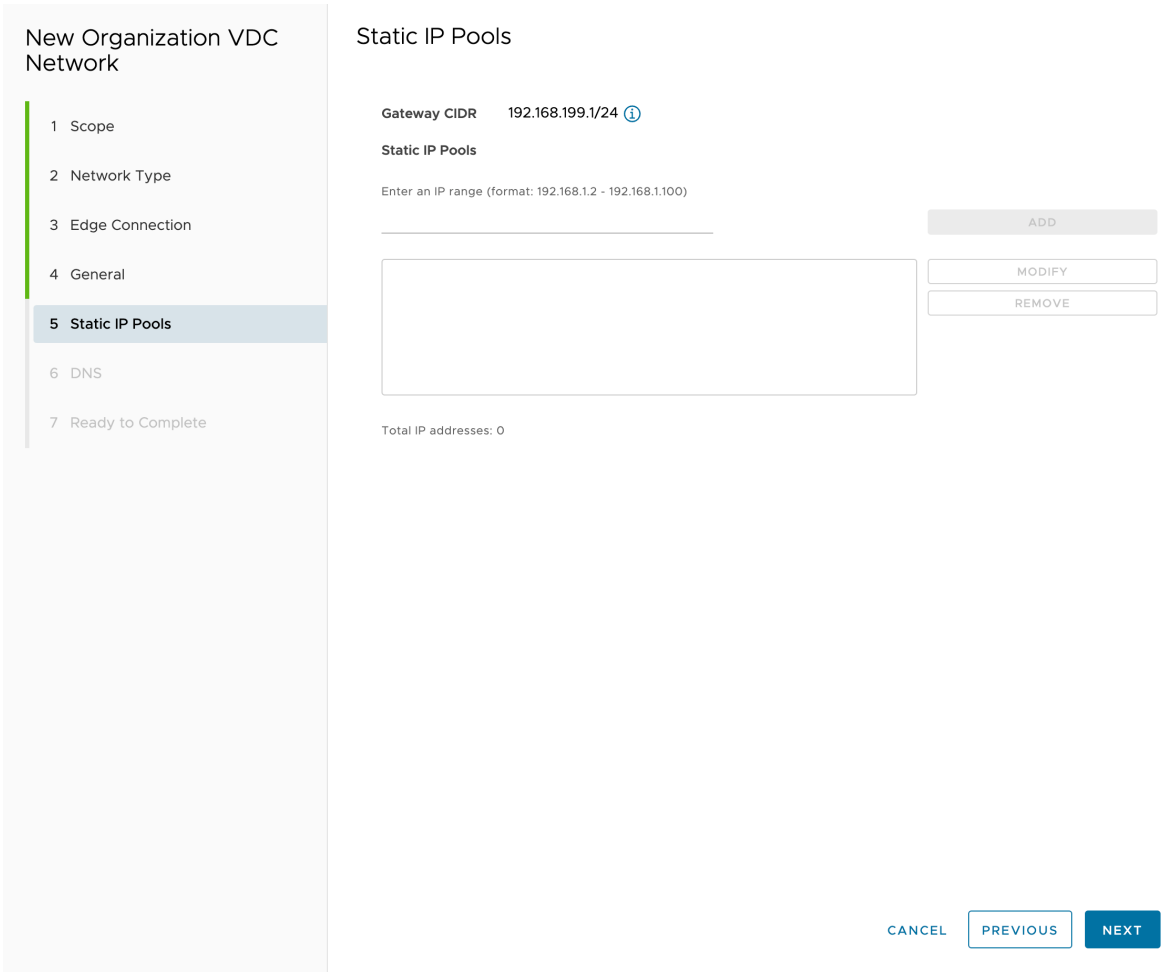
1. Go to the “Networking” tab and click “NEW”:



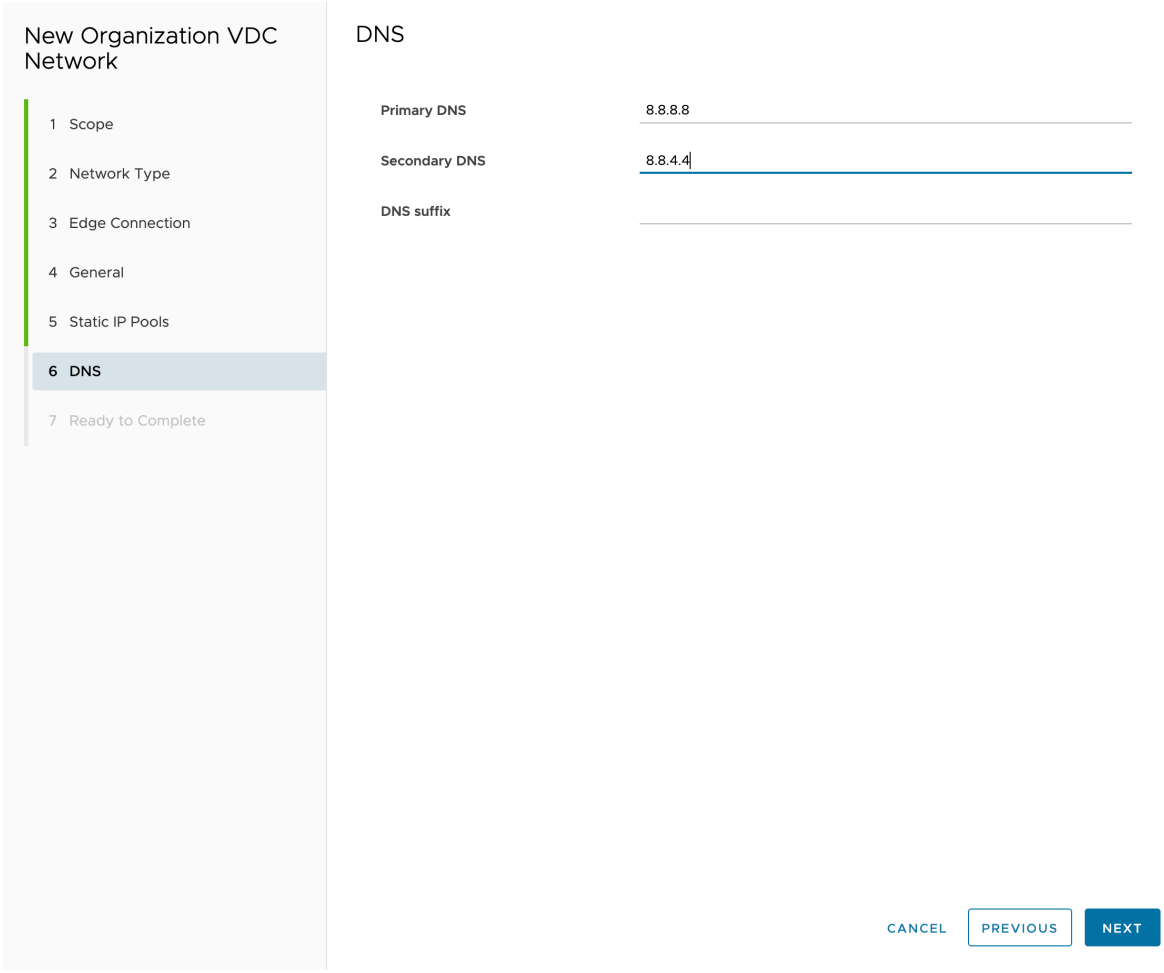
2. Select the Data Center:



3. At the “Network type” step, select “Routed”:



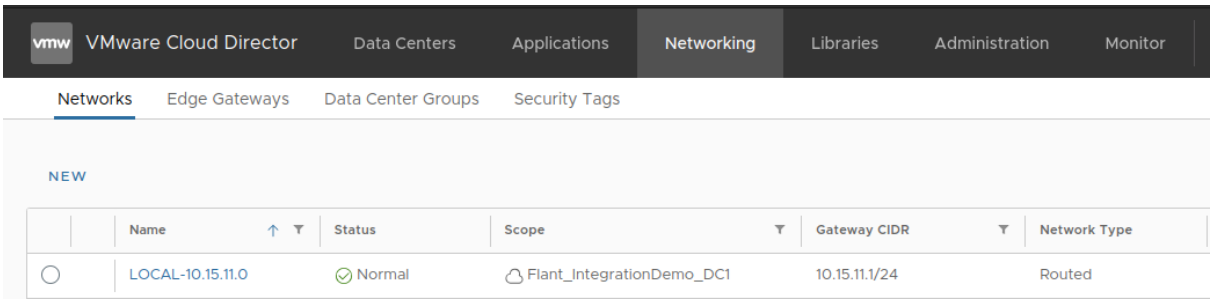
4. Connect `EdgeRouter` to the network:



5. Specify the network name and CIDR:

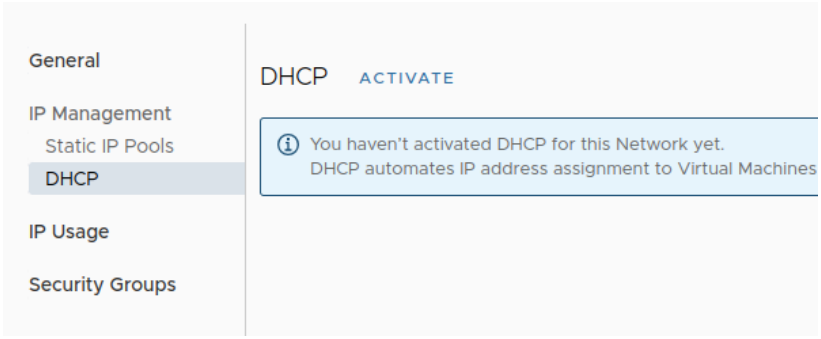
6. Do not add “Static IP Pools” because DHCP will be used:

7. Specify the DNS server addresses:



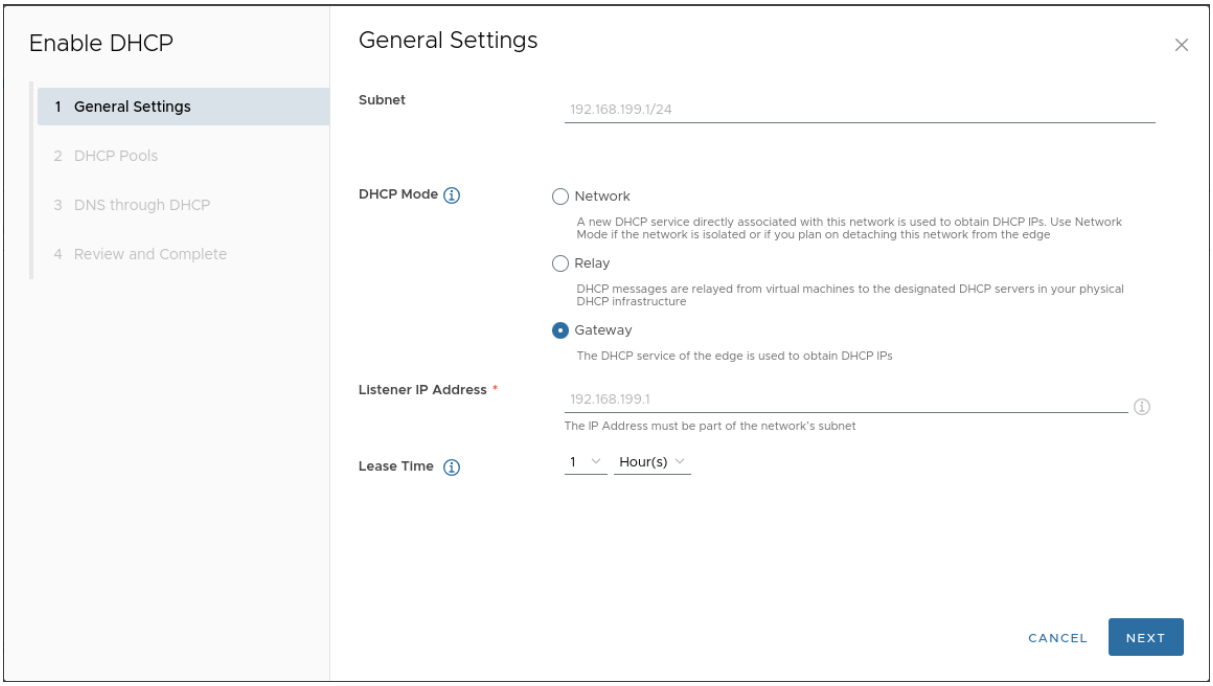
Configuring DHCP

> **i** This instruction is applicable only for the `Standard` layout.

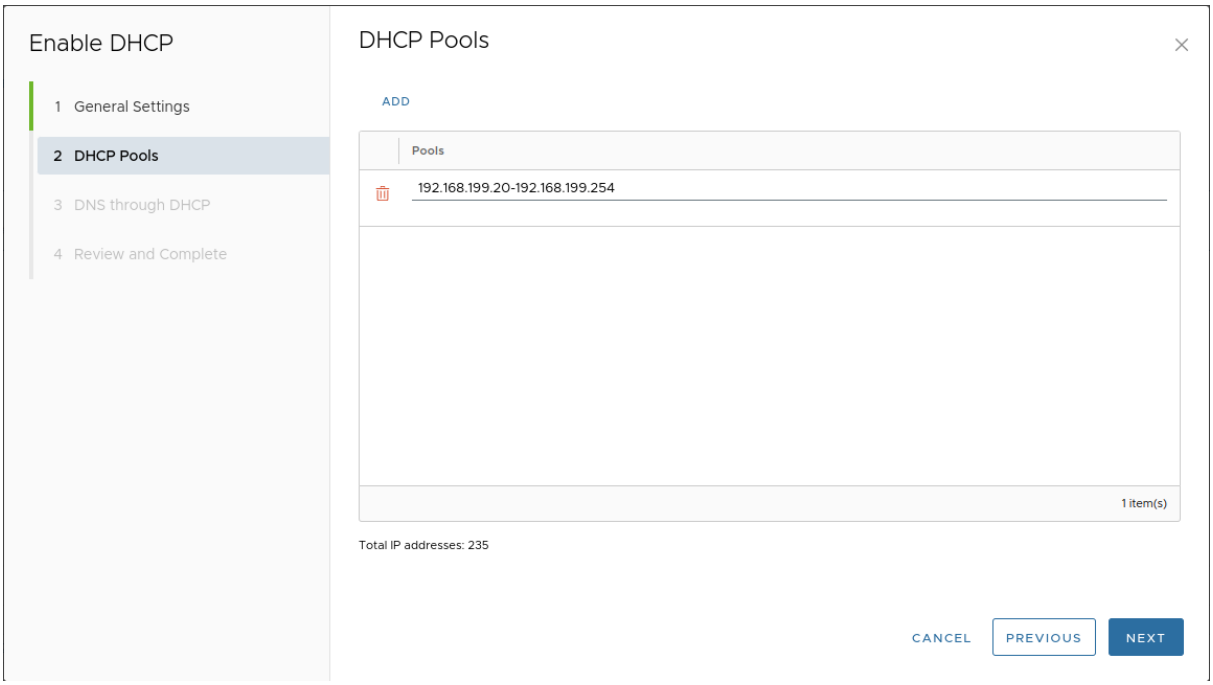


To provision nodes dynamically, enable the DHCP server for the internal network.

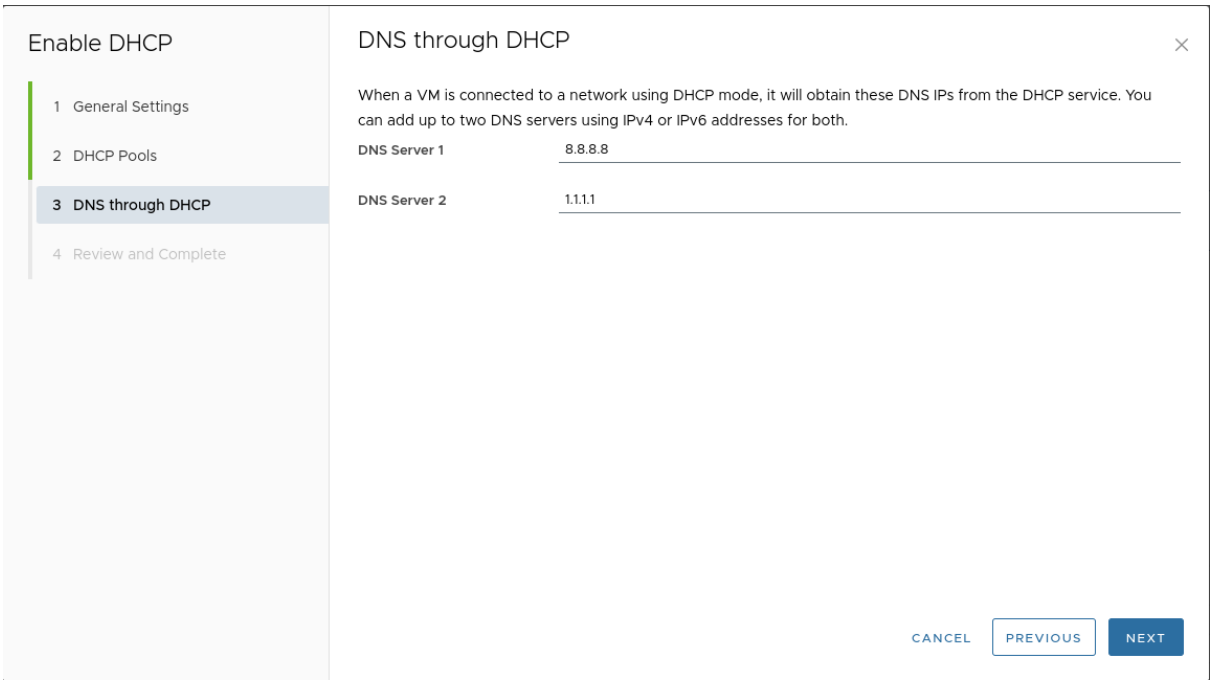
> **i** We recommend allocating the beginning of the network address range to system consumers (control plane, frontend nodes, system nodes) and the rest to the DHCP pool. For example, for a `/24` mask network it would be enough to allocate 20 addresses to system consumers.



1. Click the “Networking” tab and open the network you created:

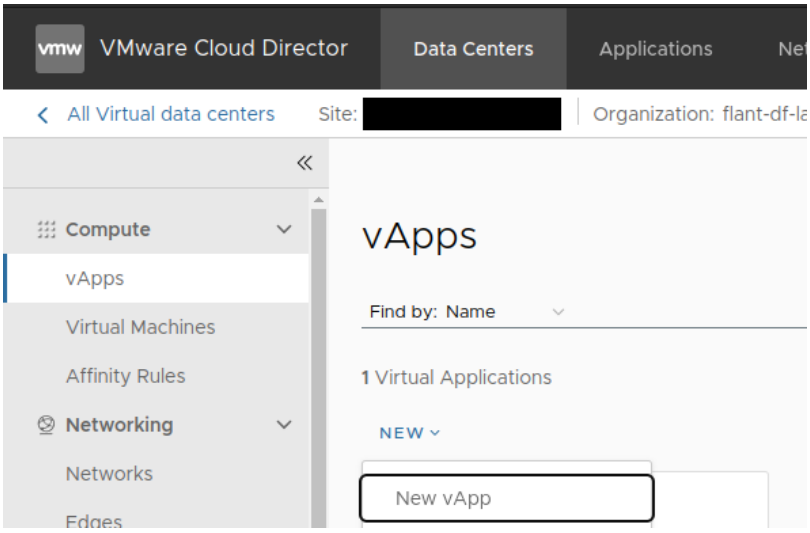


2. In the opened window, select “IP Management” → “DHCP” → “Activate”:

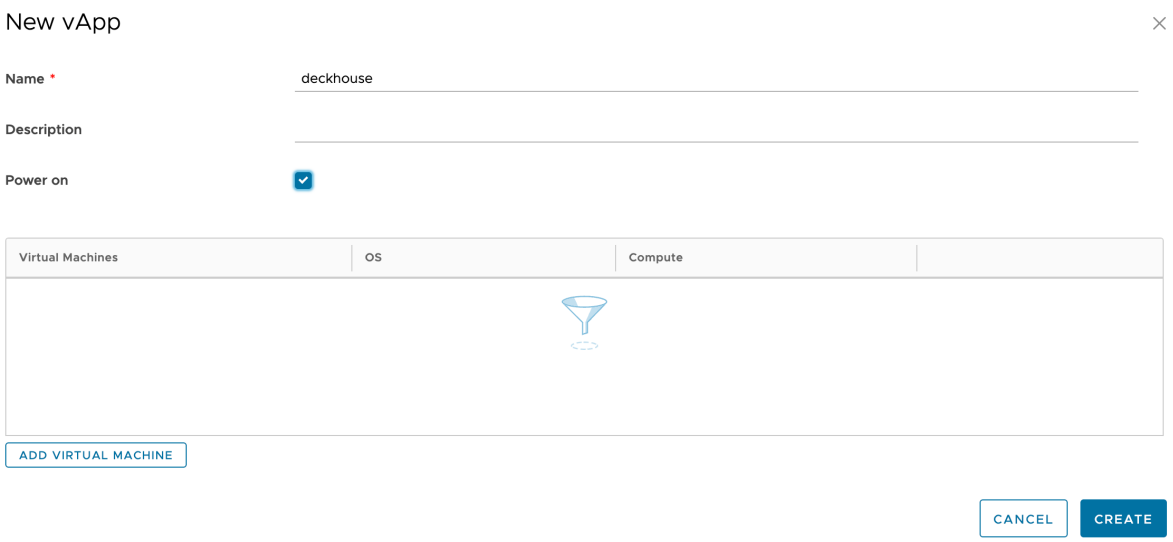


3. In the “General settings” tab, set the parameters as shown in the example:

4. Add a pool:



5. Set the DNS server addresses:

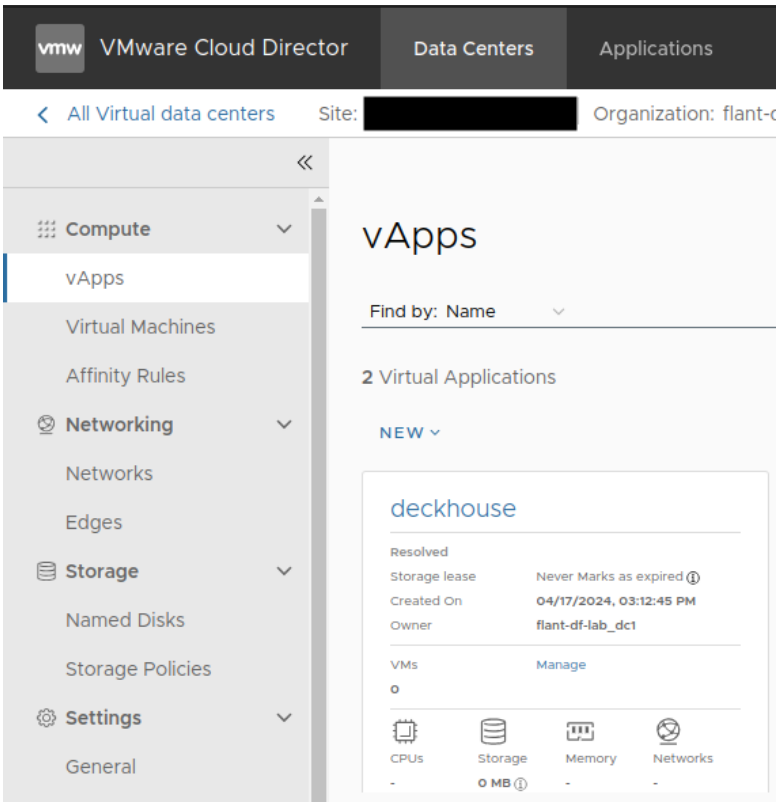


Adding a vApp

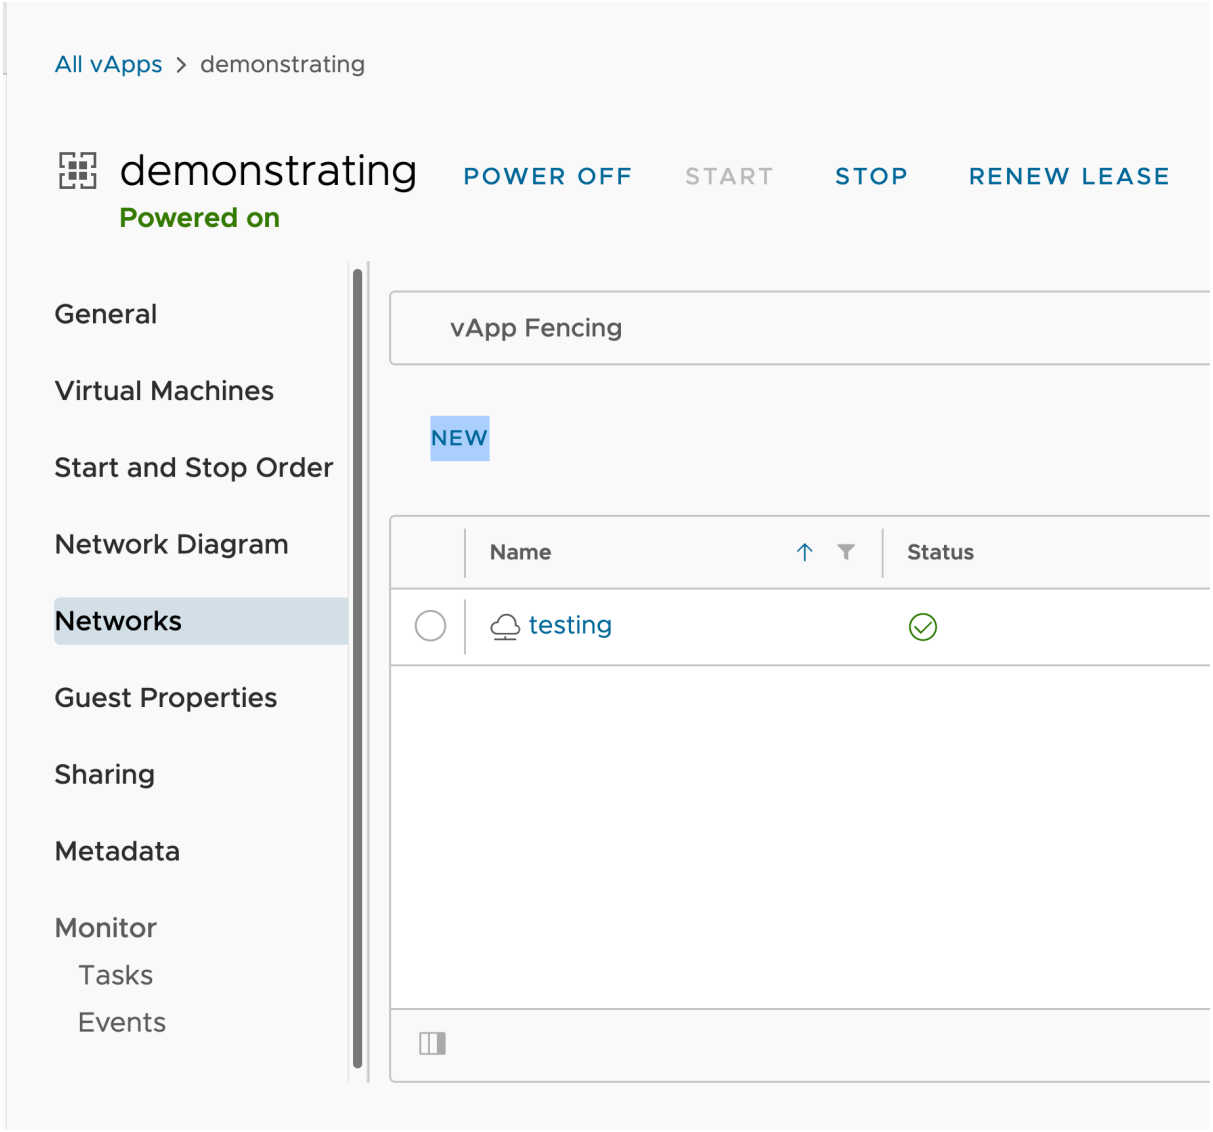
> **i** This instruction is applicable only for the `Standard` deployment layout.

1. Switch to the “Data Centers” tab → “vApps” → “NEW” → “New vApp”:

2. Specify a name and enable the vApp:

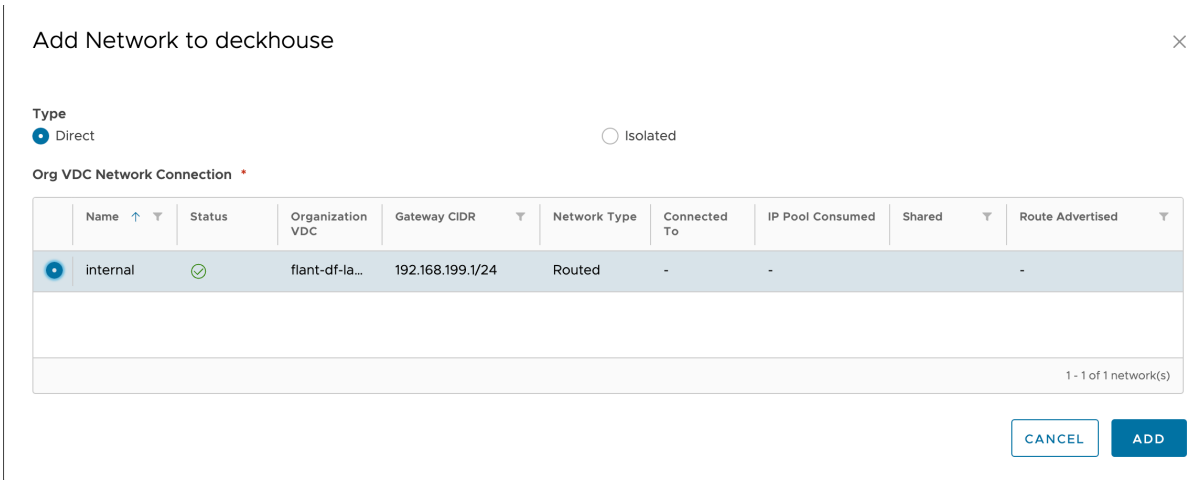


Adding a network to the vApp



> **i** This instruction is applicable only for the `Standard` deployment layout.

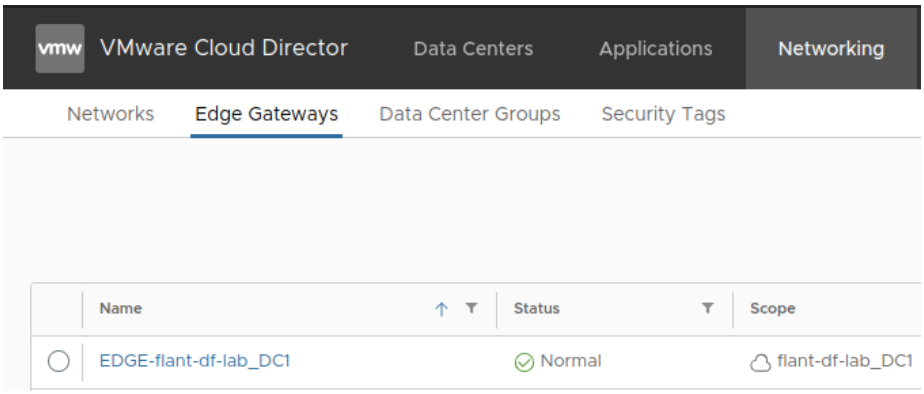
Once the vApp is created, connect the created internal network to it.



1. Switch to the “Data Centers” tab → “vApps” and open the target vApp:

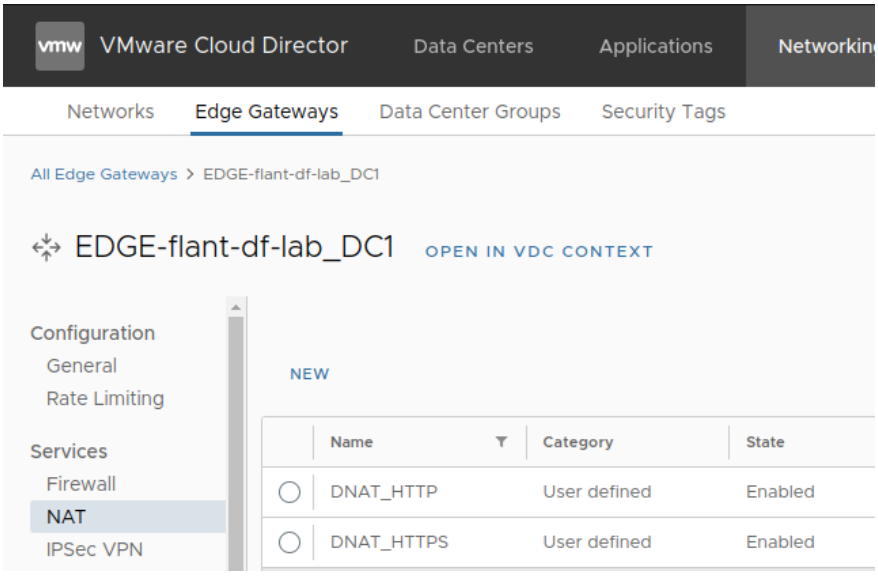
2. Go to the “Networks” tab and click “NEW”:

3. In the opened window, click the “Direct” type and select the network:



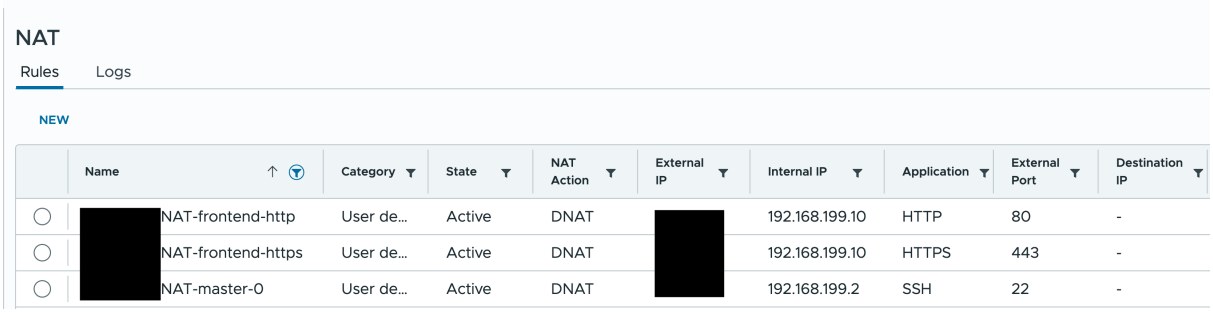
Incoming traffic

Incoming traffic should be routed to the edge router (ports `80`, `443`) using DNAT rules to be forwarded to a dedicated address on the internal network.
This address can be created by running MetalLB in L2 mode for dedicated frontend nodes.



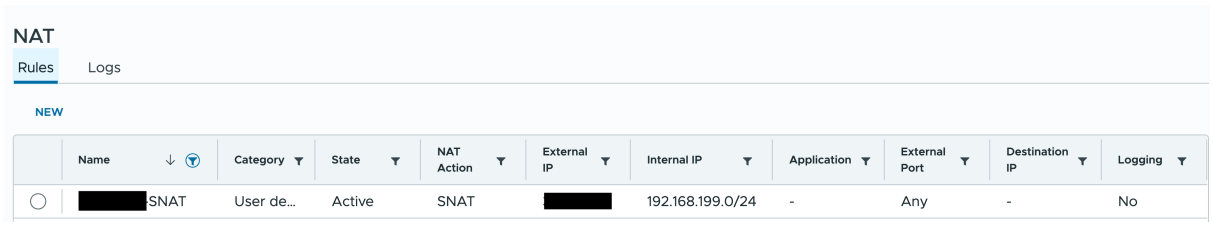
Configuring DNAT/SNAT rules on the edge gateway

> **i** This instruction is applicable only for the `Standard` deployment layout.



1. Navigate to the “Networking” tab → “Edge Gateways” and open the edge gateway:

2. Switch to the “Services” tab → “NAT”:



3. Add the following rules:

   The first two rules are used for incoming traffic, while the third rule is used for SSH access to the control plane host (without this rule the installation will not be possible).

4. To allow virtual machines to access the Internet, configure SNAT rules following the example:

   This rule will allow virtual machines from the `192.168.199.0/24` subnet to access the Internet.

Let’s Encrypt certificate issuance

> **i** This instruction is applicable only for the `Standard` deployment layout.

When using `cert-manager` with the HTTP-01 ACME challenge type, you may need to configure Hairpin NAT (NAT loopback) on the Edge Gateway.

This is required when the Ingress domain name resolves to the external IP address of the Edge Gateway, while requests to

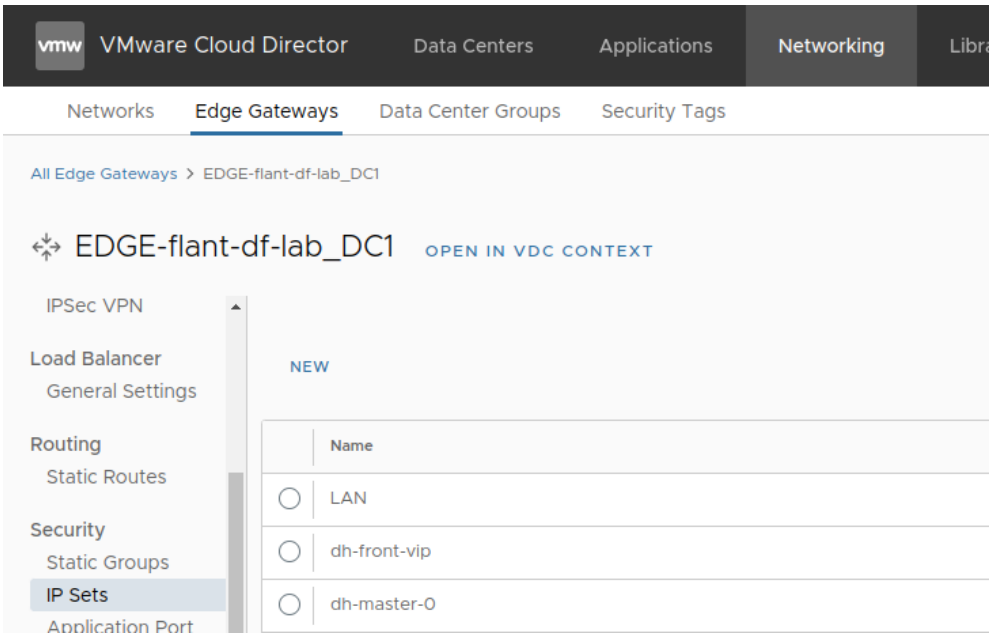
that address are made from **inside** the cluster (from the node network). In this case, the traffic must be correctly routed back to the internal network to the Ingress address (for example, the MetalLB address).

This is important for issuing Let's Encrypt certificates because cert-manager performs a preliminary self-check of the challenge URL before sending a request to the ACME provider. If the URL is not reachable from inside the cluster, certificate issuance will not start, even if the address is accessible from outside.

Example (cluster network `192.168.199.0/24`):

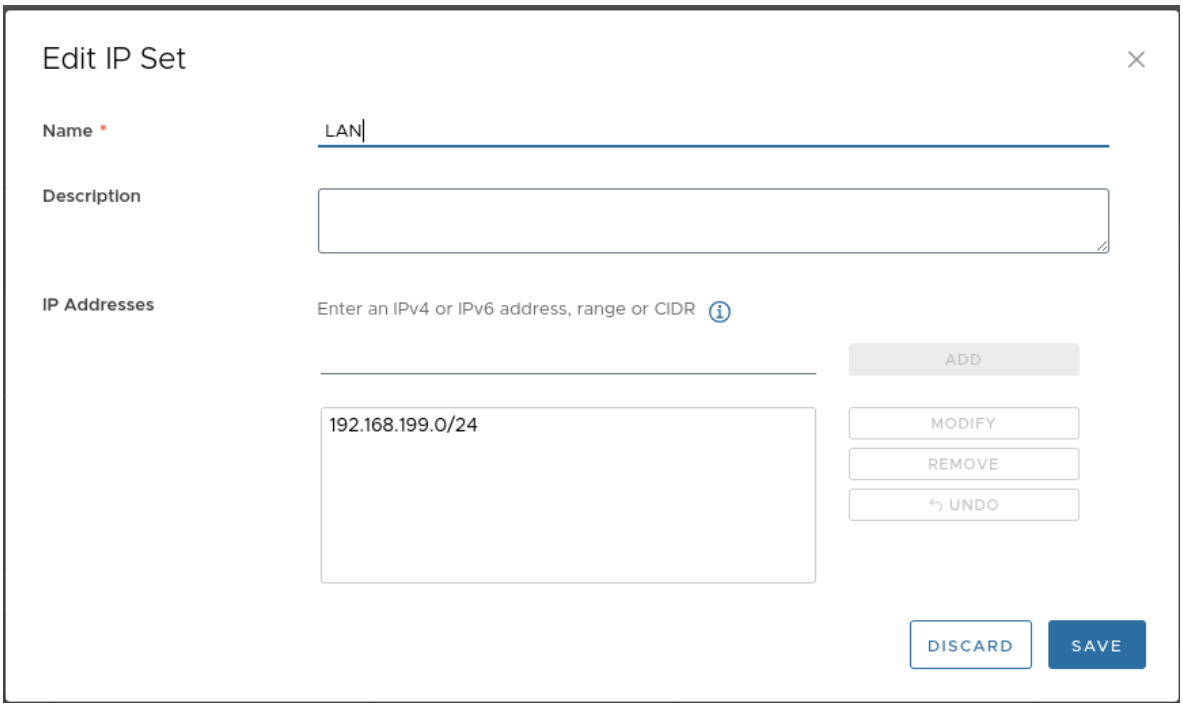
- internal node network: `192.168.199.0/24`
- external Edge Gateway IP address: `194.117.83.19`
- internal Ingress address (for example, MetalLB): `192.168.199.251`.

In this case, you must configure Hairpin NAT for traffic from the `192.168.199.0/24` network that is sent to the external IP `194.117.83.19`, with translation to the internal Ingress address `192.168.199.251`.

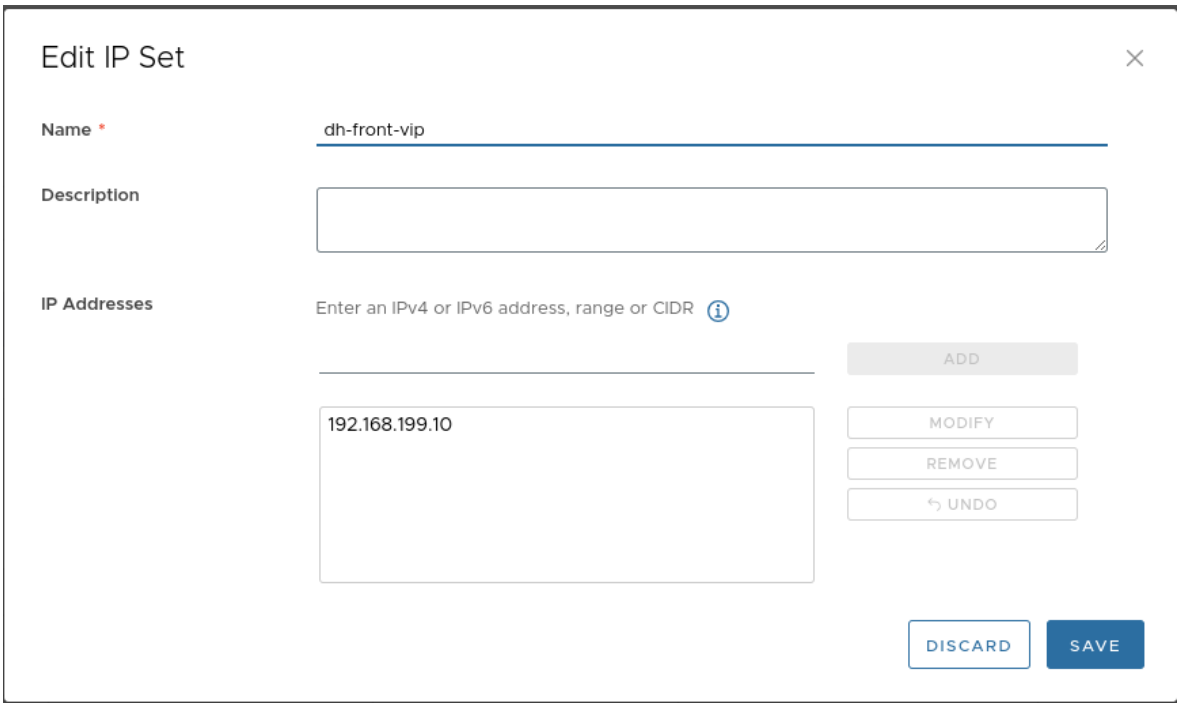


> **i** Hairpin NAT configuration may be required for Edge Gateway based on NSX-V.
>
> For NSX-T, the loopback scenario is often supported by default, but the actual behavior depends on the VMware Cloud Director provider configuration.

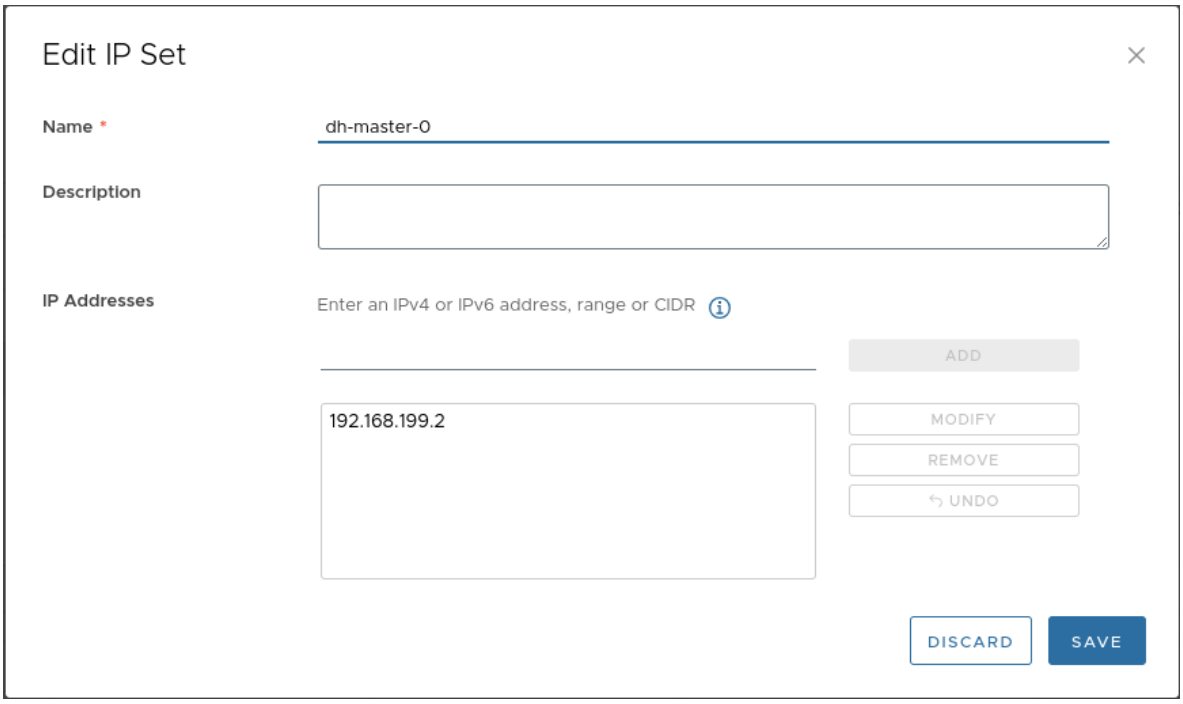
Configuring a firewall



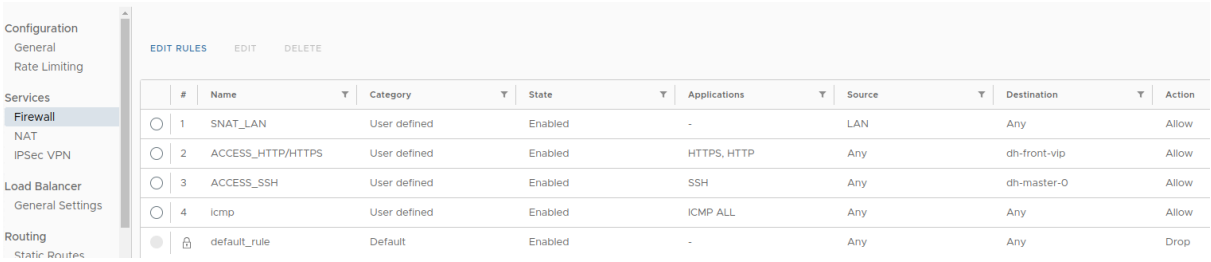
> **i** This instruction is applicable only for the `Standard` deployment layout.



Once DNAT is configured, set up the firewall. Start by configuring the IP sets.



1. Switch to the "Security" tab → "IP Sets":



2. Create the following set of IPs (the MetalLB address here is `.10` and the control plane node address is `.2`):

Edit IP Set
Name *
LAN
Description
IP Addresses
Enter an IPv4 or IPv6 address, range or CIDR
ADD
192.168.199.0/24
MODIFY
REMOVE
UNDO
DISCARD
SAVE

Edit IP Set
Name *
dh-front-vip
Description
IP Addresses
Enter an IPv4 or IPv6 address, range or CIDR
ADD
192.168.199.10
MODIFY
REMOVE
UNDO
DISCARD
SAVE

3. Add the following firewall rules:

Virtual machine template

⚠ The provider is confirmed to work with Ubuntu 22.04-based virtual machine templates only.

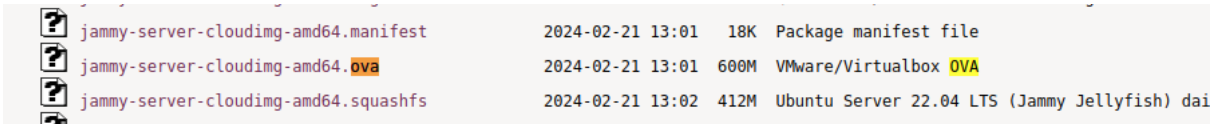
⚠ Disable vApp/Guest OS Customization (Guest Customization, vApp Customization, and similar mechanisms) for the cluster template and virtual machines in VMware Cloud Director. DP performs the initial node provisioning via `cloud-init` (OVF/VMware GuestInfo datasource). If customization is enabled, it may conflict with `cloud-init` and result in incorrect node initialization.

⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

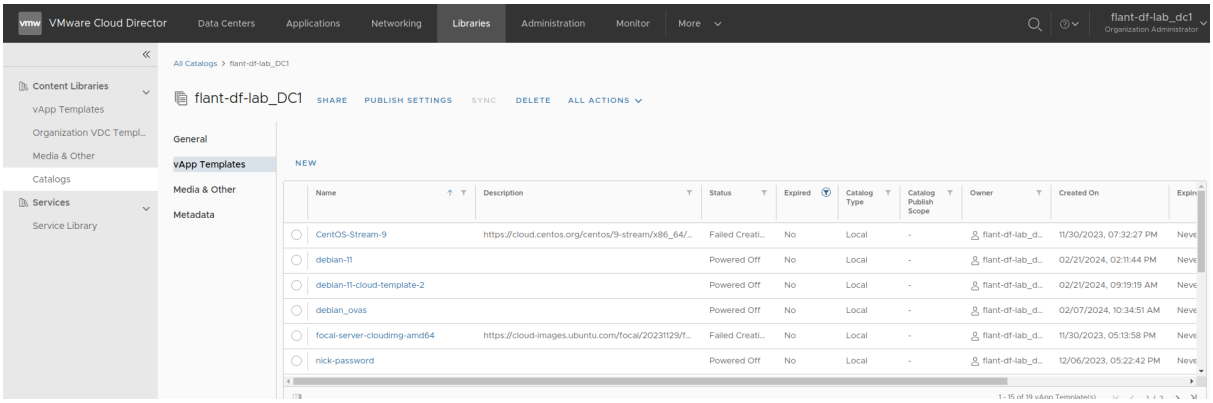
For more information, see the documentation.

⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:



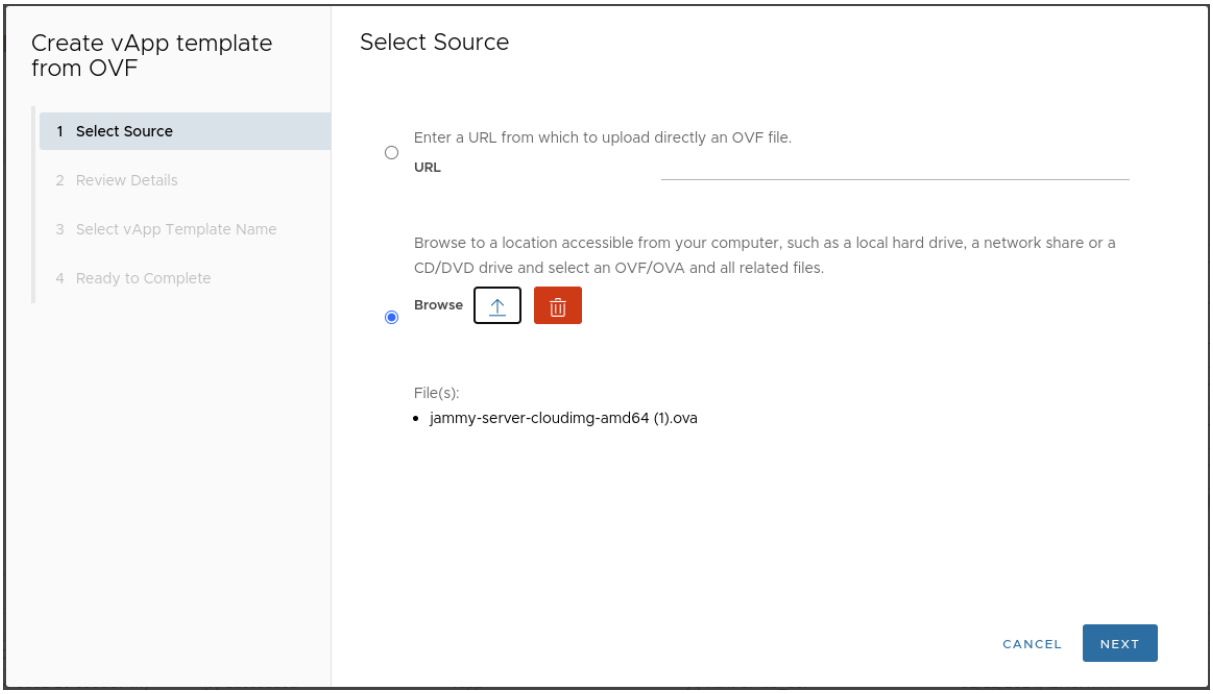
- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

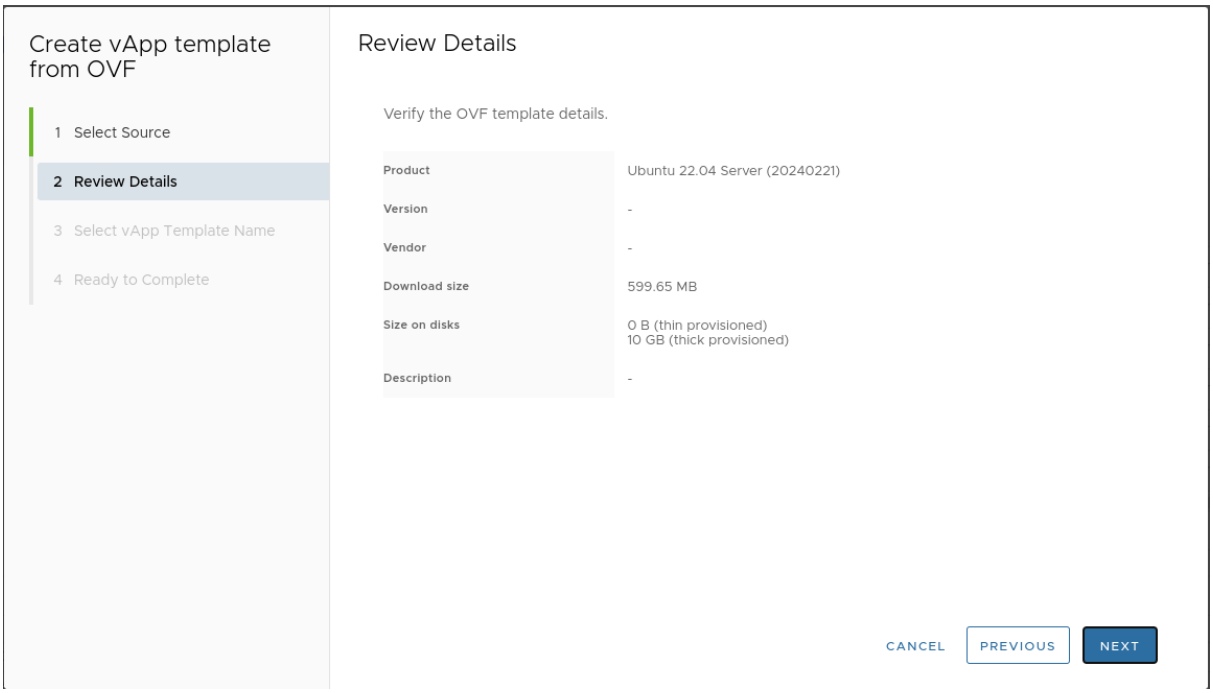


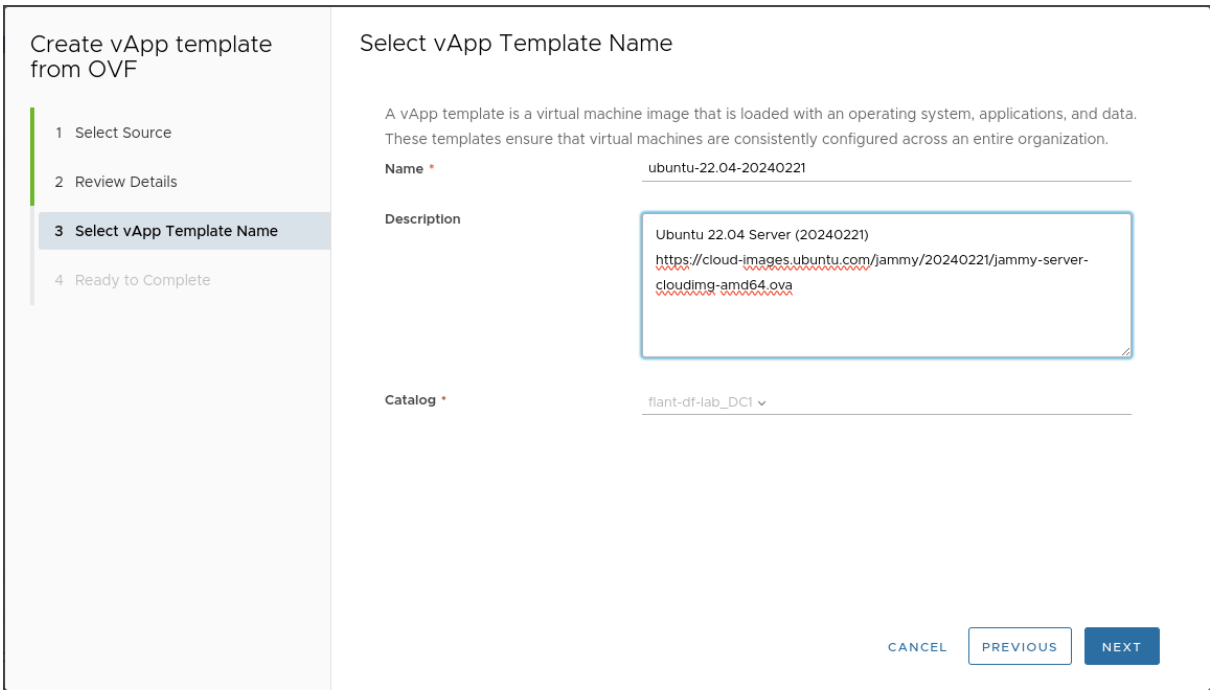
The example below uses the OVA file provided by Ubuntu, updated to include two fixes. Those fixes are essential for CloudPermanent nodes to be provisioned correctly and to be able to mount CSI-created disks.

Making a template from an OVA file

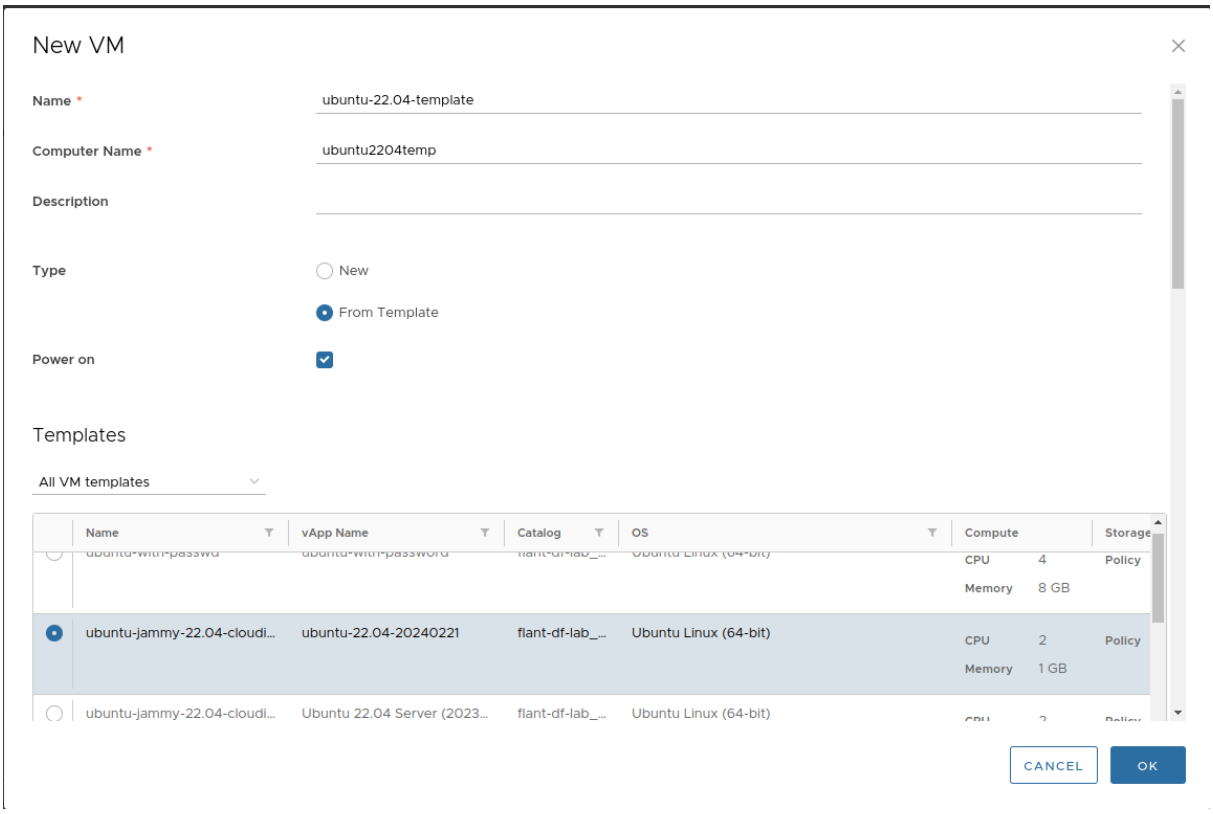


1. Download the OVA file:

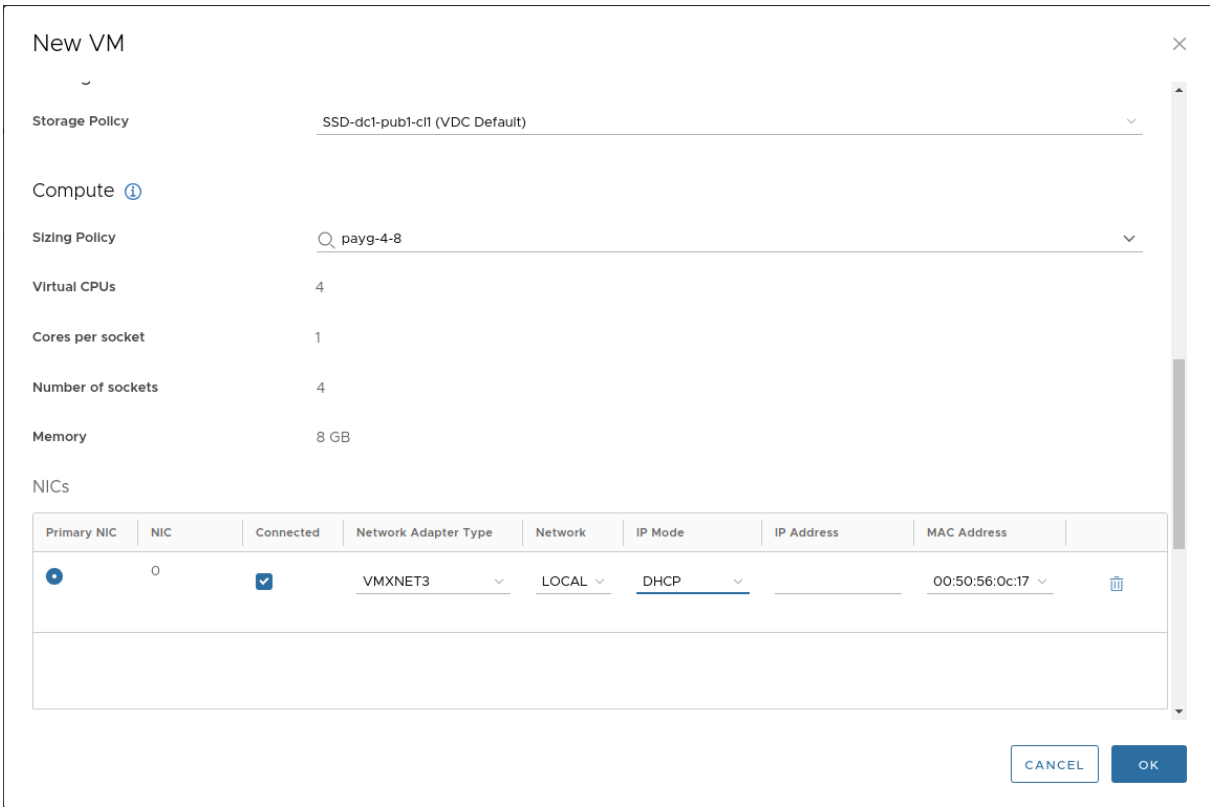


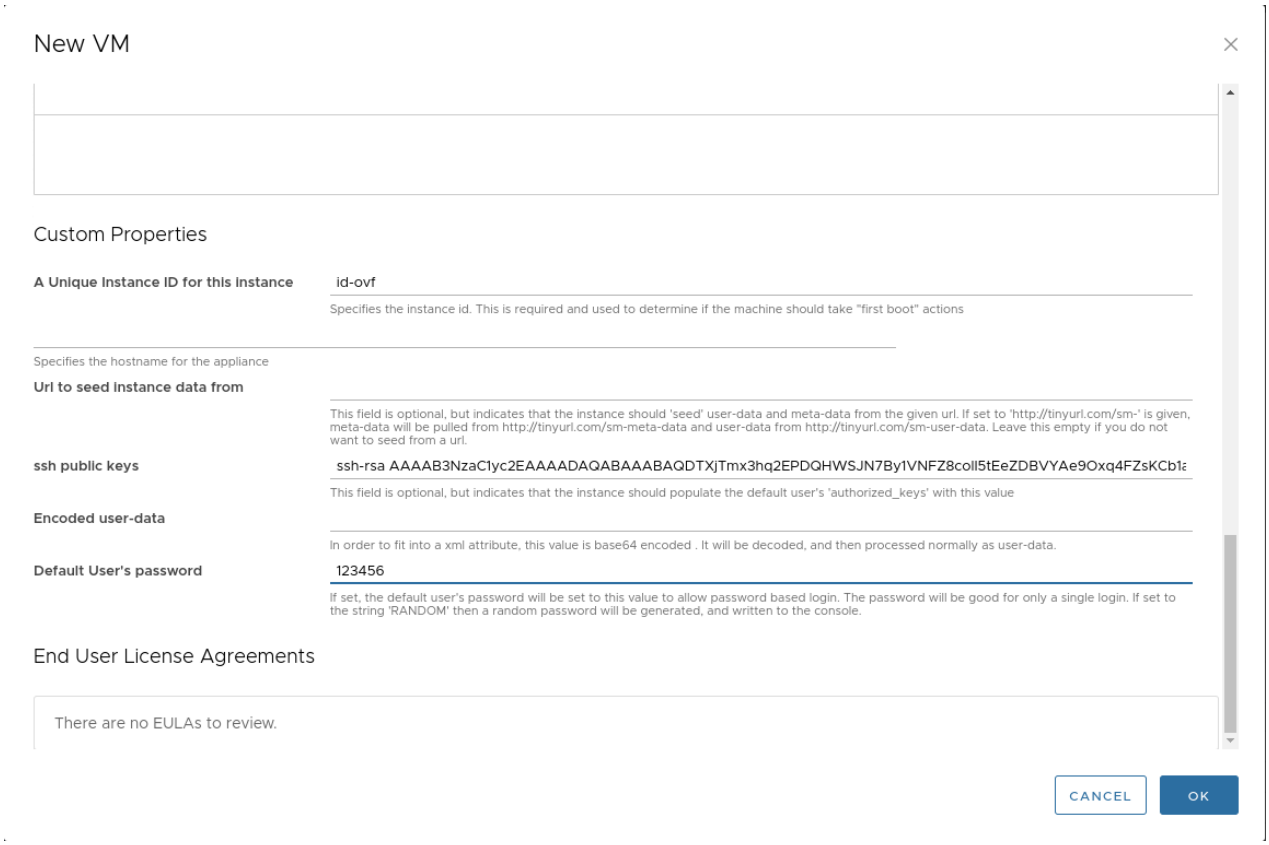


2. Switch to the “Libraries” tab → “Catalogs” → “Organization Catalog”:

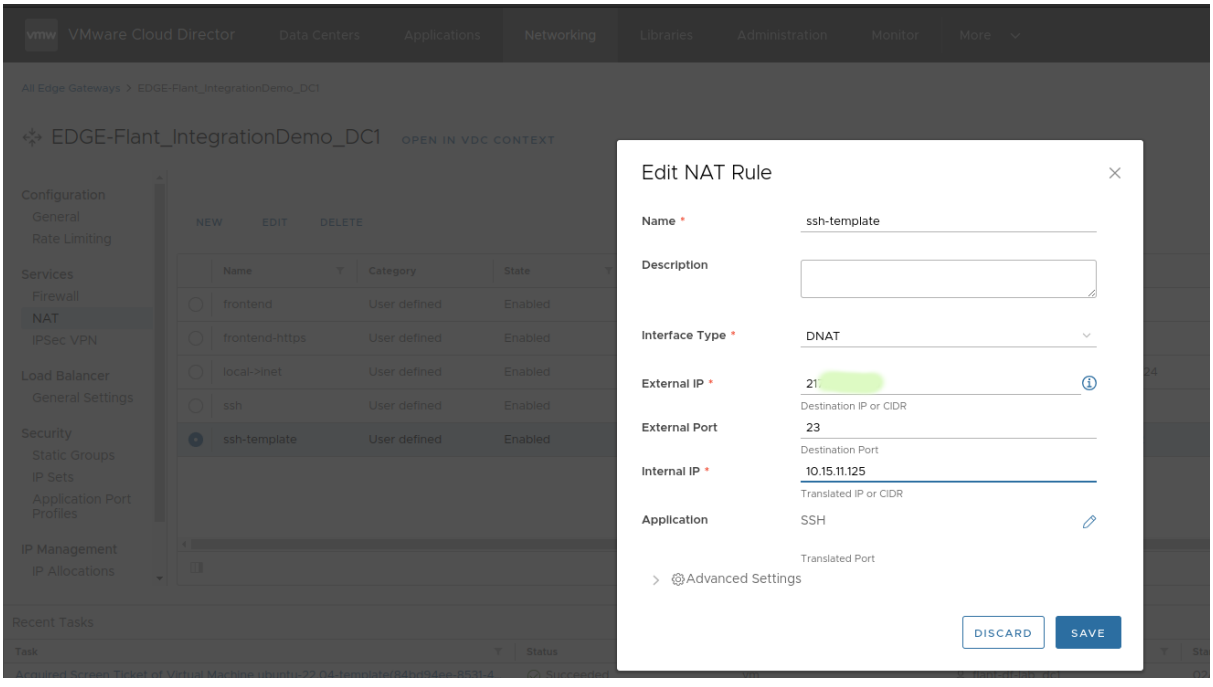


3. Select the template you downloaded and add it to the catalog:



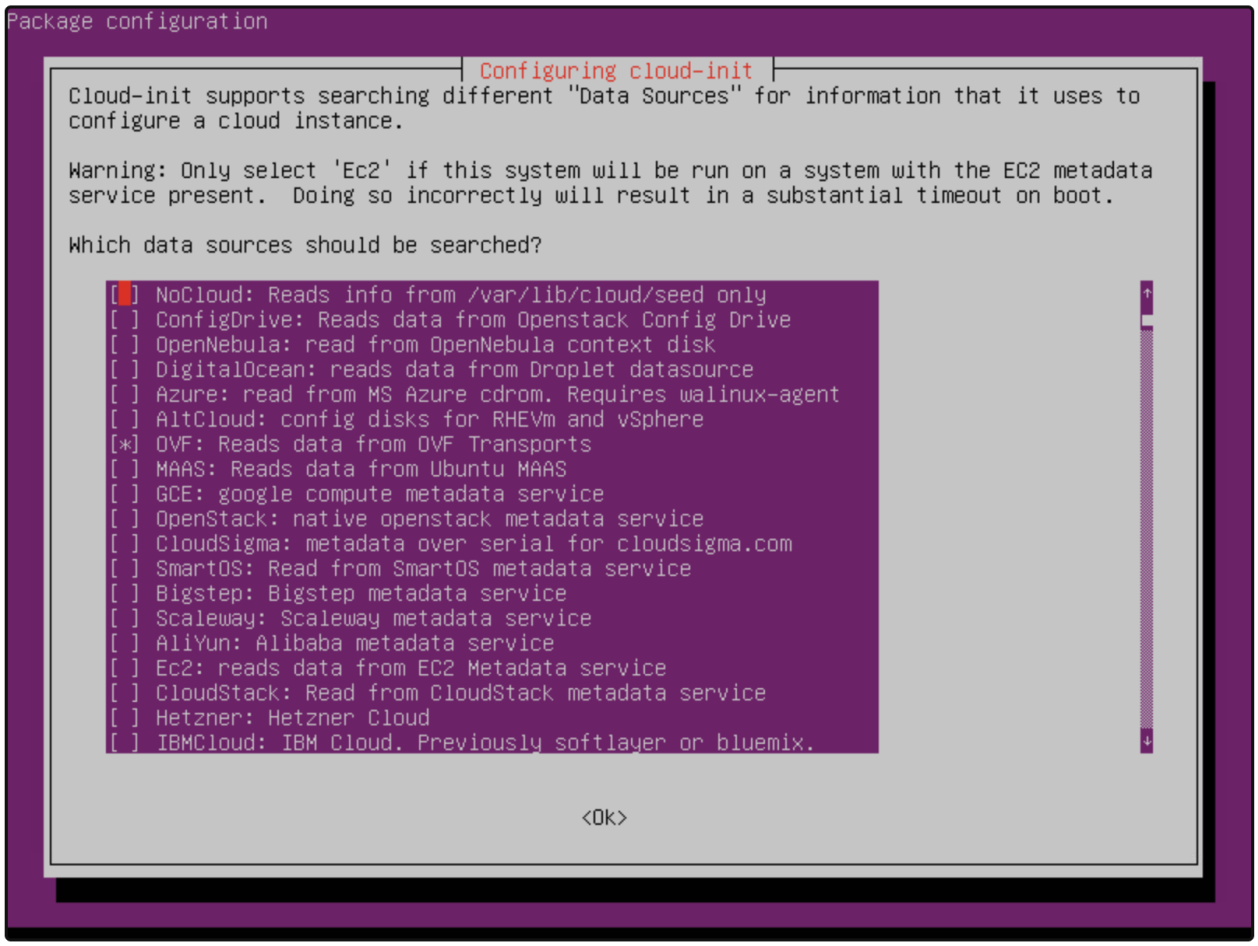


4. Create a virtual machine from the template:



⚠ Enter the default password and public key. You will need them to log in to the VM console.

Follow these steps to be able to connect to the virtual machine:



1. Start the virtual machine.
2. Wait for the IP address to be set.
3. Forward port `22` to the virtual machine:

Log on to the virtual machine over SSH and run the following commands:

```
rm /etc/netplan/99-netcfg-vmware.yaml
echo -e '\n[deployPkg]\nwait-cloudinit-timeout=1800\n' >> /etc/vmware-tools/tools.conf
echo 'disable_vmware_customization: true' > /etc/cloud/cloud.cfg.d/91_vmware_cust.cfg
dpkg-reconfigure cloud-init
```

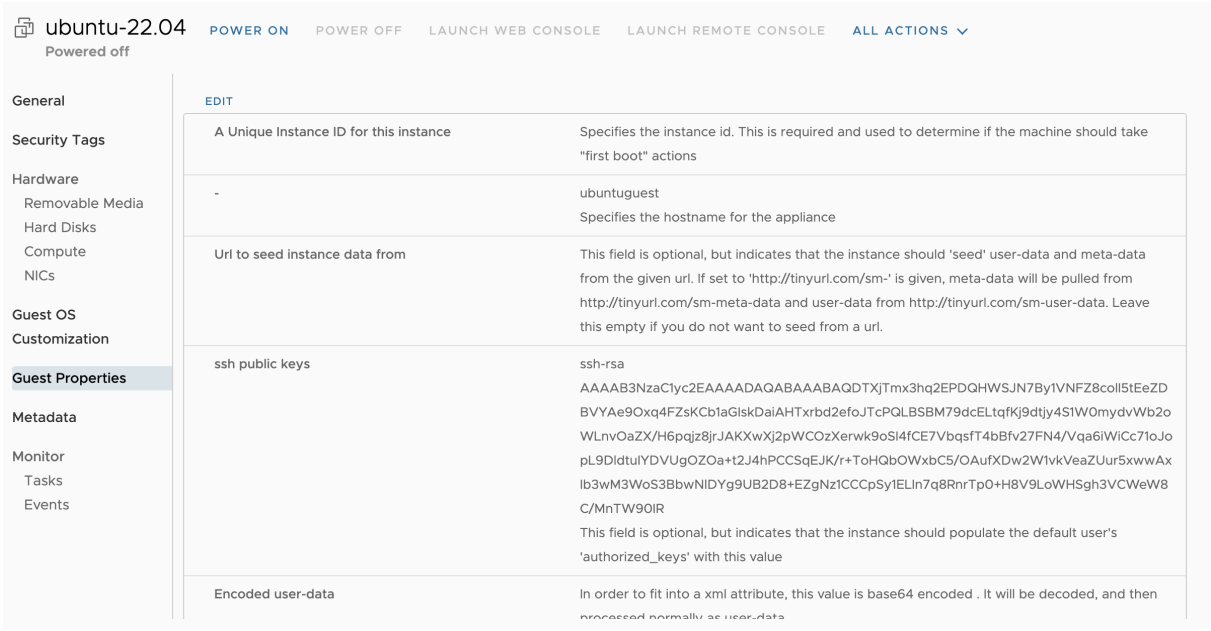
In the dialog box that appears, leave the checkmark only on `OVF: Reads data from OVF transports`, and make sure to scroll down and remove checkmarks from other options:

Make sure that the `datasource_list` parameter is specified in the `cloud-init` configuration. You can verify this using the following command:

```
cat /etc/cloud/cloud.cfg.d/90_dpkg.cfg
```

If the output is empty, execute the following command:

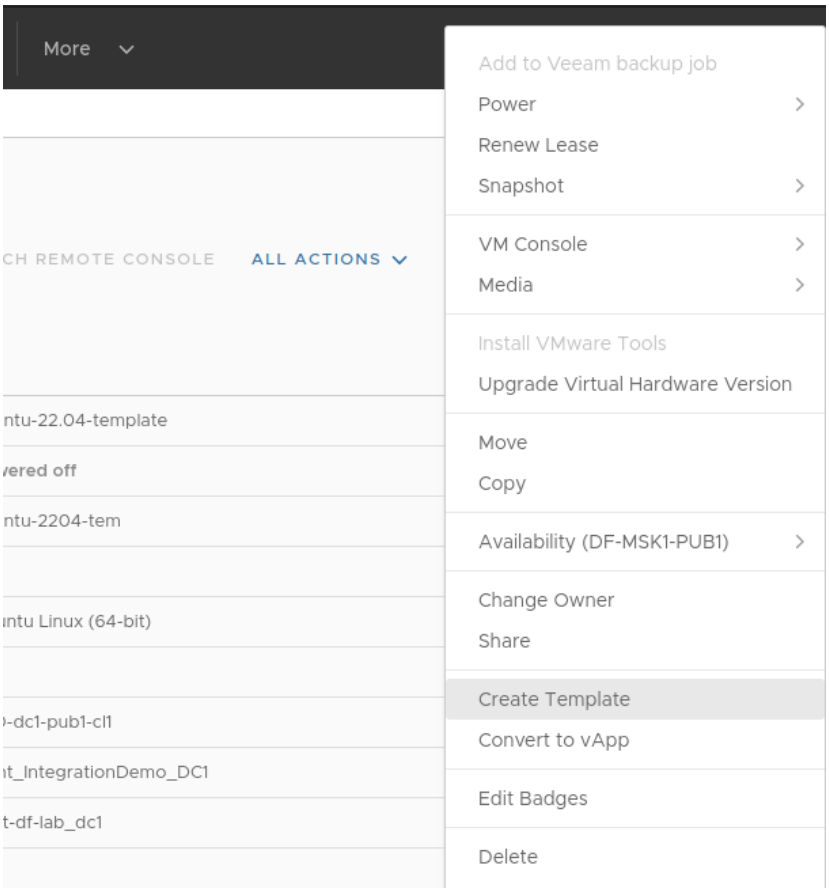
```
echo "datasource_list: [ OVF, VMware, None ]" > /etc/cloud/cloud.cfg.d/90_dpkg.cfg
```



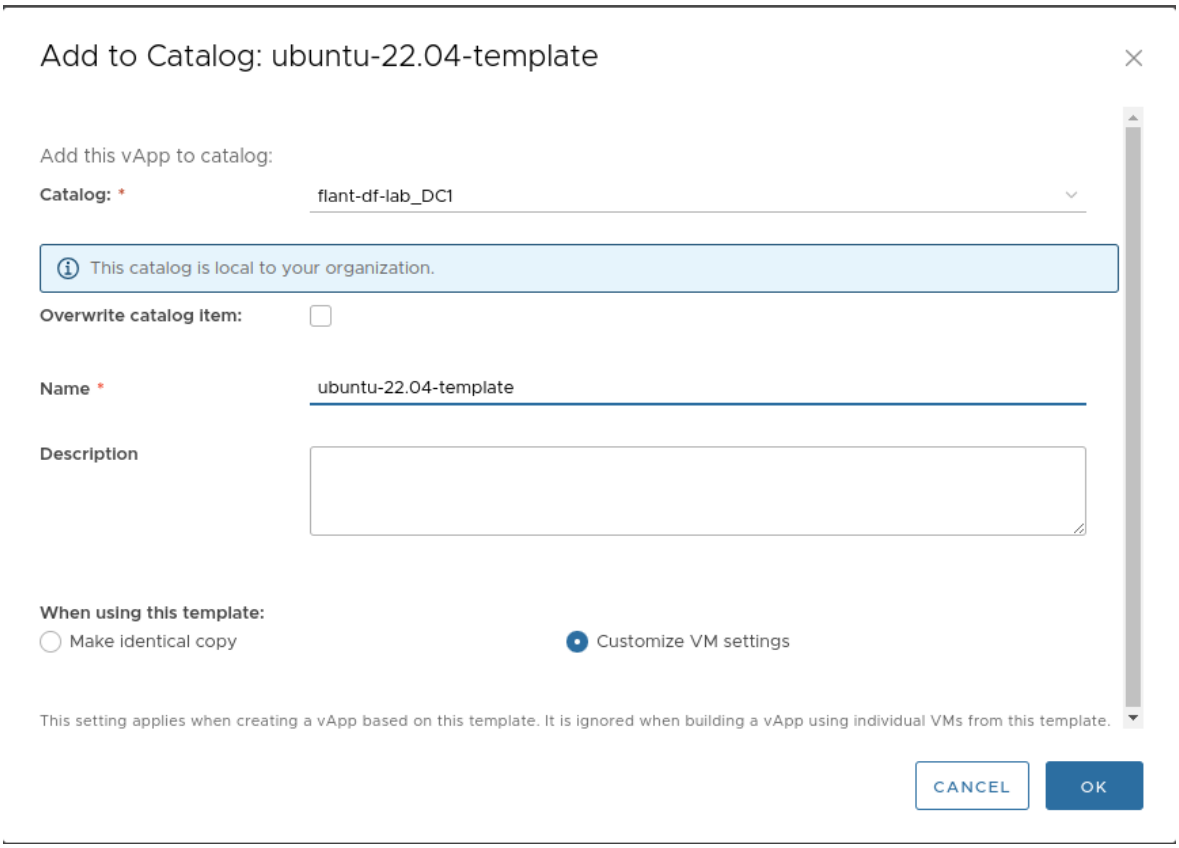
Execute the remaining commands:

```
truncate -s 0 /etc/machine-id
rm /var/lib/dbus/machine-id
ln -s /etc/machine-id /var/lib/dbus/machine-id
cloud-init clean --logs --seed
passwd -d ubuntu
passwd -d root
rm /home/ubuntu/.ssh/authorized_keys
history -c

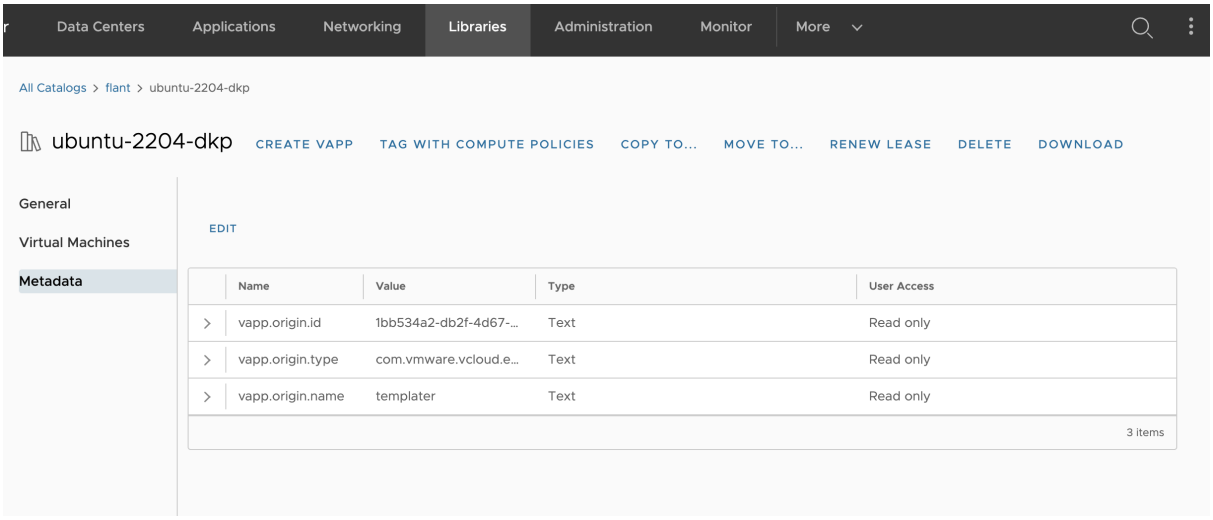
shutdown -P now
```



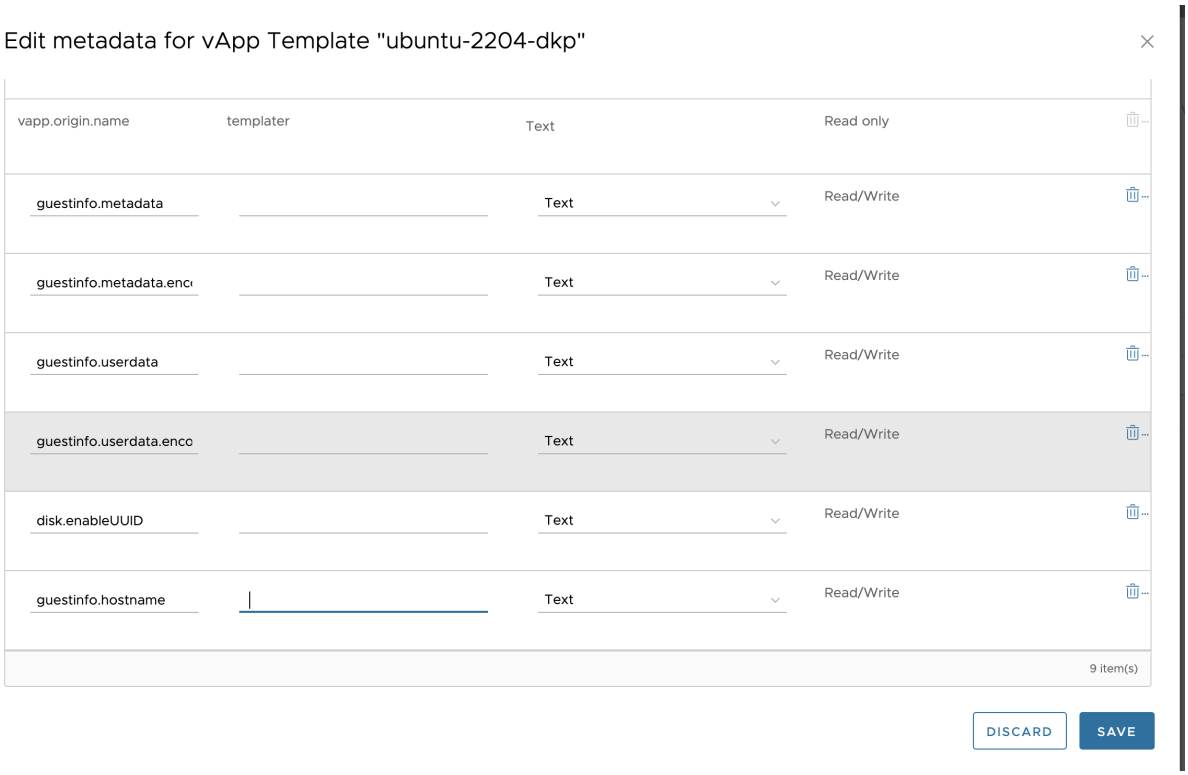
Setting up the template in VCD



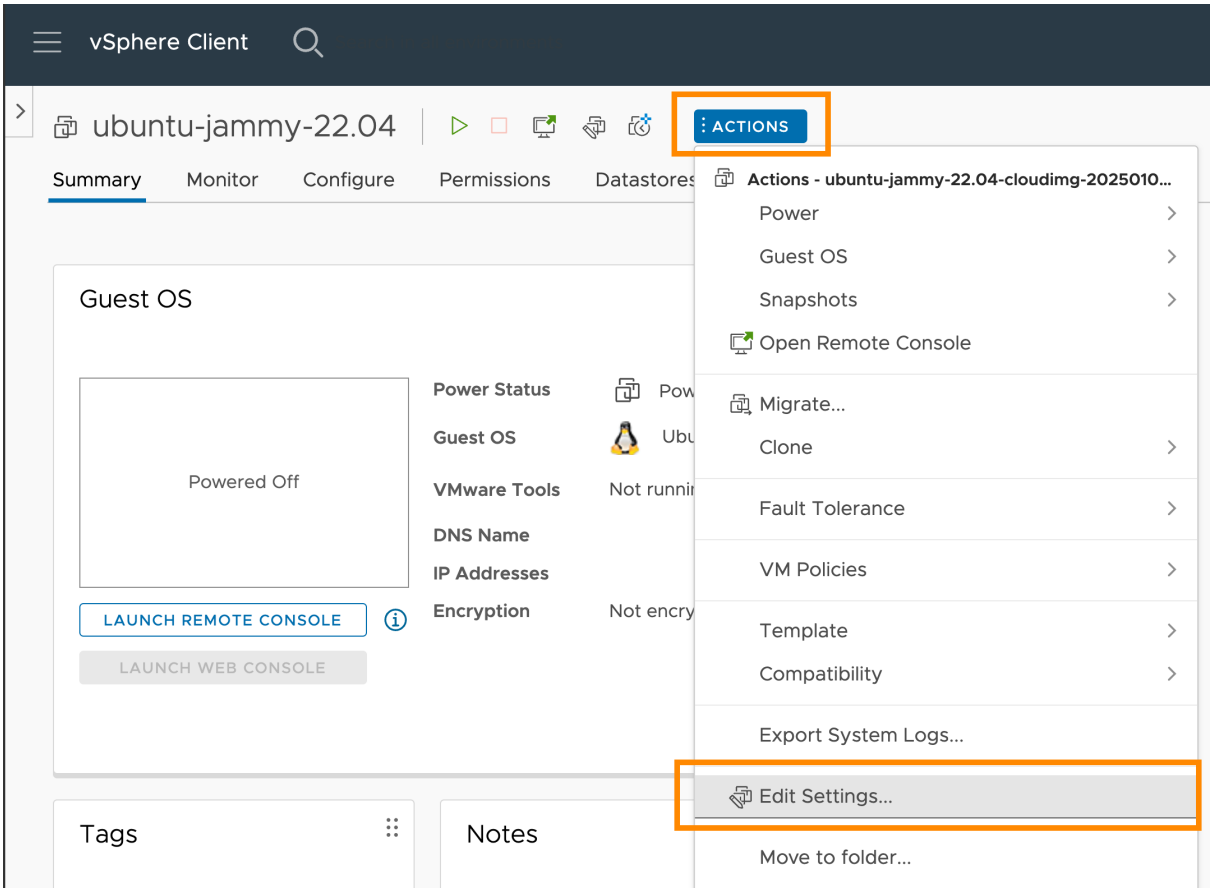
1. Shut down the virtual machine and clear all populated fields in “Guest Properties”:



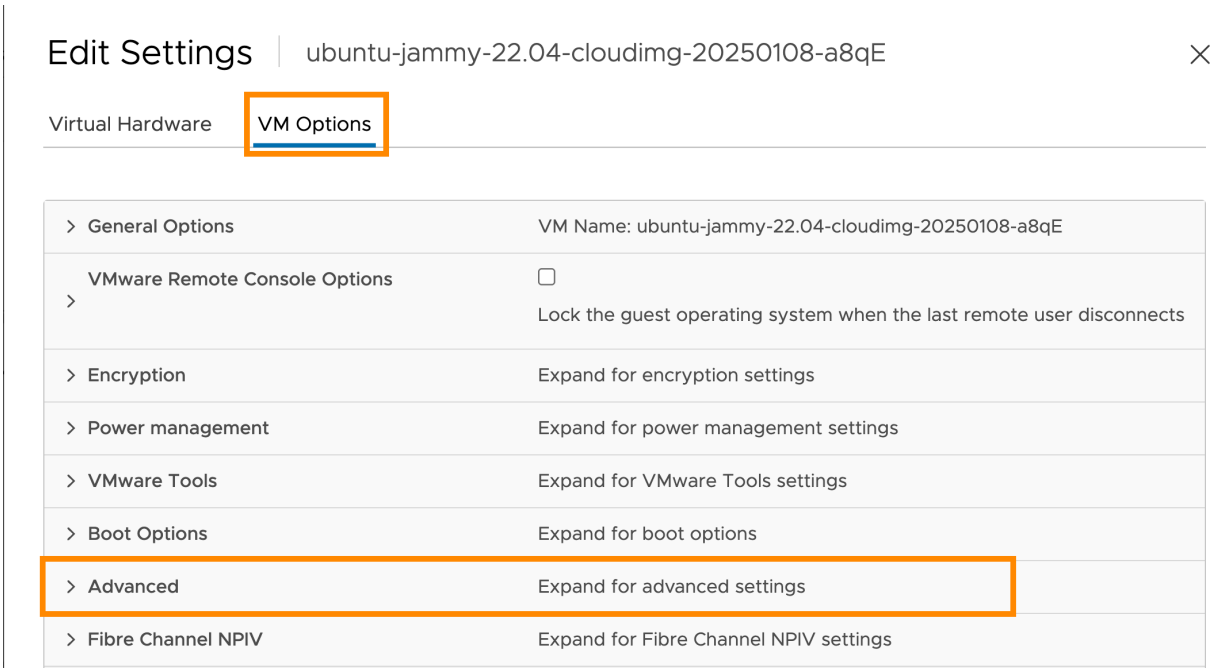
2. Create a virtual machine template:



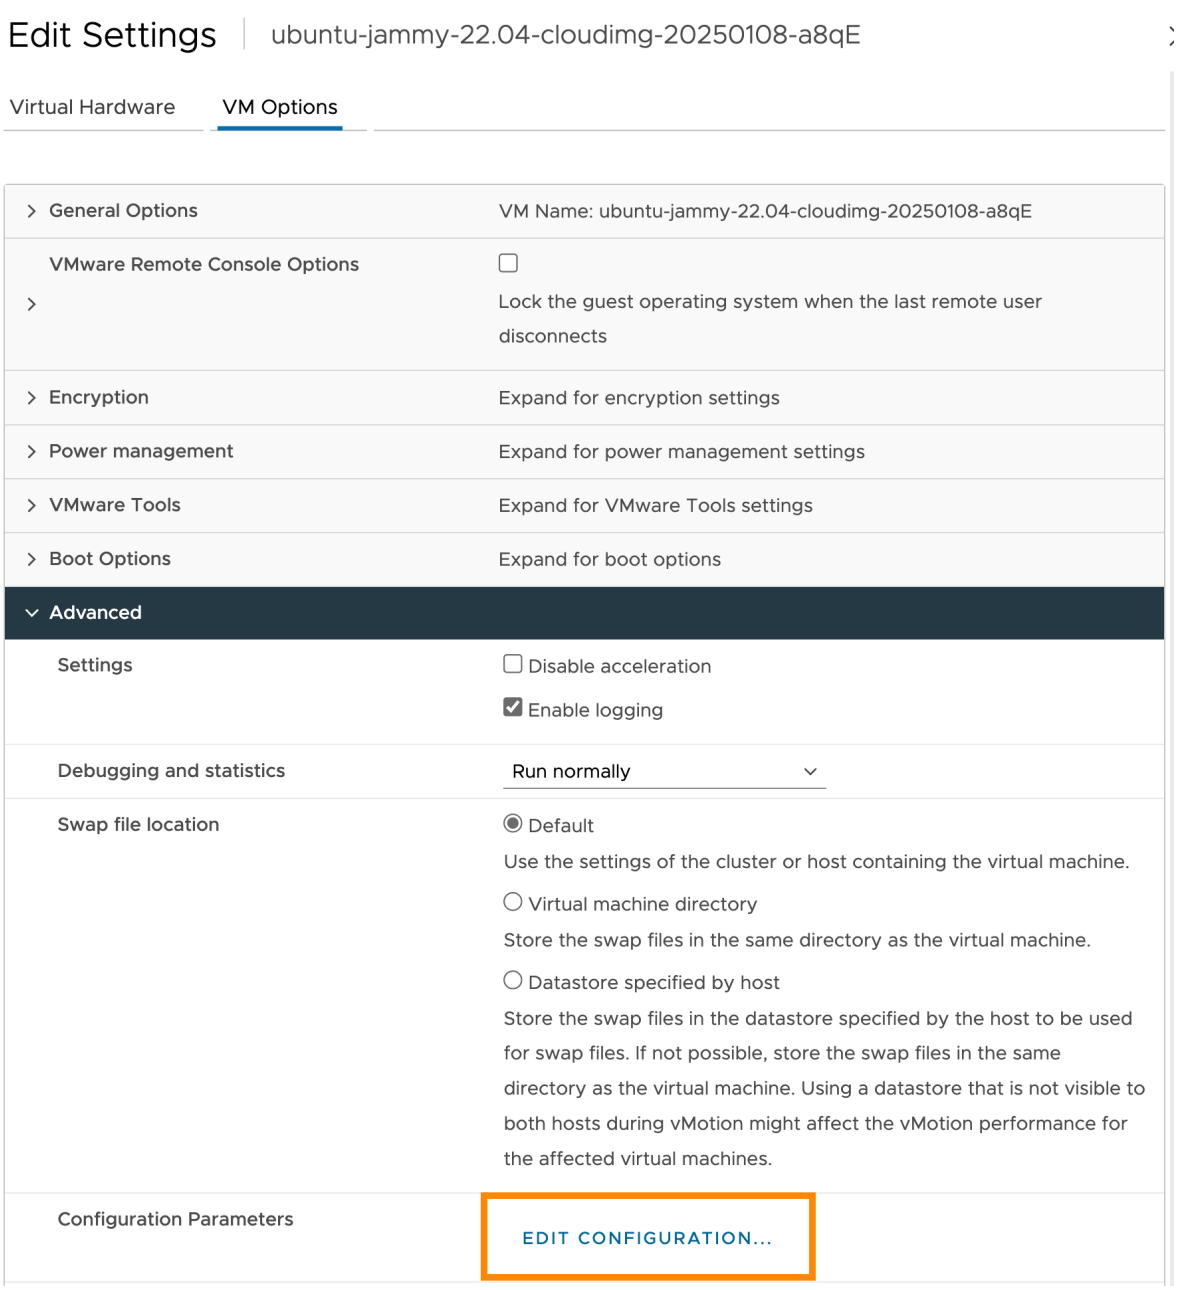
3. In the created template, navigate to the “Metadata” tab and add the following six fields:
   - `guestinfo.metadata`
   - `guestinfo.metadata.encoding`
   - `guestinfo.userdata`
   - `guestinfo.userdata.encoding`
   - `disk.enableUUID`
   - `guestinfo.hostname`



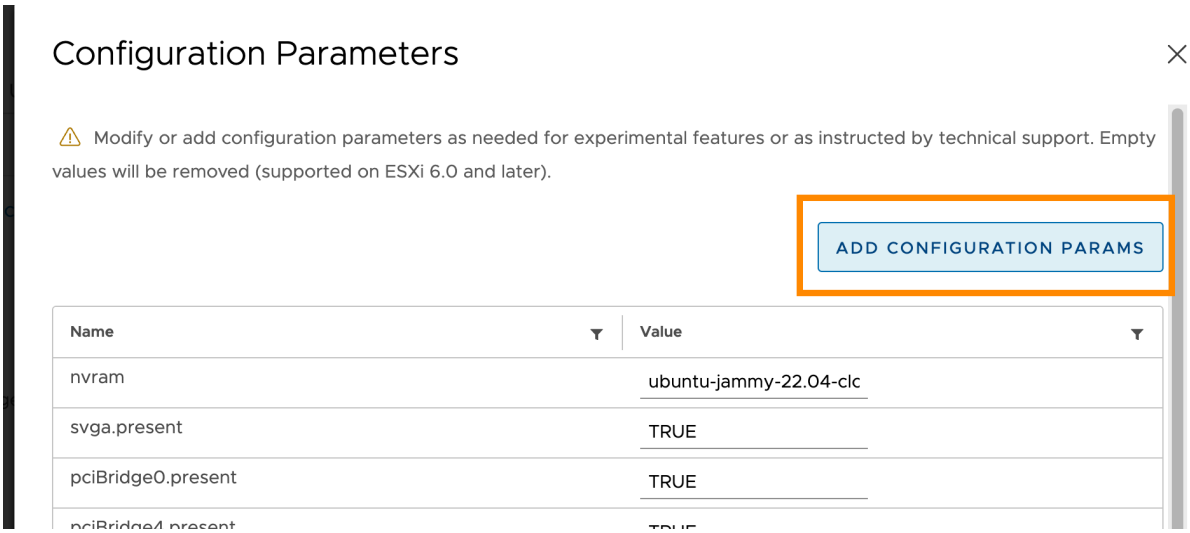
For **each** field in the add/edit form, set the following:

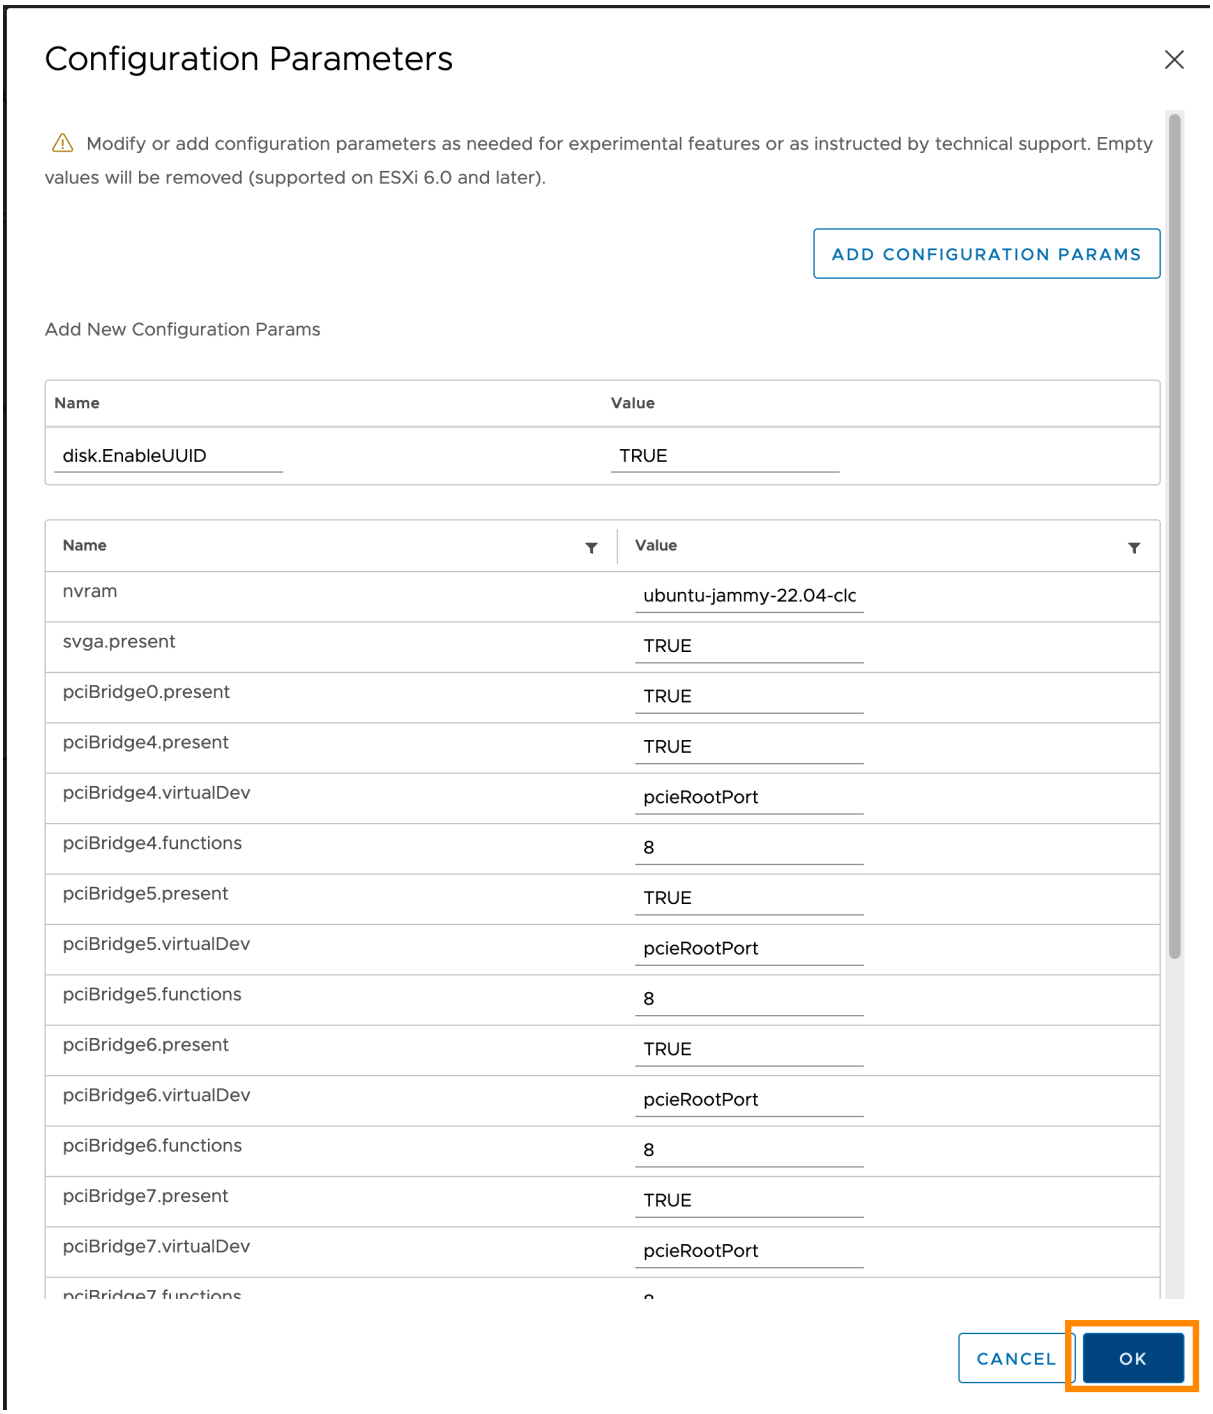


- “Type”: `Text` (text value)
- “User access”: `Read/Write`
- “Value”: A single space



> **i** The VCD UI may not save metadata with an empty value. A single space is used as a placeholder and does not affect functionality. The actual values will be populated automatically when virtual machines are created.





4. In the vCenter management panel for the template, enable the `disk.EnableUUID` parameter:

Use the settings of the cluster or host containing the virtual machine.
Virtual machine directory
Store the swap files in the same directory as the virtual machine.
Datastore specified by host
Store the swap files in the datastore specified by the host to be used for swap files. If not possible, store the swap files in the same directory as the virtual machine. Using a datastore that is not visible to both hosts during vMotion might affect the vMotion performance for the affected virtual machines.
Configuration Parameters
EDIT CONFIGURATION...

Replacing the OS image

Deckhouse Platform creates the nodes from a virtual machine template that is specified in the `template` parameter of the

VCDInstanceClass resource for `CloudEphemeral` nodes and in the `instanceClass` section of the VCDClusterConfiguration resource for `CloudPermanent` nodes and master nodes.

To move the nodes to a new OS image, prepare a new template based on it and follow the steps from “How do I replace the OS image in a cloud cluster?”.

Using the storage

- VCD supports CSI; disks are created as VCD Independent Disks.
- The `disk.EnableUUID` guest property must be set for the virtual machine templates in use.
- Deckhouse Platform supports disk resizing as of v1.59.1.

Using the LoadBalancer

- DP components support `Service` resources of type `LoadBalancer` when deployed on VMware Cloud Director (VCD).
- VMware NSX Advanced Load Balancer (ALB or Avi Networks) is used as the load balancer.
- Support is available **only** when using the `NSX-T` network virtualization platform.
- The load balancer functionality must be enabled on the Edge Gateway by your VCD provider. You can verify this under **Edge Gateway → Load Balancer → General Settings** — the `State` parameter must be `Active`.
- If the load balancer was enabled after the DP cluster was successfully created, the components will automatically pick up the changes within an hour (no additional actions are required).
- For each open port, a **Pool + Virtual Service** pair is created.
- If a firewall is in place, you must create an allow rule for the load balancer’s external IP address and the corresponding ports.

To assign a predefined external IP address to a VCD load balancer, add the `vcd.cpi.flant.com/load-balancer-ip` annotation to the Service.

If both `vcd.cpi.flant.com/load-balancer-ip` annotation and `.spec.loadBalancerIP` filed are set, the annotation takes precedence. The `spec.loadBalancerIP` field remains supported as a deprecated fallback for compatibility.

Example:

```
apiVersion: v1
kind: Service
metadata:
  name: example
  annotations:
    vcd.cpi.flant.com/load-balancer-ip: "192.0.2.10"
spec:
  type: LoadBalancer
  selector:
    app: example
  ports:
    - name: https
      port: 443
      targetPort: 8443
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

VCDInstanceClass

Scope: Cluster
Version: v1

Parameters of a group of VCD VirtualMachines used by `cluster-api-controller-manager` (the cloud-provider-vcd module).

- **spec**
  object

  Required value

  - **spec.additionalMetadata**
    object

Custom string key-value pairs to be stored in the Metadata of every node VM, useful for organizing and categorizing your virtualization inventory.

The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the VCDProviderClusterConfiguration spec. This field will take precedence over the existing metadata in cases of duplicate keys.

> **Warning.** Changing the `additionalMetadata` will cause the recreation of CloudEphemeral NodeGroups referring the VCDInstanceClass.

- **spec.affinityRule**
  object

  Specifies the affinity rule applied only to virtual machines of node groups referencing this instance class within the cluster. Affinity rules determine how nodes are scheduled in relation to each other at the hypervisor level, which can help improve fault tolerance, and control the distribution of workloads. If not specified, no affinity rule will be applied by default.

  - **spec.affinityRule.polarity**
    string

    Required value

    The polarity of the affinity rule. Must be either `Affinity` or `AntiAffinity`. `Affinity` means that nodes should be placed on the same host, while `AntiAffinity` means they should be placed on different hosts.

    Allowed values: `Affinity`, `AntiAffinity`

  - **spec.affinityRule.required**
    boolean

    Indicates whether the affinity rule is mandatory (`true`) or only preferred (`false`). If set to `true`, the rule must be enforced; if `false`, the rule is applied if possible but not strictly required.

    Default: `false`

- **spec.mainNetwork**
  string

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  Example:

  ```
  mainNetwork: internal
  ```

- **spec.placementPolicy**
  string

  PlacementPolicy is the placement policy to be used on this machine. If no placement policy is specified, default placement policy will be used to create the nodes.

  Example:

  ```
  placementPolicy: Hypervisor1
  ```

- **spec.rootDiskSizeGb**
  integer

  root disk size in gigabytes.

  Default: `20`

  Example:

  ```
  rootDiskSizeGb: 20
  ```

- **spec.sizingPolicy**
  string

  SizingPolicy is the sizing policy to be used on this machine. If no sizing policy is specified, default sizing policy will be used to create the nodes.

  Example:

  ```
  sizingPolicy: 4Cpu8Memory
  ```

- **spec.storageProfile**
  string

  Required value

  StorageProfile is the storage profile to be used on this machine.

  Example:

```
storageProfile: ssd
```

- **spec.template**
  string

  Required value

  Path of the template OVA that is to be used. Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

  If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

  You can find the template identifier in the URL when you open the template in the vCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

  Examples:

```
template: Linux/ubuntu2204-cloud-ova
```

```
template: MyOrg/Linux/ubuntu2204-cloud-ova
```

```
template: Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
```

```
template: MyOrg/Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

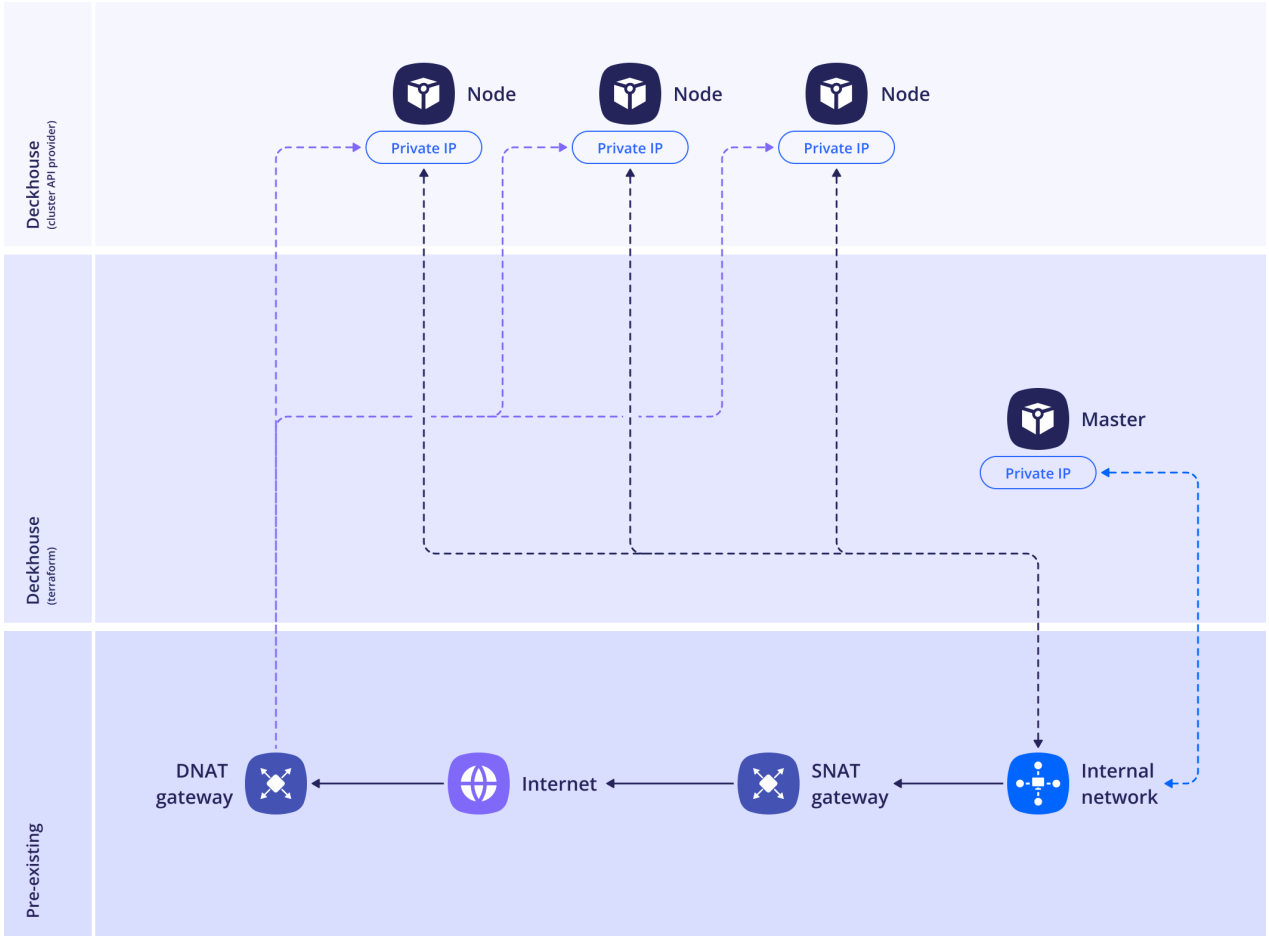
Examples

> The module lifecycle stage: General Availability

Below is an example VCDInstanceClass configuration for ephemeral nodes of VMware Cloud Director cloud provider.

Example configuration of the VCDInstanceClass custom resource

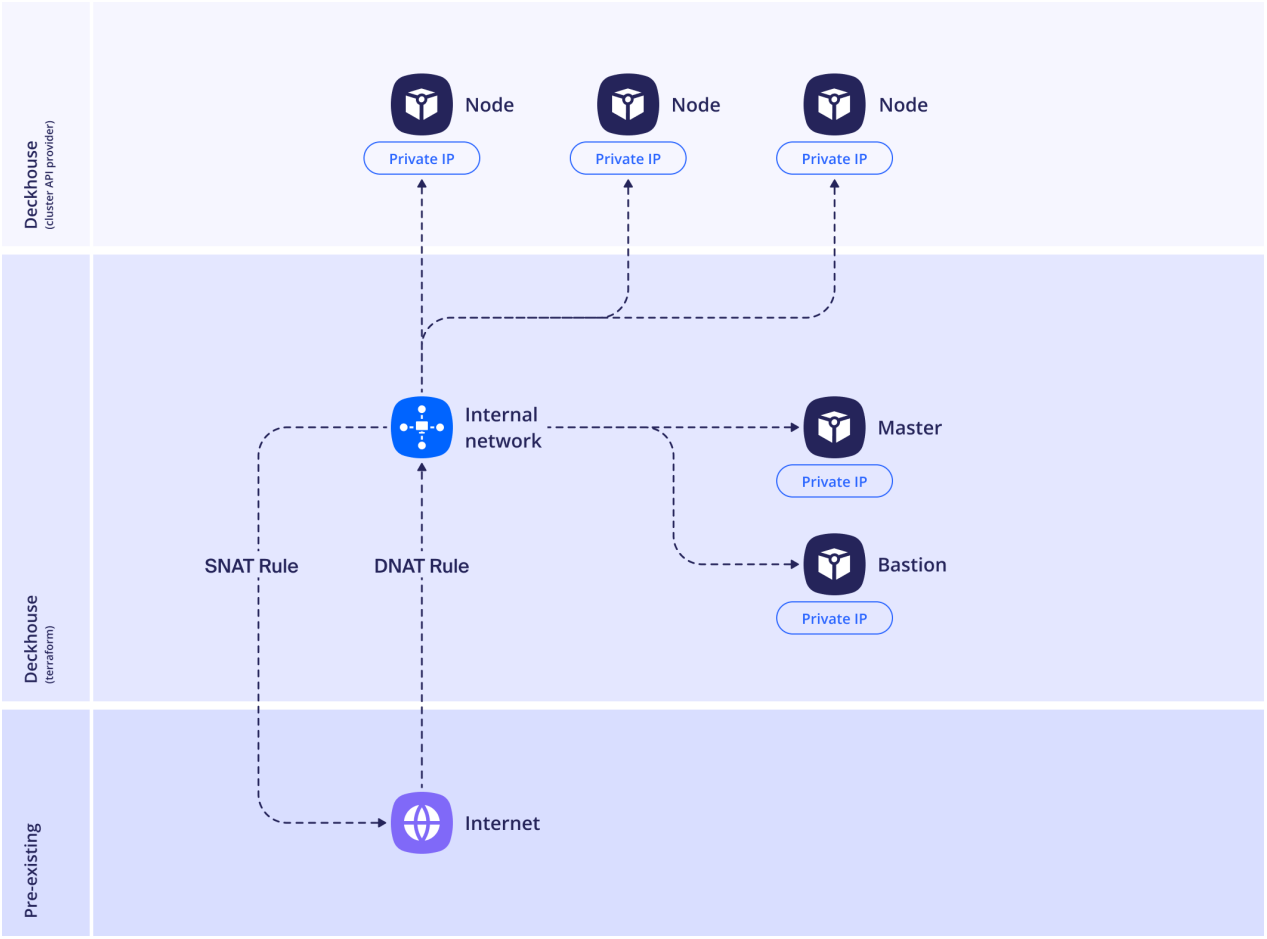


```
apiVersion: deckhouse.io/v1
kind: VCDInstanceClass
metadata:
  name: test
spec:
  rootDiskSizeGb: 90
  sizingPolicy: payg-4-8
  storageProfile: SSD-dc1-pub1-cl1
  template: MyOrg/Linux/ubuntu2204-cloud-ova
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider - VMware Cloud Director: Layouts

> The module lifecycle stage: General Availability



Standard

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1alpha1
kind: VCDClusterConfiguration
layout: Standard
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
sshPublicKey: <SSH_PUBLIC_KEY>
organization: deckhouse
virtualDataCenter: MSK-1
virtualApplicationName: deckhouse
internalNetworkCIDR: 192.168.199.0/24
masterNodeGroup:
  replicas: 1
  instanceClass:
    storageProfile: "Fast vHDD"
    sizingPolicy: 4cpu8mem
    template: "catalog/Ubuntu 22.04 Server"
    mainNetworkIPAddresses:
    - 192.168.199.2
```

WithNAT

When using this placement scheme, you must check with the administrator which network virtualization platform is in use and specify it in the `edgeGateway.type` parameter.
Two options are supported: `NSX-T` and `NSX-V`.

To ensure administrative access to the cluster nodes, a bastion is deployed. The parameters for its configuration are described in the `bastion` section.

If the Edge Gateway is based on `NSX-T`, a DHCP server will be automatically enabled in the created network for the nodes. It will assign IP addresses starting from the 30th address in the subnet up to the second-to-last (just before the broadcast address).
You can change the starting address of the DHCP pool using the `internalNetworkDHCPPoolStartAddress` parameter.

If `NSX-V` is used, DHCP must be configured manually. Otherwise, nodes that rely on dynamic IP assignment will not be able to obtain an address.

⚠ It is not recommended to use dynamic addressing for the first master node in combination with `NSX-V`.

The deployment scheme assumes automated creation of NAT rules:

- An SNAT rule for translating the addresses of the internal node network to the external address specified in the `edgeGateway.externalIP` property.
- A DNAT rule for translating the external address and port, specified in the `edgeGateway.externalIP` and `edgeGateway.externalPort` properties, respectively, to the internal address of the bastion instance on port 22 using the `TCP` protocol for administrative access to the nodes via SSH.

⚠ If the Edge Gateway is provided by `NSX-V`, you must specify the name and type of the network to which the rule will be bound in the `edgeGateway.NSX-V.externalNetworkName` and `edgeGateway.NSX-V.externalNetworkType` properties, respectively. Typically, this is a network connected to the Edge Gateway in `Gateway Interface` and having an external IP address.

Additionally, you can enable the creation of default firewall rules using the `createDefaultFirewallRules` property.

⚠ If the Edge Gateway is provided by `NSX-T`, existing rules on the Edge Gateway will be overwritten. It is assumed that using this option implies that only one cluster will be deployed per Edge Gateway.

The following rules will be created:

- Allow any outgoing traffic
- Allow incoming traffic over the `TCP` protocol on port 22 to enable SSH access to the cluster nodes
- Allow any incoming traffic over the `ICMP` protocol
- Allow incoming traffic over the `TCP` and `UDP` protocols on ports 30000–32767 for NodePort usage

Example of the layout configuration using `NSX-T`:

```
---
apiVersion: deckhouse.io/v1alpha1
kind: VCDClusterConfiguration
layout: WithNAT
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
sshPublicKey: <SSH_PUBLIC_KEY>
organization: deckhouse
virtualDataCenter: MSK-1
virtualApplicationName: deckhouse
internalNetworkCIDR: 192.168.199.0/24
internalNetworkDNSServers:
  - 77.88.8.8
  - 1.1.1.1
mainNetwork: internal
bastion:
  instanceClass:
    rootDiskSizeGb: 30
    sizingPolicy: 2cpu1mem
    template: "catalog/Ubuntu 22.04 Server"
    storageProfile: Fast vHDD
    mainNetworkIPAddress: 10.1.4.10
edgeGateway:
  name: "edge-gateway-01"
  type: "NSX-T"
  externalIP: 10.0.0.1
  externalPort: 10022
createDefaultFirewallRules: false
masterNodeGroup:
  replicas: 1
  instanceClass:
    storageProfile: "Fast vHDD"
    sizingPolicy: 4cpu8mem
    template: "catalog/Ubuntu 22.04 Server"
    mainNetworkIPAddresses:
    - 192.168.199.2
```

Example of the layout configuration using `NSX-V`:

```
---
apiVersion: deckhouse.io/v1alpha1
kind: VCDClusterConfiguration
layout: WithNAT
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
sshPublicKey: <SSH_PUBLIC_KEY>
organization: deckhouse
virtualDataCenter: MSK-1
virtualApplicationName: deckhouse
internalNetworkCIDR: 192.168.199.0/24
internalNetworkDNSServers:
  - 77.88.8.8
  - 1.1.1.1
mainNetwork: internal
bastion:
  instanceClass:
    rootDiskSizeGb: 30
    sizingPolicy: 2cpu1mem
    template: "catalog/Ubuntu 22.04 Server"
    storageProfile: Fast vHDD
    mainNetworkIPAddress: 10.1.4.10
edgeGateway:
  name: "edge-gateway-01"
  type: "NSX-V"
  externalIP: 10.0.0.1
  externalPort: 10022
  NSX-V:
    externalNetworkName: external
    externalNetworkType: ext
createDefaultFirewallRules: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    storageProfile: "Fast vHDD"
    sizingPolicy: 4cpu8mem
    template: "catalog/Ubuntu 22.04 Server"
    mainNetworkIPAddresses:
    - 192.168.199.2
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — VMware vSphere

Included in extensions: **On-prem IaaS**

The module lifecycle stage: General Availability

The `cloud-provider-vsphere` module integrates Deckhouse Platform with VMware vSphere. It allows the `node-manager` module to use vSphere resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-vsphere` module:

- Managing vSphere resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the vSphere side;
  - updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in vSphere.
- Provisioning disks via CSI on datastore. By default, CNS volumes with online resize are used. First-Class Disk (FCD) mode is available as legacy and is configured with the `compatibilityFlag` parameter.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-vsphere`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM). Virtual machine parameters are set in the VsphereInstanceClass resource.
- Registering with `node-manager` so that VsphereInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

⚠ The module is moving CloudEphemeral node management from Machine Controller Manager (MCM) to Cluster API (CAPI). Existing NodeGroups keep running on MCM, new ones are created on CAPI by default. The procedure for moving existing groups is described in How to migrate node groups to Cluster API (CAPI).

Nodes managed by CAPI

vSphere requirement

The vSphere cluster that hosts CAPI-managed nodes must have DRS enabled. The module does not pick a specific host when cloning a virtual machine, so vSphere chooses the host within the cluster. Without DRS the choice is not made, and the nodes of the group are not created.

The same requirement applies to master nodes and CloudPermanent nodes created by Terraform. Node groups managed by MCM also worked in a cluster without DRS.

The remaining environment requirements are listed in Connecting to and authenticating with VMware vSphere.

vCenter tags

The module assigns the `deckhouse-cluster-name/<CLUSTER UUID>` tag to every virtual machine it creates, the same way MCM did. The `deckhouse-node-role/<NODE_GROUP>-<ZONE>` tag that MCM assigned as well is not assigned under CAPI. To select the nodes of a single group, use the `node.deckhouse.io/group` label.

Virtual machine placement

The module honors both placement parameters of the VsphereInstanceClass resource, `resourcePool` and `datastore`. When at least one of them is set in the instance class, the virtual machines of the group are created in the specified resource pool and on the specified datastore in every zone the group spans. A parameter left unset takes the default value defined for the cluster at installation.

Third-party components

List of third-party software used in the `cloud-provider-vsphere` module:

- VMware vSphere Cloud provider v1.33.1, v1.34.0, v1.35.1, v1.35.1, v1.37.0

  License: Apache License 2.0

  Cloud Controller Manager for VMware vSphere.

- VMware vSphere CSI driver v3.7.1, v3.7.1, v3.7.1, v3.7.1, v3.7.3

  License: Apache License 2.0

  CSI driver for VMware vSphere.

- VMware vSphere Terraform provider 2.0.2

  License: Mozilla Public License 2.0

  Terraform provider for VMware vSphere.

- VMware vSphere Cluster API provider v1.15.3

  License: Apache License 2.0

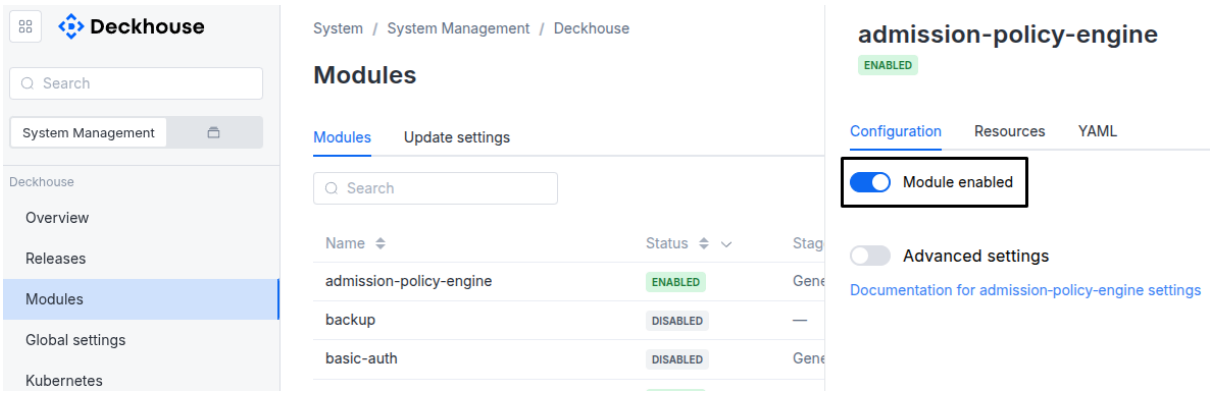
  Infrastructure provider for Kubernetes Cluster API in VMware vSphere.

ℹ **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

ℹ Included in extensions: **On-prem IaaS**



ℹ The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in vSphere.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vsphere` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

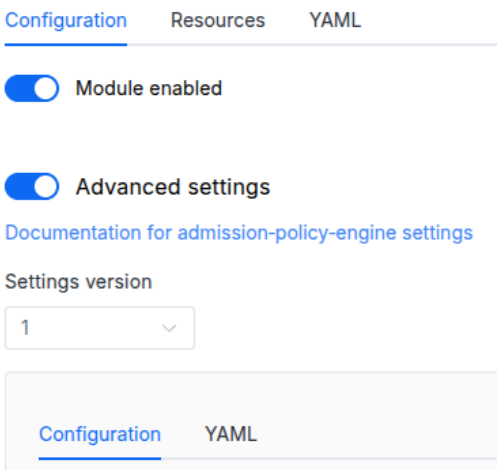
  ```
  d8 system module enable cloud-provider-vsphere
  ```

- **Using ModuleConfig `cloud-provider-vsphere`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-vsphere` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-vsphere`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-vsphere
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vsphere` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-vsphere` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-vsphere`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-vsphere` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-vsphere
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the

`spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `cloud-provider-vsphere` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-vsphere`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vsphere
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  If the field `.storageClass.compatibilityFlag` exists, capitalize the field value.

If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-vsphere` module in the Deckhouse configuration (see below). Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the VsphereClusterConfiguration structure for configuration.

You can configure the number and parameters of ordering machines in the cloud via the `NodeGroup` custom resource of the `node-manager` module. Also, in this custom resource, you can specify the instance class's name for the above group of nodes (the `cloudInstances.ClassReference` parameter of NodeGroup). In the case of the vSphere cloud provider, the instance class is the `VsphereInstanceClass` custom resource that stores specific parameters of the machines.

Storage

The module automatically creates a StorageClass for each Datastore and DatastoreCluster in the zone (or zones).

Also, it can set the name of StorageClass that will be used in the cluster by default (the default parameter), and filter out the unnecessary StorageClasses (the exclude parameter).

CSI

By default, the storage subsystem uses CNS volumes with the ability of online-resize. FCD volumes are also supported, but only in the legacy or migration modes. You can set this via the compatibilityFlag parameter.

Important information concerning the increase of the PVC size

Due to the nature f volume-resizer, CSI, and vSphere API, you have to do the following after increasing the PVC size:

1. On the node where the Pod is located, run the `d8 k cordon <node_name>` command.
2. Delete the Pod.
3. Make sure that the resize was successful. The PVC object must *not have* the `Resizing` condition.

   > **i** The `FileSystemResizePending` state is OK.

4. On the node where the Pod is located, run the `d8 k uncordon <node_name>` command.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.caBundle**
    string

    PEM-encoded CA certificate chain used to verify the vCenter TLS certificate. Use this parameter instead of setting `insecure: true` when the vCenter certificate is signed by a custom or enterprise CA.

  - **settings.disableTimesync**
    boolean

    Disable time synchronization on the vSphere side.

> **Caution!** This parameter will not disable the NTP daemons in the guest OS, but only disable the time correction on the part of ESXi.

- **settings.externalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert ExternalIP into the `.status.addresses` field in the Node API object.

- **settings.host**
  string

  The domain of the vCenter server.

- **settings.insecure**
  boolean

  Set to `true` if vCenter has a self-signed certificate.

- **settings.internalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert InternalIP into the `.status.addresses` field in the Node API object.

- **settings.nsxt**
  object

  Kubernetes load balancer support using NSX-T for the vSphere cloud controller manager.

  - **settings.nsxt.caBundle**
    string

    A certificate authority (CA) certificate chain in PEM format used to verify the NSX-T TLS certificate. Use this parameter instead of `insecureFlag` if the NSX-T TLS certificate is signed by a custom or corporate certificate authority.

  - **settings.nsxt.defaultIpPoolName**
    string

    Required value

    Name of the default IP pool used for the SVC's without `loadbalancer.vmware.io/class` annotation set.

    Example:

    ```
    defaultIpPoolName: pool1
    ```

  - **settings.nsxt.defaultTcpAppProfileName**
    string

    Name of default NSX-T application profile used for TCP connections.

    Default: `default-tcp-lb-app-profile`

    Examples:

    ```
    defaultTcpAppProfileName: default-tcp-lb-app-profile
    ```

    ```
    defaultTcpAppProfileName: tcp-profile1
    ```

  - **settings.nsxt.defaultUdpAppProfileName**
    string

    Name of default NSX-T application profile used for UDP connections.

    Default: `default-udp-lb-app-profile`

    Examples:

    ```
    defaultUdpAppProfileName: default-udp-lb-app-profile
    ```

    ```
    defaultUdpAppProfileName: udp-profile1
    ```

  - **settings.nsxt.host**
    string

    Required value

    NSX-T host.

    Example:

    ```
    host: 1.2.3.4
    ```

- **settings.nsxt.insecureFlag**
  boolean

  To be set to true if NSX-T uses self-signed certificate.

  Examples:

  ```
  insecureFlag: true
  ```

  ```
  insecureFlag: false
  ```

- **settings.nsxt.loadBalancerClass**
  array

  Additional section to define Load Balancer Classes (to use class, set annotation `loadbalancer.vmware.io/class: <class name>` to SVC).

  Examples:

  ```
  loadBalancerClass: []
  ```

  ```
  loadBalancerClass:
    name: LBC1
    ipPoolName: pool2
  ```

  ```
  loadBalancerClass:
    name: LBC1
    ipPoolName: pool2
    tcpAppProfileName: profile2
    udpAppProfileName: profile3
  ```

  - **settings.nsxt.loadBalancerClass.ipPoolName**
    string

    Required value

    Name of the IP pool.

  - **settings.nsxt.loadBalancerClass.name**
    string

    Required value

    Load Balancer Class name to use in SVC annotation `loadbalancer.vmware.io/class: <class name>`.

  - **settings.nsxt.loadBalancerClass.tcpAppProfileName**
    string

    Name of application profile used for TCP connections.

    Default: `defaultTcpAppProfileName`

  - **settings.nsxt.loadBalancerClass.udpAppProfileName**
    string

    Name of application profile used for UDP connections.

    Default: `defaultUdpAppProfileName`

- **settings.nsxt.password**
  string

  Required value

  NSX-T password.

  Example:

  ```
  password: password
  ```

- **settings.nsxt.size**
  string

  Size of load balancer service.

  Default: `MEDIUM`

  Allowed values: `SMALL`, `MEDIUM`, `LARGE`, `XLARGE`

  Example:

  ```
  size: SMALL
  ```

- **settings.nsxt.tier1GatewayPath**
  string

  Required value

  Policy path for the NSX-T tier1 gateway.

  Example:

  ```
  tier1GatewayPath: "/path/tier1"
  ```

- **settings.nsxt.user**
  string

  Required value

  NSX-T user name.

  Example:

  ```
  user: user
  ```

- **settings.password**
  string

  The user's password.

- **settings.region**
  string

  Is a tag added to the vSphere Datacenter where all actions will occur: provisioning VirtualMachines, storing virtual disks on datastores, connecting to the network.

- **settings.regionTagCategory**
  string

  The name of the tag category used to identify the region (vSphere Datacenter).

- **settings.sshKeys**
  array of strings

  A list of public SSH keys in plain-text format.

- **settings.storageClass**
  object

  - **settings.storageClass.compatibilityFlag**
    string

    A flag allowing the use of the old CSI version:

    - `Legacy` — use the old version of the driver. FCD discs only, no online-resizing;
    - `Migration` — in this case, both drivers will be available in the cluster at the same time. This mode is used to migrate from an old driver.

    Allowed values: `Legacy`, `Migration`

  - **settings.storageClass.default**
    Deprecated
    string

    The name of StorageClass that will be used in the cluster by default.

    If the parameter is omitted, the default StorageClass is either:

    - an arbitrary StorageClass present in the cluster that has the default annotation;
    - the first (in lexicographic order) StorageClass created by the module.

    > **i** **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

    Example:

    ```
    default: fast-lun102-7d0bf578
    ```

  - **settings.storageClass.exclude**
    array of strings

    A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

    Example:

    ```
    exclude:
    - ".*-lun101-.*"
    - slow-lun103-1c280603
    ```

- **settings.username**
  string

Username.

> **Warning.** Make sure to specify the username together with the domain, for example: `username@domain.local`.
>
> You can find the correct domain in the vCenter control panel.

- **settings.vmFolderPath**
  string

  The path to the VirtualMachine Folder where the cloned VMs will be created.

- **settings.zoneTagCategory**
  string

  The name of the tag category used to identify the zone (vSphere Cluster).

- **settings.zones**
  array of strings

  The globally restricted set of zones that this Cloud Provider works with.

Provider configuration

> The module lifecycle stage: General Availability

> If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-vsphere` module in the Deckhouse configuration. Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the VsphereClusterConfiguration structure for configuration.
>
> Additional info about Vsphere Cloud Load Balancers.

VsphereClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in vSphere.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes section. Information about reducing the number of nodes and deleting nodes is provided in the Integration with VMware vSphere services section.

Example:

```
apiVersion: deckhouse.io/v1
kind: VsphereClusterConfiguration
sshPublicKey: "<SSH_PUBLIC_KEY>"
layout: Standard
vmFolderPath: folder/prefix
regionTagCategory: k8s-region
zoneTagCategory: k8s-zone
region: region2
zones:
- region2-a
externalNetworkNames:
- net3-k8s
internalNetworkNames:
- K8S_3
internalNetworkCIDR: 172.16.2.0/24
baseResourcePool: kubernetes/cloud
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: Templates/ubuntu-focal-20.04
    mainNetwork: net3-k8s
    additionalNetworks:
    - K8S_3
    datastore: lun10
    rootDiskSize: 50
    runtimeOptions:
      nestedHardwareVirtualization: false
nodeGroups:
- name: worker
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: Templates/ubuntu-focal-20.04
    datastore: lun10
    mainNetwork: net3-k8s
provider:
  server: "<SERVER>"
  username: "<USERNAME@DOMAIN.LOCAL>"
  password: "<PASSWORD>"
  insecure: true
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **baseResourcePool**
  string

  A path (relative to vSphere Cluster) to the existing parent `resourcePool` for all `resourcePool` created in each zone.

- **disableTimesync**
  boolean

  Disable time synchronization on the vSphere side.

  > **Caution!** This parameter will not disable the NTP daemons in the guest OS, but only disable the time correction on the part of ESXi.

  Default: `true`

- **externalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert ExternalIP into the `.status.addresses` field in the Node API object.

  Example:

```
externalNetworkNames:
- MAIN-1
- public
```

- **internalNetworkCIDR**
  string

  Subnet for master nodes in the internal network.

  Addresses are allocated starting with the tenth address. E.g., if you have the `192.168.199.0/24` subnet, addresses will be allocated starting with `192.168.199.10`.

  The `internalNetworkCIDR` is used if `additionalNetworks` are defined in `masterInstanceClass`.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **internalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert InternalIP into the `.status.addresses` field in the Node API object.

  Example:

```
internalNetworkNames:
- KUBE-3
- devops-internal
```

- **kind**
  string

  Required value

  Allowed values: `VsphereClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the VsphereInstanceClass.

    - **masterNodeGroup.instanceClass.additionalNetworks**
      array of strings

      Paths to networks that VirtualMachines' secondary NICs will connect to. Relative to the datacenter.

      Example:

```
additionalNetworks:
- DEVOPS_32
- DEVOPS_50
```

    - **masterNodeGroup.instanceClass.datastore**
      string

      Required value

      Path to a Datastore in which VirtualMachines will be cloned. Relative to the datacenter.

      Both a plain Datastore name (`lun-1201`) and a path with parent folders (`DS_PARENT_FOLDER/lun-1201`) are supported.

      Example:

```
datastore: lun-1201
```

- **masterNodeGroup.instanceClass.mainNetwork**
  string

  Required value

  Path to the network that VirtualMachines’ primary NICs will connect to (default gateway). Relative to the datacenter.

  Example:

  ```
  mainNetwork: k8s-msk-178
  ```

- **masterNodeGroup.instanceClass.mainNetworkIPAddresses**
  array of objects

  A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

  By default, the DHCP client is enabled.

  Example:

  ```
  mainNetworkIPAddresses:
  - address: 10.1.14.20/24
    gateway: 10.1.14.254
    nameservers:
      addresses:
      - 8.8.8.8
      - 8.8.4.4
  ```

  - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.address**
    string

    Required value

    An IP address with a CIDR prefix.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.gateway**
    string

    Required value

    The IP address of the default gateway.

    It must be located in the subnet specified in the `address` parameter

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

  - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.nameservers**
    object

    Required value

    - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.nameservers.addresses**
      array of strings

      A list of DNS servers.

      Example:

      ```
      addresses:
      - 8.8.8.8
      - 8.8.4.4
      ```

      - **Element of the array**
        string

        Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

    - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.nameservers.search**
      array of strings

      A list of DNS search domains.

      Example:

      ```
      search:
      - tech.lan
      ```

- **masterNodeGroup.instanceClass.memory**

integer

Required value

Memory in MiB to allocate to vSphere VirtualMachines.

Example:

```
memory: 8192
```

- **masterNodeGroup.instanceClass.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **masterNodeGroup.instanceClass.resourcePool**
  string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  Example:

  ```
  resourcePool: rp-2012
  ```

- **masterNodeGroup.instanceClass.rootDiskSize**
  integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Example:

  ```
  rootDiskSize: 50
  ```

- **masterNodeGroup.instanceClass.runtimeOptions**
  object

  Additional VM’s parameters.

  - **masterNodeGroup.instanceClass.runtimeOptions.cpuLimit**
    integer

    CPU limit in MHz.

  - **masterNodeGroup.instanceClass.runtimeOptions.cpuReservation**
    integer

    CPU reservation in MHz.

  - **masterNodeGroup.instanceClass.runtimeOptions.cpuShares**
    integer

    The relative amount of CPU Shares for VMs to be created.

  - **masterNodeGroup.instanceClass.runtimeOptions.memoryLimit**
    integer

    Memory limit in MB.

  - **masterNodeGroup.instanceClass.runtimeOptions.memoryReservation**
    integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Allowed values: `0 <= X <= 100`

  - **masterNodeGroup.instanceClass.runtimeOptions.memoryShares**
    integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **masterNodeGroup.instanceClass.runtimeOptions.nestedHardwareVirtualization**
    boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

- **masterNodeGroup.instanceClass.template**
  string

  Required value

Path to the template to be cloned. Relative to the datacenter.

Example:

```
template: dev/golden_image
```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the VsphereInstanceClass.

    - **nodeGroups.instanceClass.additionalNetworks**
      array of strings

      Paths to networks that VirtualMachines’ secondary NICs will connect to. Relative to the datacenter.

      Example:

      ```
      additionalNetworks:
      - DEVOPS_32
      - DEVOPS_50
      ```

    - **nodeGroups.instanceClass.datastore**
      string

      Required value

      Path to a Datastore in which VirtualMachines will be cloned. Relative to the datacenter.

      Both a plain Datastore name (`lun-1201`) and a path with parent folders (`DS_PARENT_FOLDER/lun-1201`) are supported.

      Example:

      ```
      datastore: lun-1201
      ```

    - **nodeGroups.instanceClass.mainNetwork**
      string

      Required value

      Path to the network that VirtualMachines’ primary NICs will connect to (default gateway). Relative to the datacenter.

      Example:

      ```
      mainNetwork: k8s-msk-178
      ```

    - **nodeGroups.instanceClass.mainNetworkIPAddresses**
      array of objects

      A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

      By default, the DHCP client is enabled.

      Example:

```
mainNetworkIPAddresses:
- address: 10.1.14.20/24
  gateway: 10.1.14.254
  nameservers:
    addresses:
    - 8.8.8.8
    - 8.8.4.4
```

- **nodeGroups.instanceClass.mainNetworkIPAddresses.address**
  string

  Required value

  An IP address with a CIDR prefix.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **nodeGroups.instanceClass.mainNetworkIPAddresses.gateway**
  string

  Required value

  The IP address of the default gateway.

  It must be located in the subnet specified in the `address` parameter

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **nodeGroups.instanceClass.mainNetworkIPAddresses.nameservers**
  object

  Required value

  - **nodeGroups.instanceClass.mainNetworkIPAddresses.nameservers.addresses**
    array of strings

    A list of DNS servers.

    Example:

    ```
    addresses:
    - 8.8.8.8
    - 8.8.4.4
    ```

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

  - **nodeGroups.instanceClass.mainNetworkIPAddresses.nameservers.search**
    array of strings

    A list of DNS search domains.

    Example:

    ```
    search:
    - tech.lan
    ```

- **nodeGroups.instanceClass.memory**
  integer

  Required value

  Memory in MiB to allocate to vSphere VirtualMachines.

  Example:

  ```
  memory: 8192
  ```

- **nodeGroups.instanceClass.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **nodeGroups.instanceClass.resourcePool**
  string

Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

Example:

```
resourcePool: rp-2012
```

- **nodeGroups.instanceClass.rootDiskSize**
  integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Example:

  ```
  rootDiskSize: 50
  ```

- **nodeGroups.instanceClass.runtimeOptions**
  object

  Additional VM’s parameters.

  - **nodeGroups.instanceClass.runtimeOptions.cpuLimit**
    integer

    CPU limit in MHz.

  - **nodeGroups.instanceClass.runtimeOptions.cpuReservation**
    integer

    CPU reservation in MHz.

  - **nodeGroups.instanceClass.runtimeOptions.cpuShares**
    integer

    The relative amount of CPU Shares for VMs to be created.

  - **nodeGroups.instanceClass.runtimeOptions.memoryLimit**
    integer

    Memory limit in MB.

  - **nodeGroups.instanceClass.runtimeOptions.memoryReservation**
    integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Allowed values: `0 <= X <= 100`

  - **nodeGroups.instanceClass.runtimeOptions.memoryShares**
    integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **nodeGroups.instanceClass.runtimeOptions.nestedHardwareVirtualization**
    boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

- **nodeGroups.instanceClass.template**
  string

  Required value

  Path to the template to be cloned. Relative to the datacenter.

  Example:

  ```
  template: dev/golden_image
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

```
annotations:
  ai.fleet.com/discombobulate: 'true'
```

- **nodeGroups.nodeTemplate.labels**
  object

  A list of labels to attach to cluster resources.

  The same as the `metadata.labels` standard field.

  Example:

  ```
  labels:
    environment: production
    app: warp-drive-ai
  ```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeGroups.zones**
  array of strings

  A limited set of zones in which nodes can be created.

- **nsxt**
  object

  Kubernetes load balancer support using NSX-T for the vSphere cloud controller manager.

  - **nsxt.caBundle**
    string

    A certificate authority (CA) certificate chain in PEM format used to verify the NSX-T TLS certificate. Use this parameter instead of `insecureFlag` if the NSX-T TLS certificate is signed by a custom or corporate certificate authority.

  - **nsxt.defaultIpPoolName**
    string

    Required value

    Name of the default IP pool used for the SVC's without `loadbalancer.vmware.io/class` annotation set.

    Example:

    ```
    defaultIpPoolName: pool1
    ```

  - **nsxt.defaultTcpAppProfileName**
    string

    Name of default NSX-T application profile used for TCP connections.

    Default: `default-tcp-lb-app-profile`

    Examples:

```
defaultTcpAppProfileName: default-tcp-lb-app-profile
```

```
defaultTcpAppProfileName: tcp-profile1
```

- **nsxt.defaultUdpAppProfileName**
  string

  Name of default NSX-T application profile used for UDP connections.

  Default: `default-udp-lb-app-profile`

  Examples:

```
defaultUdpAppProfileName: default-udp-lb-app-profile
```

```
defaultUdpAppProfileName: udp-profile1
```

- **nsxt.host**
  string

  Required value

  NSX-T host.

  Example:

```
host: 1.2.3.4
```

- **nsxt.insecureFlag**
  boolean

  To be set to true if NSX-T uses self-signed certificate.

  Examples:

```
insecureFlag: true
```

```
insecureFlag: false
```

- **nsxt.loadBalancerClass**
  array

  Additional section to define Load Balancer Classes (set annotation `loadbalancer.vmware.io/class: <CLASS NAME>` to SVC to use the class).

  Examples:

```
loadBalancerClass: []
```

```
loadBalancerClass:
  name: LBC1
  ipPoolName: pool2
```

```
loadBalancerClass:
  name: LBC1
  ipPoolName: pool2
  tcpAppProfileName: profile2
  udpAppProfileName: profile3
```

  - **nsxt.loadBalancerClass.ipPoolName**
    string

    Required value

    Name of the IP pool.

  - **nsxt.loadBalancerClass.name**
    string

    Required value

    Load Balancer Class name to use in SVC annotation `loadbalancer.vmware.io/class: <CLASS NAME>`.

  - **nsxt.loadBalancerClass.tcpAppProfileName**
    string

    Name of application profile used for TCP connections.

    Default: `defaultTcpAppProfileName`

  - **nsxt.loadBalancerClass.udpAppProfileName**

string

Name of application profile used for UDP connections.

Default: `defaultUdpAppProfileName`

- **nsxt.password**
  string

  Required value

  NSX-T password.

  Example:

  ```
  password: password
  ```

- **nsxt.size**
  string

  Size of load balancer service.

  Default: `MEDIUM`

  Allowed values: `SMALL`, `MEDIUM`, `LARGE`, `XLARGE`

  Example:

  ```
  size: SMALL
  ```

- **nsxt.tier1GatewayPath**
  string

  Required value

  Policy path for the NSX-T tier1 gateway.

  Example:

  ```
  tier1GatewayPath: "/path/tier1"
  ```

- **nsxt.user**
  string

  Required value

  NSX-T user name.

  Example:

  ```
  user: user
  ```

- **provider**
  object

  Required value

  Parameters for connecting to the vCenter.

  - **provider.caBundle**
    string

    PEM-encoded CA certificate chain used to verify the vCenter TLS certificate. Use this parameter instead of setting `insecure: true` when the vCenter certificate is signed by a custom or enterprise CA.

  - **provider.insecure**
    boolean

    Set to `true` if vCenter has a self-signed certificate.

    Default: `false`

  - **provider.password**
    string

    Required value

    The user’s password.

  - **provider.server**
    string

    Required value

    The host or the IP address of the vCenter server.

  - **provider.username**
    string

    Required value

Username.

> **Warning.** Make sure to specify the username together with the domain, for example: `username@domain.local`.
>
> You can find the correct domain in the vCenter control panel.

- **region**
  string

  Required value

  Is a tag added to the vSphere Datacenter where all actions will occur: provisioning VirtualMachines, storing virtual disks on datastores, connecting to the network.

- **regionTagCategory**
  string

  Required value

  The name of the tag category used to identify the region (vSphere Datacenter).

  Default: `k8s-region`

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **storagePolicyID**
  string

  ID of the SPBM (Storage Policy Based Management) storage policy.

- **useNestedResourcePool**
  boolean

  Create nested resource pool (`true`) or use main resource pool (`false`).

  Default: `true`

- **vmFolderExists**
  boolean

  Set the value to `true` if the path specified in `vmFolderPath` exists. Installing more than one cluster in a folder is not possible.

  Default: `false`

- **vmFolderPath**
  string

  Required value

  The path to the VirtualMachine Folder where the cloned VMs will be created.

  Example:

  ```
  vmFolderPath: dev/test
  ```

- **zoneTagCategory**
  string

  Required value

  The name of the tag category used to identify the zone (vSphere Cluster).

  Default: `k8s-zone`

- **zones**
  array of strings

  Required value

  The globally restricted set of zones that this Cloud Provider works with.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> **i** The module lifecycle stage: General Availability

Environment requirements

The following prerequisites must be met for Deckhouse Platform to work correctly with VMware vSphere:

- Access to vCenter;
- A user account with the required set of privileges;
- Tags and tag categories created in vSphere;
- Networks with DHCP and Internet access;
- Shared Datastore resources available on all ESXi hosts in use;
- vSphere version `7.x` or `8.x` with support for `Online volume expansion`;
- vCenter accessible from inside the cluster from the master nodes;
- A configured Datacenter that includes the following objects:
  1. VirtualMachine template:
     - The virtual machine image must use `Virtual machines with hardware version 15 or later` — this is required for online resize support.
     - The image must include the `open-vm-tools`, `cloud-init`, and `cloud-init-vmware-guestinfo` packages if the `cloud-init` version is lower than `21.3`.
  2. Network:
     - The network must be available on all ESXi hosts where virtual machines are planned to be created.
  3. Datastore (one or more):
     - The Datastore must be connected to all ESXi hosts where virtual machines are planned to be created.
     - A tag from the category specified in the `zoneTagCategory` parameter must be assigned to the Datastore (default: `k8s-zone`). This tag defines the zone.
     - All Cluster objects within the same zone must have access to all Datastore objects in that zone.
  4. Cluster:
     - All ESXi hosts in use must be added to the Cluster.
     - A tag from the category specified in the `zoneTagCategory` parameter must be assigned to the Cluster (default: `k8s-zone`). This tag defines the zone.
     - DRS must be enabled in the Cluster. The platform does not pick a specific host when creating a virtual machine, so vSphere chooses the host.
  5. Folder for the virtual machines being created:
     - This parameter is optional.
     - By default, the root virtual machine folder is used.
  6. Role:
     - The role must include the required set of privileges.
  7. User:
     - The user must be assigned the role specified in the previous item.
- A tag from the category specified in the `regionTagCategory` parameter must be assigned to the created Datacenter (default: `k8s-region`). This tag defines the region.

List of required vSphere resources

- **User** with required set of privileges.
- **Network** with DHCP server and access to the Internet.
- **Datacenter** with a tag in `k8s-region` category.
- **Cluster** with a tag in `k8s-zone` category.
- **Datastore** with required tags.
- **Template** — prepared VM image.

List of required privileges

> **i** Read the Configuration via vSphere Client and Configuration via govc sections for details on how to create and assign a role to a user.

A detailed list of privileges required for Deckhouse Platform to work in vSphere:

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

—	— (assigned by default when creating a role)	`System.Anonymous`
		`System.Read`
		`System.View`
			Basic access to vSphere Inventory objects required for all Deckhouse vSphere integration components.

Cns	Searchable	`Cns.Searchable`	Search and mapping of Container Native Storage objects when the CSI driver works with Kubernetes volumes.

Datastore	Allocate space,
	Browse datastore,
	Low level file operations
		`Datastore.AllocateSpace`
		`Datastore.Browse`
		`Datastore.FileManagement`
			Disk provisioning when creating virtual machines and ordering `PersistentVolumes` in the cluster.

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

Folder	Create folder,
	Delete folder,
	Move folder,
	Rename folder
		`Folder.Create`
		`Folder.Delete`
		`Folder.Move`
		`Folder.Rename`
			Grouping a Deckhouse Platform cluster in a single `Folder` in vSphere Inventory.

Global	Global tag, System tag	`Global.GlobalTag` `Global.SystemTag`	Access to global and system tags used by Deckhouse Platform when working with vSphere objects.

vSphere Tagging	Assign or Unassign vSphere Tag,
	Assign or Unassign vSphere Tag on Object,
	Create vSphere Tag,
	Create vSphere Tag Category,
	Delete vSphere Tag,
	Delete vSphere Tag Category,
	Edit vSphere Tag,
	Edit vSphere Tag Category,

		`InventoryService.Tagging.AttachTag`
		`InventoryService.Tagging.ObjectAttachable`
		`InventoryService.Tagging.CreateTag`
		`InventoryService.Tagging.CreateCategory`
		`InventoryService.Tagging.DeleteTag`
		`InventoryService.Tagging.DeleteCategory`
		`InventoryService.Tagging.EditTag`
		`InventoryService.Tagging.EditCategory`
		`InventoryService.Tagging.ModifyUsedByForCategory`
		`InventoryService.Tagging.ModifyUsedByForTag`
			Deckhouse Platform uses tags to identify the `Datacenter`, `Cluster`, and `Datastore` objects available to it, as well as to identify the virtual machines under its control.

Network	Assign network	`Network.Assign`	Connecting networks and port groups to Deckhouse Platform cluster virtual machines.

Resource	Assign virtual machine to resource pool,
	Create resource pool,
	Modify resource pool,
	Remove resource pool,
	Rename resource pool
		`Resource.AssignVMToPool`
		`Resource.CreatePool`
		`Resource.DeletePool`
		`Resource.EditPool`
		`Resource.RenamePool`
			Placement of Deckhouse Platform cluster virtual machines into the target resource pool and management of this pool.

VM Storage Policies (*Profile-driven Storage Privileges* in vSphere 7)	View VM storage policies (*Profile-driven storage view* in vSphere 7)	`StorageProfile.View`	Viewing storage policies used when creating virtual machines and dynamically provisioning volumes in the cluster.

vApp	Add virtual machine,
	Assign resource pool,
	Create,
	Delete,
	Import,
	Power Off,
	Power On,
	View OVF Environment,
	vApp application configuration,
	vApp instance configuration,
	vApp resource configuration
		`VApp.ApplicationConfig`
		`VApp.AssignResourcePool`
		`VApp.AssignVM`
		`VApp.Create`
		`VApp.Delete`
		`VApp.ExtractOvfEnvironment`
		`VApp.Import`
		`VApp.InstanceConfig`
		`VApp.PowerOff`
		`VApp.PowerOn`
		`VApp.ResourceConfig`
			Managing operations related to deployment and configuration of vApp and OVF templates used when creating virtual machines.

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

Virtual Machine > Change Configuration	Add existing disk,
	Add new disk,
	Add or remove device,
	Advanced configuration,
	Set annotation,
	Change CPU count,
	Toggle disk change tracking,
	Extend virtual disk,
	Acquire disk lease,
	Modify device settings,
	Configure managedBy,
	Change Memory,
	Query unowned files,
	Configure Raw device,
	Reload from path,
	Remove disk,

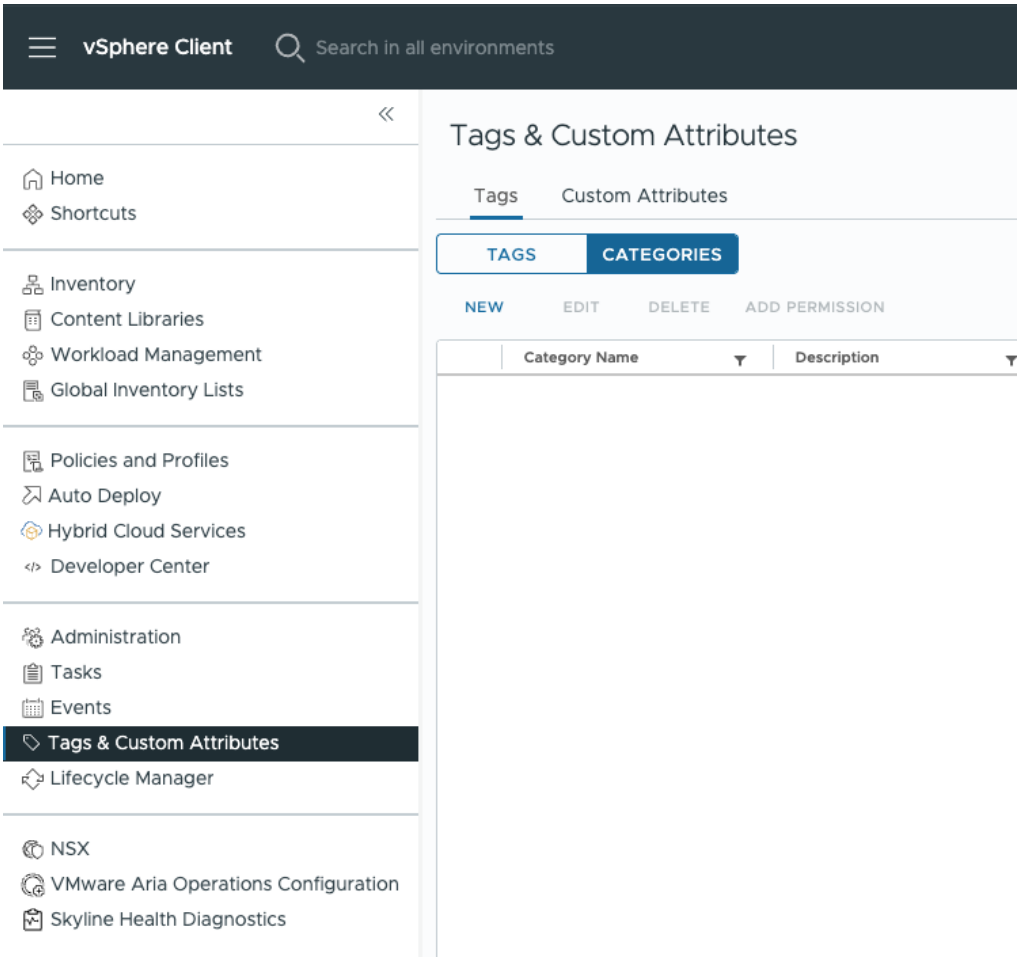
		`VirtualMachine.Interact.PowerOff`
		`VirtualMachine.Interact.PowerOn`
		`VirtualMachine.Interact.Reset`
		`VirtualMachine.Interact.SetCDMedia`
		`VirtualMachine.Interact.ToolsInstall`
			Managing virtual machine power state, device connections, and interaction with the guest operating system.

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

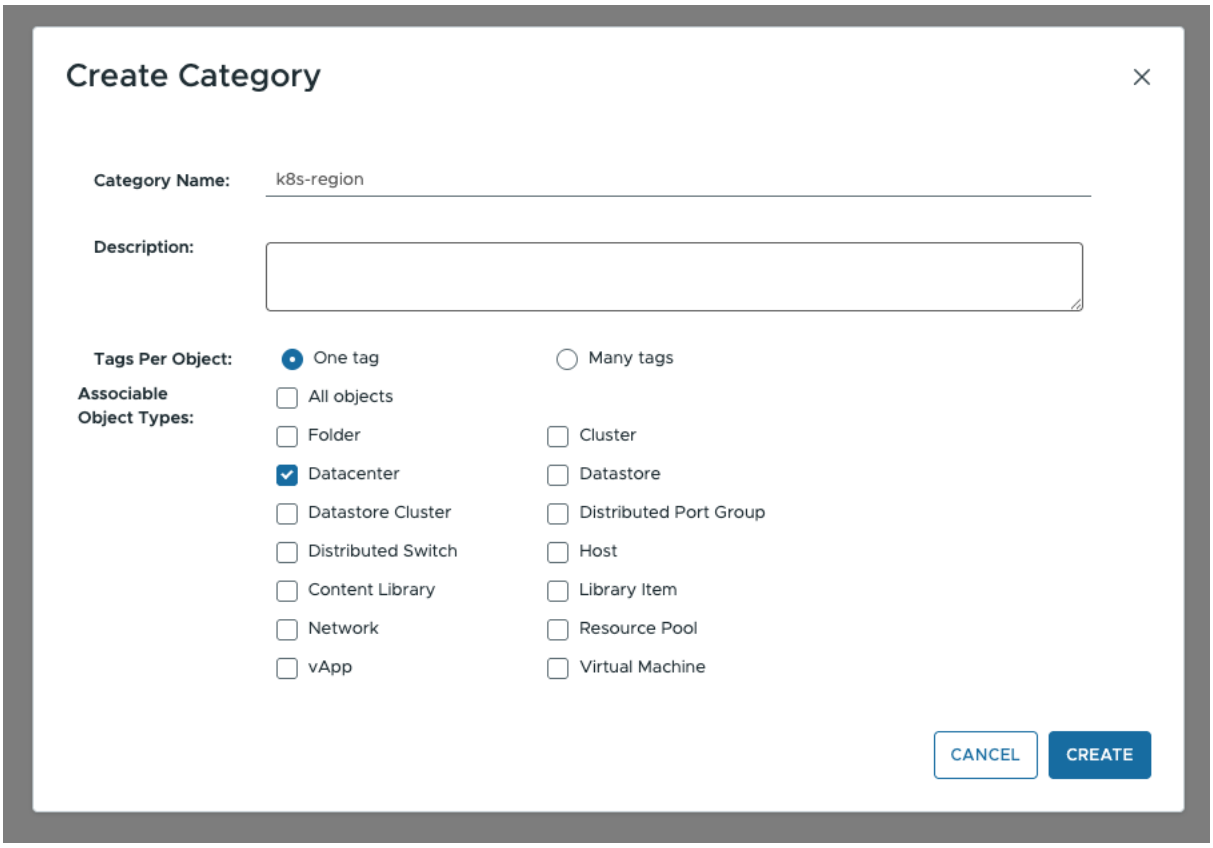
Virtual Machine > Provisioning	Clone virtual machine,
	Customize guest,
	Deploy template,
	Allow virtual machine download,
	Allow virtual machine files upload,
	Read customization specifications
		`VirtualMachine.Provisioning.Clone`
		`VirtualMachine.Provisioning.Customize`
		`VirtualMachine.Provisioning.DeployTemplate`
		`VirtualMachine.Provisioning.GetVmFiles`
		`VirtualMachine.Provisioning.PutVmFiles`
		`VirtualMachine.Provisioning.ReadCustSpecs`
			Cloning virtual machine templates, customizing them, and deploying them when creating Deckhouse Platform cluster nodes.

Virtual Machine > Snapshot Management	Create snapshot,
	Remove Snapshot,
	Rename Snapshot
		`VirtualMachine.State.CreateSnapshot`
		`VirtualMachine.State.RemoveSnapshot`
		`VirtualMachine.State.RenameSnapshot`
			Managing snapshots of virtual machines and volumes in scenarios where this functionality is used by platform components.



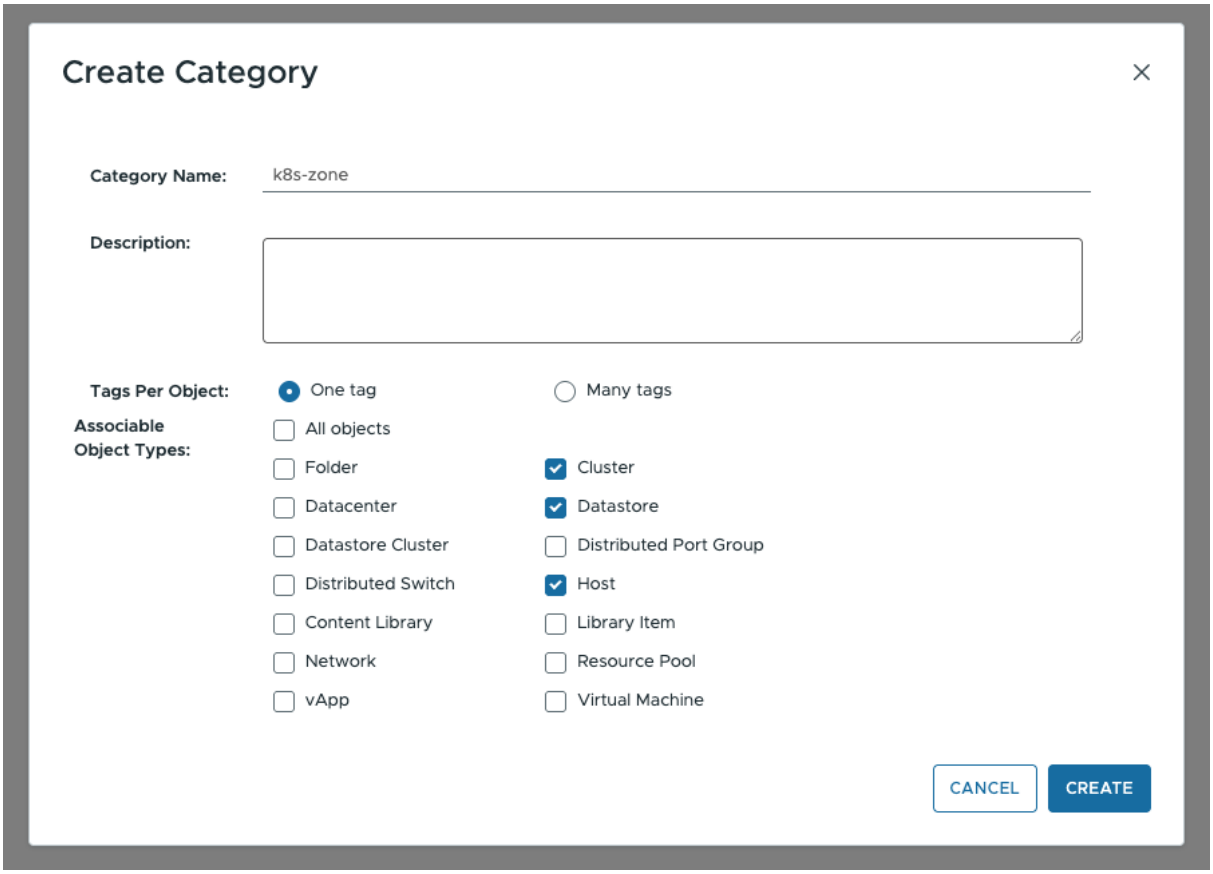
vSphere configuration

Configuration in vSphere Client

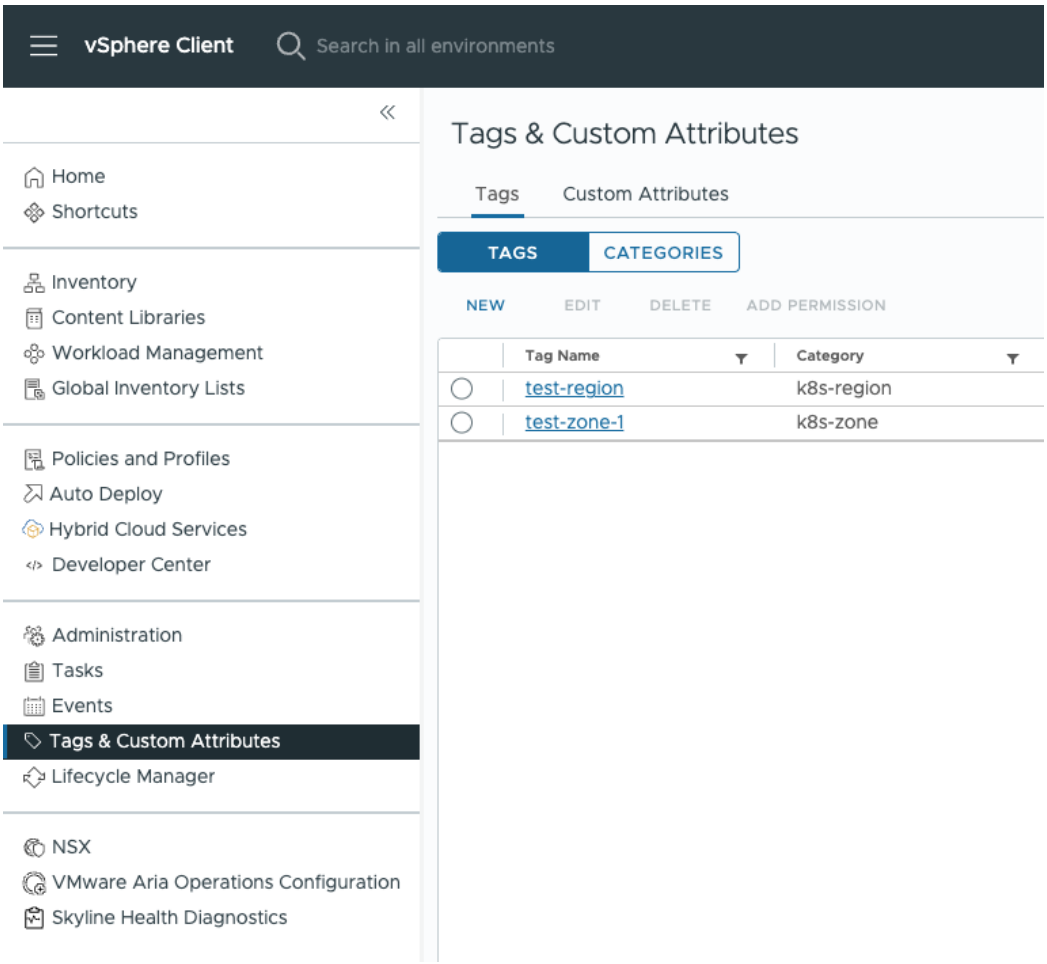


Creating tags and tag categories in vSphere Client

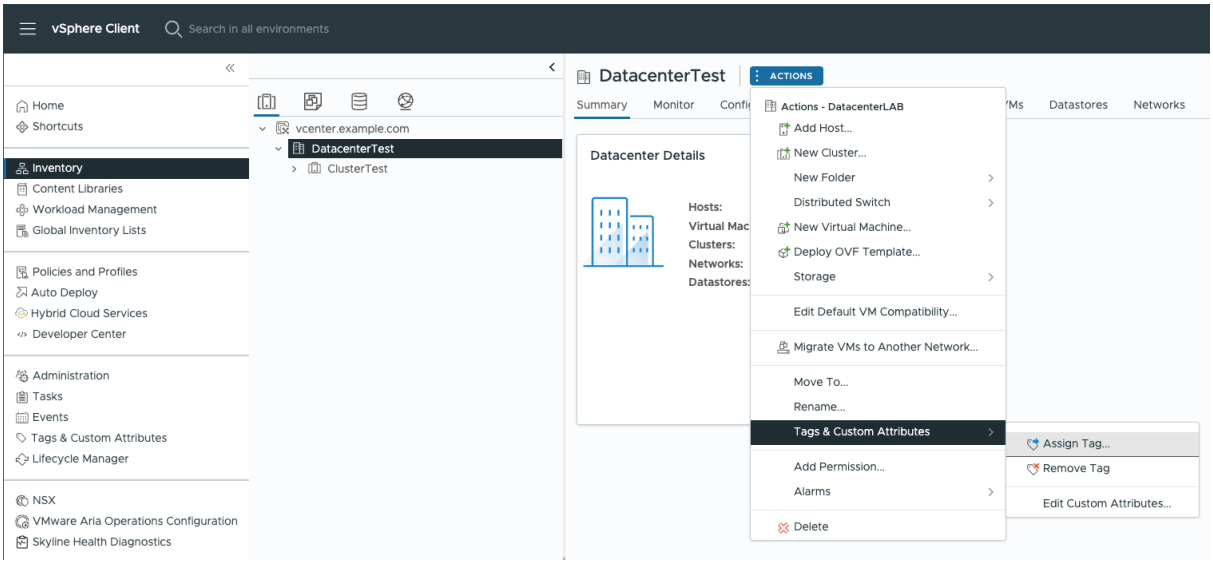
VMware vSphere does not have built-in concepts of a “region” or a “zone”. In vSphere, a Datacenter acts as a region, and a Cluster acts as a zone. Tags are used to establish this mapping.



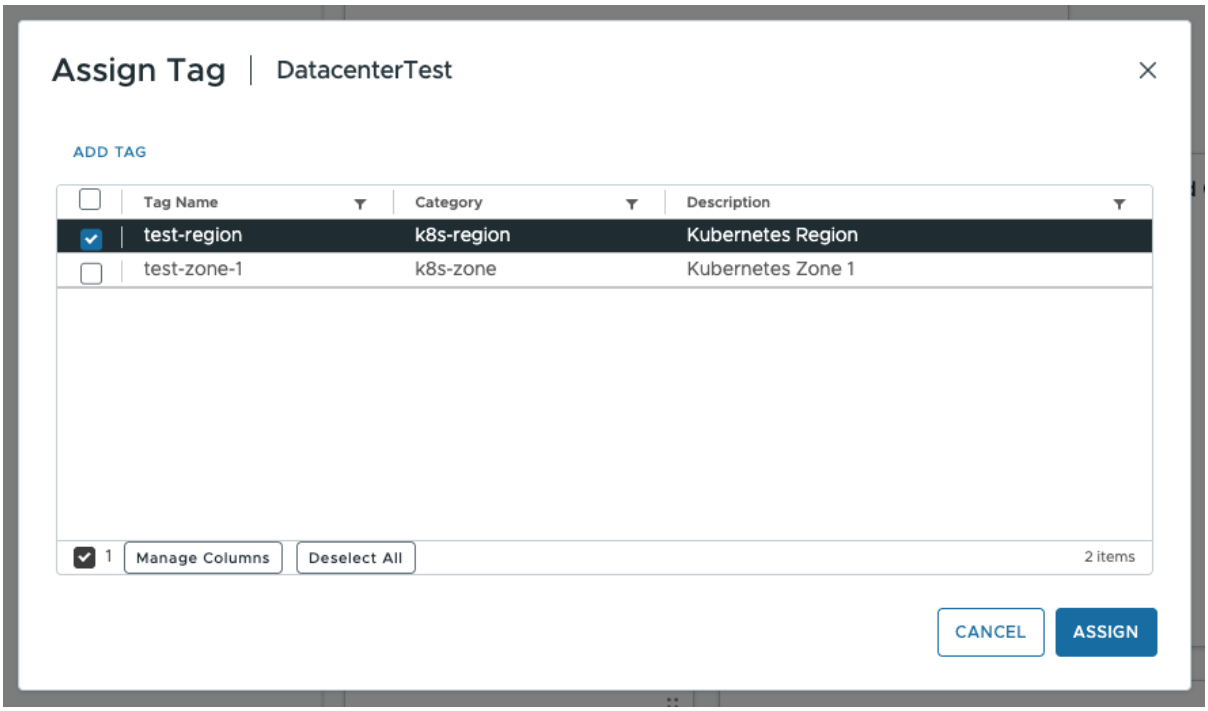
1. Open vSphere Client and go to “Menu” → “Tags & Custom Attributes” → “Tags”.



2. Open the “Categories” tab and click “NEW”. Create a category for regions (for example, `k8s-region`): set “Tags Per Object” to “One tag” and specify the applicable object types, including Datacenter.

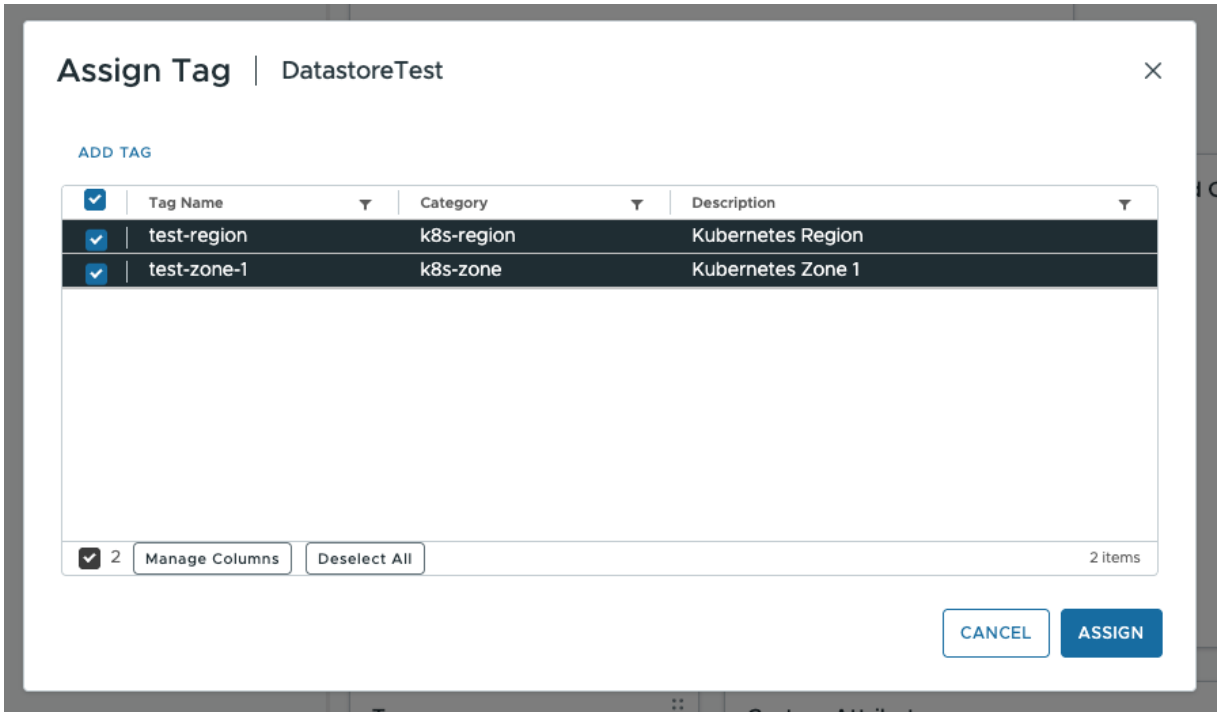


3. Create a second category for zones (for example, `k8s-zone`) with the object types Host, Cluster, and Datastore.

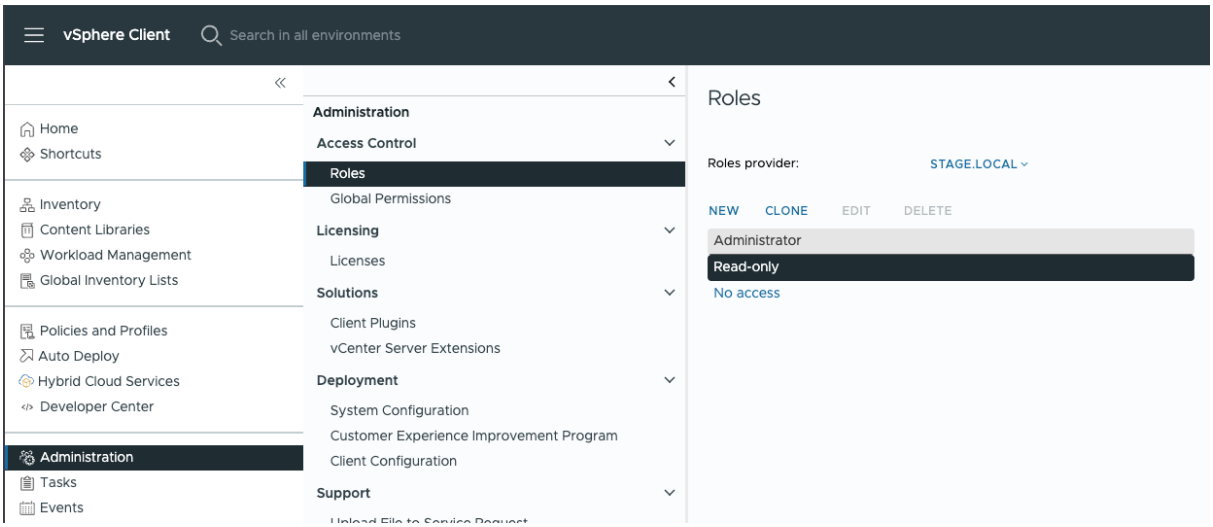


4. Go to the “Tags” tab and create at least one tag in the region category and one tag in the zone category (for example, `test-region`, `test-zone-1`).

5. In the “Inventory” tab, select the target Datacenter, open the “Summary” panel, then choose “Actions” → “Tags & Custom Attributes” → “Assign Tag” and assign the region tag. Repeat this step for each Cluster that will host nodes, assigning the appropriate zone tags.

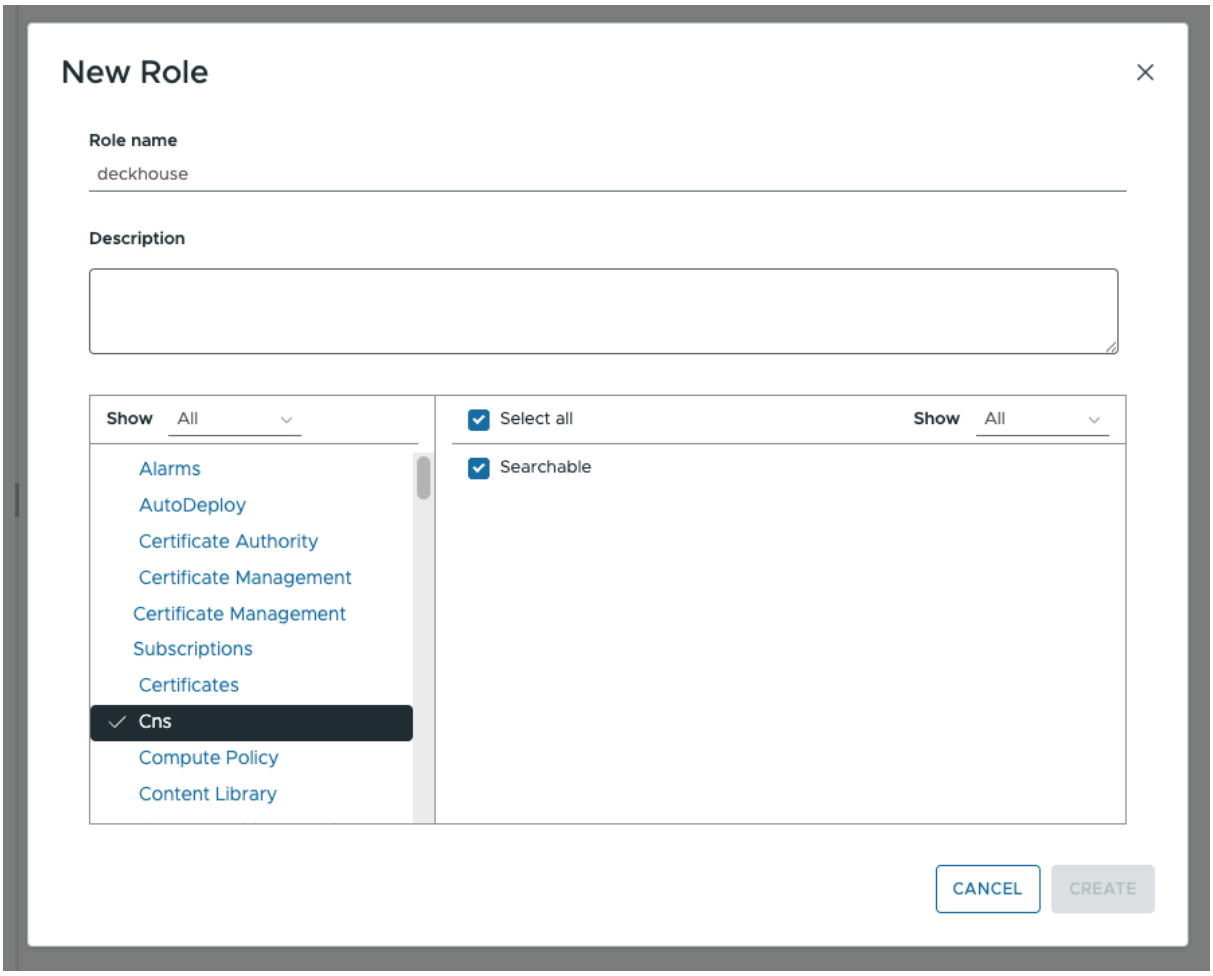


Configuring Datastore in vSphere Client

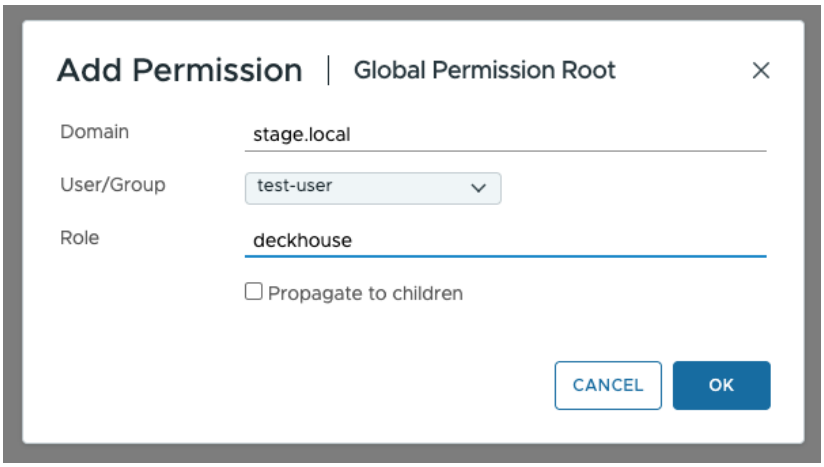


> ⚠ For dynamic provisioning of PersistentVolume, the Datastore must be available on **every** ESXi host in the zone (shared datastore).

In the “Inventory” tab, select the Datastore, open the “Summary” panel, then choose “Actions” → “Tags & Custom Attributes” → “Assign Tag”. Assign the Datastore the same region tag as the corresponding Datacenter, and the same zone tag as the corresponding Cluster.



Creating and assigning a role in vSphere Client



1. Go to “Menu” → “Administration” → “Access Control” → “Roles”.

2. Click “NEW”, enter a role name (for example, `deckhouse`), and add the privileges from the list.

3. Assign the role to the Deckhouse service account: go to “Menu” → “Administration” → “Access Control” → “Global Permissions”, click “ADD”, and select the user and the `deckhouse` role.

Configuration via govc

Installing govc

To continue configuring vSphere, install the govc CLI utility.

After installation, set the environment variables required to connect to `vCenter`.

⚠ Make sure to specify the username together with the domain, for example: `username@domain.local`.

```
export GOVC_URL=example.com
export GOVC_USERNAME=<username>@vsphere.local
export GOVC_PASSWORD=<password>
export GOVC_INSECURE=1
```

Creating tags and tag categories with govc

VMware vSphere does not have built-in concepts of a “region” or a “zone”. In vSphere, a Datacenter acts as a region, and a Cluster acts as a zone. Tags are used to establish this mapping.

Create tag categories with the following commands:

```
govc tags.category.create -d "Kubernetes Region" k8s-region
govc tags.category.create -d "Kubernetes Zone" k8s-zone
```

Create tags in each category. If you intend to use multiple “zones” (Cluster), create a tag for each one of them:

```
govc tags.create -d "Kubernetes Region" -c k8s-region test-region
govc tags.create -d "Kubernetes Zone Test 1" -c k8s-zone test-zone-1
govc tags.create -d "Kubernetes Zone Test 2" -c k8s-zone test-zone-2
```

Attach the “region” tag to Datacenter:

```
govc tags.attach -C k8s-region test-region /<DATACENTER_NAME>
```

Attach “zone” tags to the Cluster objects:

```
govc tags.attach -C k8s-zone test-zone-1 /<DATACENTER_NAME>/host/<CLUSTER_NAME_1>
govc tags.attach -C k8s-zone test-zone-2 /<DATACENTER_NAME>/host/<CLUSTER_NAME_2>
```

Datastore configuration with govc

⚠ For dynamic PersistentVolume provisioning, a Datastore must be available on **each** ESXi host (shared datastore).

Assign the “region” and “zone” tags to the Datastore objects to automatically create a StorageClass in the Kubernetes cluster:

```
govc tags.attach -C k8s-region test-region /<DATACENTER_NAME>/datastore/<DATASTORE_NAME_1>
govc tags.attach -C k8s-zone test-zone-1 /<DATACENTER_NAME>/datastore/<DATASTORE_NAME_1>

govc tags.attach -C k8s-region test-region /<DATACENTER_NAME>/datastore/<DATASTORE_NAME_2>
govc tags.attach -C k8s-zone test-zone-2 /<DATACENTER_NAME>/datastore/<DATASTORE_NAME_2>
```

Creating and assigning a role with govc

> **i** We've intentionally skipped User creation since there are many ways to authenticate a user in the vSphere.
>
> The role described below includes the privileges from the list of required privileges section. If you need a more granular Role, please contact your Deckhouse support.

Create a role with the required privileges:

```
govc role.create deckhouse \
    Cns.Searchable \
    Datastore.AllocateSpace Datastore.Browse Datastore.FileManagement \
    Folder.Create Folder.Delete Folder.Move Folder.Rename \
    Global.GlobalTag Global.SystemTag \
    InventoryService.Tagging.AttachTag InventoryService.Tagging.CreateCategory \
    InventoryService.Tagging.CreateTag InventoryService.Tagging.DeleteCategory \
    InventoryService.Tagging.DeleteTag InventoryService.Tagging.EditCategory \
    InventoryService.Tagging.EditTag InventoryService.Tagging.ModifyUsedByForCategory \
    InventoryService.Tagging.ModifyUsedByForTag InventoryService.Tagging.ObjectAttachable \
    Network.Assign \
    Resource.AssignVMToPool Resource.CreatePool Resource.DeletePool Resource.EditPool Resource.RenamePool \
    StorageProfile.View \
    System.Anonymous System.Read System.View \
    VApp.ApplicationConfig VApp.AssignResourcePool VApp.AssignVM VApp.Create VApp.Delete \
    VApp.ExtractOvfEnvironment VApp.Import VApp.InstanceConfig VApp.PowerOff VApp.PowerOn VApp.ResourceConfig \
    VirtualMachine.Config.AddExistingDisk VirtualMachine.Config.AddNewDisk VirtualMachine.Config.AddRemoveDevice \
    VirtualMachine.Config.AdvancedConfig VirtualMachine.Config.Annotation VirtualMachine.Config.CPUCount \
    VirtualMachine.Config.ChangeTracking VirtualMachine.Config.DiskExtend VirtualMachine.Config.DiskLease \
    VirtualMachine.Config.EditDevice VirtualMachine.Config.ManagedBy VirtualMachine.Config.Memory \
    VirtualMachine.Config.QueryUnownedFiles VirtualMachine.Config.RawDevice VirtualMachine.Config.ReloadFromPath \
    VirtualMachine.Config.RemoveDisk VirtualMachine.Config.Rename VirtualMachine.Config.ResetGuestInfo \
    VirtualMachine.Config.Resource VirtualMachine.Config.Settings VirtualMachine.Config.SwapPlacement \
    VirtualMachine.Config.UpgradeVirtualHardware \
    VirtualMachine.GuestOperations.Query \
    VirtualMachine.Interact.AnswerQuestion VirtualMachine.Interact.DeviceConnection \
    VirtualMachine.Interact.GuestControl VirtualMachine.Interact.PowerOff VirtualMachine.Interact.PowerOn \
    VirtualMachine.Interact.Reset VirtualMachine.Interact.SetCDMedia VirtualMachine.Interact.ToolsInstall \
    VirtualMachine.Inventory.Create VirtualMachine.Inventory.CreateFromExisting VirtualMachine.Inventory.Delete \
    VirtualMachine.Inventory.Move \
    VirtualMachine.Provisioning.Clone VirtualMachine.Provisioning.Customize VirtualMachine.Provisioning.DeployTemplate \
    VirtualMachine.Provisioning.GetVmFiles VirtualMachine.Provisioning.PutVmFiles VirtualMachine.Provisioning.ReadCustSpecs
\
    VirtualMachine.State.CreateSnapshot VirtualMachine.State.RemoveSnapshot VirtualMachine.State.RenameSnapshot
```

Assign the role to a user on the vCenter object.

> **⚠** Make sure to specify the username together with the domain, for example: `username@domain.local`.

```
govc permissions.set -principal <username>@vsphere.local -role deckhouse /
```

> **i** For more detailed permission configuration, refer to the official documentation.

VM image requirements

To create a VM template (`Template`), it is recommended to use a ready-made cloud image/OVA file provided by the OS vendor:

- **Ubuntu**
- **Debian**
- **CentOS**
- **Rocky Linux** (section *Generic Cloud / OpenStack*)

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Preparing the virtual machine image

⚠ Disable VMware Guest OS Customization (and any vApp/OS customization mechanisms, if applicable in your setup) for the template and the cluster virtual machines. DP performs the initial node configuration via `cloud-init` (VMware GuestInfo datasource). Enabled customization can conflict with `cloud-init` and lead to incorrect node initialization.

1. Install the required packages:

   If you use `cloud-init` version lower than 21.3 (VMware GuestInfo support is required):

   ```
   sudo apt-get update
   sudo apt-get install -y open-vm-tools cloud-init cloud-init-vmware-guestinfo
   ```

   If you use `cloud-init` version 21.3 or higher:

   ```
   sudo apt-get update
   sudo apt-get install -y open-vm-tools cloud-init
   ```

2. Verify that the `disable_vmware_customization: false` parameter is set in `/etc/cloud/cloud.cfg`.
3. Make sure the `default_user` parameter is specified in `/etc/cloud/cloud.cfg`. It is required to add an SSH key when the VM starts.
4. Add the VMware GuestInfo datasource — create `/etc/cloud/cloud.cfg.d/99-DataSourceVMwareGuestInfo.cfg`:

   ```
   datasource:
     VMware:
       vmware_cust_file_max_wait: 10
   ```

5. Before creating the VM template, reset the `cloud-init` identifiers and state using the following commands:

   ```
   truncate -s 0 /etc/machine-id &&
   rm /var/lib/dbus/machine-id &&
   ln -s /etc/machine-id /var/lib/dbus/machine-id
   ```

6. Clear `cloud-init` event logs:

   ```
   cloud-init clean --logs --seed
   ```

⚠ After the virtual machine starts, the following services related to the packages installed during `cloud-init` preparation must be running:

- `cloud-config.service`,
- `cloud-final.service`,
- `cloud-init.service`.

To ensure that the services are enabled, use the command:

```
systemctl is-enabled cloud-config.service cloud-init.service cloud-final.service
```

Example output for enabled services:

```
enabled
enabled
enabled
```

i DP creates VM disks of type `eagerZeroedThick`, but the type of disks of created VMs may be changed without notification according to the `VM Storage Policy` settings in vSphere.
For more details, see the documentation.

i DP uses the `ens192` interface as the default interface for VMs in vSphere. Therefore, when using static IP addresses in `mainNetwork`, you must create an interface named `ens192` in the OS image as the default interface.

Replacing the OS image

Deckhouse Platform creates the nodes from a virtual machine template that is specified in the `template` parameter of the VsphereInstanceClass resource for `CloudEphemeral` nodes and in the `instanceClass` section of the VsphereClusterConfiguration resource for `CloudPermanent` nodes and master nodes.

To move the nodes to a new OS image, prepare a new template based on it and follow the steps from “How do I replace the OS image in a cloud cluster?”.

Infrastructure

Networking

A VLAN with DHCP and Internet access is required for the running cluster:

- If the VLAN is public (public addresses), then you have to create a second network to deploy cluster nodes (DHCP is not needed in this network).
- If the VLAN is private (private addresses), then this network can be used for cluster nodes.

Inbound traffic

- You can use an internal load balancer (if present) and direct traffic directly to the front nodes of the cluster.
- If there is no load balancer, you can use MetalLB in BGP mode to organize fault-tolerant load balancers (recommended). In this case, front nodes of the cluster will have two interfaces. For this, you will need:
  - A dedicated VLAN for traffic exchange between BGP routers and MetalLB. This VLAN must have DHCP and Internet access.
  - IP addresses of BGP routers.
  - ASN — the AS number on the BGP router.
  - ASN — the AS number in the cluster.
  - A range to announce addresses from.

Using the datastore

Various types of storage can be used in the cluster; for the minimum configuration, you will need:

- Datastore for provisioning PersistentVolumes to the Kubernetes cluster.
- Datastore for provisioning root disks for the VMs (it can be the same Datastore as for PersistentVolume).

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> **i** The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

VsphereInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of vSphere VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines’ secondary NICs will connect to. Relative to the datacenter.

    Examples:

    ```
    additionalNetworks: DEVOPS_32
    ```

```
additionalNetworks: DEVOPS_50
```

- **spec.datastore**
  string

  Path to a Datastore in which VirtualMachines will be cloned. Relative to the datacenter.

  Both a plain Datastore name (`lun-1201`) and a path with parent folders (`DS_PARENT_FOLDER/lun-1201`) are supported.

  By default, a datastore from the `master` InstanceClass is used.

  Example:

  ```
  datastore: lun-1201
  ```

- **spec.disableTimesync**
  boolean

  Disable time synchronization in Guest VM.

  > **Note:** this won't disable any NTP daemons running on the guest OS, it only disables time synchronization from ESXi.

  Default: `true`

- **spec.mainNetwork**
  string

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway). Relative to the datacenter.

  If no value is specified, the value specified in `VsphereClusterConfiguration` will be used.

  Example:

  ```
  mainNetwork: k8s-msk-178
  ```

- **spec.memory**
  integer

  Required value

  Memory in MiB to allocate to vSphere VirtualMachines.

  Example:

  ```
  memory: 8192
  ```

- **spec.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **spec.resourcePool**
  string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  By default, the value from `VsphereCloudDiscoveryData` is used.

  Example:

  ```
  resourcePool: rp-2012
  ```

- **spec.rootDiskSize**
  integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Default: `20`

  Example:

  ```
  rootDiskSize: 20
  ```

- **spec.runtimeOptions**
  object

  Additional VM’s parameters.

  - **spec.runtimeOptions.cpuLimit**
    integer

    CPU limit in MHz.

  - **spec.runtimeOptions.cpuReservation**
    integer

    CPU reservation in MHz.

  - **spec.runtimeOptions.cpuShares**
    integer

    The relative amount of CPU Shares for VMs to be created.

  - **spec.runtimeOptions.memoryLimit**
    integer

    Memory limit in MB.

  - **spec.runtimeOptions.memoryReservation**
    integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Default: `80`

    Allowed values: `0 <= X <= 100`

  - **spec.runtimeOptions.memoryShares**
    integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **spec.runtimeOptions.nestedHardwareVirtualization**
    boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

- **spec.template**
  string

  Path to the template to be cloned. Relative to the datacenter.

  By default, a template from the `master` InstanceClass is used.

  Example:

  ```
  template: dev/golden_image
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of vSphere VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines’ secondary NICs will connect to. Relative to the datacenter.

    Examples:

    ```
    additionalNetworks: DEVOPS_32
    ```

    ```
    additionalNetworks: DEVOPS_50
    ```

  - **spec.datastore**
    string

    Path to a Datastore in which VirtualMachines will be cloned. Relative to the datacenter.

    Both a plain Datastore name (`lun-1201`) and a path with parent folders (`DS_PARENT_FOLDER/lun-1201`) are supported.

By default, a datastore from the `master` InstanceClass is used.

Example:

```
datastore: lun-1201
```

- **spec.disableTimesync**
  boolean

  Disable time synchronization in Guest VM.

  > **i** **Note:** this won't disable any NTP daemons running on the guest OS, it only disables time synchronization from ESXi.

  Default: `true`

- **spec.mainNetwork**
  string

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway). Relative to the datacenter.

  If no value is specified, the value specified in `VsphereClusterConfiguration` will be used.

  Example:

  ```
  mainNetwork: k8s-msk-178
  ```

- **spec.memory**
  integer

  Required value

  Memory in MiB to allocate to vSphere VirtualMachines.

  Example:

  ```
  memory: 8192
  ```

- **spec.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **spec.resourcePool**
  string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  By default, the value from `VsphereCloudDiscoveryData` is used.

  Example:

  ```
  resourcePool: rp-2012
  ```

- **spec.rootDiskSize**
  integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Default: `20`

  Example:

  ```
  rootDiskSize: 20
  ```

- **spec.runtimeOptions**
  object

  Additional VM's parameters.

  - **spec.runtimeOptions.cpuLimit**
    integer

    CPU limit in MHz.

  - **spec.runtimeOptions.cpuReservation**

integer

CPU reservation in MHz.

- **spec.runtimeOptions.cpuShares**
  integer

  The relative amount of CPU Shares for VMs to be created.

- **spec.runtimeOptions.memoryLimit**
  integer

  Memory limit in MB.

- **spec.runtimeOptions.memoryReservation**
  integer

  VM memory reservation in percent (relative to `.spec.memory`).

  Default: `80`

  Allowed values: `0 <= X <= 100`

- **spec.runtimeOptions.memoryShares**
  integer

  The relative amount of Memory Shares for VMs to be created.

  Allowed values: `0 <= X <= 100`

- **spec.runtimeOptions.nestedHardwareVirtualization**
  boolean

  Whether to enable or disable nested Hardware Assisted Virtualization.

- **spec.template**
  string

  Path to the template to be cloned. Relative to the datacenter.

  By default, a template from the `master` InstanceClass is used.

  Example:

  ```
  template: dev/golden_image
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

The module lifecycle stage: General Availability

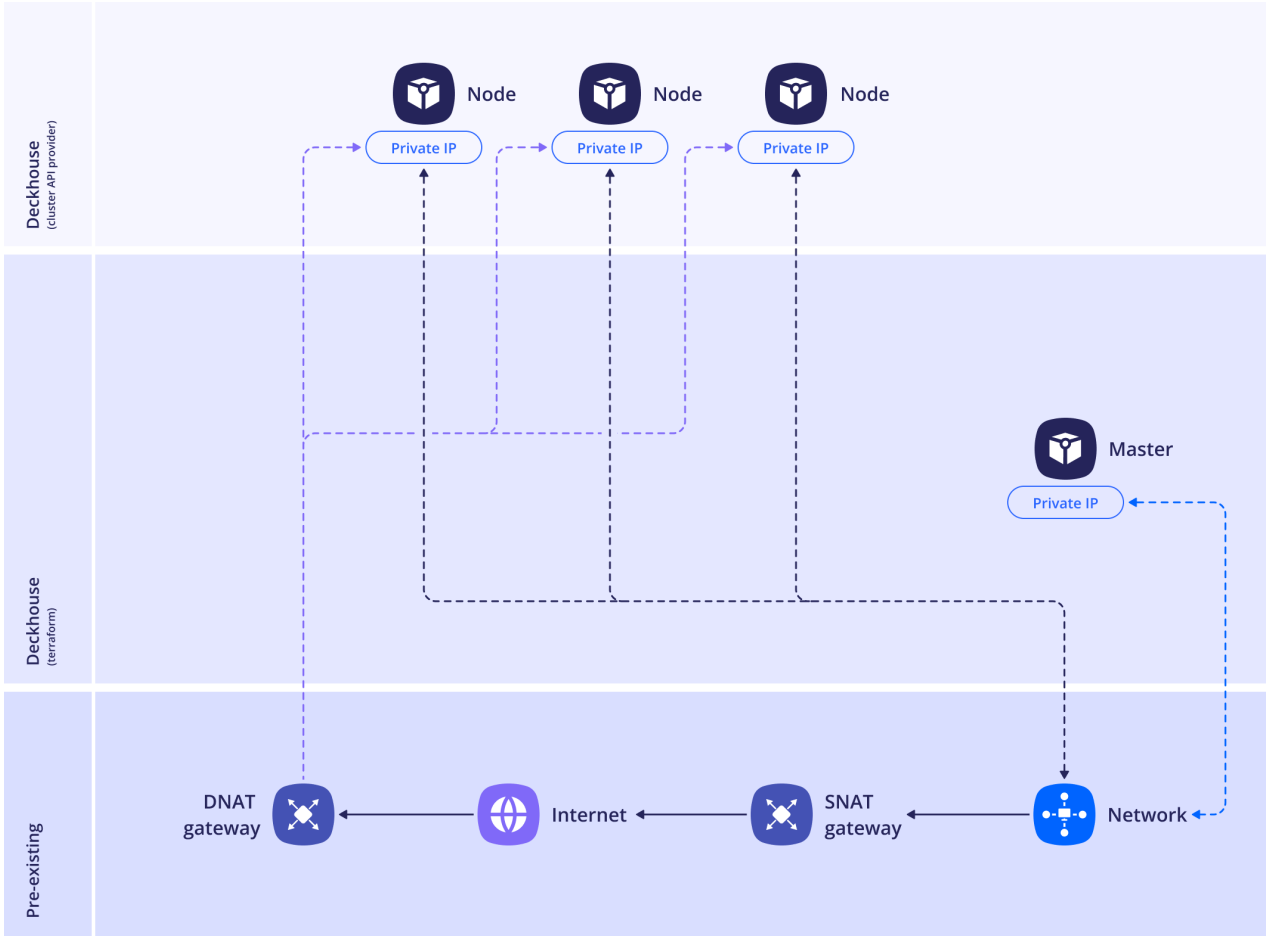
Below is an example configuration for a VMware vSphere cloud provider.

An example of the configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vsphere
spec:
  version: 2
  enabled: true
  settings:
    host: vc-3.internal
    username: user
    password: password
    vmFolderPath: dev/test
    insecure: true
    region: moscow-x001
    sshKeys:
    - "ssh-rsa AAAAB3N....6xHJwwj"
    externalNetworkNames:
    - KUBE-3
    - devops-internal
    internalNetworkNames:
    - KUBE-3
    - devops-internal
    nsxt:
      defaultIpPoolName: "External IP Pool"
      tier1GatewayPath: flant_tier1
      user: guestuser1
      password: pass
      host: 1.2.3.4
      insecureFlag: true
      size: SMALL
```

An example of the `VsphereInstanceClass` custom resource

```
apiVersion: deckhouse.io/v1
kind: VsphereInstanceClass
metadata:
  name: test
spec:
  numCPUs: 2
  memory: 2048
  rootDiskSize: 20
  template: dev/golden_image
  mainNetwork: k8s-msk-178
  datastore: <DS_PARENT_FOLDER>/lun-1201 # <DS_PARENT_FOLDER> — parent Datastore folder.
```



Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider - VMware vSphere: Layouts

The module lifecycle stage: General Availability

Standard

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: VsphereClusterConfiguration
layout: Standard
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
vmFolderPath: dev
regionTagCategory: k8s-region
zoneTagCategory: k8s-zone
region: X1
internalNetworkCIDR: 192.168.199.0/24
masterNodeGroup:
  replicas: 1
  zones:
  - ru-central1-a
  - ru-central1-b
  instanceClass:
    numCPUs: 4
    memory: 8192

- ru-central1-b
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — Yandex Cloud

The module lifecycle stage: General Availability

The `cloud-provider-yandex` module integrates Deckhouse Platform with Yandex Cloud. It allows the `node-manager` module to use Yandex Cloud resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-yandex` module:

- Managing Yandex Cloud resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the Yandex Cloud side;
  - creates Network Load Balancers and target groups for Services of the LoadBalancer type;
  - updates instance and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in Yandex Cloud.
- Provisioning disks via the Yandex CSI driver (`yandex.csi.flant.com`) and creating StorageClasses for Yandex Cloud disk types so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-yandex`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM) or Cluster API (CAPI). Virtual machine parameters are set in the YandexInstanceClass resource.
- Registering with `node-manager` so that YandexInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. Starting with DP 1.76, `cni-cilium` is used by default.

⚠ If the cluster was installed with the YandexClusterConfiguration schema, it must be migrated to the ModuleConfig-based configuration. Until the migration is complete, the `D8CloudProviderYandexCloudMigrationPending` alert fires and a Deckhouse Platform update can be blocked.

The migration procedure is described in “How to migrate a cloud provider to ModuleConfig-based configuration”.

⚠ The module is migrating CloudEphemeral node management from Machine Controller Manager (MCM) to Cluster API (CAPI). Existing NodeGroups continue to use MCM, while new ones are created with CAPI by default. For migrating existing groups, see “How to migrate node groups to Cluster API (CAPI)”.

Third-party components

List of third-party software used in the `cloud-provider-yandex` module:

- Yandex Cloud Terraform provider 0.174.0

  License: Mozilla Public License 2.0

  Terraform provider for Yandex Cloud.

- Yandex Cloud provider v0.33.7

  License: Apache License 2.0

  Cloud Controller Manager for Yandex Cloud.

- Yandex Cloud CSI driver v0.16.1

  License: Apache License 2.0

  CSI driver for Yandex Compute Disks.

- Yandex Cloud Cluster API provider v0.2.0

  License: Apache License 2.0

  Infrastructure provider for Kubernetes Cluster API in Yandex Cloud.

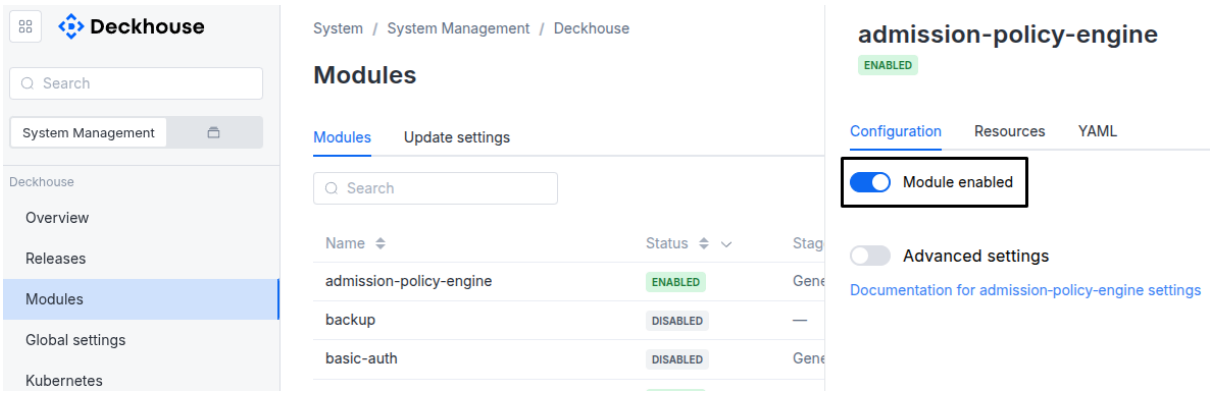
ℹ **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

ℹ The module lifecycle stage: General Availability

Deckhouse Platform reads the credentials for accessing the Yandex Cloud API from the `d8-credentials` Secret, whose format is described in “Credentials Secret”.



⚠ When the module settings change, the existing Machine objects are not recreated, and only new objects are created with the new parameters. Nodes are recreated when the parameters of NodeGroup and YandexInstanceClass change. For recreating nodes manually, see “How do I redeploy ephemeral machines in the cloud with a new configuration?”.

The module has 4 alerts.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-yandex` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

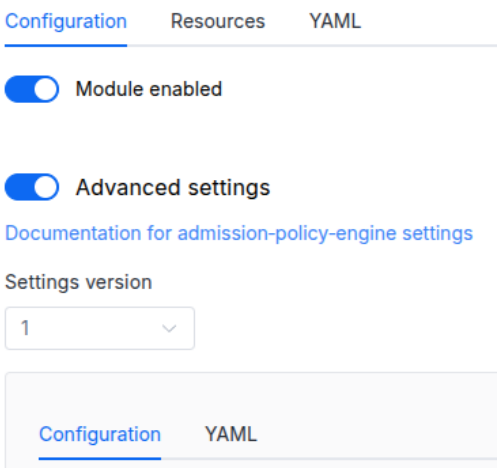
  ```
  d8 system module enable cloud-provider-yandex
  ```

- **Using ModuleConfig `cloud-provider-yandex`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-yandex` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-yandex`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-yandex
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-yandex` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-yandex` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-yandex`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-yandex` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-yandex
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the

`spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `cloud-provider-yandex` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-yandex`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  The settings are grouped under the `provider`, `nodes`, `storage`, and `ccm` parameters. The conversion does the following:

  - The `cloudID`, `folderID`, `layout`, `nodeNetworkCIDR`, and `sshPublicKey` parameters have to be filled in manually.
  - The `storageClass.exclude` parameter is renamed to `excludedStorageClasses`, and `storageClass.provision` to `provisionedStorageClasses`.
  - The `storageClass.default` parameter is removed. Set the default StorageClass with the global `defaultClusterStorageClass` parameter.
  - The `additionalExternalNetworkIDs` parameter is moved to `ccm.parameters.additionalExternalNetworkIDs`.

Module configuration

Every provider setting except the credentials is defined in the module’s ModuleConfig resource. Deckhouse Platform applies the settings both when creating a cluster and in a running cluster.

The settings are grouped under four top-level parameters:

- `provider` sets the Yandex Cloud cloud and folder IDs, the parameter is required;
- `nodes` sets the layout, the network parameters, and the parameters of the nodes being created, the parameter is required;
- `storage` sets the StorageClass the module creates;
- `ccm` sets how the cloud controller manager works.

The nodes, storage, and cloud controller manager subsystems are turned off with the nested `disabled` parameter.

Example module configuration with provider, node, storage, and cloud controller manager settings:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        cloudID: <CLOUD_ID>
        folderID: <FOLDER_ID>
    nodes:
      parameters:
        layout: Standard
        nodeNetworkCIDR: 10.241.32.0/20
        sshPublicKey: <SSH_PUBLIC_KEY>
    storage:
      parameters:
        excludedStorageClasses:
          - network-hdd
    ccm:
      parameters:
        additionalExternalNetworkIDs:
          - enp6t4snovl2ko4p15em
```

Where:

- `CLOUD ID` and `FOLDER_ID` are the Yandex Cloud cloud and folder IDs;
- `SSH_PUBLIC_KEY` is the public SSH key for accessing the nodes.

The virtual machine parameters are set in the YandexInstanceClass resource that a NodeGroup refers to.

Storage

The module automatically creates a StorageClass for every Yandex Cloud disk type:

Type	StorageClass name	Note
network-hdd	network-hdd	
network-ssd	network-ssd	
network-ssd-nonreplicated	network-ssd-nonreplicated	Disk size must be a multiple of 93 GB.
network-ssd-io-m3	network-ssd-io-m3	Disk size must be a multiple of 93 GB.

You can filter out the unnecessary StorageClasses via the `excludedStorageClasses` parameter.

The `provisionedStorageClasses` parameter lets you create additional StorageClasses or override the parameters of StorageClasses created by the module by default.

Use the `blockSize` parameter to set the block size for provisioned disks. The block size determines the maximum disk size. It is `8Ti` for `4Ki` and doubles with each next block size, up to `256Ti` for `128Ki`.

Example configuration of the `cloud-provider-yandex` module with an additional StorageClass configured with a block size of `64Ki`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        cloudID: <CLOUD_ID>
        folderID: <FOLDER_ID>
    nodes:
      parameters:
        layout: Standard
        nodeNetworkCIDR: 192.168.12.0/24
        sshPublicKey: <SSH_PUBLIC_KEY>
    storage:
      parameters:
        provisionedStorageClasses:
          - name: network-ssd-64k
            type: network-ssd
            blockSize: 64Ki
```

⚠ After a disk is created, its block size cannot be changed. Changing the `blockSize` parameter recreates the StorageClass, but does not change the block size of previously provisioned volumes.

LoadBalancer

The module watches Service objects of the `LoadBalancer` type and creates a network load balancer and a target group for them in Yandex Cloud. The annotations that configure the balancer are listed in “Service annotations”.

For more information, see the Kubernetes Cloud Controller Manager for Yandex Cloud documentation.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.ccm**
    object

    Cloud Controller Manager (CCM) subsystem settings.

    CCM creates Network Load Balancers and target groups for Service objects of the `LoadBalancer` type, maintains routes to pod subnets in the route table, and keeps node metadata up to date.

    - **settings.ccm.disabled**
      boolean

      Disables the Cloud Controller Manager.

      When set to `true`, the cluster does not manage load balancers and routes in Yandex Cloud.

      Default: `false`

    - **settings.ccm.parameters**
      object

      Required value

      Parameters of the Cloud Controller Manager subsystem.

      - **settings.ccm.parameters.additionalExternalNetworkIDs**
        array of strings

        Additional external network IDs to be recognized as external networks by the CCM.

      - **settings.ccm.parameters.additionalInternalNetworkIDs**
        array of strings

        Additional internal network IDs to be recognized as internal networks by the CCM.

  - **settings.nodes**
    object

    Required value

    Nodes subsystem settings.

    The subsystem describes the infrastructure the cluster nodes are created in, including the layout, the networks,

the zones, and the SSH key.

- **settings.nodes.disabled**
  boolean

  Disables the nodes subsystem.

  When set to `true`, the cluster creates no nodes in Yandex Cloud, and the cloud controller manager does not start either.

  Default: `false`

- **settings.nodes.parameters**
  object

  Required value

  Parameters of the nodes subsystem.

  - **settings.nodes.parameters.dhcpOptions**
    object

    A list of DHCP parameters to use for all subnets.

    Setting the parameter can disrupt name resolution on the nodes. The symptoms and the ways to address them are described in DHCPOptions-related problems and ways to address them.

    - **settings.nodes.parameters.dhcpOptions.domainName**
      string

      Domain appended to an incomplete host name when the node resolves it.

    - **settings.nodes.parameters.dhcpOptions.domainNameServers**
      array of strings

      A list of recursive DNS addresses.

  - **settings.nodes.parameters.existingNetworkID**
    string

    The ID of the existing VPC Network.

  - **settings.nodes.parameters.existingRouteTableID**
    string

    The ID of the existing route table associated with the subnets.

    Normally the value is produced when DP creates the infrastructure. Set the parameter explicitly in a cluster where DP does not create the infrastructure, for example in a cluster with static master nodes that adds ephemeral nodes in Yandex Cloud.

  - **settings.nodes.parameters.existingZoneToSubnetIDMap**
    object

    One or more pre-existing subnets mapped to respective zone.

    Warning. With the `cni-simple-bridge` module, DP creates a route table that has to be associated with the listed subnets manually. A subnet accepts only one route table, so two clusters using `cni-simple-bridge` cannot share subnets. Starting with DP 1.76, new clusters in Yandex Cloud use the `cni-cilium` module in VXLAN mode, where pod traffic routing does not depend on Yandex Cloud route tables.

  - **settings.nodes.parameters.externalIPAddresses**
    object

    External IP addresses per node group name.

    The key is the node group name (e.g., `system`, `master`, `worker`), and the value is the list of external IP addresses for nodes in that group, listed in the order of the zones where nodes will be created.

    The following values can be specified in the list:

    - IP address from an additional external network for the corresponding zone, listed in the `externalSubnetIDs` parameter;
    - reserved public IP address, if the `externalSubnetIDs` parameter is not set;
    - `Auto`, to order a public IP address in the corresponding zone.
  - **settings.nodes.parameters.externalSubnetIDs**
    object

    IDs of additional external networks per node group name.

    The key is the node group name (e.g., `system`, `master`, `worker`), and the value is the list of external subnet IDs for nodes in that group, listed in the order of the zones where nodes will be created.

  - **settings.nodes.parameters.labels**
    object

    Labels to attach to resources created in the Yandex Cloud.

    Note that you have to re-create all the machines to add new labels if labels were modified in the

running cluster.

- **settings.nodes.parameters.layout**
  string

  Required value

  The way resources are located in the cloud.

  The available layouts are described in “Layouts”.

  Allowed values: `Standard`, `WithoutNAT`, `WithNATInstance`

- **settings.nodes.parameters.nodeNetworkCIDR**
  string

  Required value

  IP address range for node subnets.

  Deckhouse Platform divides the range into four equal parts:

  - `ru-central1-a` uses the first part.
  - `ru-central1-b` uses the second part.
  - `ru-central1-e` uses the third part.
  - `ru-central1-d` uses the fourth part.

  Instructions for using the `ru-central1-f` zone are provided in “Using the ru-central1-f zone”.

- **settings.nodes.parameters.sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **settings.nodes.parameters.withNATInstance**
  object

  Settings for the `WithNATInstance` layout.

  - **settings.nodes.parameters.withNATInstance.externalSubnetID**
    string

    If specified, an additional network interface will be added to the node (the latter will use it as a default route).

  - **settings.nodes.parameters.withNATInstance.internalSubnetCIDR**
    string

    CIDR of an automatically created subnet for the internal interface. Takes precedence over the `internalSubnetID` parameter.

  - **settings.nodes.parameters.withNATInstance.internalSubnetID**
    string

    ID of a subnet for the internal interface.

  - **settings.nodes.parameters.withNATInstance.natInstanceExternalAddress**
    string

    A reserved external IP address. When the `externalSubnetID` parameter is set, specify an address from that subnet.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **settings.nodes.parameters.withNATInstance.natInstanceInternalAddress**
    string

    Internal IP address of the NAT instance. To let Yandex Cloud assign the address, leave this parameter unset.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **settings.nodes.parameters.withNATInstance.natInstanceResources**
    object

    Computing resources that are allocated to the NAT instance. If not specified, the default values will be used.

    Warning. When these parameters change, the `terraform-manager` module restarts the NAT instance automatically if the `autoConvergerEnabled` parameter is set to `true`. The restart interrupts cluster network traffic for a short time.

    - **settings.nodes.parameters.withNATInstance.natInstanceResources.cores**
      integer

      Amount of CPU cores to provision on the NAT instance.

      Default: `2`

    - **settings.nodes.parameters.withNATInstance.natInstanceResources.memory**
      integer

Amount of primary memory in MB provision on the NAT instance.

Default: `2048`

- **settings.nodes.parameters.withNATInstance.natInstanceResources.platform**
string

Processor platform type on the NAT instance.

Default: `standard-v2`

- **settings.nodes.parameters.zones**
array of strings

Limits the zones where the cloud provider places cluster nodes.

You can list up to four zones. If the parameter is not set, Deckhouse Platform uses `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, and `ru-central1-e`.

Instructions for using the `ru-central1-f` zone are provided in “Using the ru-central1-f zone”.

- **Element of the array**
string

Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, `ru-central1-e`, `ru-central1-f`

- **settings.provider**
object

Required value

Yandex Cloud connection settings.

The provider reads the service account key from the `d8-credentials` Secret.

- **settings.provider.parameters**
object

Required value

Contains settings to connect to the Yandex Cloud API.

- **settings.provider.parameters.cloudID**
string

Required value

The cloud ID.

- **settings.provider.parameters.folderID**
string

Required value

ID of the directory.

- **settings.storage**
object

Storage subsystem settings.

The subsystem provides the CSI driver and the StorageClasses for Yandex Cloud disk types.

- **settings.storage.disabled**
boolean

Disables the storage subsystem.

When set to `true`, disk provisioning in the cluster is unavailable.

Default: `false`

- **settings.storage.parameters**
object

Required value

Parameters of the storage subsystem.

- **settings.storage.parameters.excludedStorageClasses**
array of strings

List of StorageClasses to exclude from use in the cluster.

Each item is a regular expression matched against the whole StorageClass name. For example, `network-ssd` excludes only the `network-ssd` StorageClass, and `network-ssd.*` excludes every StorageClass whose name starts with `network-ssd`.

The list is applied after `provisionedStorageClasses`, so it also filters out the StorageClass defined there.

- **settings.storage.parameters.provisionedStorageClasses**
array of objects

Defines additional StorageClasses or overrides the parameters of the ones created by default.

A StorageClass created by default is overridden when its name matches the `name` field exactly.

- **settings.storage.parameters.provisionedStorageClasses.blockSize**
  string

  The block size of disks created by this StorageClass.

  If the parameter is omitted, the default Yandex Cloud block size is used — `4Ki`.

  The block size determines the maximum size of a network disk: for a `4Ki` block it is `8Ti`, and it doubles with each next increase of the block size — up to `256Ti` for a `128Ki` block.

  After a disk is created, its block size cannot be changed. Changing the `blockSize` parameter recreates the StorageClass, but does not change the block size of previously provisioned volumes.

  For details, see the official Yandex Cloud documentation.

  Allowed values: `4Ki`, `8Ki`, `16Ki`, `32Ki`, `64Ki`, `128Ki`
- **settings.storage.parameters.provisionedStorageClasses.name**
  string

  Required value

  The name of the StorageClass to create.
- **settings.storage.parameters.provisionedStorageClasses.type**
  string

  Required value

  The disk type.

  Allowed values: `network-hdd`, `network-ssd`, `network-ssd-nonreplicated`, `network-ssd-io-m3`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Provider configuration

> The module lifecycle stage: General Availability

YandexClusterConfiguration

Version: deckhouse.io/v1

> **Warning.** The resource is deprecated. The cloud provider configuration is set in the ModuleConfig resource of the `cloud-provider-yandex` module. Migrate the cluster to ModuleConfig as described in “How to migrate a cloud provider to ModuleConfig-based configuration”.

Describes the configuration of a cloud cluster in Yandex Cloud.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: YandexClusterConfiguration
layout: Standard
nodeNetworkCIDR: 127.0.0.1/8
labels:
  label-2: b
sshPublicKey: "<SSH_PUBLIC_KEY>"
masterNodeGroup:
  replicas: 1
  instanceClass:
    cores: 4
    memory: 8192
    imageID: fd83ica41cade1mj35sr
nodeGroups:
- name: worker
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    cores: 4
    memory: 8192
    imageID: fd83ica41cade1mj35sr
    coreFraction: 50
    externalIPAddresses:
    - 198.51.100.5
    - Auto
provider:
  cloudID: "<CLOUD_ID>"
  folderID: "<FOLDER_ID>"
  serviceAccountJSON: |
    {
    "id": "id",
    "service_account_id": "service_account_id",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----\nMIIwID....AQAB\n-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----\nMIIE....1ZPJeBLt+\n-----END PRIVATE KEY-----\n"
    }
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **dhcpOptions**
  object

  A list of DHCP parameters to use for all subnets.

  Note that setting dhcpOptions may lead to problems.

  - **dhcpOptions.domainName**
    string

    The name of the search domain.

  - **dhcpOptions.domainNameServers**
    array of strings

    A list of recursive DNS addresses.

    - **Element of the array**
      string

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **existingNetworkID**
  string

  The ID of the existing VPC Network.

- **existingZoneToSubnetIDMap**
  object

  One or more pre-existing subnets mapped to respective zone.

  Warning. When using `cni-simple-bridge`, DP creates a route table that must be manually associated with the specified subnets. Only one route table can be associated with a subnet, so multiple clusters using `cni-simple-bridge` cannot be deployed in the same subnets. Starting with DP 1.76, new clusters in Yandex Cloud use `cni-cilium` in `VXLAN` mode by default. In this mode, pod traffic routing does not depend on Yandex Cloud route tables.

Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

Example:

```
existingZoneToSubnetIDMap:
  ru-central1-a: e2lu8r1tbbtryhdpa9ro
  ru-central1-b: e2lu8r1tbbtryhdpa9ro
  ru-central1-d: e2lu8r1tbbtryhdpa9ro
  ru-central1-e: e2lu8r1tbbtryhdpa9ro
  ru-central1-f: e2lu8r1tbbtryhdpa9ro
```

- **kind**
  string

  Required value

  Allowed values: `YandexClusterConfiguration`

- **labels**
  object

  Labels to attach to resources created in the Yandex Cloud.

  Note that you have to re-create all the machines to add new labels if labels were modified in the running cluster.

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

  Allowed values: `Standard`, `WithoutNAT`, `WithNATInstance`

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the YandexInstanceClass.

    - **masterNodeGroup.instanceClass.additionalLabels**
      object

      Additional labels.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **masterNodeGroup.instanceClass.cores**
      integer

      Required value

      Amount of CPU cores to provision on a Yandex Compute Instance.

    - **masterNodeGroup.instanceClass.diskSizeGB**
      integer

      Yandex Compute Instance disk size in gibibytes.

      Default: `50`

      Example:

      ```
      diskSizeGB: 0
      ```

    - **masterNodeGroup.instanceClass.diskType**
      string

      Yandex Compute Instance disk type. Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

Default: `network-ssd`

Allowed values: `network-ssd`, `network-ssd-io-m3`, `network-ssd-nonreplicated`

Example:

```
diskType: network-ssd-io-m3
```

- **masterNodeGroup.instanceClass.etcdDiskSizeGb**
  integer

  etcd disk size in gibibytes.

  If this parameter is changed, each etcd disk must be manually expanded in the Yandex Cloud interface (the reason for this behavior is in the issue).

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **masterNodeGroup.instanceClass.externalIPAddresses**
  array of strings

  A list of external IP addresses, listed in the order of the zones where nodes will be created.

  The following values can be specified in the list:

  - IP address from an additional external network for the corresponding zone (parameter `externalSubnetIDs`);
  - reserved public IP address, if the list of additional external networks is not defined (parameter `externalSubnetIDs`);
  - `Auto`, to order a public IP address in the corresponding zone.

  Please note:

  - The array elements must be listed according to the order of zones (parameter `zones`) in which the nodes will be created.

    For example:

    ```
    - <RU-CENTRAL1-A-IP-ADDRESS>
    - <RU-CENTRAL1-B-IP-ADDRESS>
    - <RU-CENTRAL1-D-IP-ADDRESS>
    ```

  - The number of elements in the `externalIPAddresses` array must equal the number of nodes in the group (the `replicas` parameter). To automatically order public IP addresses in the zone, use the value `Auto` in the list of the `externalIPAddresses` parameter at the corresponding position (matching the order of zones).
  - If `externalIPAddresses` is not specified, the nodes in the group will be ordered without external IP addresses.
  - **Element of the array**
    string

    Pattern: `^([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})|(Auto)$`

- **masterNodeGroup.instanceClass.externalSubnetID**
  Deprecated
  string

  If specified, an additional network interface will be added to the node (the latter will use it as a default route).

- **masterNodeGroup.instanceClass.externalSubnetIDs**
  array of strings

  List of additional external networks connected to the nodes.

  The node interface that is in the list will be assigned as the default gateway.

  Also, a route for the node’s internal network interface will be added for the entire subnet specified in nodeNetworkCIDR.

  The array elements **must** be listed in the same order as the zones (parameter `zones`) in which the nodes will be created. For example:

  ```
  - <RU-CENTRAL1-A-SUBNET-ID>
  - <RU-CENTRAL1-B-SUBNET-ID>
  - <RU-CENTRAL1-D-SUBNET-ID>
  ```

- **masterNodeGroup.instanceClass.imageID**
  string

  Required value

  Image ID to use while provisioning Yandex Compute Instances.

Example:

```
imageID: fd83ica41cade1mj35sr
```

- **masterNodeGroup.instanceClass.memory**
  integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: 8192
  ```

- **masterNodeGroup.instanceClass.networkType**
  string

  Network type.

  Default: `Standard`

  Allowed values: `Standard`, `SoftwareAccelerated`

- **masterNodeGroup.instanceClass.platform**
  string

  The type of virtual machine to create.

  Default: `standard-v2`

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array

  Not required value.

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

  - **Element of the array**

    Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, `ru-central1-e`, `ru-central1-f`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the YandexInstanceClass.

    - **nodeGroups.instanceClass.additionalLabels**
      object

      Additional labels.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **nodeGroups.instanceClass.coreFraction**
      integer

      Percent of reserved CPU capacity on a Yandex Compute Instance. Details...

      Default: `100`

      Allowed values: `5`, `20`, `50`, `100`

      Example:

```
coreFraction: 20
```

- **nodeGroups.instanceClass.cores**
  integer

  Required value

  Amount of CPU cores to provision on a Yandex Compute Instance.

- **nodeGroups.instanceClass.diskSizeGB**
  integer

  Yandex Compute Instance disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGB: 0
  ```

- **nodeGroups.instanceClass.diskType**
  string

  Yandex Compute Instance disk type. Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

  Default: `network-ssd`

  Allowed values: `network-ssd`, `network-ssd-io-m3`, `network-ssd-nonreplicated`

  Example:

  ```
  diskType: network-ssd-io-m3
  ```

- **nodeGroups.instanceClass.externalIPAddresses**
  array of strings

  A list of external IP addresses, listed in the order of the zones where nodes will be created.

  The following values can be specified in the list:

  - IP address from an additional external network for the corresponding zone (parameter `externalSubnetIDs`);
  - reserved public IP address, if the list of additional external networks is not defined (parameter `externalSubnetIDs`);
  - `Auto`, to order a public IP address in the corresponding zone.

  Please note:

  - The array elements must be listed according to the order of zones (parameter `zones`) in which the nodes will be created.

    For example:

    ```
    - <RU-CENTRAL1-A-IP-ADDRESS>
    - <RU-CENTRAL1-B-IP-ADDRESS>
    - <RU-CENTRAL1-D-IP-ADDRESS>
    ```

  - The number of elements in the `externalIPAddresses` array must equal the number of nodes in the group (the `replicas` parameter). To automatically order public IP addresses in the zone, use the value `Auto` in the list of the `externalIPAddresses` parameter at the corresponding position (matching the order of zones).
  - If `externalIPAddresses` is not specified, the nodes in the group will be ordered without external IP addresses.
  - **Element of the array**
    string

    Pattern: `^([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})|(Auto)$`

- **nodeGroups.instanceClass.externalSubnetID**
  Deprecated
  string

  If specified, an additional network interface will be added to the node (the latter will use it as a default route).

- **nodeGroups.instanceClass.externalSubnetIDs**
  array of strings

  List of additional external networks connected to the nodes.

  The node interface that is in the list will be assigned as the default gateway.

  Also, a route for the node's internal network interface will be added for the entire subnet specified in nodeNetworkCIDR.

  The array elements **must** be listed in the same order as the zones (parameter `zones`) in which the nodes will be created. For example:

```
- <RU-CENTRAL1-A-SUBNET-ID>
- <RU-CENTRAL1-B-SUBNET-ID>
- <RU-CENTRAL1-D-SUBNET-ID>
```

- **nodeGroups.instanceClass.imageID**
  string

  Required value

  Image ID to use while provisioning Yandex Compute Instances.

  Example:

  ```
  imageID: fd83ica41cade1mj35sr
  ```

- **nodeGroups.instanceClass.memory**
  integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: 8192
  ```

- **nodeGroups.instanceClass.networkType**
  string

  Network type.

  Default: `Standard`

  Allowed values: `Standard`, `SoftwareAccelerated`

- **nodeGroups.instanceClass.platform**
  string

  The type of virtual machine to create.

  Default: `standard-v2`

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: "true"
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

> **i** Available fields: `effect`, `key`, and `values`.

Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string
- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.
- **nodeGroups.zones**
  array

  A limited set of zones in which nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

  - **Element of the array**

    Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, `ru-central1-e`, `ru-central1-f`

- **nodeNetworkCIDR**
  string

  Required value

  IP address range for node subnets.

  Deckhouse Platform divides the range into four equal parts:

  - `ru-central1-a` uses the first part.
  - `ru-central1-b` uses the second part.
  - `ru-central1-e` uses the third part.
  - `ru-central1-d` uses the fourth part.

  Instructions for using the `ru-central1-f` zone are provided in “Using the ru-central1-f zone”.
- **provider**
  object

  Required value

  Contains settings to connect to the Yandex Cloud API.

  - **provider.cloudID**
    string

    Required value

    The cloud ID.
  - **provider.folderID**
    string

    Required value

    ID of the directory.
  - **provider.serviceAccountJSON**
    string

    Required value

    A key to the Service Account in the JSON format.

    You can get it by using `[yc iam key create](environment.html)` command.

    Pattern: `^[ \t\n]*\{(.|\n)*\}[ \t\n]*$`

    Example:

```
serviceAccountJSON: |
  {
    "id": "...",
    "service_account_id": "...",
    "created_at": "2022-08-04T05:38:34.756137618Z",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----...-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----...-----END PRIVATE KEY-----\n"
  }
```

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **withNATInstance**
  object

  Settings for the `WithNATInstance` layout.

  - **withNATInstance.exporterAPIKey**
    string

    API-key for cloud metrics exporter.

    - If parameter is empty, cloud metrics exporter will not be deployed in the cluster.
    - If parameter is `Auto`, Deckhouse will create service account with the `monitoring.viewer` role and create API-key manually. Provider service account should have the `admin` role.
    - Any other value is considered a valid API-key. See this instruction for creating API-key. Service account should have `monitoring.viewer` role.

    Default:

  - **withNATInstance.externalSubnetID**
    string

    If specified, an additional network interface will be added to the node (the node will use it as a default route).

  - **withNATInstance.internalSubnetCIDR**

    CIDR of an automatically created subnet for the internal interface. Overrides `internalSubnetID` parameter.

  - **withNATInstance.internalSubnetID**
    string

    ID of a subnet for the internal interface.

  - **withNATInstance.natInstanceExternalAddress**
    string

    A reserved external IP address (or `externalSubnetID` address if specified).

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **withNATInstance.natInstanceInternalAddress**
    Deprecated
    string

    Consider using automatically generated address instead.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **withNATInstance.natInstanceResources**
    object

    Computing resources that are allocated to the NAT instance. If not specified, the default values will be used.

    > **i** **Warning.** If these parameters are changed, `terraform-auto-converger` will automatically restart NAT-instance if autoConvergerEnabled is set to `true`. This may result in a temporary interruption of network traffic in the cluster.

    - **withNATInstance.natInstanceResources.cores**
      integer

      Amount of CPU cores to provision on the NAT instance.

      Default: `2`

    - **withNATInstance.natInstanceResources.memory**
      integer

      Amount of primary memory in MB provision on the NAT instance.

      Default: `2048`

    - **withNATInstance.natInstanceResources.platform**

string

Processor platform type on the NAT instance.

Default: `standard-v2`

- **zones**
  array

  Limits the zones that the cloud provider works with.

  You can list up to four zones. If the parameter is not set, Deckhouse Platform uses `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, and `ru-central1-e`.

  Instructions for using the `ru-central1-f` zone are provided in “Using the ru-central1-f zone”.

  - **Element of the array**

    Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, `ru-central1-e`, `ru-central1-f`

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

The module lifecycle stage: General Availability

To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

For more information, see the documentation.

The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:

- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Creating a service account

You need to create a service account with the editor role with the cloud provider so that Deckhouse Platform (DP) can manage cloud resources. The detailed instructions for creating a service account with Yandex Cloud are available in the provider’s documentation. Below, we will provide a brief overview of the necessary actions:

1. Create a user named `deckhouse`:

   ```
   yc iam service-account create --name deckhouse
   ```

   The command output will contain its parameters:

   ```
   id: <USER_ID>
   folder_id: <FOLDER_ID>
   created_at: "YYYY-MM-DDTHH:MM:SSZ"
   name: deckhouse
   ```

2. Assign the required roles to the newly created user for your cloud:

```
yc resource-manager folder add-access-binding --id <FOLDER_ID> --role compute.editor --subject serviceAccount:
<USER_ID>
yc resource-manager folder add-access-binding --id <FOLDER_ID> --role vpc.admin --subject serviceAccount:<USER_ID>
yc resource-manager folder add-access-binding --id <FOLDER_ID> --role load-balancer.editor --subject
serviceAccount:<USER_ID>
```

3. Create a JSON file containing the parameters for user authorization in the cloud. These parameters will be used to log in to the cloud:

```
yc iam key create --service-account-name deckhouse --output deckhouse-sa-key.json
```

> **i** A new cluster may require increased quotas. If necessary, also reserve a public IP address as described in “Reserving a public IP address”.

Credentials Secret

The service account key is stored in a separate Secret rather than in ModuleConfig. The provider reads it when starting the components that access the Yandex Cloud API.

The Secret is created during cluster installation together with the other resources of the initial configuration. If the provider is connected to a running cluster, the Secret is applied after the module creates the namespace. The Secret must meet the following requirements:

- The name is `d8-credentials` and the namespace is `d8-cloud-provider-yandex`.
- The type is `cloud-provider.deckhouse.io/credentials`.
- The `authScheme` field is set to `serviceAccount`.
- The `secret` field contains the service account key in JSON.

```
apiVersion: v1
kind: Secret
metadata:
  name: d8-credentials
  namespace: d8-cloud-provider-yandex
type: cloud-provider.deckhouse.io/credentials
stringData:
  authScheme: serviceAccount
  secret: |
    <SERVICE_ACCOUNT_JSON>
```

Replace `<SERVICE_ACCOUNT_JSON>` with the contents of the `deckhouse-sa-key.json` file.

To change the credentials, update the `secret` field:

```
d8 k -n d8-cloud-provider-yandex edit secret d8-credentials
```

In the “WithNATInstance layout”, the API key for monitoring the NAT instance is stored in a second Secret, `d8-credentials-exporter`, in the same namespace. Its `authScheme` field is set to `apiToken` and the key is placed in the `secret` field.

In clusters migrated to ModuleConfig, the service account key moves to the `d8-credentials` Secret from the `provider.serviceAccountJSON` parameter of the YandexClusterConfiguration resource. The monitoring API key moves to the `d8-credentials-exporter` Secret from the `withNATInstance.exporterAPIKey` parameter.

Quotas

> **i** Note that you need to increase the quotas using the Yandex console when provisioning a new cluster.

Recommended quotas for a new cluster:

- The number of virtual processors: 64.
- The total volume of SSD disks: 2000 GB.
- The number of virtual machines: 25.
- The total amount of RAM of virtual machines: 256 GB.

Yandex Cloud integration

> **⚠** Starting with DP version 1.77, Yandex Cloud uses the `cilium` CNI by default for new clusters. Existing clusters keep the current CNI configuration.
>
> New clusters require Linux kernel version 5.8 or newer on all nodes. Make sure firewalls or security groups allow inter-node UDP traffic for Cilium VXLAN. For details, see the installation requirements, “Network interaction of the platform components”, and the `cni-cilium` module documentation.

Configuring security groups

For every cloud network, Yandex Cloud creates a default security group, including for the cluster network. That group allows any inbound and outbound traffic and applies to the virtual machine network interfaces that are not assigned another group.

You can restrict the cluster traffic with the rules of that group. Assigning another security group to the nodes is not possible, as neither the module settings nor the YandexInstanceClass resource have parameters for that.

⚠ Do not assign security groups to the nodes manually in the Yandex Cloud console. The `dhctl converge` command brings the virtual machines to the state described in the cluster configuration and may remove such an assignment.

✖ Do not delete the rules that allow any traffic until you have configured the other rules of the group. Otherwise, the group blocks the traffic between the nodes and the cluster components lose connection to each other.

Errors in the rules disrupt the cluster. Before configuring the rules in a production cluster, consult the security group usage details in Yandex Cloud.

If the cluster uses `cilium` in VXLAN mode, make sure the security group allows inter-node UDP traffic on the ports required for Cilium. These ports are listed in “Network interaction of the platform components”.

To configure the rules of the security group:

1. Find out in which cloud network the Deckhouse Platform cluster is running.

   The network name matches the `prefix` parameter of the ModuleConfig `global`. You can retrieve it using the following command:

   ```
   d8 k get mc global -o jsonpath='{.spec.settings.prefix}{"\n"}'
   ```

   If the value is empty, get it from the deprecated `cloud.prefix` parameter of ClusterConfiguration (the prefix has moved to the ModuleConfig `global`):

   ```
   d8 k get secrets -n kube-system d8-cluster-configuration -ojson | \
     jq -r '.data."cluster-configuration.yaml"' | base64 -d | grep prefix | cut -d: -f2
   ```

2. In the Yandex Cloud console, select the Virtual Private Cloud service and navigate to the “Security Groups” section. You should see a single security group labeled `Default`.

3. Create rules as described in Yandex Cloud instructions.

4. Delete the rule that allows for any **inbound** traffic (in the screenshot above it has already been deleted), and save the changes.

Yandex Lockbox integration

The External Secrets Operator allows you to synchronize Yandex Lockbox secrets with the Deckhouse Platform cluster secrets.

The instructions below are meant to be viewed as a *Quick Start* guide. To use integration in production environments, please review the following resources:

- Yandex Lockbox
- Synchronizing with Yandex Lockbox secrets
- External Secrets Operator

Deployment instructions

1. Create a service account required for the External Secrets Operator:

   ```
   yc iam service-account create --name eso-service-account
   ```

2. Create an authorized key for the service account and save it to a file:

   ```
   yc iam key create --service-account-name eso-service-account --output authorized-key.json
   ```

3. Assign `lockbox.editor`, `lockbox.payloadViewer`, and `kms.keys.encrypterDecrypter` roles to a service account to access all catalog secrets:

```
folder_id=<FOLDER_ID>
yc resource-manager folder add-access-binding --id=${folder_id} --service-account-name eso-service-account --
role lockbox.editor
yc resource-manager folder add-access-binding --id=${folder_id} --service-account-name eso-service-account --
role lockbox.payloadViewer
yc resource-manager folder add-access-binding --id=${folder_id} --service-account-name eso-service-account --
role kms.keys.encrypterDecrypter
```

For advanced customization, check out access control in Yandex Lockbox.

4. Install the External Secrets Operator using the Helm chart according to instructions.

   Note that you may need to set `nodeSelector`, `tolerations` and other parameters. To do this, use the `./external-secrets/values.yaml` file after unpacking the Helm chart.

   Pull and extract the chart:

   ```
   helm pull oci://cr.yandex/yc-marketplace/yandex-cloud/external-secrets/chart/external-secrets \
     --version 0.5.5 \
     --untar
   ```

   Install the Helm chart:

   ```
   helm install -n external-secrets --create-namespace \
     --set-file auth.json=authorized-key.json \
     external-secrets ./external-secrets/
   ```

   Where:

   - `authorized-key.json` — the name of the file with the authorized key from step 2.

5. Create a SecretStore with the `sa-creds` secret in it:

   ```
   d8 k -n external-secrets apply -f - <<EOF

   apiVersion: external-secrets.io/v1alpha1
   kind: SecretStore
   metadata:
     name: secret-store
   spec:
     provider:
       yandexlockbox:
         auth:
           authorizedKeySecretRef:
             name: sa-creds
             key: key
   EOF
   ```

   Where:

   - `sa-creds` — the name of the Secret that contains the authorized key. This secret should show up after the Helm chart has been installed.
   - `key` — the name of the key in the `.data` field of the secret above.

Checking that everything works as expected

1. Check the status of the External Secrets Operator:

   ```
   d8 k -n external-secrets get po
   ```

   An example of the output:

   ```
   NAME                                                READY   STATUS    RESTARTS   AGE
   external-secrets-55f78c44cf-dbf6q                   1/1     Running   0          77m
   external-secrets-cert-controller-78cbc7d9c8-rszhx   1/1     Running   0          77m
   external-secrets-webhook-6d7b66758-s7v9c            1/1     Running   0          77m
   ```

2. Check the state of the secrets store you created:

   ```
   d8 k -n external-secrets get secretstores.external-secrets.io
   ```

   An example of the output:

```
NAME           AGE   STATUS
secret-store   69m   Valid
```

3. Create a Yandex Lockbox secret with the following parameters:
   - **Name** — `lockbox-secret`.
   - **Key** — enter the non-confidential identifier `password`.
   - **Value** — enter the confidential data to store `p@$$w0rd`.
4. Create an ExternalSecret object that refers to the `lockbox-secret` secret in the `secret-store`:

```
d8 k -n external-secrets apply -f - <<EOF

apiVersion: external-secrets.io/v1alpha1
kind: ExternalSecret
metadata:
  name: external-secret
spec:
  refreshInterval: 1h
  secretStoreRef:
    name: secret-store
    kind: SecretStore
  target:
    name: k8s-secret
  data:
  - secretKey: password
    remoteRef:
      key: <SECRET_ID>
      property: password
EOF
```

   Where:

   - `spec.target.name` — the name of the new secret. The External Secrets Operator will create this secret in the Deckhouse Platform cluster and populate it with the parameters of the Yandex Lockbox's `lockbox-secret`.
   - `spec.data[].secretKey` — the name of the key in the `.data` field of the secret that the External Secrets Operator will create.
   - `spec.data[].remoteRef.key` — identifier of the Yandex Lockbox's `lockbox-secret` created earlier, e.g., `e6q28nvfmhu539******`.
   - `spec.data[].remoteRef.property` — the **key** you specified earlier for the Yandex Lockbox's `lockbox-secret`.
5. Make sure that the new `k8s-secret` key contains the `lockbox-secret` value:

```
d8 k -n external-secrets get secret k8s-secret -ojson | jq -r '.data.password' | base64 -d
```

   The output of the command should contain the **value** of the `password` key of the `lockbox-secret` created earlier:

```
p@$$w0rd
```

Yandex Managed Service for Prometheus integration

This integration lets you use the Yandex Managed Service for Prometheus as an external metrics repository, e.g., for long-term metrics storage.

Writing metrics

1. Create a service account with the `monitoring.editor` role.
2. Create an API key for the service account.
3. Create a PrometheusRemoteWrite resource:

```
d8 k apply -f - <<EOF
apiVersion: deckhouse.io/v1
kind: PrometheusRemoteWrite
metadata:
  name: yc-remote-write
spec:
  url: <URL_TO_WRITE_METRICS>
  bearerToken: <API_KEY>
EOF
```

   Where:

   - `<URL_TO_WRITE_METRICS>` — URL from the Yandex Monitoring/Prometheus/Writing Metrics page.
   - `<API_KEY>` — the API key you created in the previous step, e.g.,

`AQVN1HHJRSrfo9jU3aopsXrJyfq_UHs********`.

You may also specify additional parameters; refer to the documentation.

More details about this feature can be found in Yandex Cloud documentation.

Reading metrics with Grafana

1. Create a service account with the `monitoring.viewer` role.
2. Create an API key for the service account.
3. Create a GrafanaAdditionalDatasource resource:

```
d8 k apply -f - <<EOF

apiVersion: deckhouse.io/v1
kind: GrafanaAdditionalDatasource
metadata:
  name: managed-prometheus
spec:
  type: prometheus
  access: Proxy
  url: <URL_READING_METRICS_WITH_GRAFANA>
  basicAuth: false
  jsonData:
    timeInterval: 30s
    httpMethod: POST
    httpHeaderName1: Authorization
  secureJsonData:
    httpHeaderValue1: Bearer <API_KEY>
EOF
```

Where:

- `<URL_READING_METRICS_WITH_GRAFANA>` — URL from the Yandex Monitoring/Prometheus/Reading Metrics with Grafana page.
- `<API_KEY>` — the API key you created in the previous step, e.g., `AQVN1HHJReSrfo9jU3aopsXrJyfq_UHs********`.

You may also specify additional parameters; refer to the documentation.

More details about this feature can be found in Yandex Cloud documentation.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

YandexInstanceClass

Scope: Cluster

- v1
- v1alpha1

- **metadata**
  object
- **spec**
  object

  Required value

  YandexInstanceClassSpec defines the desired state of the YandexInstanceClass.

  - **spec.additionalLabels**
    object

    Additional labels to be attached to the Yandex Compute Instance resource.

Example:

```
additionalLabels: "{project: cms-production, severity: critical}"
```

- **spec.additionalSubnets**
  array of strings

  Subnet IDs that VirtualMachines' secondary NICs will connect to.

  For `CloudEphemeral` nodes, every subnet in the list is attached as a separate network interface.

  For `CloudPermanent` nodes, a single subnet is selected from the list by the node index, so the list must contain at least as many subnets as there are nodes in the group.

  Example:

  ```
  additionalSubnets: "[b0csh41c1or82vuch89v, e2lgddi5svochh5fbq96]"
  ```

- **spec.assignPublicIPAddress**
  boolean

  Should a public external IPv4 address be assigned to a provisioned Yandex Compute Instance.

  Default: `false`

  Example:

  ```
  assignPublicIPAddress: 'false'
  ```

- **spec.coreFraction**
  integer

  Percent of reserved CPU capacity on a Yandex Compute Instance.

  More about performance levels.

  Default: `100`

  Allowed values: `5`, `20`, `50`, `100`

  Example:

  ```
  coreFraction: '20'
  ```

- **spec.cores**
  integer

  Required value

  Amount of CPU cores to provision on a Yandex Compute Instance.

  Example:

  ```
  cores: '4'
  ```

- **spec.diskSizeGB**
  integer

  Yandex Compute Instance disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGB: '20'
  ```

- **spec.diskType**
  string

  Instance disk type.

  Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

  Default: `"network-hdd"`

  Allowed values: `network-ssd`, `network-hdd`, `network-ssd-nonreplicated`, `network-ssd-io-m3`

  Example:

  ```
  diskType: network-hdd
  ```

- **spec.etcdDiskSizeGB**
  integer

  Disk size for etcd is set only for InstanceClass intended for master NodeGroup. The value is specified in `GiB`.

  Example:

```
etcdDiskSizeGB: '20'
```

- **spec.gpus**
  integer

  Number of GPUs on a Yandex Compute Instance.

  Default: `0`

  Example:

  ```
  gpus: '4'
  ```

- **spec.imageID**
  string

  Image ID to use while provisioning Yandex Compute Instances.

  If the parameter is not set, the image of the instance class of the `master` node group is used. In a cluster that has not been migrated to the ModuleConfig settings, the `masterNodeGroup.instanceClass.imageID` parameter of the YandexClusterConfiguration resource is used instead.

  Example:

  ```
  imageID: fd83ica41cade1mj35sr
  ```

- **spec.mainSubnet**
  string

  Subnet ID that VirtualMachines' primary NIC will connect to.

  If the parameter is not specified, Deckhouse Platform selects the network. When the `existingZoneToSubnetIDMap` parameter is set, the network is taken from it, otherwise the network created during the cluster deployment is used.

  Example:

  ```
  mainSubnet: e9bnc7g9mu9mper9clk4
  ```

- **spec.memory**
  integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: '8192'
  ```

- **spec.networkType**
  string

  Network type: `Standard` or `SoftwareAccelerated`.

  Default: `Standard`

  Allowed values: `Standard`, `SoftwareAccelerated`

- **spec.platformID**
  string

  Platform ID.

  List of available platforms...

  Default: `standard-v3`

- **spec.preemptible**
  boolean

  Should a provisioned Yandex Compute Instance be preemptible.

  For more information about preemptible virtual machines, read the provider's documentation.

  Default: `false`

- **status**
  object

  YandexInstanceClassStatus stores information about the YandexInstanceClass resource.

  - **status.nodeGroupConsumers**
    array of strings

    NodeGroupConsumers lists the names of NodeGroups that use this instance class.

- **metadata**

object

- **spec**
  object

  Required value

  InstanceClassSpec defines the desired state of the YandexInstanceClass.

  - **spec.additionalLabels**
    object

    Additional labels to be attached to the Yandex Compute Instance resource.

    Example:

    ```
    additionalLabels: "{project: cms-production, severity: critical}"
    ```

  - **spec.additionalSubnets**
    array of strings

    Subnet IDs that VirtualMachines' secondary NICs will connect to.

    For `CloudEphemeral` nodes, every subnet in the list is attached as a separate network interface.

    For `CloudPermanent` nodes, a single subnet is selected from the list by the node index, so the list must contain at least as many subnets as there are nodes in the group.

    Example:

    ```
    additionalSubnets: "[b0csh41c1or82vuch89v, e2lgddi5svochh5fbq96]"
    ```

  - **spec.assignPublicIPAddress**
    boolean

    Should a public external IPv4 address be assigned to a provisioned Yandex Compute Instance.

    Default: `false`

    Example:

    ```
    assignPublicIPAddress: 'false'
    ```

  - **spec.coreFraction**
    integer

    Percent of reserved CPU capacity on a Yandex Compute Instance.

    More about performance levels.

    Default: `100`

    Allowed values: `5`, `20`, `50`, `100`

    Example:

    ```
    coreFraction: '20'
    ```

  - **spec.cores**
    integer

    Required value

    Amount of CPU cores to provision on a Yandex Compute Instance.

    Example:

    ```
    cores: '4'
    ```

  - **spec.diskSizeGB**
    integer

    Yandex Compute Instance disk size in gibibytes.

    Default: `20`

    Example:

    ```
    diskSizeGB: '50'
    ```

  - **spec.diskType**
    string

    Instance disk type.

    Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

    For more information about possible disk types, read the provider's documentation.

Default: `"network-hdd"`

Allowed values: `network-ssd`, `network-hdd`, `network-ssd-nonreplicated`

Example:

```
diskType: network-hdd
```

- **spec.gpus**
integer

  Number of GPUs on a Yandex Compute Instance.

  Default: `0`

  Example:

  ```
  gpus: '4'
  ```

- **spec.imageID**
string

  Image ID to use while provisioning Yandex Compute Instances.

  If the parameter is not set, the image of the instance class of the `master` node group is used. In a cluster that has not been migrated to the ModuleConfig settings, the `masterNodeGroup.instanceClass.imageID` parameter of the YandexClusterConfiguration resource is used instead.

  Example:

  ```
  imageID: fd83ica41cade1mj35sr
  ```

- **spec.mainSubnet**
string

  Subnet ID that VirtualMachines’ primary NIC will connect to.

  If the parameter is not specified, Deckhouse Platform selects the network. When the `existingZoneToSubnetIDMap` parameter is set, the network is taken from it, otherwise the network created during the cluster deployment is used.

  Example:

  ```
  mainSubnet: e9bnc7g9mu9mper9clk4
  ```

- **spec.memory**
integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: '8192'
  ```

- **spec.networkType**
string

  Network type: STANDARD or SOFTWARE_ACCELERATED

  Default: `STANDARD`

  Allowed values: `STANDARD`, `SOFTWARE_ACCELERATED`

- **spec.platformID**
string

  Platform ID.

  List of available platforms...

  Default: `standard-v2`

- **spec.preemptible**
boolean

  Should a provisioned Yandex Compute Instance be preemptible.

  For more information about preemptible virtual machines, read the provider’s documentation.

  Default: `false`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

Setting up the INTERNAL LoadBalancer

Attach the following annotation to the service:

```
yandex.cpi.flant.com/listener-subnet-id: SubnetID
```

The annotation links the LoadBalancer with the appropriate Subnet.

Using a separate target group for a NodeGroup

By default, Yandex Cloud Controller Manager adds all suitable cluster nodes to the default target group. To assign nodes to a separate target group, use the `yandex.cpi.flant.com/target-group-name-prefix` annotation. The annotation is described in the “Service annotations” section.

1. In the NodeGroup whose nodes should be included in a separate target group, specify the `yandex.cpi.flant.com/target-group-name-prefix` annotation in the `spec.nodeTemplate.annotations` parameter. For example:

   ```
   spec:
     nodeTemplate:
       annotations:
         yandex.cpi.flant.com/target-group-name-prefix: frontend-
   ```

   The annotation is propagated to the Node objects. Yandex Cloud Controller Manager adds all suitable nodes carrying the same annotation value to the target group, regardless of their NodeGroup.

2. In the Service object of the LoadBalancer type, specify the same annotation with the same value. For example:

   ```
   metadata:
     annotations:
       yandex.cpi.flant.com/target-group-name-prefix: frontend-
   ```

   The annotation on the Service identifies the target group used by the LoadBalancer but does not select nodes.

3. Make sure that the values of `yandex.cpi.flant.com/target-group-name-prefix` in the NodeGroup and Service match. In the example above, both resources use the `frontend-` value.

4. The target group will be created with a name generated according to the following pattern:

   ```
   <ANNOTATION_VALUE><YANDEX_CLOUD_CLUSTER_NAME><NETWORK_ID>
   ```

   For example, if the annotation value is `frontend-`, the cluster name is `my-cluster-`, and the network ID is `enp123456789`, the target group name will be:

   ```
   frontend-my-cluster-enp123456789
   ```

Configuration example:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: frontend
spec:
  nodeType: CloudEphemeral
  nodeTemplate:
    annotations:
      yandex.cpi.flant.com/target-group-name-prefix: frontend-
---
apiVersion: v1
kind: Service
metadata:
  name: nginx-frontend
  annotations:
    yandex.cpi.flant.com/target-group-name-prefix: frontend-
spec:
  type: LoadBalancer
```

⚠ Yandex Cloud does not allow a single target, identified by the (`SubnetID, IP`) pair, to belong to multiple target groups at the same time.

When the target group is changed, Yandex Cloud Controller Manager first removes the target from the current group and then adds it to the new one. This transition may cause a brief interruption in traffic handling.

Nodes with a dedicated target group prefix are excluded from the default target group. As a result, load balancers that use the default target group stop routing traffic to those nodes.

This automatic transition is performed only between target groups managed by Yandex Cloud Controller Manager. If a target already belongs to another target group that is not managed by Yandex Cloud Controller Manager, remove it from that group before using the annotation.

After the prefix is changed or removed, the previous target group may remain empty. If it is no longer used by any load balancers, delete it manually.

Reserving a public IP address

This on is used in `externalIPAddresses` and `natInstanceExternalAddress`. It also can be used for a bastion host.

```
$ yc vpc address create --external-ipv4 zone=ru-central1-a
id: e9b4cfmmnc1mhgij75n7
folder_id: b1gog0h9k05lhqe5d88l
created_at: "2020-09-01T09:29:33Z"
external_ipv4_address:
  address: 178.154.226.159
  zone_id: ru-central1-a
  requirements: {}
reserved: true
```

dhcpOptions-related problems and ways to address them

Using DNS servers that differ from those provided by Yandex Cloud in the DHCP settings is a temporary solution. It will be abandoned after Yandex Cloud will introduce the Managed DNS service. To get around the restrictions described below, we recommend using `stubZones` from the `kube-dns` module.

Editing parameters

Pay attention to the following nuances:

1. When changing parameters, you need to invoke `netplan apply` or a similar command that forces the update of the DHCP lease.
2. You will need to restart all hostNetwork Pods (especially `kube-dns`) for the new `resolv.conf` settings to take effect.

Aspects of the use

If the dhcpOptions parameter is set, all DNS are routed to the DNS servers specified. These DNS servers **must** serve DNS requests to the Internet and (if needed) resolve intranet resources.

Do not use this option if the recursive DNSs specified cannot resolve the same list of zones that the recursive DNSs in the Yandex Cloud subnet can resolve.

Changing `networkType` does not recreate CloudEphemeral nodes

In clusters that use Machine Controller Manager (MCM), changing the `networkType` parameter in a YandexInstanceClass resource does not trigger automatic recreation of existing CloudEphemeral nodes. Although the MachineClass is updated, the network acceleration type of existing virtual machines in Yandex Cloud remains unchanged.

DP intentionally does not take the `networkType` parameter into account when determining whether CloudEphemeral nodes should be recreated in MCM. If it did, updating DP would recreate CloudEphemeral nodes in all clusters where `networkType` is specified, even if its value had not changed.

In Cluster API, the `networkType` parameter is taken into account when determining whether nodes should be recreated, so changing it automatically triggers node recreation. New CloudEphemeral NodeGroups in Yandex Cloud use Cluster API by default.

If you changed `networkType` in an MCM-based cluster and want the new value to apply to existing CloudEphemeral nodes, recreate them manually — instructions in the documentation.

Setting a custom StorageClass as default

Specify the StorageClass name in the global `defaultClusterStorageClass` parameter. After that, DP removes the `storageclass.kubernetes.io/is-default-class='true'` annotation from the StorageClass that was set as the default one before.

```
d8 k edit mc global
```

Resizing a PVC

You can increase the size of an existing PVC by changing the value of the `spec.resources.requests.storage` parameter, without stopping or recreating the pod that uses it.

After the value of `spec.resources.requests.storage` is changed, the CSI driver performs the following operations:

- increases the size of the disk in Yandex Cloud;
- updates the size of the associated PersistentVolume;
- expands the file system on the node to which the volume is attached.

During the operation, the pod continues running, and the mounted volume remains available to the application. After the resize operation is complete, the new file system size becomes available inside the container without restarting the pod.

> **i** Decreasing the size of a PVC is not supported.

To increase the size of a PVC, follow these steps:

1. Get the name of the StorageClass used by the PVC:

   ```
   d8 k -n <NAMESPACE> get pvc <PVC_NAME> \
     -o jsonpath='{.spec.storageClassName}{"\n"}'
   ```

   Where:

   - `<NAMESPACE>` — the namespace containing the PVC;
   - `<PVC_NAME>` — the name of the PVC to resize.

   For example:

   ```
   d8 k -n production get pvc application-data \
     -o jsonpath='{.spec.storageClassName}{"\n"}'
   ```

   Example output:

   ```
   network-ssd
   ```

   In this example, the `application-data` PVC uses the `network-ssd` StorageClass.

2. Make sure that the StorageClass allows volume expansion:

   ```
   d8 k get storageclass <STORAGECLASS_NAME> \
     -o jsonpath='{.allowVolumeExpansion}{"\n"}'
   ```

   Where `<STORAGECLASS_NAME>` is the name of the StorageClass obtained in the previous step.

   For example:

   ```
   d8 k get storageclass network-ssd \
     -o jsonpath='{.allowVolumeExpansion}{"\n"}'
   ```

   Example output:

   ```
   true
   ```

3. Check the current status and size of the PVC:

```
d8 k -n <NAMESPACE> get pvc <PVC_NAME>
```

For example:

```
d8 k -n production get pvc application-data
```

Example output:

```
NAME               STATUS   VOLUME                                     CAPACITY   ACCESS MODES
STORAGECLASS
application-data   Bound    pvc-65e92674-077c-4b4f-b65d-19e92f04e103   20Gi       RWO
network-ssd
```

Make sure that:

- the PVC is in the `Bound` state;
- the `CAPACITY` field shows the current PVC size;
- the `STORAGECLASS` field shows the StorageClass checked in the previous step.

4. Increase the PVC size:

```
d8 k -n <NAMESPACE> edit pvc <PVC_NAME>
```

For example:

```
d8 k -n production edit pvc application-data
```

Specify the new PVC size in the `spec.resources.requests.storage` field:

```
spec:
  resources:
    requests:
      storage: 30Gi
```

In this example, the PVC size is increased to `30Gi`.

Save the changes and close the editor.

> ⚠ For the `network-ssd-nonreplicated` and `network-ssd-io-m3` StorageClasses, the size must be a multiple of 93Gi.

5. Wait for the PVC resize operation to complete:

```
d8 k -n <NAMESPACE> get pvc <PVC_NAME> --watch
```

Where:

- `<NAMESPACE>` — the namespace containing the PVC;
- `<PVC_NAME>` — the name of the PVC being resized.

For example:

```
d8 k -n production get pvc application-data --watch
```

During the resize operation, the `CAPACITY` field may continue to show the previous size:

```
NAME               STATUS   VOLUME                                     CAPACITY   ACCESS MODES
STORAGECLASS
application-data   Bound    pvc-65e92674-077c-4b4f-b65d-19e92f04e103   20Gi       RWO
network-ssd
```

The operation is complete when the `CAPACITY` field shows the new PVC size:

```
NAME               STATUS   VOLUME                                     CAPACITY   ACCESS MODES
STORAGECLASS
application-data   Bound    pvc-65e92674-077c-4b4f-b65d-19e92f04e103   30Gi       RWO
network-ssd
```

6. Check the PVC events:

```
d8 k -n <NAMESPACE> describe pvc <PVC_NAME>
```

For example:

```
d8 k -n production describe pvc application-data
```

The following events may appear during the resize operation:

```
ExternalExpanding
Resizing
FileSystemResizeRequired
```

The following event indicates that the file system was successfully expanded:

```
FileSystemResizeSuccessful
```

For example:

```
Normal  FileSystemResizeSuccessful  kubelet  MountVolume.NodeExpandVolume succeeded for volume
"pvc-65e92674-077c-4b4f-b65d-19e92f04e103"
```

7. Check the file system size inside the pod:

```
d8 k -n <NAMESPACE> exec <POD_NAME> -- \
  df -hT <MOUNT_PATH>
```

Where:

- `<NAMESPACE>` — the namespace containing the pod;
- `<POD_NAME>` — the name of the pod using the PVC;
- `<MOUNT_PATH>` — the path inside the container where the PVC is mounted.

For example:

```
d8 k -n production exec application-0 -- \
  df -hT /data
```

Example output:

```
Filesystem   Type   Size    Used   Avail   Use%   Mounted on
/dev/vde     ext4   29.4G   22M    29.4G    1%    /data
```

> **i** The actual file system size may be slightly smaller than the PVC size due to file system metadata.

Adding CloudStatic nodes to a cluster

For VMs that you want to add to the cluster as nodes, add the `node-network-cidr` key to the metadata (Edit VM -> Metadata) with a value equal to the cluster's `nodeNetworkCIDR`.

You can find out the `nodeNetworkCIDR` of the cluster using the command below:

```
d8 k get mc cloud-provider-yandex -o jsonpath='{.spec.settings.nodes.parameters.nodeNetworkCIDR}{"\n"}'
```

Creating a cluster in a new VPC and setting up a bastion host to access the nodes

1. Bootstrap the base-infrastructure of the cluster:

```
dhctl bootstrap-phase base-infra --config config.yml
```

2. Create a bastion host:

```
yc compute instance create \
--name bastion \
--hostname bastion \
--create-boot-disk image-family=ubuntu-2404-lts,image-folder-id=standard-images,size=20,type=network-hdd \
--memory 2 \
--cores 2 \
--core-fraction 100 \
--ssh-key ~/.ssh/<SSH_PUBLIC_KEY_FILE> \
--zone ru-central1-a \
--public-address 178.154.226.159
```

> **i** Replace `<SSH_PUBLIC KEY FILE>` here with the name of your public key. For example, for a key with RSA encryption, it will be `id_rsa.pub`, and for a key with ED25519 encryption, it will be with `id_ed25519.pub`.

3. Continue installing the cluster by specifying the bastion host data. Answer `y` to the question about the Terraform cache:

```
dhctl bootstrap --ssh-bastion-host=178.154.226.159 --ssh-bastion-user=yc-user \
--ssh-user=ubuntu --ssh-agent-private-keys=/tmp/.ssh/<SSH_PRIVATE_KEY_FILE> --config=/config.yml
```

> **i** Replace `<SSH_PRIVATE KEY_FILE>` here with the name of your private key. For example, for a key with RSA encryption it can be `id_rsa`, and for a key with ED25519 encryption it can be `id_ed25519`.

Long switching to nodes in lower-priority groups

If switching to nodes in lower-priority groups takes a long time (for example, when node groups with preemptible instances are set to the highest priority and, if such instances are unavailable, switching to nodes from other groups takes a very long time), follow the instructions.

Replacing the OS image on the nodes

The `imageID` parameter of YandexInstanceClass defines the image for `CloudEphemeral` nodes. With a ModuleConfig-based provider configuration, this parameter also defines the image for `CloudPermanent` nodes and master nodes.

With a YandexClusterConfiguration-based configuration, the image for `CloudPermanent` nodes and master nodes is set by `imageID` in `nodeGroups[].instanceClass` and `masterNodeGroup.instanceClass`, respectively.

The replacement procedure is described in “How do I replace the OS image in a cloud cluster?”.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> **i** The module lifecycle stage: General Availability

Below is an example of the Yandex Cloud cloud provider configuration.

An example of the module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        cloudID: b1g0ldjdpa8rtm2ru3s4
        folderID: b1gq1vn5jqk0tmh4u7bp
    nodes:
      parameters:
        layout: Standard
        nodeNetworkCIDR: 10.241.32.0/20
        sshPublicKey: ssh-rsa AAAAB3Nza...
        zones:
          - ru-central1-a
          - ru-central1-b
        labels:
          billing: prod
        externalSubnetIDs:
          worker:
            - e2lu8r1tbbtryhdpa9ro
        externalIPAddresses:
          worker:
            - Auto
    storage:
      parameters:
        excludedStorageClasses:
          - network-hdd
        provisionedStorageClasses:
          - name: network-ssd-64k
            type: network-ssd
            blockSize: 64Ki
    ccm:
      parameters:
        additionalExternalNetworkIDs:
          - enp6t4snovl2ko4p15em
        additionalInternalNetworkIDs:
          - enpmhcdmtvs6ptdq3mkt
```

The service account key is not stored in this resource, it is set in a separate Secret.

Using the ru-central1-f zone

To place nodes in `ru-central1-f`, explicitly list it in `zones` in place of one of the default zones. You can list up to four zones in `zones`. If the parameter is not set, Deckhouse Platform uses `ru-central1-a`, `ru-central1-b`, `ru-central1-d`, and `ru-central1-e`.

1. Select one of the default zones to replace with `ru-central1-f`. The following example excludes `ru-central1-e`.
2. List `ru-central1-f` and the other selected zones in the `zones` parameter of the `cloud-provider-yandex` ModuleConfig:

   ```
   spec:
     settings:
       nodes:
         parameters:
           layout: Standard
           nodeNetworkCIDR: 10.241.32.0/20
           sshPublicKey: ssh-rsa AAAAB3Nza...
           zones:
             - ru-central1-a
             - ru-central1-b
             - ru-central1-d
             - ru-central1-f
   ```

   Deckhouse Platform creates a subnet in `ru-central1-f` using the part of `nodeNetworkCIDR` assigned to the excluded zone. In a running cluster with the default zones, replacing `ru-central1-e` with `ru-central1-f` deletes the subnet in `ru-central1-e` and creates a new one in `ru-central1-f`. Subnets in the other selected zones are retained.

Using existing subnets

If `existingZoneToSubnetIDMap` is set, Deckhouse Platform uses the subnets specified by the parameter without creating or deleting them. The four-zone limit does not apply to `existingZoneToSubnetIDMap`. If `zones` is not set, nodes are placed in all zones specified in `existingZoneToSubnetIDMap`, including zones outside the default set.

Changing zones in a running cluster

To add `ru-central1-f`, update `zones`.

> **i** When you add `ru-central1-f`, Deckhouse Platform deletes subnets in the excluded default zones. Replacing `[ru-central1-a, ru-central1-b]` with `[ru-central1-a, ru-central1-b, ru-central1-f]` deletes the subnets in `ru-central1-d` and `ru-central1-e`. A subnet in `ru-central1-f` is created using the address range of one of the deleted subnets.

Changing the zone list may cause an address range conflict. This occurs if a subnet in a default zone you add needs to use the address range of the `ru-central1-f` subnet. Deckhouse Platform rejects such a change with an error. To resolve the conflict, apply the changes in two stages:

1. Remove `ru-central1-f` from `zones` and apply the changes. Deckhouse Platform deletes the subnet in `ru-central1-f`.
2. Set the final zone list including `ru-central1-f` and apply the changes again.

For example, this conflict may occur when replacing `ru-central1-d` with `ru-central1-e` while keeping `ru-central1-f` in the list.

If there is no conflict, you can change the zone list directly. The `ru-central1-f` subnet retains its address range.

If NAT subnets are not explicitly specified in the `WithNATInstance` layout, NAT instance placement is determined by `zones`:

Zone list	NAT instance placement
Contains only default zones	The NAT instance remains in `ru-central1-a`
Contains a zone outside the default set and excludes `ru-central1-a`	The NAT instance is recreated in the alphabetically first zone in `zones`

> **⚠** Cluster egress is interrupted while the NAT instance is recreated.

An example of the YandexInstanceClass custom resource

YandexInstanceClass describes the virtual machines that DP provisions for a node group. Only two parameters are required, `cores` and `memory`. The other parameters are optional.

The example below also sets the OS image, the disk type and size, the share of a vCPU, and the network interface mode:

```
apiVersion: deckhouse.io/v1
kind: YandexInstanceClass
metadata:
  name: worker
spec:
  cores: 4
  memory: 8192
  coreFraction: 50
  imageID: fd8bhu2b2bsbnqkhhd2k
  diskType: network-ssd
  diskSizeGB: 50
  networkType: SoftwareAccelerated
```

LoadBalancer

Service annotations

Default values are configured in the cluster for placing load balancer resources (the network for the target group and the subnet for the Listener). These values are set automatically during cluster setup and can be overridden with annotations at the individual Service level.

> **i** The default behavior (external or internal LB) depends on the cluster configuration. To explicitly choose the type, use the `yandex.cpi.flant.com/loadbalancer-external` annotation.

The following annotations are supported by Yandex Cloud Controller Manager:

1. `yandex.cpi.flant.com/target-group-network-id` — specifies the NetworkID in which the target group for this Service will be created. Overrides the corresponding default value.

2. `yandex.cpi.flant.com/listener-subnet-id` — sets the SubnetID for the Listeners of the LB created for this Service. Overrides the corresponding default value.
3. `yandex.cpi.flant.com/listener-address-ipv4` — sets a predefined IPv4 address for the Listeners (supported for both internal and external LBs).
4. `yandex.cpi.flant.com/loadbalancer-external` — enables creation of an external LB for this Service (use it when you need to explicitly create an external load balancer). Overrides the default behavior.
5. `yandex.cpi.flant.com/target-group-name-prefix` — specifies the name prefix of the target group used by the LoadBalancer. The annotation on the Service identifies the target group but does not select nodes. To include nodes in the target group, set the same annotation value in `spec.nodeTemplate.annotations` in the NodeGroup. Yandex Cloud Controller Manager includes all suitable nodes carrying this annotation value, regardless of their NodeGroup. The target group name is formed as `<ANNOTATION_VALUE><YANDEX_CLOUD_CLUSTER_NAME><NETWORK_ID>`. For details, see “Using a separate target group for a NodeGroup”.

If separate target groups are created for the control plane or master nodes, add the label `node.kubernetes.io/exclude-from-external-load-balancers: ""` to the master nodes. This prevents the controller from automatically adding master nodes to new target groups for load balancers.

If you create your own load balancer for master nodes and want YCC to also be able to place its load balancers on master nodes, pre-create a target group with a name matching the pattern `${CLUSTER-NAME}${VPC.ID}`.

Target group health checks

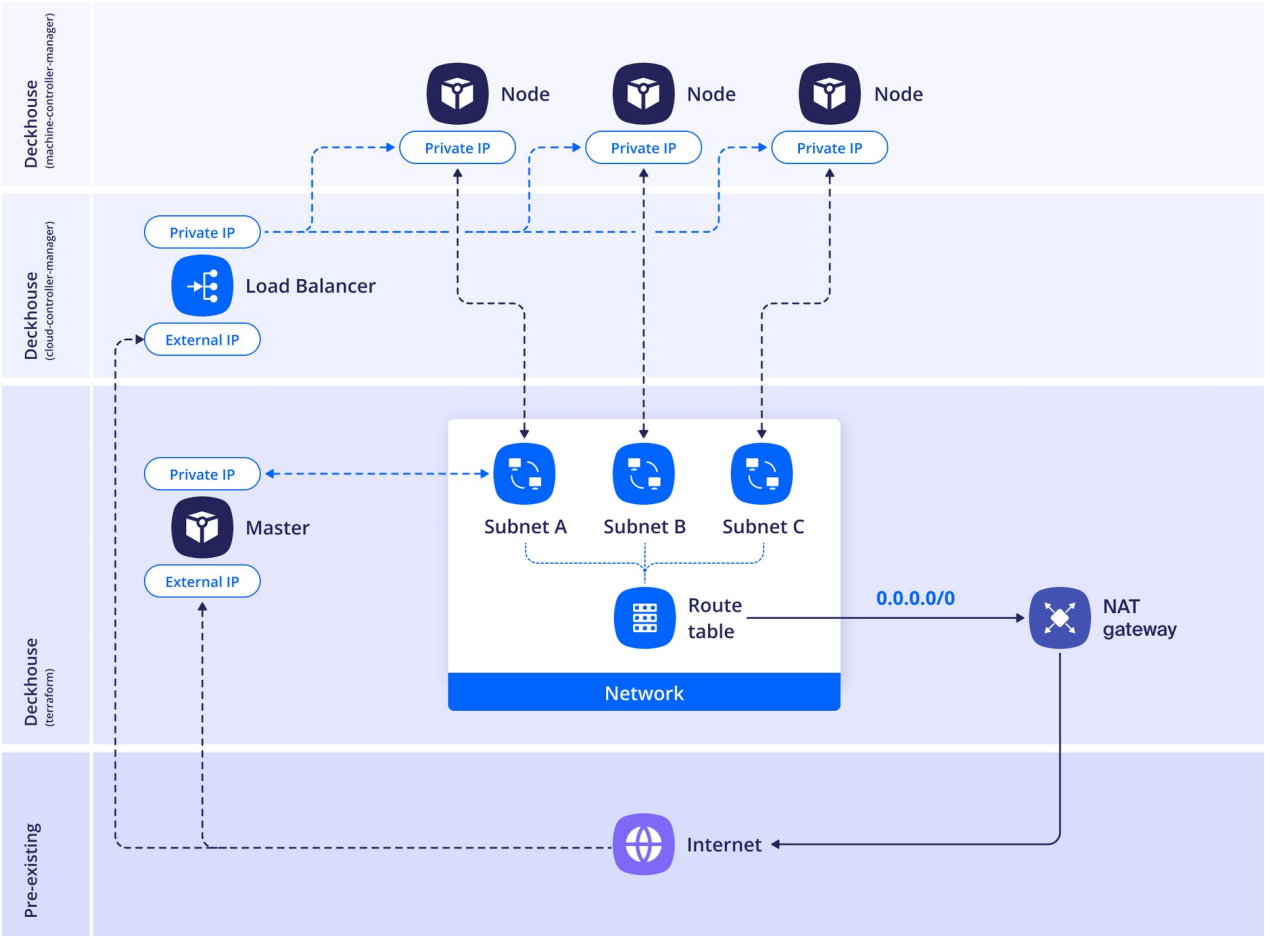
Health check parameters (for LB target groups created by the controller):

1. `yandex.cpi.flant.com/healthcheck-interval-seconds` — how often to run the check, in seconds (default: 2).
2. `yandex.cpi.flant.com/healthcheck-timeout-seconds` — how long to wait for an endpoint response, in seconds. If no response is received within this time, the check is considered failed (default: 1).
3. `yandex.cpi.flant.com/healthcheck-unhealthy-threshold` — how many consecutive failed checks are required to mark an endpoint as unhealthy and exclude it from load balancing (default: 2).
4. `yandex.cpi.flant.com/healthcheck-healthy-threshold` — how many consecutive successful checks are required to return an endpoint to healthy status and include it back in load balancing (default: 2).

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Layouts



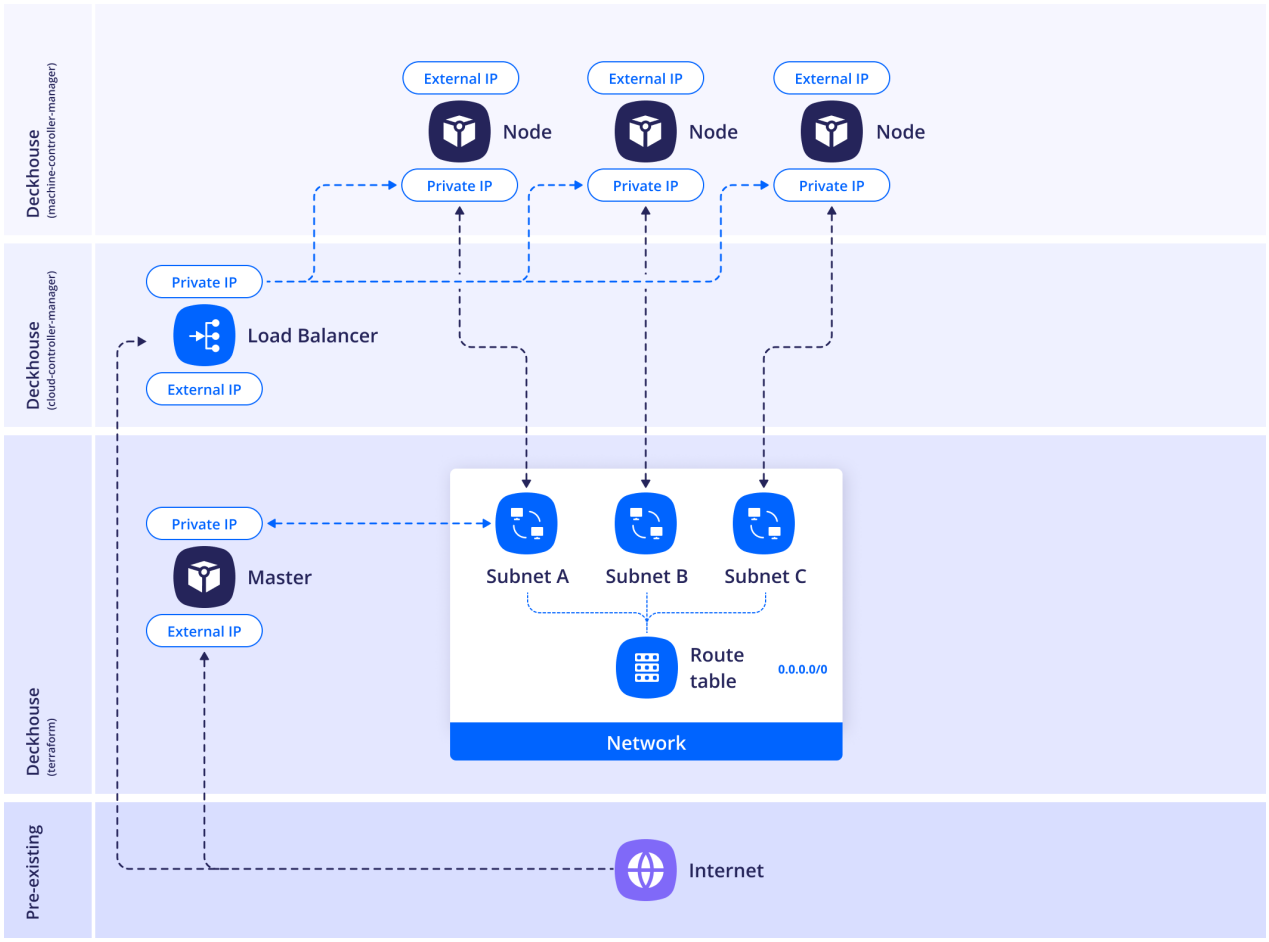
The module lifecycle stage: General Availability

Three layouts are supported. The layout is specified by the `layout` parameter in the section of the `cloud-provider-yandex` module’s ModuleConfig resource. Below is more information about each of them.

Standard

In this placement strategy, nodes do not have public IP addresses allocated to them; they use NAT gateway service in Yandex Cloud to connect to the Internet. NAT Gateway uses random public IP addresses from dedicated ranges. Because of this, it is impossible to whitelist the IP addresses of cloud resources located behind a specific NAT gateway on the side of other services.

Because nodes are created without public IP addresses in this layout, the master node must be accessible over SSH from the machine where `dhctl` is running: either directly over a private network or through a bastion host. If the master node is not directly accessible, run the installation with the `--ssh-bastion-host`, `--ssh-bastion-user`, and, if needed, `--ssh-bastion-port` parameters.



Example of the layout configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        cloudID: <CLOUD_ID>
        folderID: <FOLDER_ID>
    nodes:
      parameters:
        layout: Standard
        sshPublicKey: <SSH_PUBLIC_KEY>
        nodeNetworkCIDR: 192.168.12.0/24
        existingNetworkID: <EXISTING_NETWORK_ID>
        zones:
          - ru-central1-a
          - ru-central1-b
          - ru-central1-d
        labels:
          billing: prod
        dhcpOptions:
          domainName: test.local
          domainNameServers:
            - <DNS_SERVER_1>
            - <DNS_SERVER_2>
```

WithoutNAT

In this layout, NAT (of any kind) is not used, and each node is assigned a public IP.

⚠ The `cloud-provider-yandex` module does not assign security groups to the nodes, so in this layout the nodes are accessible from the outside without restrictions. To restrict the traffic, use the rules of the default group as described in “Configuring security groups”.

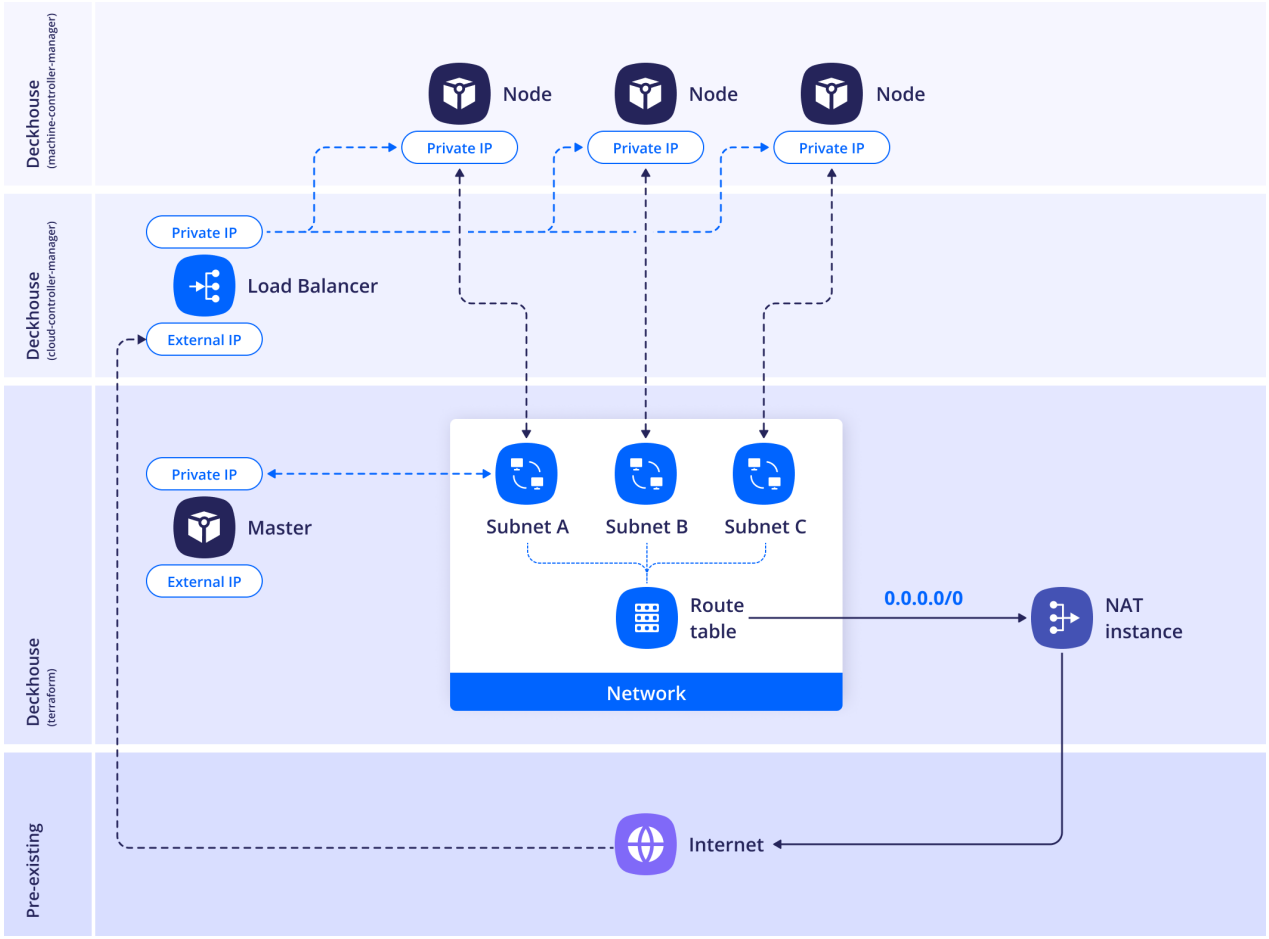
Example of the layout configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        cloudID: <CLOUD_ID>
        folderID: <FOLDER_ID>
    nodes:
      parameters:
        layout: WithoutNAT
        sshPublicKey: <SSH_PUBLIC_KEY>
        nodeNetworkCIDR: 192.168.12.0/24
        existingNetworkID: <EXISTING_NETWORK_ID>
        zones:
          - ru-central1-a
          - ru-central1-b
          - ru-central1-d
        externalIPAddresses:
          master:
            - Auto
            - Auto
            - Auto
          worker:
            - <ZONE_A_EXTERNAL_IP_WORKER_1>
            - Auto
        externalSubnetIDs:
          master:
            - <ZONE_A_SUBNET_ID>
            - <ZONE_B_SUBNET_ID>
            - <ZONE_D_SUBNET_ID>
          worker:
            - <ZONE_A_SUBNET_ID>
            - <ZONE_B_SUBNET_ID>
        dhcpOptions:
          domainName: test.local
          domainNameServers:
            - <DNS_SERVER_1>
            - <DNS_SERVER_2>
```

WithNATInstance

In this layout, a NAT instance is created in a separate subnet, and the route table of the zone subnets gets a `0.0.0.0/0` route with the NAT instance as the next hop. The subnet is allocated to prevent routing loops and must not overlap with other networks used in the cluster.

To place the NAT instance in an existing subnet, use the `withNATInstance.internalSubnetID` parameter — the instance will be created in the zone corresponding to that subnet.



If you need to create a new subnet, specify the `withNATInstance.internalSubnetCIDR` parameter — the NAT instance will be deployed in it.

One of the parameters — `withNATInstance.internalSubnetID` or `withNATInstance.internalSubnetCIDR` — is required.

When the `withNATInstance.internalSubnetCIDR` parameter is specified, the NAT instance will be created in a single instance in zone `a`.

When the `withNATInstance.internalSubnetID` parameter is specified, the NAT instance will be created in a single instance in the zone specified in the designated network settings.

If the `withNATInstance.externalSubnetID` is provided in addition to previous ones, the NAT instance will be attached to it via secondary interface.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        cloudID: <CLOUD_ID>
        folderID: <FOLDER_ID>
    nodes:
      parameters:
        layout: WithNATInstance
        sshPublicKey: <SSH_PUBLIC_KEY>
        nodeNetworkCIDR: 192.168.12.0/24
        existingNetworkID: <EXISTING_NETWORK_ID>
        zones:
          - ru-central1-a
        withNATInstance:
          natInstanceExternalAddress: <NAT_INSTANCE_EXTERNAL_ADDRESS>
          internalSubnetID: <INTERNAL_SUBNET_ID>
          externalSubnetID: <EXTERNAL_SUBNET_ID>
        dhcpOptions:
          domainName: test.local
          domainNameServers:
            - <DNS_SERVER_1>
            - <DNS_SERVER_2>
```

i

In this example, master and worker nodes are created without public IP addresses and without additional external network interfaces. Outbound traffic from the cluster subnets goes through the NAT instance.

The NAT instance is not automatically used by the `dhctl` installer as a bastion host or jump host. To install the cluster, the master node must be accessible over SSH from the machine where `dhctl` is running: either directly or through a bastion host.

If the master node does not have a public IP address or is not directly accessible, run the installation with the `--ssh-bastion-host` and `--ssh-bastion-user` parameters.

If you need to connect directly to a master node using a public IP address, specify the `externalIPAddresses` and `externalSubnetIDs` parameters in the `nodes.parameters` section of the `cloud-provider-yandex` module's ModuleConfig resource. Note that the interface connected to the network specified in `externalSubnetIDs` will be used as the node's default gateway.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Cloud provider — zVirt

> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability

The `cloud-provider-zvirt` module integrates Deckhouse Platform with zVirt. It allows the `node-manager` module to use zVirt resources when provisioning nodes for a NodeGroup.

The module is automatically enabled for all cloud clusters deployed in zVirt.

Features of the `cloud-provider-zvirt` module:

- Managing zVirt resources via `cloud-controller-manager`, which updates Kubernetes node addresses and removes from Kubernetes the nodes whose virtual machines no longer exist in zVirt.
- Provisioning disks via the zVirt CSI driver (`csi.ovirt.org`) and creating StorageClasses for zVirt storage domains so that PersistentVolumes can be requested from the cluster.
- Provisioning CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-ovirt`.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the ZvirtInstanceClass resource.
- Registering with `node-manager` so that ZvirtInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

> ⚠ If the cluster was installed with the ZvirtClusterConfiguration schema, it must be migrated to the ModuleConfig-based configuration. Until the migration is complete, the `D8CloudProviderZvirtMigrationPending` alert may fire and Deckhouse Platform updates may be blocked.
>
> The migration procedure is described in “How to migrate a cloud provider to ModuleConfig-based configuration?”.

Third-party components

List of third-party software used in the `cloud-provider-zvirt` module:

- zVirt CSI driver release-4.22

  License: Apache License 2.0

  CSI driver for zVirt (OpenShift oVirt CSI driver).

- zVirt Terraform provider 2.2.0

  License: BSD 3-Clause License

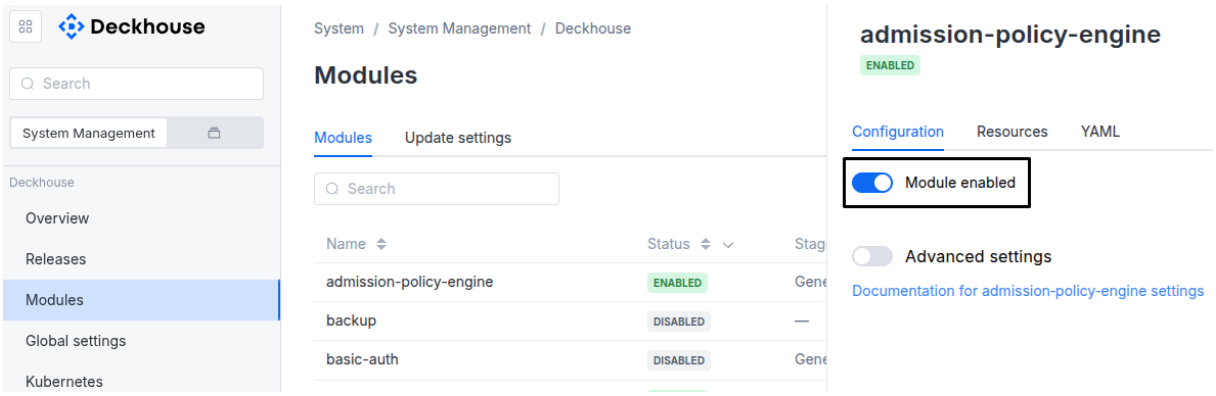
  Terraform provider for zVirt (oVirt).

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Included in extensions: **On-prem IaaS**

> The module lifecycle stage: General Availability



The module has 1 alert.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-zvirt` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

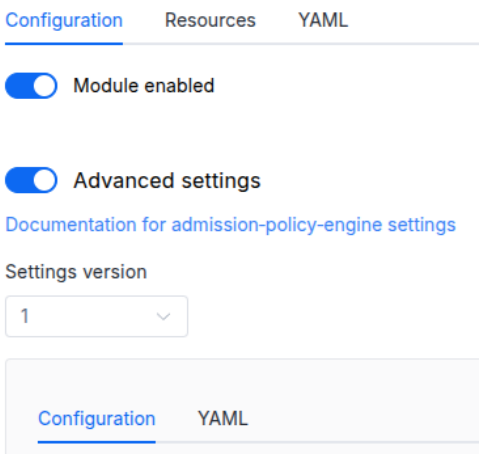
  ```
  d8 system module enable cloud-provider-zvirt
  ```

- **Using ModuleConfig `cloud-provider-zvirt`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-zvirt` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-zvirt`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-zvirt
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-zvirt` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-zvirt` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-zvirt`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-zvirt` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-zvirt
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-zvirt` using the example below. Fill in the

`spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-zvirt`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-zvirt
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  The settings are grouped under the `provider`, `nodes`, `storage`, and `ccm` parameters.

  The conversion sets temporary values for the `server`, `clusterID`, and `sshPublicKey` parameters. Replace them with the actual values.

  The zVirt login and password are not stored in the module settings. The module reads them from the `d8-credentials` Secret of the `cloud-provider.deckhouse.io/credentials` type.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.ccm**
    object

    Cloud Controller Manager (CCM) subsystem settings.

    CCM keeps the cluster node metadata up to date and removes from the cluster the nodes whose virtual machines no longer exist in zVirt.

    - **settings.ccm.disabled**
      boolean

      Disables the Cloud Controller Manager.

      When set to `true`, the module does not deploy CCM.

      Default: `false`

    - **settings.ccm.parameters**
      object

      Required value

      Parameters of the CCM subsystem.

  - **settings.nodes**
    object

    Required value

    Nodes subsystem settings.

    The subsystem describes how the cluster nodes are created in zVirt, including the layout, the SSH key, and the static network configuration.

    - **settings.nodes.disabled**
      boolean

      Disables the nodes subsystem.

      When set to `true`, the cluster does not create CloudEphemeral nodes in zVirt.

      Default: `false`

    - **settings.nodes.parameters**
      object

      Required value

      Parameters of the nodes subsystem.

- **settings.nodes.parameters.customNetworkConfigs**
  object

  Static network configuration of the nodes of CloudPermanent NodeGroups.

  The key is the name of a CloudPermanent NodeGroup, for example `master`. Nodes of a NodeGroup that is not listed get their network settings over DHCP.

  Addresses from the `networkInterfaceAddresses` list are assigned by node index. The first address goes to the node with index 0, the second address goes to the node with index 1, and so on. If the list holds fewer addresses than the NodeGroup has replicas, the remaining nodes get their addresses over DHCP.

  - **settings.nodes.parameters.customNetworkConfigs.<KEY_NAME>**
    object

    `<KEY_NAME>` — item (key) name.

    Static network configuration of a node network interface.

    - **settings.nodes.parameters.customNetworkConfigs.<KEY_NAME>.dnsServers**
      array of strings

      List of DNS servers.

      Example:

      ```
      dnsServers:
      - 8.8.8.8
      - 8.8.4.4
      ```

    - **settings.nodes.parameters.customNetworkConfigs.<KEY_NAME>.networkInterfaceAddresses**
      array of strings

      Required value

      List of IP addresses to assign to the interface, one address per node.

      Example:

      ```
      networkInterfaceAddresses:
      - 192.168.1.10
      - 192.168.1.11
      ```

    - **settings.nodes.parameters.customNetworkConfigs.<KEY_NAME>.networkInterfaceGateway**
      string

      Required value

      Default network gateway.

      Example:

      ```
      networkInterfaceGateway: 192.168.1.1
      ```

    - **settings.nodes.parameters.customNetworkConfigs.<KEY_NAME>.networkInterfaceName**
      string

      Required value

      Name of the network interface to apply the static configuration to.

      Example:

      ```
      networkInterfaceName: enp1s0
      ```

    - **settings.nodes.parameters.customNetworkConfigs.<KEY_NAME>.networkInterfaceNetmask**
      string

      Required value

      Subnet mask for the interface.

      Example:

      ```
      networkInterfaceNetmask: 255.255.255.0
      ```

- **settings.nodes.parameters.layout**
  string

  Required value

  Layout name.

  The available layouts are described in “Layouts”.

  Allowed values: `Standard`

        - **settings.nodes.parameters.sshPublicKey**
          string

          Required value

          Public SSH key for accessing the nodes.

- **settings.provider**
  object

  Required value

  zVirt connection settings.

  - **settings.provider.parameters**
    object

    Required value

    Parameters for connecting to the zVirt API.

    The login and the password are not set in the module settings. The module reads them from the `d8-credentials` Secret of the `cloud-provider.deckhouse.io/credentials` type in the `d8-cloud-provider-zvirt` namespace.

    - **settings.provider.parameters.caBundle**
      string

      Base64-encoded bundle of CA certificates in PEM format to verify the zVirt API certificate.

      When the `insecure` parameter is set to `true`, the bundle is ignored.

    - **settings.provider.parameters.clusterID**
      string

      Required value

      ID of the zVirt cluster to create virtual machines in.

      The cluster must have shared storage domains and CPUs of the same type.

      Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

      Example:

      ```
      clusterID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
      ```

    - **settings.provider.parameters.insecure**
      boolean

      Disables verification of the zVirt API certificate.

      Set to `true` if zVirt uses a self-signed certificate.

      Default: `false`

    - **settings.provider.parameters.server**
      string

      Required value

      URL of the zVirt API endpoint.

      Specify a URL with the `http` or `https` scheme.

- **settings.storage**
  object

  Storage subsystem settings.

  The subsystem provides the CSI driver and the StorageClasses for zVirt storage domains.

  - **settings.storage.disabled**
    boolean

    Disables the storage subsystem.

    When set to `true`, disk provisioning in the cluster is unavailable.

    Default: `false`

  - **settings.storage.parameters**
    object

    Required value

    Parameters of the storage subsystem.

    - **settings.storage.parameters.excludedStorageClasses**
      array of strings

      List of StorageClasses to exclude from creation in the cluster.

      The module creates a StorageClass for each active zVirt storage domain. Each item of the list is a regular expression matched against the whole StorageClass name. For example, `data` excludes only the `data` StorageClass, and `data.*` excludes every StorageClass whose name starts with `data`.

Provider configuration

> The module lifecycle stage: General Availability

ZvirtClusterConfiguration

Version: deckhouse.io/v1

> **Warning.** The resource is deprecated. The cloud provider configuration is set in the ModuleConfig resource of the `cloud-provider-zvirt` module. Migrate the cluster to ModuleConfig as described in “How to migrate a cloud provider to ModuleConfig-based configuration?”.

Describes the configuration of a cloud cluster in zVirt.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: ZvirtClusterConfiguration
layout: Standard
clusterID: b46372e7-0d52-40c7-9bbf-fda31e187088
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: debian-bookworm
    vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
    storageDomainID: c4bf82a5-b803-40c3-9f6c-b9398378f424
nodeGroups:
- name: worker
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: debian-bookworm
    vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
provider:
  server: "<SERVER>"
  username: "<USERNAME>"
  password: "<PASSWORD>"
  insecure: true
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **clusterID**
  string

  Required value

  Cluster ID with shared storage domains and CPUs of the same type to create virtual machines.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

```
clusterID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
```

- **kind**
  string

  Required value

  Allowed values: `ZvirtClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the ZvirtInstanceClass.

    - **masterNodeGroup.instanceClass.customNetworkConfig**
      object

      Enables a custom static network configuration for nodes in this NodeGroup.

      If specified, you must set `networkInterfaceName`, `networkInterfaceAddress`, `networkInterfaceGateway` and `networkInterfaceNetmask`.

      - **masterNodeGroup.instanceClass.customNetworkConfig.dnsServers**
        string

        List of DNS servers.

        Example:

        ```
        dnsServers: 8.8.8.8 8.8.4.4
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceAddress**
        array of strings

        List of IP addresses to assign to the interface (one IP address per node).

        Example:

        ```
        networkInterfaceAddress:
        - 192.168.1.10
        - 192.168.1.11
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceGateway**
        string

        Default network gateway.

        Example:

        ```
        networkInterfaceGateway: 192.168.1.1
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceName**
        string

        Name of the network interface to apply the static configuration to.

        Example:

        ```
        networkInterfaceName: enp1s0
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceNetmask**
        string

        Subnet mask for the interface.

        Example:

```
networkInterfaceNetmask: 255.255.255.0
```

- **masterNodeGroup.instanceClass.etcdDiskSizeGb**
  integer

  Etcd disk size in GiB.

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **masterNodeGroup.instanceClass.memory**
  integer

  Required value

  Memory in MiB to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  memory: 8192
  ```

- **masterNodeGroup.instanceClass.numCPUs**
  integer

  Required value

  Number of vCPUs to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  numCPUs: 2
  ```

- **masterNodeGroup.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in zVirt VirtualMachines.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **masterNodeGroup.instanceClass.storageDomainID**
  string

  Required value

  Storage domain id which contains the shared resources that must be available to all datacenter hosts.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  storageDomainID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **masterNodeGroup.instanceClass.template**
  string

  Required value

  Template name to be cloned.

  Example:

  ```
  template: debian-bookworm
  ```

- **masterNodeGroup.instanceClass.vnicProfileID**
  string

  Required value

  Virtual NIC profile ID on the basis of which the virtual NIC will be created.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **masterNodeGroup.replicas**
  integer

Required value

The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

Allowed values: `1 <= X`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the.

    - **nodeGroups.instanceClass.customNetworkConfig**
      object

      Enables a custom static network configuration for nodes in this NodeGroup.

      If specified, you must set `networkInterfaceName`, `networkInterfaceAddress`, `networkInterfaceGateway` and `networkInterfaceNetmask`.

      - **nodeGroups.instanceClass.customNetworkConfig.dnsServers**
        string

        List of DNS servers.

        Example:

        ```
        dnsServers: 8.8.8.8 8.8.4.4
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceAddress**
        array of strings

        List of IP addresses to assign to the interface (one IP address per node).

        Example:

        ```
        networkInterfaceAddress:
        - 192.168.1.10
        - 192.168.1.11
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceGateway**
        string

        Default network gateway.

        Example:

        ```
        networkInterfaceGateway: 192.168.1.1
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceName**
        string

        Name of the network interface to apply the static configuration to.

        Example:

        ```
        networkInterfaceName: enp1s0
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceNetmask**
        string

        Subnet mask for the interface.

        Example:

        ```
        networkInterfaceNetmask: 255.255.255.0
        ```

    - **nodeGroups.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in GiB.

      Default: `10`

      Example:

      ```
      etcdDiskSizeGb: 10
      ```

    - **nodeGroups.instanceClass.memory**
      integer

      Required value

      Memory in MiB to allocate to the VM.

Allowed values: `1 <= X`

Example:

```
memory: 8192
```

- **nodeGroups.instanceClass.numCPUs**
  integer

  Required value

  Number of vCPUs to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  numCPUs: 2
  ```

- **nodeGroups.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in zVirt VirtualMachines.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **nodeGroups.instanceClass.storageDomainID**
  string

  Storage domain id which contains the shared resources that must be available to all datacenter hosts.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  storageDomainID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **nodeGroups.instanceClass.template**
  string

  Required value

  Template name to be cloned.

  Example:

  ```
  template: debian-bookworm
  ```

- **nodeGroups.instanceClass.vnicProfileID**
  string

  Required value

  Virtual NIC profile ID on the basis of which the virtual NIC will be created.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

The same as the `metadata.labels` standard field.

Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **provider**
  object

  Required value

  Parameters for connecting to the Zvirt.

  - **provider.caBundle**
    string

    CA certificate in base64.

    Default:
  - **provider.insecure**
    boolean

    Set to `true` if Zvirt has a self-signed certificate.

    Default: `false`
  - **provider.password**
    string

    Required value

    The user’s password.
  - **provider.server**
    string

    Required value

    The URL to the Zvirt API endpoint.
  - **provider.username**
    string

    Required value

    The login ID.

- **sshPublicKey**
  string

  Required value

  a public key for accessing nodes.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> The module lifecycle stage: General Availability

Environment requirements

The provider requires the following:

- A working zVirt installation with an accessible API
- zVirt version `4.0-4.4`
- A user with the permissions listed in the “User permissions” section
- A storage domain with an uploaded cloud image of the operating system
- A virtual machine template prepared from the cloud image

If the zVirt API uses a self-signed certificate, pass the CA certificate in the `caBundle` parameter or set the `insecure` parameter to `true`.

User permissions

Deckhouse Platform does not require the `SuperUser` role for the zVirt user. It is enough to assign the following predefined zVirt roles to the user on the objects the cluster works with:

Role	Object	Purpose
`UserVmManager`	zVirt cluster from the `clusterID` parameter	Creating, starting, stopping, and deleting node virtual machines, creating their network interfaces, attaching and detaching disks
`UserTemplateBasedVm`	Virtual machine template	Creating virtual machines from the template
`DiskOperator`	Storage domains that contain the template disk and where disks for etcd and cluster volumes are created	Creating, resizing, attaching, detaching, and deleting disks
`VnicProfileUser`	vNIC profile	Creating a virtual machine network interface from the vNIC profile
`TagManager`	Entire system (system permission)	Creating the cluster tag and assigning it to virtual machines of CloudEphemeral nodes

The `TagManager` role is assigned only on the entire system, because zVirt checks the tag management permission at this level.

> ⚠ The `TagManager` role is administrative. With it, the user can view all objects via the zVirt API but can modify only the objects on which the roles from the table are assigned to the user.

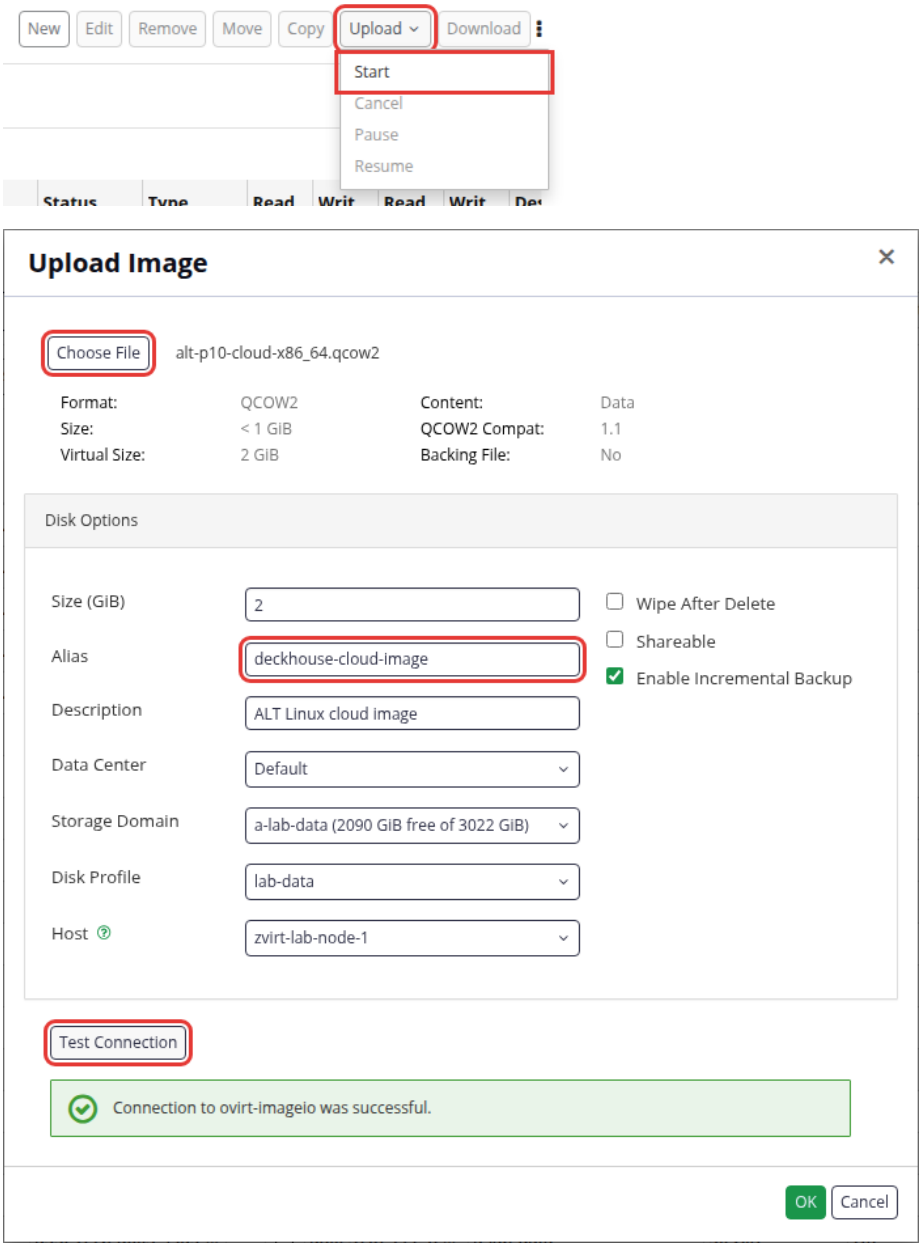
zVirt assigns some roles to the Everyone group by default, so you do not need to assign them to the user separately:

- `UserTemplateBasedVm` on a template created with the “Allow all users to access this Template” checkbox selected
- `VnicProfileUser` on a public vNIC profile
- `CpuProfileOperator` on the cluster CPU profile
- `DiskProfileUser` on the disk profiles of storage domains

If these permissions were removed in your zVirt installation, assign the roles to the user.

To assign a role on an object:

1. Open the object in the zVirt Administration Portal, for example, a cluster in the “Compute → Clusters” section.
2. Go to the “Permissions” tab and click “Add”.
3. Select the user and the role and save the permission.



Assign the `TagManager` role in the “Administration → Configure” section on the “System Permissions” tab.

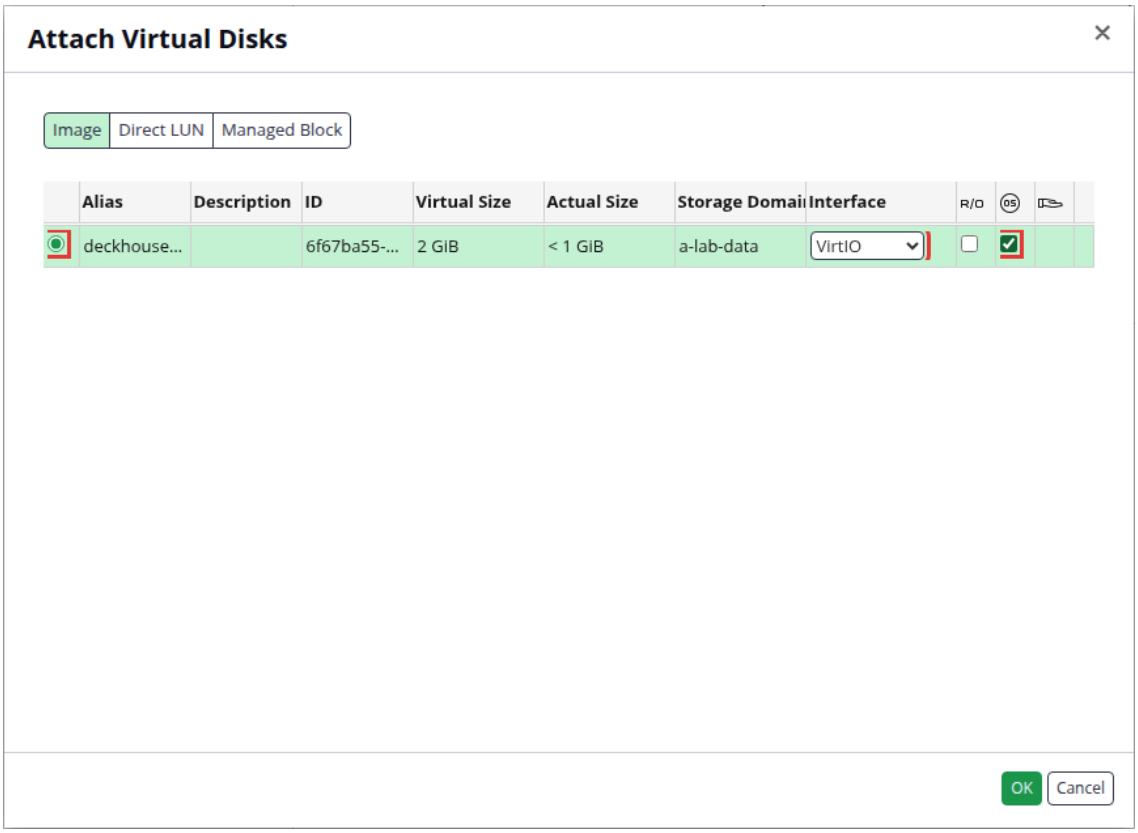
Prepare an operating system image

Operating system (OS) vendors usually provide special cloud builds of their OSes for virtualization environments. These builds contain virtual hardware drivers, `cloud-init`, and virtualization guest agents and are distributed as IMG or QCOW2 disk images. Use these cloud images as the OS of the cluster nodes.

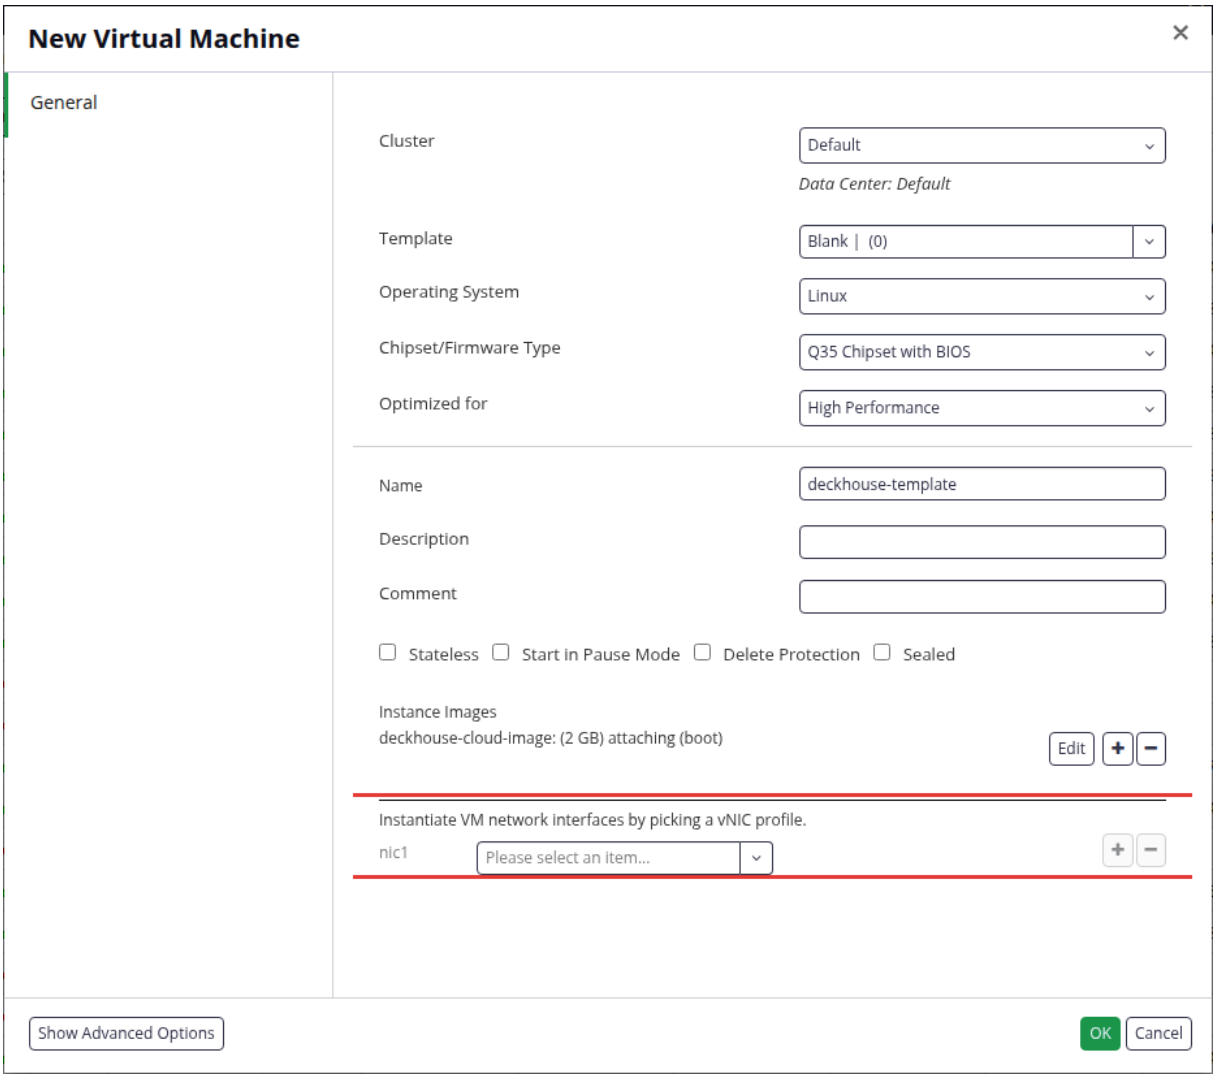
The OS cloud image must be placed in the zVirt disk storage. To upload the image to the storage:

1. Open the zVirt Administration Portal and go to the “Storage → Disks” section.
2. Upload the OS cloud image to the storage.

3. Wait until the image upload is complete. The `OK` status must appear in the “Status” column.

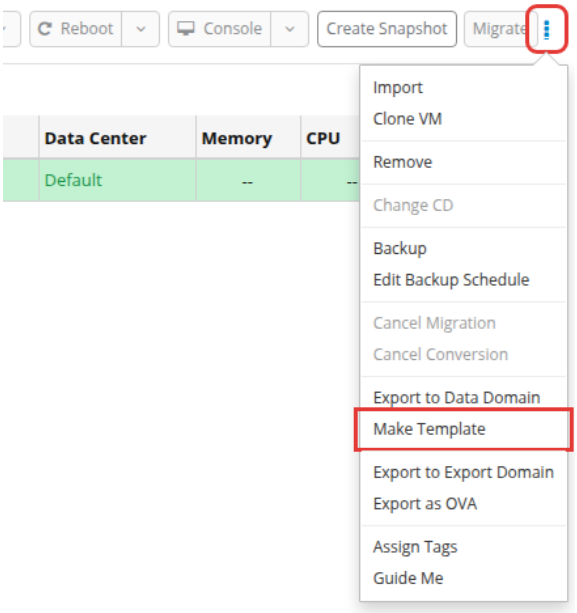


Prepare a virtual machine template

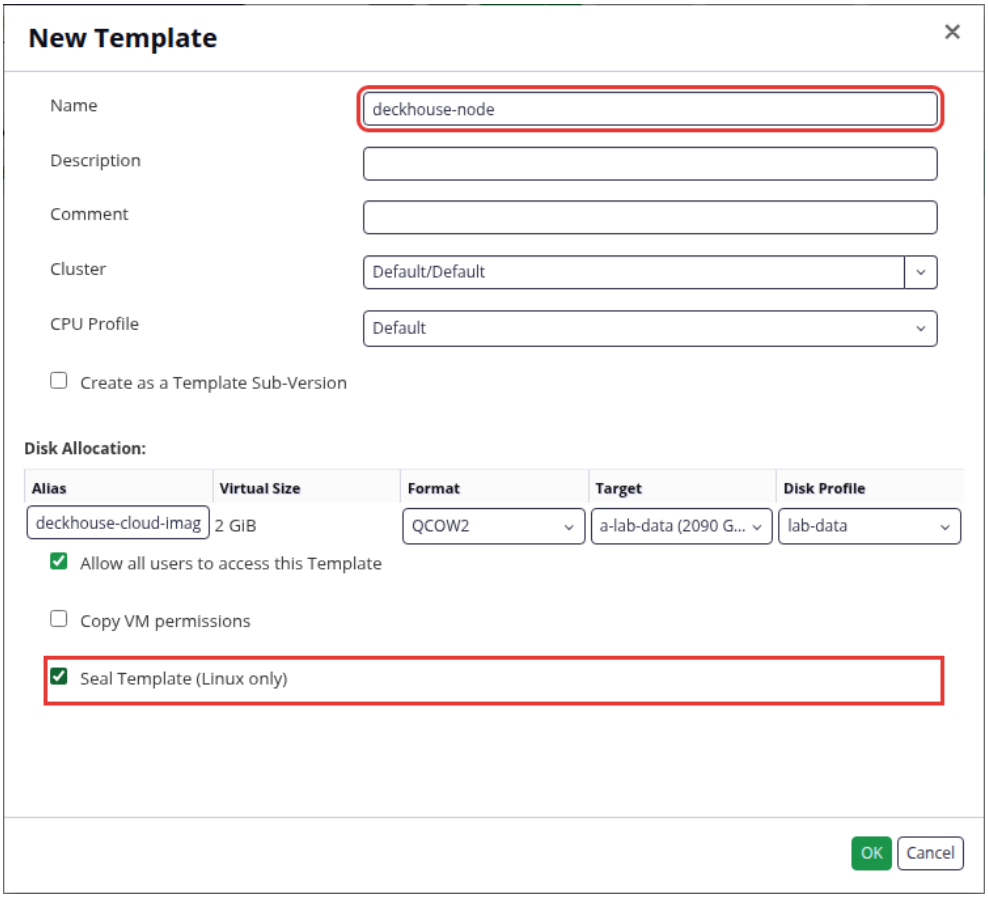


> ⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

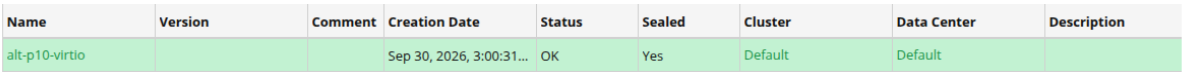
The template is created from a virtual machine (VM) with the OS cloud image attached. To prepare the template:



1. In the zVirt Administration Portal, go to the “Compute → Virtual Machines” section and create a VM. In the “General” section, set the following parameters:
   - “Template”: `Blank`.
   - “Operating System”: The OS of the cloud image.
   - “Optimized for”: “High Performance”.
   - “Instance Images”: Click “Attach”, select the uploaded OS cloud image, select the checkbox in the “OS” column to make the disk bootable, and select the “VirtIO” interface. Do not create or attach other disks.



2. Do not attach network interfaces. Deckhouse Platform creates a network interface when it creates a VM for a node.



3. Leave the other parameters at their defaults and create the VM.
4. When the VM is created, select it in the list, open the additional actions menu (⋮), and select “Make Template”.

5. Specify the template name and enable the “Seal Template (Linux only)” parameter. The other template parameters are optional.

6. Wait until the template is created. While the template is being created, the VM and the cloud image disk are in the “Image Locked” state. The created template is displayed in the “Compute → Templates” section.

Replacing the OS image

The `template` parameter of ZvirtInstanceClass defines the image for `CloudEphemeral` nodes. With a ModuleConfig-based provider configuration, this parameter also defines the image for `CloudPermanent` nodes and master nodes.

With a ZvirtClusterConfiguration-based configuration, the image for `CloudPermanent` nodes and master nodes is set by `template` in `nodeGroups[].instanceClass` and `masterNodeGroup.instanceClass`, respectively.

The replacement procedure is described in “How do I replace the OS image in a cloud cluster?” .

Credentials Secret

The zVirt user login and password are stored in a separate Secret rather than in the ModuleConfig. The module reads it and passes the credentials to its components that access the zVirt API.

The Secret is created during cluster installation together with the other resources of the initial configuration. The Secret must meet the following requirements:

- The name is `d8-credentials` and the namespace is `d8-cloud-provider-zvirt`.
- The type is `cloud-provider.deckhouse.io/credentials`.
- The `authScheme` field is set to `userPassword`.
- The `identity` field contains the zVirt user login.
- The `secret` field contains the zVirt user password.

```
apiVersion: v1
kind: Secret
metadata:
  name: d8-credentials
  namespace: d8-cloud-provider-zvirt
type: cloud-provider.deckhouse.io/credentials
stringData:
  authScheme: userPassword
  identity: <USERNAME>
  secret: <PASSWORD>
```

Replace `<USERNAME>` and `<PASSWORD>` with the zVirt user login and password.

A Secret that does not meet these requirements fails the check both during cluster installation and when applied in a running cluster.

To change the credentials, update the `identity` and `secret` fields:

```
d8 k -n d8-cloud-provider-zvirt edit secret d8-credentials
```

In clusters migrated to ModuleConfig, the login and password are moved to this Secret from the `provider.username` and `provider.password` parameters of the ZvirtClusterConfiguration resource.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

ZvirtInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of the zVirt virtual machines that Deckhouse Platform creates for the cluster nodes.

The resource is referenced in the `cloudInstances.classReference` parameter of a NodeGroup.

- **metadata**
  object
- **spec**
  object

  Required value

  Defines the parameters of a zVirt virtual machine.

  - **spec.etcdDiskSizeGb**
    integer

    Size of the etcd disk, in GiB.

    The parameter is required in the instance class of the `master` NodeGroup and cannot be set in the instance classes of other NodeGroups.

    Allowed values: `1 <= X`

    Example:

    ```
    etcdDiskSizeGb: 10
    ```

- **spec.memory**
  integer

  Required value

  Amount of memory allocated to the virtual machine, in MiB.

  Allowed values: `1 <= X`

  Example:

  ```
  memory: 8192
  ```

- **spec.numCPUs**
  integer

  Required value

  Number of vCPUs allocated to the virtual machine.

  Allowed values: `1 <= X`

  Example:

  ```
  numCPUs: 2
  ```

- **spec.rootDiskSizeGb**
  integer

  Size of the virtual machine root disk, in GiB.

  The root disk created from the template is resized to this value.

  If the parameter is not set, the disk size is 50 GiB for CloudPermanent nodes and 20 GiB for CloudEphemeral nodes.

  Allowed values: `1 <= X`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **spec.storageDomainID**
  string

  ID of the zVirt storage domain to create the etcd disk of master nodes in.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  storageDomainID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **spec.template**
  string

  Required value

  Name of the zVirt template to clone virtual machines from.

  Example:

  ```
  template: debian-bookworm
  ```

- **spec.vnicProfileID**
  string

  Required value

  ID of the virtual network interface card (vNIC) profile used to create the virtual machine network interface.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **status**
  object

  Status of the ZvirtInstanceClass resource.

  - **status.nodeGroupConsumers**
    array of strings

    Names of the NodeGroups that use this instance class.

Parameters of the zVirt virtual machines that Deckhouse Platform creates for the cluster nodes.

The resource is referenced in the `cloudInstances.classReference` parameter of a NodeGroup.

- **metadata**

object
- **spec**
  object

  Required value

  - **spec.memory**
    integer

    Required value

    Amount of memory allocated to the virtual machine, in MiB.

    Example:

    ```
    memory: 8192
    ```
  - **spec.numCPUs**
    integer

    Required value

    Number of vCPUs allocated to the virtual machine.

    Example:

    ```
    numCPUs: 2
    ```
  - **spec.rootDiskSizeGb**
    integer

    Size of the virtual machine root disk, in GiB.

    The root disk created from the template is resized to this value.

    Default: `30`

    Example:

    ```
    rootDiskSizeGb: 30
    ```
  - **spec.template**
    string

    Required value

    Name of the zVirt template to clone virtual machines from.

    Example:

    ```
    template: debian-bookworm
    ```
  - **spec.vnicProfileID**
    string

    Required value

    ID of the virtual network interface card (vNIC) profile used to create the virtual machine network interface.

    Pattern: `^[0-9a-fA-F]{8}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{12}$`

    Example:

    ```
    vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
    ```
- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

    Names of the NodeGroups that use this instance class.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Usage

> The module lifecycle stage: General Availability

Provider configuration

All provider settings except the credentials are set in the ModuleConfig resource of the module. Deckhouse Platform applies them both when creating the cluster and in a running cluster.

The login and password for accessing the zVirt API are not stored in the module settings. The module reads them from the `d8-credentials` Secret, whose format is covered in the “Credentials Secret” section.

Virtual machine parameters are set in the ZvirtInstanceClass resource referenced by a NodeGroup. An example configuration with all the resources is given on the “Layouts” page.

FAQ

> **i** The module lifecycle stage: General Availability

How to get the vNIC profile ID?

You can get the ID of the vNIC profile set in the `vnicProfileID` parameter of the ZvirtInstanceClass resource by querying the zVirt API:

1. Get an access token for the zVirt API:

   ```
   curl -s -X POST <ZVIRT_ENGINE_URL>/sso/oauth/token \
     -H "Accept: application/json" \
     --data-urlencode "grant_type=password" \
     --data-urlencode "scope=ovirt-app-api" \
     --data-urlencode "username=<USERNAME>" \
     --data-urlencode "password=<PASSWORD>"
   ```

   Replace `<ZVIRT ENGINE URL>` with the URL from the `server` parameter of the module settings without the trailing `/api`, for example, `https://zvirt.example.com/ovirt-engine`. Replace `<USERNAME>` and `<PASSWORD>` with the zVirt user login and password in the same format as in the credentials Secret.

   The token is given in the `access_token` field of the response.

2. Get the list of vNIC profiles:

   ```
   curl -s -H "Authorization: Bearer <TOKEN>" <ZVIRT_ENGINE_URL>/api/vnicprofiles
   ```

   Replace `<TOKEN>` with the token from the previous step.

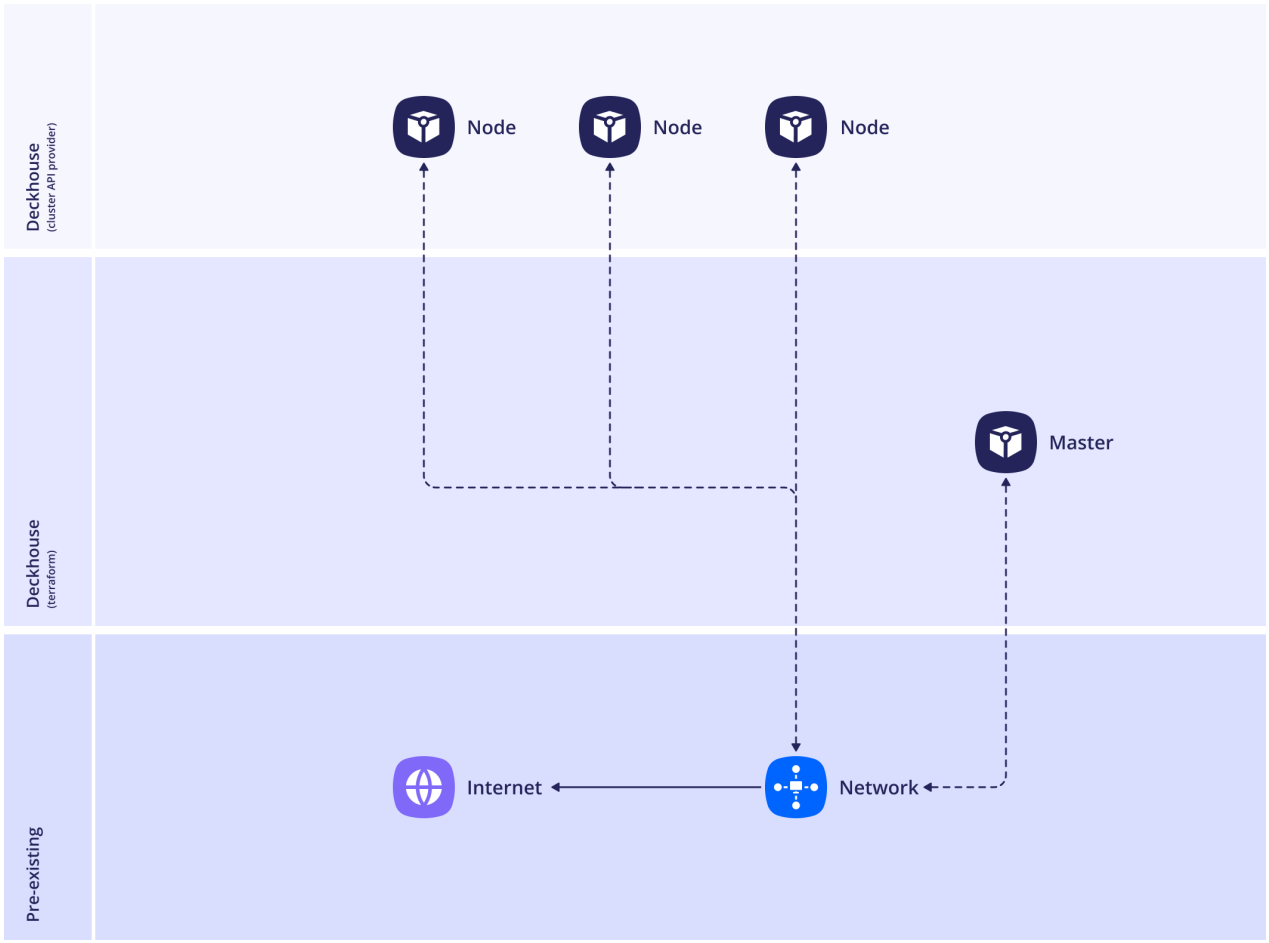
The profile ID is given in the `id` attribute of the `vnic_profile` element. Response example:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<vnic_profiles>
   <vnic_profile href="/ovirt-engine/api/vnicprofiles/49bb4594-0cd4-4eb7-8288-8594eafd5a86"
id="49bb4594-0cd4-4eb7-8288-8594eafd5a86">
      <name>vm-net-01</name>
      <link href="/ovirt-engine/api/vnicprofiles/49bb4594-0cd4-4eb7-8288-8594eafd5a86/permissions"
rel="permissions"/>
      <pass_through>
         <mode>disabled</mode>
      </pass_through>
      <port_mirroring>false</port_mirroring>
      <network href="/ovirt-engine/api/networks/74a741c9-0d40-4008-8e58-1c903ee6eba7" id="74a741c9-0d40-
4008-8e58-1c903ee6eba7"/>
   </vnic_profile>
   ...
</vnic_profiles>
```

How to disable individual provider subsystems?

To disable the nodes, storage, or Cloud Controller Manager subsystem, in the ModuleConfig resource of the `cloud-provider-zvirt` module, set the `nodes.disabled`, `storage.disabled`, or `ccm.disabled` parameter to `true`.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.



Layouts

> **i** The module lifecycle stage: General Availability

Only the Standard layout is supported. The layout is set with the `layout` parameter in the ModuleConfig resource of the module.

Standard

In the Standard layout, all cluster nodes are created in a single zVirt cluster set with the `clusterID` parameter. Virtual machines are cloned from a prepared template, and their network interface is created from a vNIC profile.

Example of the layout configuration with one master node:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-zvirt
spec:
  version: 2
  enabled: true
  settings:
    provider:
      parameters:
        server: <ZVIRT_API_URL>
        clusterID: <CLUSTER_ID>
    nodes:
      parameters:
        layout: Standard
        sshPublicKey: <SSH_PUBLIC_KEY>
---
apiVersion: v1
kind: Secret
metadata:
  name: d8-credentials
  namespace: d8-cloud-provider-zvirt
type: cloud-provider.deckhouse.io/credentials
stringData:
  authScheme: userPassword
  identity: <USERNAME>
  secret: <PASSWORD>
---
apiVersion: deckhouse.io/v1
kind: ZvirtInstanceClass
metadata:
  name: master
spec:
  numCPUs: 4
  memory: 8192
  rootDiskSizeGb: 50
  etcdDiskSizeGb: 10
  template: <TEMPLATE_NAME>
  vnicProfileID: <VNIC_PROFILE_ID>
  storageDomainID: <STORAGE_DOMAIN_ID>
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: master
spec:
  nodeType: CloudPermanent
  cloudInstances:
    classReference:
      kind: ZvirtInstanceClass
      name: master
    minPerZone: 1
    maxPerZone: 1
```

Where:

- `ZVIRT_API_URL`: URL of the zVirt API endpoint, for example, `https://zvirt.example.com/ovirt-engine/api`.
- `CLUSTER_ID`: ID of the zVirt cluster to create virtual machines in.
- `SSH_PUBLIC_KEY`: Public SSH key for accessing the nodes.
- `USERNAME` and `PASSWORD`: zVirt user login and password for the Secret whose format is covered in the “Credentials Secret” section.
- `TEMPLATE_NAME`: Name of the virtual machine template prepared as described in the “Prepare a virtual machine template” section.
- `VNIC_PROFILE_ID`: ID of the vNIC profile that you can get as described in the “How to get the vNIC profile ID?” section.
- `STORAGE_DOMAIN_ID`: ID of the zVirt storage domain to create the etcd disk in.

The number of master nodes is set with the `minPerZone` parameter of the `master` node group. In the ZvirtInstanceClass resource of the `master` group, set the `etcdDiskSizeGb` and `storageDomainID` parameters, which set the size and the storage domain of a separate disk for etcd. The `etcdDiskSizeGb` parameter cannot be set in the instance classes of other CloudPermanent groups.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The cni-cilium module

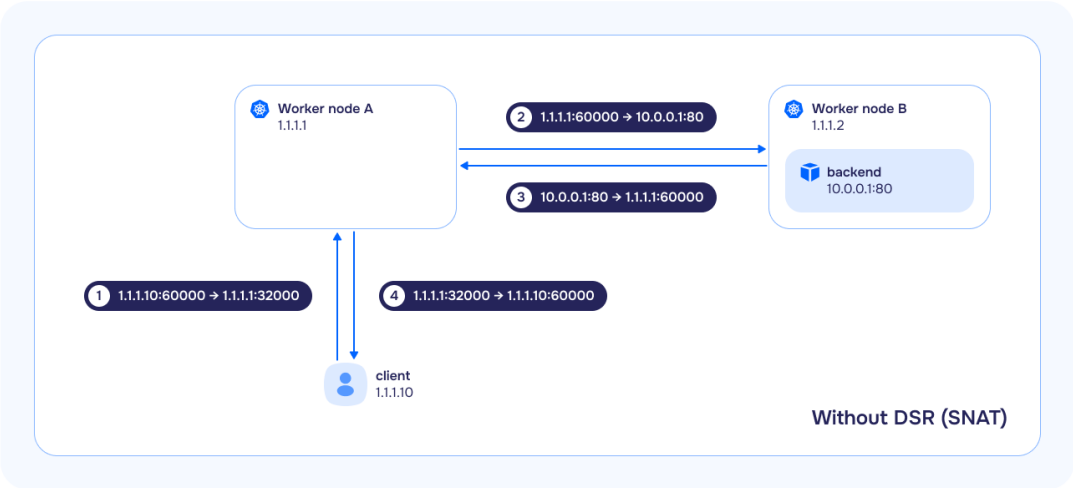
> **i** Available with limitations in: **Open/CE, Core, BE, SE**
>
> Available without limitations in: **SE+, Ultimate/EE**

> **i** Included with limitations in extensions: **Advanced Networking**
>
> Included without limitations in extensions: **Cluster Union**

> **i** The module lifecycle stage: General Availability

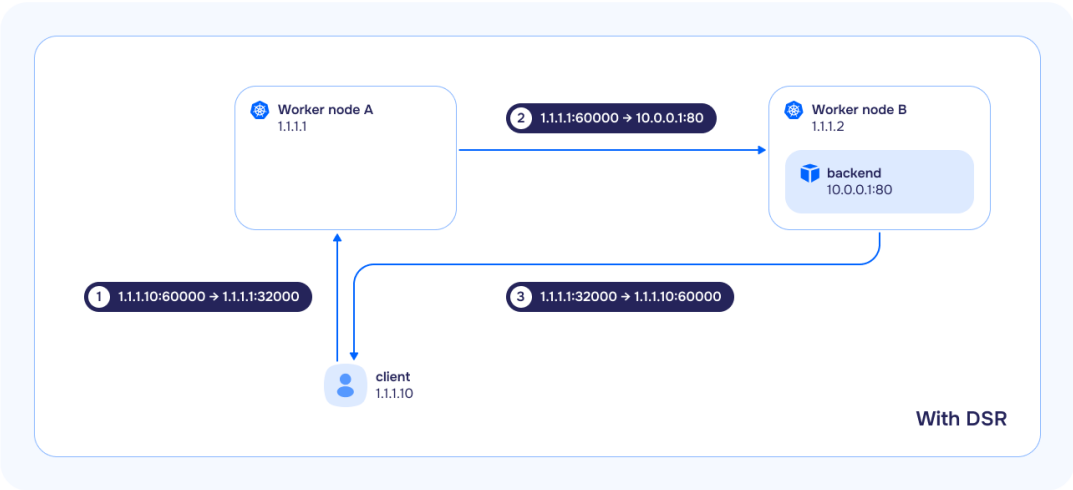
The `cni-cilium` module provides a network in a cluster. It is based on the Cilium project.

Limitations



1. Services with type `NodePort` and `LoadBalancer` are incompatible with hostNetwork endpoints in LB mode `DSR`. Switch to `SNAT` mode if it is required.
2. `HostPort` pods only bind to one IP address. If the OS has multiple interfaces/IP, Cilium will choose one, preferring `private` to `public`.
3. If a node's `ExternalIP` is not assigned to any of the node's network interfaces but is provided by external infrastructure (for example, via 1:1 NAT), traffic from the PodNetwork to that `ExternalIP` is not supported. As a result, Pods that do not use `hostNetwork` cannot access a port exposed via `hostPort` using the node's `ExternalIP`. Use the node's `InternalIP` for such connections.
4. To ensure the stable operation of `cni-cilium` on cluster nodes, disable Elastic Agent or restrict its access to the Elastic management server. Elastic Agent includes an Elastic Endpoint component which uses the Extended Berkeley Packet Filter (eBPF) technology on cluster nodes and may remove critical eBPF programs required for `cni-cilium` to work correctly. For detailed information and discussion of the issue, refer to the publications of the Cilium and Elastic projects.
5. Kernel requirements:
   - Linux kernel version not lower than `5.8` for the `cni-cilium` module to work and work together with the istio, openvpn or node-local-dns modules.
6. OS compatibility:
   - Ubuntu:
     - incompatible with version 18.04;
     - HWE kernel installation required for working with version 20.04.
   - Astra Linux:
     - incompatible with the "Smolensk" edition.
   - CentOS:
     - for versions 7 and 8, a new kernel from the repository is required.

Handling external traffic in different `bpfLB` modes (replacing kube-proxy from Cilium)



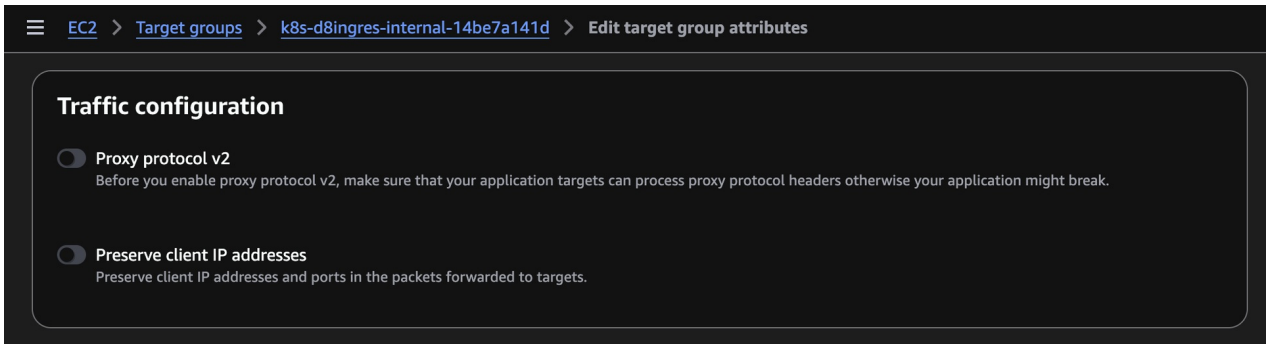
Kubernetes typically uses schemes where traffic comes to a balancer that distributes it among many servers. Both incoming and outgoing traffic passes through the balancer. Thus, the total throughput is limited by the resources and channel width of the balancer. To optimize traffic and unload the balancer, the `DSR` mechanism was invented, in which incoming packets go through the balancer, and outgoing ones go directly from the terminating servers. Since responses are usually much larger in size than requests, this approach can significantly increase the overall throughput of the scheme.

To extend the capabilities, the module allows selectable mode of operation, which affects the behavior of `Service` with the `NodePort` and `LoadBalancer` types:

- `SNAT` (Source Network Address Translation) — is a subtype of NAT in which, for each outgoing packet, the source IP address is translated to the IP address of the gateway from the target subnet, and incoming packets passing through the gateway are translated back based on a translation table. In this mode, `bpfLB` fully replicates the logic of `kube-proxy`:
  - if `externalTrafficPolicy: Local` is specified in the `Service`, the traffic will be forwarded and balanced only to those target pods running on the same node where the traffic arrived. If the target pod is not running on this node, the traffic will be dropped.
  - if `externalTrafficPolicy: Cluster` is specified in the `Service`, the traffic will be forwarded and balanced to all target pods in the cluster. At the same time, if the target pods are located on other nodes, SNAT will be performed when transmitting traffic to them (the source IP address will be replaced with the InternalIP of the node).

- `DSR` (Direct Server Return) — is a method where all incoming traffic passes through the load balancer, and all outgoing traffic bypasses it. This method is used instead of `SNAT`. Often, responses are much larger than requests, and `DSR` can significantly increase the overall throughput of the scheme:
  - if `externalTrafficPolicy: Local` is specified in the `Service`, its behavior is completely analogous to `kube-proxy` and `bpfLB` in `SNAT` mode.
  - if `externalTrafficPolicy: Cluster` is specified in the `Service`, the traffic will be forwarded and balanced to all target pods in the cluster. It is important to take into account the following features:
    - if the target pods are on other nodes, then the source IP address will be preserved when incoming traffic is sent to them;
    - outgoing traffic will go directly from the node on which the target pod was launched;
    - the source IP address will be replaced with the external IP address of the node to which the incoming request originally came.

⚠ In case of using `DSR` and `Service` mode with `externalTrafficPolicy: Cluster` additional network environment settings are required. Network equipment must be ready for asymmetric traffic flow: IP address anti-spoofing tools (`uRPF`, `sourceGuard`, etc.) must be disabled or configured accordingly.



- `Hybrid` — in this mode, TCP traffic is processed in `DSR` mode, and UDP in `SNAT` mode.

Operational specifics of CNI Cilium on AWS

If Cilium runs in VXLAN mode (the only mode available on AWS), then by default connections from inside the cluster (from a node or a pod) to internal resources exposed through an `internal` load balancer (Load Balancer) do not work. From outside the cluster, the load balancer address answers. The cause is the enabled `preserve_client_ip` option (“Preserve client IP addresses”) on the target group: the load balancer skips NAT and the return traffic goes straight through the VXLAN tunnel past the load balancer. The traffic becomes asymmetric, and the connection drops. To fix it, disable `preserve_client_ip` on the target group in one of two ways.

⚠ After you disable `preserve_client_ip`, the load balancer performs SNAT, and the application stops seeing the real client IP address at the network level. For HTTP/HTTPS traffic this is not a problem: the address is still passed in the `X-Forwarded-For` header.

Using the AWS web console. Open **EC2 → Target groups**, select the load balancer target group (for example, `k8s-d8ingres-internal-...`), click **Edit target group attributes**, and in the **Traffic configuration** block turn off the **Preserve client IP addresses** toggle.

Using the AWS CLI. Run the command with your own target group ARN and region (you can get the ARN in the same **Target groups** section or with `aws elbv2 describe-target-groups`):

```
aws elbv2 modify-target-group-attributes \
  --target-group-arn arn:aws:elasticloadbalancing:REGION:ACCOUNT:targetgroup/NAME/ID \
  --attributes Key=preserve_client_ip.enabled,Value=false \
  --region REGION
```

Using CiliumClusterwideNetworkPolicy

✖ Applying CiliumClusterwideNetworkPolicy without `policyAuditMode` enabled may break control plane operation or cut SSH access to all cluster nodes.

The safe rollout procedure for CiliumClusterwideNetworkPolicy, including mandatory control plane and host firewall rules, is described in the Network policies section of the documentation. For details on the Cilium policy formats, refer to CiliumNetworkPolicy and CiliumClusterwideNetworkPolicy.

Changing Cilium Operation Mode

When changing Cilium's operation mode (the tunnelMode parameter) from `Disabled` to `VXLAN` or vice versa, it is necessary to reboot all nodes, otherwise, pod availability issues may occur.

Disabling the kube-proxy Module

Cilium fully replaces the functionality of the `kube-proxy` module, so `kube-proxy` is automatically disabled when the `cni-cilium` module is enabled.

Using selective load balancing algorithm for services

In Deckhouse Platform, you can apply the following algorithms to load balance service traffic:

- `Random`: Randomly select a backend for each connection. Easy to implement, but does not always provide even distribution.
- `Maglev`: Uses consistent hashing to distribute traffic evenly, suitable for large-scale services.
- `Least Connections`: Directs traffic to the backend with the lowest number of active connections, optimizing load for applications with long-lived connections.

By default, the Random balancing algorithm is set for all services. However, Deckhouse allows you to override the algorithm for individual services. To use a selective balancing algorithm for a specific service, follow these steps:

- Edit the `cni-cilium` module configuration in Deckhouse by enabling the `extraLoadBalancerAlgorithmsEnabled` parameter. This activates support for service annotations for selective algorithms.
- In the service manifest, specify the `service.cilium.io/lb-algorithm` annotation with one of the values: `random`, `maglev`, or `least-conn`.

⚠ This mechanism requires Linux kernel version 5.15 or higher to work correctly.

Using Egress Gateway

Egress Gateway in Deckhouse Platform can be used in one of two modes: Basic mode and Virtual IP mode. Use Custom Resource EgressGateway (parameter `spec.sourceIP.mode`) to select the mode.

Basic mode

Pre-configured IP addresses are used on egress nodes.

Virtual IP mode

The ability to dynamically assign additional IP addresses to nodes is implemented.

Exporting data from Hubble

Deckhouse Platform allows to configure data export from Hubble running inside Cilium agents using the cluster-scoped custom resource HubbleMonitoringConfig. To enable export, create a HubbleMonitoringConfig resource.

⚠ Creating or modifying the HubbleMonitoringConfig resource will restart all Cilium agents in the cluster.

After the manifest is applied:

- Hubble metrics become available in Prometheus. All exported metrics have the `hubble_*` prefix;
- Hubble logs are written to the `/var/log/cilium/hubble/flow.log` file on each node.

Third-party components

List of third-party software used in the `cni-cilium` module:

- Cilium 1.17.17

  License: Apache License 2.0

  Cilium is open source software for providing and transparently securing network connectivity and loadbalancing between application workloads such as application containers or processes.

- CNI plugins 1.9.1

  License: Apache License 2.0

  Some reference and example networking plugins, maintained by the CNI team.

- Gops 0.3.27

  License: BSD 3-Clause License

  A tool to list and diagnose Go processes currently running on your system.

ℹ **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

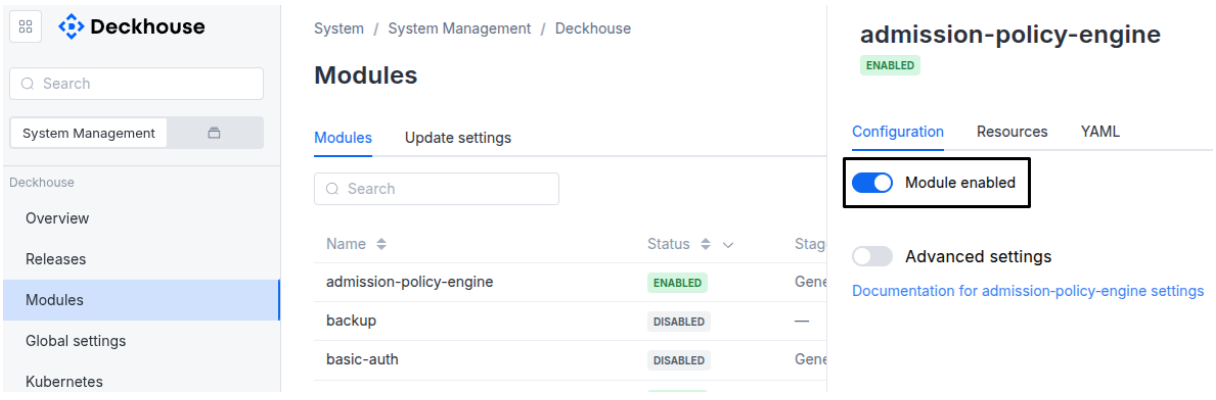
ℹ Available with limitations in: **Open/CE, Core, BE, SE**

Available without limitations in: **SE+, Ultimate/EE**

ℹ Included with limitations in extensions: **Advanced Networking**

Included without limitations in extensions: **Cluster Union**

ℹ The module lifecycle stage: General Availability



The module has 17 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-cilium` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module

(you need Deckhouse CLI (d8), configured to work with the cluster).

Example of enabling the module:

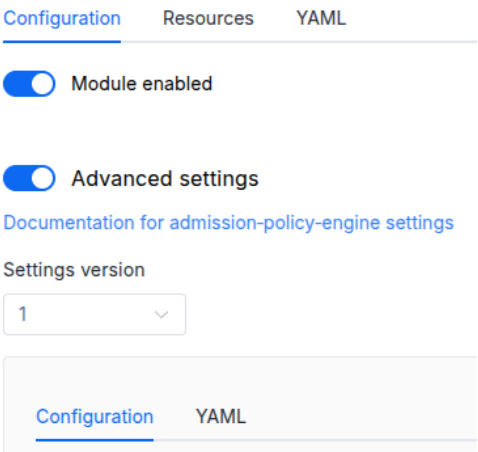
```
d8 system module enable cni-cilium
```

- **Using ModuleConfig `cni-cilium`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cni-cilium` (create it if necessary);

  Example of a manifest to enable module `cni-cilium`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cni-cilium
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-cilium` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cni-cilium` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cni-cilium`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cni-cilium` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc cni-cilium
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cni-cilium` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

  Example of a manifest for ModuleConfig `cni-cilium`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cni-cilium
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.activeL2NeighborDiscoveryEnabled**
    boolean

    Enables the Cilium `L2 neighbor discovery` mechanism, which helps ensure that ARP table entries are kept up-to-date on all cluster nodes.

    Default: `true`

  - **settings.bpfLBMode**
    string

    eBPF LoadBalancer mode:

    - `SNAT` — traffic from the client to the pod (and back) passes through NAT, and accordingly the sender's address is lost.
    - `DSR` — traffic from the client to the pod passes with the sender's address preserved, and back - according to the routing rules (bypassing the balancer). This mode saves network traffic and reduces delays, but only works for TCP traffic.
    - `Hybrid` — TCP traffic is processed in DSR mode, and UDP traffic is processed in SNAT mode.

    Default: `Hybrid`

    Allowed values: `SNAT`, `Hybrid`, `DSR`

  - **settings.createNodeRoutes**
    boolean

    Create routes to Pods on other Nodes.

    All Nodes must be located in the same L2 domain.

  - **settings.debugLogging**
    boolean

    Enables debug logging for Cilium components.

    Default: `false`

  - **settings.encryption**
    object

    CNI Cilium encryption settings.

    - **settings.encryption.mode**
      string

      Encryption mode:

      - `Disabled` — encryption is disabled.
      - `WireGuard` — enables traffic encryption between pods using WireGuard.

        > **i** Note! Before using WireGuard encryption, please ensure that the Linux kernel running on the cluster nodes has support WireGuard (either via the CONFIG_WIREGUARD=m kernel config option on Linux 5.6 and newer, or using an external WireGuard module for older kernels).

        > **i** Note! Using WireGuard may cause significant CPU consumption by Cilium agent pods.

      Default: `Disabled`

      Allowed values: `Disabled`, `WireGuard`

    - **settings.encryption.nodeToNodeModeEnabled**
      boolean

      Enabling traffic encryption between nodes and pods in HostNetwork.

      > **i** Note! The node-to-node traffic from and to the control-plane nodes is left unencrypted to prevent possible communication issues when renewing WireGuard public keys. At the same time, the traffic between control-plane components is still encrypted at the application layer.

      > **i** Note! When this mode is active, `NodePort` and `HostPort` are not available from the `PodNetwork`.

      Default: `false`

  - **settings.exclusiveCNIPlugin**
    boolean

    Prevents additional CNI plugins from being enabled on cluster nodes. If the Istio module's `dataPlane.trafficRedirectionSetupMode` setting is set to `CNIPlugin`, the option will be automatically set to

`false`.

Explicitly disabling this option is recommended only when using an additional CNI or a specific CNI plugin in the cluster. An example of such a use case could be the Linkerd CNI plugin.

Default: `true`

- **settings.extraLoadBalancerAlgorithmsEnabled**
  boolean

  Allows selectively overriding the load balancing algorithm using eBPF between backends for individual services. The annotation `service.cilium.io/lb-algorithm` is used for overriding with one of the following values: `random`, `maglev`, or `least-conn`.

  > **i** Note! This option requires the Linux kernel version on the nodes to be at least 5.15.

  Default: `false`

- **settings.ipv4OptionsGuard**
  object

  Mitigation of CVE-2026-98432 (use-after-free in the Linux IPv4 TCP handshake triggered by a TCP SYN with IP options).

  A sidecar of the CNI agent installs a filter into the host network namespace and into every pod network namespace on the node, including pods started later. The filter matches IPv4 TCP SYN packets and IPv4 fragments carrying IP options.

  The filter follows the iptables mode (nft or legacy) that iptables-wrapper selects on the node, the same as the other Deckhouse components. In the nft mode, the filter uses native nftables expressions. In the legacy mode, it uses iptables with the `u32` match. No kernel modules are loaded unless `allowKernelModuleLoad` is set. If the kernel modules of the selected mode are not loaded but those of the other mode are, the filter uses the other mode, and the node is reported by the `D8IPv4OptionsGuardBackendMismatch` alert. A node that cannot be protected is reported by the `D8IPv4OptionsGuardNodeUnprotected` alert.

  To exclude a node (for example, a node with CIPSO labeled networking), set the `ipv4-options-guard.deckhouse.io/disabled: "true"` label on it: the changes are reverted on that node.

  The mitigation does not fix the vulnerability: update the node kernel as soon as a fixed version is available.

  - **settings.ipv4OptionsGuard.allowKernelModuleLoad**
    boolean

    The filter needs the `nf_tables` kernel module in the nft mode and the `ip_tables`, `iptable_raw`, `xt_tcpudp` and `xt_u32` kernel modules in the legacy mode.

    By default, kernel modules are not loaded: if a module of the mode selected by iptables-wrapper is not loaded, the filter uses the other mode when its modules are loaded, and the node is reported as unprotected otherwise. Set to `true` to load the modules of the selected mode.

    Default: `false`

  - **settings.ipv4OptionsGuard.disableMPTCP**
    boolean

    In the `Enforce` mode, set `net.mptcp.enabled=0` in the host and in every pod network namespace. This removes the precondition of the published exploit.

    Listeners opened before the change stay MPTCP until the process is restarted. After a node reboot, MPTCP on the host is disabled again once the CNI agent starts.

    Default: `true`

  - **settings.ipv4OptionsGuard.mode**
    string

    Operating mode.

    If the mode is not set, it is `Enforce` in clusters installed with the mitigation and `Audit` in clusters that existed before it.

    - `Audit` — matching packets are only counted (the `d8_ipv4_options_guard_matched_packets_total` metric and the `D8IPv4OptionsGuardMatchedTraffic` alert). Use it to check that no workload relies on IP options. While any node is in this mode, the `D8IPv4OptionsGuardAuditMode` alert reminds that the cluster is not protected yet.
    - `Enforce` — matching packets are dropped, and MPTCP is disabled if `disableMPTCP` is set.
    - `Disabled` — the filter is removed from all network namespaces, including running pods, and `net.mptcp.enabled` is restored to the value it had before.

    The mode is applied without restarting the CNI agent pods.

    In the `Audit` and `Enforce` modes with `bpfLBMode` set to `DSR` or `Hybrid`, the backend node also removes the DSR IPv4 option from service packets before they reach the pod. Switching to or from `Disabled` turns this on or off and restarts the Cilium agents.

    Allowed values: `Audit`, `Enforce`, `Disabled`

- **settings.labelsRegex**
  array of strings

  Cilium creates security identifiers based on the k8s entity labels. The more labels are involved in this process, the higher the access granularity that can be achieved. However, in large clusters, excessive granularity can create a

heavy load. You can use the `labelsRegex` option to explicitly specify which labels are to be used for security policies, and which labels are to be neglected. Refer to the documentation to learn more about reducing the identity cardinality

Each label must be specified by a RegExp expression in YAML quoted string format. Note that special characters must be escaped.

Example:

```
labelsRegex:
- k8s:!app\.kubernetes\.io
- k8s:io\.cilium\.k8s\.policy
```

- **settings.loadBalancerICMPReplyEnabled**
  boolean

  Enable ICMP Echo Reply generation for LoadBalancer service IPs.

  When enabled, nodes respond to ICMP Echo Requests (ping) addressed to LoadBalancer external IPs.

  Default: `false`

- **settings.loadBalancerSourceRangeAllTypes**
  boolean

  Enable loadBalancerSourceRanges CIDR filtering for all service types, not just LoadBalancer services. The corresponding NodePort and ClusterIP will also apply the CIDR filter. For more detailed information, please visit the link.

  Default: `true`

- **settings.masqueradeMode**
  string

  Cilium masquerade work mode for pods traffic leaving the cluster.

  - `BPF` - use cilium BPF. Basic operation mode.

    In this mode, masquerade will not be used if the destination IP address is within the `podSubnetCIDR` or `InternalIP/ExternalIP` of any of the cluster nodes.

  - `Netfilter` - use kernel Netfilter(iptables/nf_tables).

    In this mode, masquerade will not be used if the destination IP address is within the `podSubnetCIDR` or `InternalIP/ExternalIP` of any of the cluster nodes.

  > **i** In `BPF` mode, if `ExternalIP` other than `InternalIP` is specified for a cluster node, and that IP address is not currently assigned to any interface on the node, it will not be reachable from neighboring nodes from pods network. The `Netfilter` mode allows you to bypass this limitation, but some other features stop working, such as `EgressGateway`.

  Default: `BPF`

  Allowed values: `Netfilter`, `BPF`

- **settings.networkPeering**
  object

  Available in editions: Ultimate/EE

  Experimental.

  NetworkPeering: direct pod-to-pod connectivity with the clusters this cluster is peered with by the `peering` module, built on Cilium ClusterMesh.

  A peer is connected when its `ClusterPeer` lists the `network` capability on both sides; the module shows the state of the mesh with it in a `ClusterNetworkPeer` object. Requires `tunnelMode: VXLAN` and `encryption.mode: Disabled` on every cluster of the mesh, the same VXLAN port, and non-overlapping pod subnets.

  The cluster name in the mesh is the cluster UUID without dashes (32 characters).

  > **i** The cluster name and ID become part of every Cilium identity. Enabling NetworkPeering on a running cluster reallocates identities: plan pod restarts.

  - **settings.networkPeering.clusterID**
    integer

    Cluster ID in the mesh. Must be unique among all clusters this cluster is meshed with, and among their own peers.

    Allowed values: `1 <= X <= 255`

    Example:

    ```
    clusterID: 11
    ```

  - **settings.networkPeering.enabled**
    boolean

Enable NetworkPeering.

Default: `false`

- **settings.networkPeering.hostPort**
  object

  Settings for the `HostPort` inlet.

  - **settings.networkPeering.hostPort.port**
    integer

    Host port of the etcd of `clustermesh-apiserver` on control-plane nodes. Must be reachable from the control-plane nodes of the peer clusters, where their kvstoremesh runs. Must not collide with another host port of the platform. Must not be 2379, which the control-plane etcd uses.

    Default: `4294`

    Allowed values: `1024 <= X <= 65535`

    Example:

    ```
    port: 4294
    ```

- **settings.networkPeering.inlet**
  string

  How `clustermesh-apiserver` is exposed to the peers.

  - `HostPort`: one replica per control-plane node, each on a host port. A peer connects to one replica at a time and moves to another only when that one fails, so a reconnection does not land on a different etcd instance at random.

  Default: `HostPort`

  Allowed values: `HostPort`

- **settings.nodePortAddresses**
  array of strings

  List of CIDRs that restrict which node IP addresses are used for Cilium BPF NodePort listeners.

  Only addresses assigned to selected network devices and matching one of the configured CIDRs will be exposed as NodePort frontends.

  Example:

  ```
  nodePortAddresses:
  - 192.168.1.100/32
  - 10.0.0.0/8
  - 192.168.1.0/24
  ```

- **settings.policyAuditMode**
  boolean

  Do not enforce any Network Policy. Just log allowed/disallowed connections.

  Default: `false`

- **settings.resourcesManagement**

  Settings for CPU and memory requests and limits by cilium agent pods.

  Examples:

  ```
  resourcesManagement:
    mode: VPA
    vpa:
      mode: InPlaceOrRecreate
      cpu:
        min: 50m
        max: 2
        limitRatio: 1.5
      memory:
        min: 256Mi
        max: 2Gi
        limitRatio: 1.5
  ```

```
resourcesManagement:
  mode: Static
  static:
    requests:
      cpu: 55m
      memory: 256Mi
    limits:
      cpu: 2
      memory: 2Gi
```

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: Auto
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

- **settings.resourcesManagement.mode**
  string

  Resource management mode:

  - `Static` is a classic one. In it, you specify requests/limits. The parameters of this mode are defined in the static parameter section;
  - `VPA` mode uses VPA. You can configure this mode by modifying parameters in the vpa parameter section.

  Default: `VPA`

  Allowed values: `VPA`, `Static`

- **settings.resourcesManagement.static**
  object

  Resource management options for the `Static` mode.

  - **settings.resourcesManagement.static.limits**
    object

    Configuring CPU and memory limits.

    - **settings.resourcesManagement.static.limits.cpu**
      string or number

      Configuring CPU limits.

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.static.limits.memory**
      string or number

      Configuring memory limits.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.resourcesManagement.static.requests**
    object

    Resource requests settings for pods.

    - **settings.resourcesManagement.static.requests.cpu**
      string or number

      Configuring CPU requests.

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.static.requests.memory**
      string or number

      Configuring memory requests.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.resourcesManagement.vpa.cpu.limitRatio**

number

The CPU limits/requests ratio.

This ratio is used for calculating the initial CPU limits for a pod.

If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

- **settings.resourcesManagement.vpa.cpu.max**
  string or number

  The maximum value that the VPA can set for the CPU requests.

  Default: `4`

  Pattern: `^[0-9]+m?$`

- **settings.resourcesManagement.vpa.cpu.min**
  string or number

  The minimum value that the VPA can set for the CPU requests.

  Default: `100m`

  Pattern: `^[0-9]+m?$`

- **settings.resourcesManagement.vpa.memory**
  object

  Memory-related VPA settings.

  - **settings.resourcesManagement.vpa.memory.limitRatio**
    number

    The memory limits/requests ratio.

    This ratio is used for calculating the initial memory limits for a pod.

    If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

  - **settings.resourcesManagement.vpa.memory.max**
    string or number

    The maximum memory requests the VPA can set.

    Default: `4Gi`

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.resourcesManagement.vpa.memory.min**
    string or number

    The minimum memory requests the VPA can set.

    Default: `128Mi`

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa.mode**
  string

  VPA operating mode.

  - `Initial` — VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
  - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.
  - `Auto` — VPA automatically recreates pods to apply updated resource values.

    > **i** Starting from Deckhouse version 1.75, this mode is considered legacy. It is recommended to use `InPlaceOrRecreate` instead.

  Default: `Initial`

  Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **settings.sctpEnabled**
  boolean

  Enable SCTP support for Cilium (for both incoming and outgoing traffic).

  > **i** **Note.** Cilium implements only basic SCTP support. Therefore, when using SCTP with Cilium, please be aware of the following limitations:

  - The following features are not currently supported: `SCTP multi-homing`, `NetworkPolicies for pod-to-VIP`.
  - For incoming SCTP packets port overwriting is not supported. This means that applications must be published through either HostPort or Service, where the `targetPort` MUST match the `port` specified. Otherwise, the packet will be dropped.

    - For outgoing SCTP packets, only 1:1 SNAT is supported by default. In this mode, only the src_ip is replaced, while the src_port remains unchanged. If the src_port is already in use on the node, the packet will be rejected. To enable src_port substitution, you must switch the `masqueradeMode` parameter to `Netfilter` mode.

  Default: `false`

- **settings.svcSourceRangeCheck**
  boolean

  For services of the `loadBalancer` type, enables checking the source IP for compliance with loadBalancer.sourceRanges. The check is not performed if access is made from within the cluster or the `sourceRanges` parameter is empty/not specified. Some cloud providers support filtering of incoming traffic based on the `sourceRanges` parameter in their loadBalancer implementations. In such cases, the cilium documentation recommends disabling the `svcSourceRangeCheck` option.

  Do not enable if another balancer or any type of SNAT is running in front of the services.

  Default: `false`

- **settings.tunnelMode**
  string

  Tunnel mode.

  > **i** Note! After changing the parameter, it is necessary to restart all nodes, otherwise, there may be problems with the availability of Pods!

  > **i** Note! VXLAN mode is not compatible with following bpfLBMode modes: Hybrid, DSR. bpfLBMode will be overriden to SNAT if the tunnelMode is VXLAN.

  Default: `Disabled`

  Allowed values: `Disabled`, `VXLAN`

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> **i** The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

EgressGatewayPolicy

Scope: Cluster
Version: v1alpha1

Interface for configuring policies to redirect application traffic to specific egress gateways described through the EgressGateway interface.

- **spec**
  object

  Required value

  - **spec.destinationCIDRs**
    array of strings

    Available in editions: SE+, Ultimate/EE

    Network requests towards these subnets will be routed through the egress gateway.

  - **spec.egressGatewayName**
    string

    Required value

    Available in editions: SE+, Ultimate/EE

    The name of the EgressGateway resource that describes the egress gateway for handling traffic.

  - **spec.excludedCIDRs**
    array of strings

    Available in editions: SE+, Ultimate/EE

    Network ranges that are required to be excluded from the ranges described in `destinationCIDRs`. Note that you do not need to exclude the special cluster ranges (`podSubnetCIDR` and `serviceSubnetCIDR`).

- **spec.selectors**
  array of objects

  Available in editions: SE+, Ultimate/EE

  Application Pod Selectors. Their traffic will be routed through the appropriate egress gateway. For namespase designation use the `io.kubernetes.pod.namespace` pseudo-label.

  - **spec.selectors.podSelector**
    object

    Required value

    Available in editions: SE+, Ultimate/EE

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

    - **spec.selectors.podSelector.matchExpressions**
      array of objects

      Available in editions: SE+, Ultimate/EE

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **spec.selectors.podSelector.matchExpressions.key**
        string

        Required value

        Available in editions: SE+, Ultimate/EE

        key is the label key that the selector applies to.

      - **spec.selectors.podSelector.matchExpressions.operator**
        string

        Required value

        Available in editions: SE+, Ultimate/EE

        operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

      - **spec.selectors.podSelector.matchExpressions.values**
        array of strings

        Available in editions: SE+, Ultimate/EE

        values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

    - **spec.selectors.podSelector.matchLabels**
      object

      Available in editions: SE+, Ultimate/EE

      matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **status**
  object

EgressGateway

Scope: Cluster
Version: v1alpha1

Interface for configuring a fault-tolerant egress gateway based on a group of nodes.

The configured egress gateways can be used in EgressGatewayPolicy interface to configure egress gateway for application Pods.

- **spec**
  object
  - **spec.nodeSelector**
    object

    Available in editions: SE+, Ultimate/EE

    The selector for a group of nodes that will transfer network requests to external services.

    Among these nodes, eligible nodes will be detected and one of them will be assigned as the active one. Signs of an eligible node:

    - The node is in Ready state.
    - Node is not cordoned.
    - The cilium-agent on the node is in the Ready state.

    Different EgressGateways can use common nodes for operation, and active nodes will be selected independently for

each EgressGateway, thus distributing the load between them.

- **spec.sourceIP**
  object
  - **spec.sourceIP.mode**
    string

    Required value

    Available in editions: SE+, Ultimate/EE

    A method for determining the source IP address to be assigned to requests through this gateway.

    Possible options:

    - `PrimaryIPFromEgressGatewayNodeInterface` (basic mode) — the primary IP address on the *public* network interface of the node will be used as the source IP address.

      Particularities:

      - When the active node goes down and a new node is assigned, the outgoing IP address will change.
      - The network subsystem on all egress nodes must be configured in advance:
        - the *public* interfaces must have the same name (eth1, for example),
        - all necessary routes for access to all external public services must be configured.

    - `VirtualIPAddress` (Virtual IP mode) — explicitly specify the outgoing IP address.

      Particularities:

      - If the active node goes down, the outgoing IP address will not change.
      - The network subsystem on all egress nodes must be configured in advance:
        - all necessary routes for access to all external public services must be configured,
        - the *public* interface must be prepared to automatically configure a *virtual* IP as a secondary IP address (if an egress node is designated as active, the address will not appear in the IP list on the *public* interface, but the node will emulate it with ARP-responses)

    Allowed values: `VirtualIPAddress`, `PrimaryIPFromEgressGatewayNodeInterface`

  - **spec.sourceIP.primaryIPFromEgressGatewayNodeInterface**
    object

    Used for basic mode (if `mode: PrimaryIPFromEgressGatewayNodeInterface`).

    - **spec.sourceIP.primaryIPFromEgressGatewayNodeInterface.interfaceName**
      string

      Available in editions: SE+, Ultimate/EE

      The interface name on the egress nodes through which external requests are processed.

  - **spec.sourceIP.virtualIPAddress**
    object

    Used for mode with Virtual IP (if `mode: PrimaryIPFromEgressGatewayNodeInterface`).

    - **spec.sourceIP.virtualIPAddress.interfaces**
      array of strings

      Available in editions: SE+, Ultimate/EE

      The list of network interfaces to which the *virtual* IP will be simulated.

      Default: `[]`

    - **spec.sourceIP.virtualIPAddress.ip**
      string

      Available in editions: SE+, Ultimate/EE

      The *virtual* source IP address to be assigned to outgoing requests through the egress gateway.

- **status**
  object
  - **status.activeNodeName**
    string

    The name of the current active node.

  - **status.conditions**
    array of objects
    - **status.conditions.lastHeartbeatTime**
      string
    - **status.conditions.lastTransitionTime**
      string

      Required value

      lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

    - **status.conditions.message**
      string

      Required value

message is a human readable message indicating details about the transition. This may be an empty string.

Maximum length: `32768`

- **status.conditions.observedGeneration**
  integer

  observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

  Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  status of the condition, one of True, False, Unknown.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  Type of condition in CamelCase or in foo.example.com/CamelCase.

  Many .condition.type values are consistent across resources like Available, but because arbitrary conditions can be useful (see .node.status.conditions), the ability to deconflict is important. The regex it matches is (dns1123SubdomainFmt/)?(qualifiedNameFmt)

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.observedGeneration**
  integer
- **status.readyNodes**
  integer

  Number of nodes ready to perform egress gateway functions.

HubbleMonitoringConfig

Scope: Cluster
Version: v1alpha1

- **spec**
  object

  Required value

  - **spec.extendedMetrics**
    object

    Configuration for exporting extended metrics from Cilium agents.

    Extended metrics provide deeper insight into cluster network behavior.

    > **Warning.** Changing this parameter will trigger a restart of the Cilium agents.

    For more details, see the Cilium documentation.

    Example:

```
extendedMetrics:
  enabled: true
  collectors:
  - name: drop
    contextOptions:
labelsContext=source_ip,source_namespace,source_pod,destination_ip,destination_namespace,destination_pod
  - name: flow
```

- **spec.extendedMetrics.collectors**
  array of objects

  List of Hubble extended metrics to export.

  Each collector represents a specific metric type.

  For more details, see the Cilium documentation.

  Example:

```
collectors:
- name: drop
  contextOptions:
labelsContext=source_ip,source_namespace,source_pod,destination_ip,destination_namespace,de
stination_pod
- name: flow
```

  - **spec.extendedMetrics.collectors.contextOptions**
    string

    Optional context options for Hubble metrics.

    Defines which parameters are used to break down the metrics produced by a collector. If you do not specify `contextOptions`, the collector returns the default set of metrics aggregated overall, without breakdown by individual parameters. For example, for the `drop` collector, an empty `contextOptions` returns overall drop statistics without distinguishing the exact source and destination. When you set `contextOptions`, metric values are grouped by the selected dimensions, for example by source and destination Pods, namespaces, and labels.

    > **Warning.** A large number of labels on metrics can lead to Prometheus performance degradation.

    For more information about supported options, see the Cilium documentation.

  - **spec.extendedMetrics.collectors.name**
    string

    Name of the extended metric to export.

    Allowed values: `dns`, `drop`, `flow`, `flows-to-world`, `http`, `httpV2`, `icmp`, `kafka`, `tcp`

- **spec.extendedMetrics.enabled**
  boolean

  Enables the export of extended metrics from Cilium agents.

  > All exported metrics have the prefix `hubble_*`.

  Default: `false`

- **spec.flowLogs**
  object

  Configuration for exporting event logs from Cilium agents.

  Event logs provide detailed visibility into Cilium's network events.

  > **Warning.** Changing this parameter will trigger a restart of the Cilium agents.

  For more details see the Cilium documentation.

  Example:

```
flowLogs:
  enabled: true
  allowFilterList:
  - verdict:
    - DROPPED
    - ERROR
  denyFilterList:
  - source_pod:
    - kube-system/
  - destination_pod:
    - kube-system/
  fieldMaskList:
  - time
  - source.namespace
  - verdict
  fileMaxSizeMB: 50
```

  - **spec.flowLogs.allowFilterList**

array of objects

Defines filters that control which events are exported for logging. Only events that match at least one of the specified filter objects will be exported. If no filters are specified, all events are allowed. Logical semantics: - Within a single filter object, all specified fields are combined using AND. - Across filter objects in the array, filters are combined using OR. For more details, see the Cilium documentation.

- **spec.flowLogs.allowFilterList.destination_cluster_name**
  array of strings

  Destination cluster names.

- **spec.flowLogs.allowFilterList.destination_fqdn**
  array of strings

  Destination fully qualified domain names (FQDN).

  - **Element of the array**
    string

    Maximum length: `255`

- **spec.flowLogs.allowFilterList.destination_identity**
  array of integers

  Destination security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.allowFilterList.destination_ip**
  array of strings

  Destination IP or CIDR.

- **spec.flowLogs.allowFilterList.destination_label**
  array of strings

  Destination label selectors.

  For more information, please see the Cilium documentation.

  Examples:

  ```
  destination_label: k8s:role=frontend
  ```

  ```
  destination_label: reserved:kube-apiserver
  ```

- **spec.flowLogs.allowFilterList.destination_pod**
  array of strings

  Destination Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

  ```
  destination_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
  ```

  ```
  destination_pod: kube-system/
  ```

  ```
  destination_pod: "/d8-kube-dns-7bc4648cb4-94tps"
  ```

- **spec.flowLogs.allowFilterList.destination_port**
  array of strings

  L4 destination port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.allowFilterList.destination_service**
  array of strings

  Destination service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

  ```
  destination_service: kube-system/kube-dns
  ```

  ```
  destination_service: kube-system/
  ```

  ```
  destination_service: "/kube-dns"
  ```

- **spec.flowLogs.allowFilterList.destination_workload**
  array of objects

Destination workloads.

- **spec.flowLogs.allowFilterList.destination_workload.kind**
  string

  Workload kind.

- **spec.flowLogs.allowFilterList.destination_workload.name**
  string

  Workload name.

- **spec.flowLogs.allowFilterList.dns_query**
  array of strings

  DNS query regex patterns.

- **spec.flowLogs.allowFilterList.drop_reason_desc**
  array of strings

  Drop reason (only for DROPPED verdict).

  - **Element of the array**
    string

    Allowed values: `DROP_REASON_UNKNOWN`, `INVALID_SOURCE_MAC`, `INVALID_DESTINATION_MAC`, `INVALID_SOURCE_IP`, `POLICY_DENIED`, `INVALID_PACKET_DROPPED`, `CT_TRUNCATED_OR_INVALID_HEADER`, `CT_MISSING_TCP_ACK_FLAG`, `CT_UNKNOWN_L4_PROTOCOL`, `CT_CANNOT_CREATE_ENTRY_FROM_PACKET`, `UNSUPPORTED_L3_PROTOCOL`, `MISSED_TAIL_CALL`, `ERROR_WRITING_TO_PACKET`, `UNKNOWN_L4_PROTOCOL`, `UNKNOWN_ICMPV4_CODE`, `UNKNOWN_ICMPV4_TYPE`, `UNKNOWN_ICMPV6_CODE`, `UNKNOWN_ICMPV6_TYPE`, `ERROR_RETRIEVING_TUNNEL_KEY`, `ERROR_RETRIEVING_TUNNEL_OPTIONS`, `INVALID_GENEVE_OPTION`, `UNKNOWN_L3_TARGET_ADDRESS`, `STALE_OR_UNROUTABLE_IP`, `NO_MATCHING_LOCAL_CONTAINER_FOUND`, `ERROR_WHILE_CORRECTING_L3_CHECKSUM`, `ERROR_WHILE_CORRECTING_L4_CHECKSUM`, `CT_MAP_INSERTION_FAILED`, `INVALID_IPV6_EXTENSION_HEADER`, `IP_FRAGMENTATION_NOT_SUPPORTED`, `SERVICE_BACKEND_NOT_FOUND`, `NO_TUNNEL_OR_ENCAPSULATION_ENDPOINT`, `FAILED_TO_INSERT_INTO_PROXYMAP`, `REACHED_EDT_RATE_LIMITING_DROP_HORIZON`, `UNKNOWN_CONNECTION_TRACKING_STATE`, `LOCAL_HOST_IS_UNREACHABLE`, `NO_CONFIGURATION_AVAILABLE_TO_PERFORM_POLICY_DECISION`, `UNSUPPORTED_L2_PROTOCOL`, `NO_MAPPING_FOR_NAT_MASQUERADE`, `UNSUPPORTED_PROTOCOL_FOR_NAT_MASQUERADE`, `FIB_LOOKUP_FAILED`, `ENCAPSULATION_TRAFFIC_IS_PROHIBITED`, `INVALID_IDENTITY`, `UNKNOWN_SENDER`, `NAT_NOT_NEEDED`, `IS_A_CLUSTERIP`, `FIRST_LOGICAL_DATAGRAM_FRAGMENT_NOT_FOUND`, `FORBIDDEN_ICMPV6_MESSAGE`, `DENIED_BY_LB_SRC_RANGE_CHECK`, `SOCKET_LOOKUP_FAILED`, `SOCKET_ASSIGN_FAILED`, `PROXY_REDIRECTION_NOT_SUPPORTED_FOR_PROTOCOL`, `POLICY_DENY`, `VLAN_FILTERED`, `INVALID_VNI`, `INVALID_TC_BUFFER`, `NO_SID`, `MISSING_SRV6_STATE`, `NAT46`, `NAT64`, `AUTH_REQUIRED`, `CT_NO_MAP_FOUND`, `SNAT_NO_MAP_FOUND`, `INVALID_CLUSTER_ID`, `UNSUPPORTED_PROTOCOL_FOR_DSR_ENCAP`, `NO_EGRESS_GATEWAY`, `UNENCRYPTED_TRAFFIC`, `TTL_EXCEEDED`, `NO_NODE_ID`, `DROP_RATE_LIMITED`, `IGMP_HANDLED`, `IGMP_SUBSCRIBED`, `MULTICAST_HANDLED`, `DROP_HOST_NOT_READY`, `DROP_EP_NOT_READY`, `DROP_NO_EGRESS_IP`

- **spec.flowLogs.allowFilterList.event_type**
  array of objects

  Event types to filter on.

  - **spec.flowLogs.allowFilterList.event_type.match_sub_type**
    boolean

    Whether to match on `sub_type`.

  - **spec.flowLogs.allowFilterList.event_type.sub_type**
    integer

    Secondary event type.

  - **spec.flowLogs.allowFilterList.event_type.type**
    integer

    Primary event type.

- **spec.flowLogs.allowFilterList.http_header**
  array of objects

  HTTP headers to match.

  - **spec.flowLogs.allowFilterList.http_header.key**
    string

    Header key.

  - **spec.flowLogs.allowFilterList.http_header.value**
    string

    Header value.

- **spec.flowLogs.allowFilterList.http_method**
  array of strings

  HTTP methods.

  - **Element of the array**
    string

    Allowed values: `GET`, `HEAD`, `POST`, `PUT`, `DELETE`, `CONNECT`, `OPTIONS`, `TRACE`, `PATCH`

- **spec.flowLogs.allowFilterList.http_path**
  array of strings

  Regex list to match HTTP path.

- **spec.flowLogs.allowFilterList.http_status_code**
  array of strings

  HTTP status code prefixes.

  - **Element of the array**
    string

    Pattern: `^(?:[1-5]\+|[1-5][0-9]\+|[1-5][0-9]{2})$`

- **spec.flowLogs.allowFilterList.http_url**
  array of strings

  Regex list to match HTTP URL.

- **spec.flowLogs.allowFilterList.interface**
  array of objects

  Network interface where flow was observed.

  - **spec.flowLogs.allowFilterList.interface.index**
    integer

    Interface index.

    Allowed values: `0 <= X`

  - **spec.flowLogs.allowFilterList.interface.name**
    string

    Interface name.

- **spec.flowLogs.allowFilterList.ip_version**
  array of strings

  IP version.

  - **Element of the array**
    string

    Allowed values: `IP_NOT_USED`, `IPv4`, `IPv6`

- **spec.flowLogs.allowFilterList.node_labels**
  array of strings

  Node label selectors.

  Examples:

  ```
  node_labels: node-role.kubernetes.io/control-plane=
  ```

  ```
  node_labels: topology.kubernetes.io/ru-central1-a
  ```

- **spec.flowLogs.allowFilterList.node_name**
  array of strings

  Node name patterns.

- **spec.flowLogs.allowFilterList.protocol**
  array of strings

  L4 or L7 protocol.

- **spec.flowLogs.allowFilterList.source_cluster_name**
  array of strings

  Source cluster names.

- **spec.flowLogs.allowFilterList.source_fqdn**
  array of strings

  Source fully qualified domain names (FQDN).

  - **Element of the array**
    string

    Maximum length: `255`

- **spec.flowLogs.allowFilterList.source_identity**
  array of integers

  Source security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.allowFilterList.source_ip**
  array of strings

Source IP or CIDR.

- **spec.flowLogs.allowFilterList.source_ip_xlated**
  array of strings

  Post-translation (SNAT) source IP or CIDR.

- **spec.flowLogs.allowFilterList.source_label**
  array of strings

  Source label selectors.

  For more information, please see the Cilium documentation.

  Examples:

  ```
  source_label: k8s:role=frontend
  ```

  ```
  source_label: reserved:kube-apiserver
  ```

- **spec.flowLogs.allowFilterList.source_pod**
  array of strings

  Source Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

  ```
  source_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
  ```

  ```
  source_pod: kube-system/
  ```

  ```
  source_pod: "/d8-kube-dns-7bc4648cb4-94tps"
  ```

- **spec.flowLogs.allowFilterList.source_port**
  array of strings

  L4 source port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.allowFilterList.source_service**
  array of strings

  Source service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

  ```
  source_service: kube-system/kube-dns
  ```

  ```
  source_service: kube-system/
  ```

  ```
  source_service: "/kube-dns"
  ```

- **spec.flowLogs.allowFilterList.source_workload**
  array of objects

  Source workloads.

  - **spec.flowLogs.allowFilterList.source_workload.kind**
    string

    Workload kind.

  - **spec.flowLogs.allowFilterList.source_workload.name**
    string

    Workload name.

- **spec.flowLogs.allowFilterList.tcp_flags**
  array of objects

  TCP flags to match.

  - **spec.flowLogs.allowFilterList.tcp_flags.ACK**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.CWR**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.ECE**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.FIN**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.NS**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.PSH**

boolean
- **spec.flowLogs.allowFilterList.tcp_flags.RST**
boolean
- **spec.flowLogs.allowFilterList.tcp_flags.SYN**
boolean
- **spec.flowLogs.allowFilterList.tcp_flags.URG**
boolean

- **spec.flowLogs.allowFilterList.trace_id**
array of strings

Trace ID.

- **spec.flowLogs.allowFilterList.traffic_direction**
array of strings

Traffic direction.

- **Element of the array**
string

Allowed values: `TRAFFIC_DIRECTION_UNKNOWN`, `INGRESS`, `EGRESS`

- **spec.flowLogs.allowFilterList.uuid**
array of strings

Filters by flow UUIDs.

- **spec.flowLogs.allowFilterList.verdict**
array of strings

Match by verdict.

- **Element of the array**
string

Allowed values: `VERDICT_UNKNOWN`, `FORWARDED`, `DROPPED`, `ERROR`, `AUDIT`, `REDIRECTED`, `TRACED`, `TRANSLATED`

- **spec.flowLogs.denyFilterList**
array of objects

Defines filters that control which events are explicitly excluded from logging. Any event that matches at least one of the specified filter objects will be denied from being exported. If no filters are specified, no events are denied. This allows you to refine the set of events that are logged by excluding certain types. Logical semantics: - Within a single filter object, all specified fields are combined using AND. - Across filter objects in the array, filters are combined using OR. For more details, see the Cilium documentation.

- **spec.flowLogs.denyFilterList.destination_cluster_name**
array of strings

Destination cluster names.

- **spec.flowLogs.denyFilterList.destination_fqdn**
array of strings

Destination fully qualified domain names (FQDN).

- **Element of the array**
string

Maximum length: `255`

- **spec.flowLogs.denyFilterList.destination_identity**
array of integers

Destination security identity.

- **Element of the array**
integer

Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.denyFilterList.destination_ip**
array of strings

Destination IP or CIDR.

- **spec.flowLogs.denyFilterList.destination_label**
array of strings

Destination label selectors.

For more information, please see the Cilium documentation.

Examples:

```
destination_label: k8s:role=frontend
```

```
destination_label: reserved:kube-apiserver
```

- **spec.flowLogs.denyFilterList.destination_pod**
array of strings

Destination Pod name prefixes in the form NamespacedName (`namespace/pod`).

Examples:

```
destination_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
```

```
destination_pod: kube-system/
```

```
destination_pod: "/d8-kube-dns-7bc4648cb4-94tps"
```

- **spec.flowLogs.denyFilterList.destination_port**
  array of strings

  L4 destination port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.denyFilterList.destination_service**
  array of strings

  Destination service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

```
destination_service: kube-system/kube-dns
```

```
destination_service: kube-system/
```

```
destination_service: "/kube-dns"
```

- **spec.flowLogs.denyFilterList.destination_workload**
  array of objects

  Destination workloads.

  - **spec.flowLogs.denyFilterList.destination_workload.kind**
    string

    Workload kind.

  - **spec.flowLogs.denyFilterList.destination_workload.name**
    string

    Workload name.

- **spec.flowLogs.denyFilterList.dns_query**
  array of strings

  DNS query regex patterns.

- **spec.flowLogs.denyFilterList.drop_reason_desc**
  array of strings

  Drop reason (only for DROPPED verdict).

  - **Element of the array**
    string

    Allowed values: `DROP_REASON UNKNOWN`, `INVALID SOURCE MAC`, `INVALID_DESTINATION_MAC`, `INVALID_SOURCE IP`, `POLICY_DENIED`, `INVALID_PACKET_DROPPED`, `CT TRUNCATED OR INVALID HEADER`, `CT_MISSING TCP ACK FLAG`, `CT_UNKNOWN L4 PROTOCOL`, `CT_CANNOT_CREATE_ENTRY_FROM_PACKET`, `UNSUPPORTED_L3_PROTOCOL`, `MISSED_TAIL_CALL`, `ERROR_WRITING_TO_PACKET`, `UNKNOWN_L4_PROTOCOL`, `UNKNOWN_ICMPV4_CODE`, `UNKNOWN ICMPV4 TYPE`, `UNKNOWN_ICMPV6 CODE`, `UNKNOWN ICMPV6 TYPE`, `ERROR_RETRIEVING_TUNNEL_KEY`, `ERROR_RETRIEVING_TUNNEL_OPTIONS`, `INVALID_GENEVE_OPTION`, `UNKNOWN_L3_TARGET_ADDRESS`, `STALE_OR_UNROUTABLE IP`, `NO MATCHING LOCAL CONTAINER_FOUND`, `ERROR_WHILE_CORRECTING_L3_CHECKSUM`, `ERROR_WHILE_CORRECTING_L4_CHECKSUM`, `CT_MAP_INSERTION_FAILED`, `INVALID IPV6 EXTENSION HEADER`, `IP_FRAGMENTATION_NOT_SUPPORTED`, `SERVICE_BACKEND_NOT_FOUND`, `NO_TUNNEL_OR_ENCAPSULATION_ENDPOINT`, `FAILED TO INSERT INTO PROXYMAP`, `REACHED_EDT_RATE_LIMITING_DROP_HORIZON`, `UNKNOWN_CONNECTION_TRACKING_STATE`, `LOCAL_HOST_IS_UNREACHABLE`, `NO_CONFIGURATION_AVAILABLE_TO_PERFORM_POLICY_DECISION`, `UNSUPPORTED_L2_PROTOCOL`, `NO_MAPPING_FOR_NAT_MASQUERADE`, `UNSUPPORTED_PROTOCOL_FOR_NAT_MASQUERADE`, `FIB_LOOKUP_FAILED`, `ENCAPSULATION_TRAFFIC_IS_PROHIBITED`, `INVALID_IDENTITY`, `UNKNOWN_SENDER`, `NAT_NOT_NEEDED`, `IS_A_CLUSTERIP`, `FIRST_LOGICAL_DATAGRAM_FRAGMENT_NOT_FOUND`, `FORBIDDEN_ICMPV6_MESSAGE`, `DENIED_BY_LB_SRC_RANGE_CHECK`, `SOCKET_LOOKUP_FAILED`, `SOCKET_ASSIGN_FAILED`, `PROXY_REDIRECTION_NOT_SUPPORTED_FOR_PROTOCOL`, `POLICY_DENY`, `VLAN_FILTERED`, `INVALID_VNI`, `INVALID_TC_BUFFER`, `NO_SID`, `MISSING_SRV6_STATE`, `NAT46`, `NAT64`, `AUTH_REQUIRED`, `CT_NO_MAP_FOUND`, `SNAT_NO_MAP_FOUND`, `INVALID_CLUSTER_ID`, `UNSUPPORTED_PROTOCOL_FOR_DSR_ENCAP`, `NO_EGRESS_GATEWAY`, `UNENCRYPTED_TRAFFIC`, `TTL_EXCEEDED`, `NO_NODE_ID`, `DROP_RATE_LIMITED`, `IGMP_HANDLED`, `IGMP_SUBSCRIBED`, `MULTICAST_HANDLED`, `DROP_HOST_NOT_READY`, `DROP_EP_NOT_READY`, `DROP_NO_EGRESS_IP`

- **spec.flowLogs.denyFilterList.event_type**
  array of objects

Event types to filter on.

- **spec.flowLogs.denyFilterList.event_type.match_sub_type**
  boolean

  Whether to match on `sub_type`.

- **spec.flowLogs.denyFilterList.event_type.sub_type**
  integer

  Secondary event type.

- **spec.flowLogs.denyFilterList.event_type.type**
  integer

  Primary event type.

- **spec.flowLogs.denyFilterList.http_header**
  array of objects

  HTTP headers to match.

  - **spec.flowLogs.denyFilterList.http_header.key**
    string

    Header key.

  - **spec.flowLogs.denyFilterList.http_header.value**
    string

    Header value.

- **spec.flowLogs.denyFilterList.http_method**
  array of strings

  HTTP methods.

  - **Element of the array**
    string

    Allowed values: `GET`, `HEAD`, `POST`, `PUT`, `DELETE`, `CONNECT`, `OPTIONS`, `TRACE`, `PATCH`

- **spec.flowLogs.denyFilterList.http_path**
  array of strings

  Regex list to match HTTP path.

- **spec.flowLogs.denyFilterList.http_status_code**
  array of strings

  HTTP status code prefixes.

  - **Element of the array**
    string

    Pattern: `^(?:[1-5]\+|[1-5][0-9]\+|[1-5][0-9]{2})$`

- **spec.flowLogs.denyFilterList.http_url**
  array of strings

  Regex list to match HTTP URL.

- **spec.flowLogs.denyFilterList.interface**
  array of objects

  Network interface where flow was observed.

  - **spec.flowLogs.denyFilterList.interface.index**
    integer

    Interface index.

    Allowed values: `0 <= X`

  - **spec.flowLogs.denyFilterList.interface.name**
    string

    Interface name.

- **spec.flowLogs.denyFilterList.ip_version**
  array of strings

  IP version.

  - **Element of the array**
    string

    Allowed values: `IP_NOT_USED`, `IPv4`, `IPv6`

- **spec.flowLogs.denyFilterList.node_labels**
  array of strings

  Node label selectors.

  Examples:

```
node_labels: node-role.kubernetes.io/control-plane=
```

```
node_labels: topology.kubernetes.io/ru-central1-a
```

- **spec.flowLogs.denyFilterList.node_name**
  array of strings

  Node name patterns.

- **spec.flowLogs.denyFilterList.protocol**
  array of strings

  L4 or L7 protocol.

- **spec.flowLogs.denyFilterList.source_cluster_name**
  array of strings

  Source cluster names.

- **spec.flowLogs.denyFilterList.source_fqdn**
  array of strings

  Source fully qualified domain names (FQDN).

  - **Element of the array**
    string

    Maximum length: `255`

- **spec.flowLogs.denyFilterList.source_identity**
  array of integers

  Source security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.denyFilterList.source_ip**
  array of strings

  Source IP or CIDR.

- **spec.flowLogs.denyFilterList.source_ip_xlated**
  array of strings

  Post-translation (SNAT) source IP or CIDR.

- **spec.flowLogs.denyFilterList.source_label**
  array of strings

  Source label selectors.

  For more information, please see the Cilium documentation.

  Examples:

```
source_label: k8s:role=frontend
```

```
source_label: reserved:kube-apiserver
```

- **spec.flowLogs.denyFilterList.source_pod**
  array of strings

  Source Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

```
source_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
```

```
source_pod: kube-system/
```

```
source_pod: "/d8-kube-dns-7bc4648cb4-94tps"
```

- **spec.flowLogs.denyFilterList.source_port**
  array of strings

  L4 source port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.denyFilterList.source_service**
  array of strings

  Source service name prefixes in the form NamespacedName (`namespace/service`).

Examples:

```
source_service: kube-system/kube-dns
```

```
source_service: kube-system/
```

```
source_service: "/kube-dns"
```

- **spec.flowLogs.denyFilterList.source_workload**
  array of objects

  Source workloads.

  - **spec.flowLogs.denyFilterList.source_workload.kind**
    string

    Workload kind.

  - **spec.flowLogs.denyFilterList.source_workload.name**
    string

    Workload name.

- **spec.flowLogs.denyFilterList.tcp_flags**
  array of objects

  TCP flags to match.

  - **spec.flowLogs.denyFilterList.tcp_flags.ACK**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.CWR**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.ECE**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.FIN**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.NS**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.PSH**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.RST**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.SYN**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.URG**
    boolean
- **spec.flowLogs.denyFilterList.trace_id**
  array of strings

  Trace ID.

- **spec.flowLogs.denyFilterList.traffic_direction**
  array of strings

  Traffic direction.

  - **Element of the array**
    string

    Allowed values: `TRAFFIC_DIRECTION_UNKNOWN`, `INGRESS`, `EGRESS`

- **spec.flowLogs.denyFilterList.uuid**
  array of strings

  Filters by flow UUIDs.

- **spec.flowLogs.denyFilterList.verdict**
  array of strings

  Match by verdict.

  - **Element of the array**
    string

    Allowed values: `VERDICT_UNKNOWN`, `FORWARDED`, `DROPPED`, `ERROR`, `AUDIT`, `REDIRECTED`, `TRACED`, `TRANSLATED`

- **spec.flowLogs.enabled**
  boolean

  Enables event logging for Cilium agents.

  > **i** The log file is located on the node's filesystem at `/var/log/cilium/hubble/flow.log`.

  Default: `false`

- **spec.flowLogs.fieldMaskList**
  array of strings

List of fields that should be displayed in events.

For more details, see the Cilium documentation.

- **Element of the array**
  string

  Allowed values: `time`, `uuid`, `verdict`, `drop_reason_desc`, `auth_type`, `ethernet`, `ethernet.source`, `ethernet.destination`, `IP`, `IP.source`, `IP.source_xlated`, `IP.destination`, `IP.ipVersion`, `IP.encrypted`, `l4`, `l4.TCP`, `l4.TCP.source_port`, `l4.TCP.destination_port`, `l4.TCP.flags`, `l4.TCP.flags.FIN`, `l4.TCP.flags.SYN`, `l4.TCP.flags.RST`, `l4.TCP.flags.PSH`, `l4.TCP.flags.ACK`, `l4.TCP.flags.URG`, `l4.TCP.flags.ECE`, `l4.TCP.flags.CWR`, `l4.TCP.flags.NS`, `l4.UDP`, `l4.UDP.source port`, `l4.UDP.destination port`, `l4.ICMPv4`, `l4.ICMPv4.type`, `l4.ICMPv4.code`, `l4.ICMPv6`, `l4.ICMPv6.type`, `l4.ICMPv6.code`, `l4.SCTP`, `l4.SCTP.source port`, `l4.SCTP.destination port`, `source`, `source.ID`, `source.identity`, `source.cluster_name`, `source.namespace`, `source.labels`, `source.pod_name`, `source.workloads`, `source.workloads.name`, `source.workloads.kind`, `destination`, `destination.ID`, `destination.identity`, `destination.cluster_name`, `destination.namespace`, `destination.labels`, `destination.pod_name`, `destination.workloads`, `destination.workloads.name`, `destination.workloads.kind`, `Type`, `node_name`, `node_labels`, `source_names`, `destination_names`, `l7`, `l7.type`, `l7.latency_ns`, `l7.record`, `l7.record.dns`, `l7.record.dns.query`, `l7.record.dns.ips`, `l7.record.dns.ttl`, `l7.record.dns.cnames`, `l7.record.dns.observation_source`, `l7.record.dns.rcode`, `l7.record.dns.qtypes`, `l7.record.dns.rrtypes`, `l7.record.http`, `l7.record.http.code`, `l7.record.http.method`, `l7.record.http.url`, `l7.record.http.protocol`, `l7.record.http.headers`, `l7.record.http.headers.key`, `l7.record.http.headers.value`, `l7.record.kafka`, `l7.record.kafka.error_code`, `l7.record.kafka.api_version`, `l7.record.kafka.api_key`, `l7.record.kafka.correlation_id`, `l7.record.kafka.topic`, `is_reply`, `event_type`, `event_type.type`, `event_type.sub_type`, `traffic_direction`, `trace_observation_point`, `trace_reason`, `file`, `file.name`, `file.line`, `debug_capture_point`, `interface`, `interface.index`, `interface.name`, `proxy_port`, `trace_context`, `trace_context.parent`, `trace_context.parent.trace_id`, `sock_xlate_point`, `socket_cookie`, `cgroup_id`, `extensions`, `egress_allowed_by`, `egress_allowed_by.name`, `egress_allowed_by.namespace`, `egress_allowed_by.labels`, `egress_allowed_by.revision`, `egress_allowed_by.kind`, `ingress_allowed_by`, `ingress_allowed_by.name`, `ingress_allowed_by.namespace`, `ingress_allowed_by.labels`, `ingress_allowed_by.revision`, `ingress_allowed_by.kind`, `egress_denied_by`, `egress_denied_by.name`, `egress_denied_by.namespace`, `egress_denied_by.labels`, `egress_denied_by.revision`, `egress_denied_by.kind`, `ingress_denied_by`, `ingress_denied_by.name`, `ingress_denied_by.namespace`, `ingress_denied_by.labels`, `ingress_denied_by.revision`, `ingress_denied_by.kind`, `source_service`, `source_service.name`, `source_service.namespace`, `destination_service`, `destination_service.name`, `destination_service.namespace`

- **spec.flowLogs.fileMaxSizeMB**
  integer

  Size in MB at which to rotate the Hubble export file.

  Default: `10`

  Allowed values: `1 <= X <= 150`

Usage

> The module lifecycle stage: General Availability

Cluster peering

When the administrator has meshed the cluster with other clusters (see Cluster peering in advanced usage), a pod reaches pods of other clusters by IP address, and a service can use backends of other clusters.

Pods of other clusters

A pod reaches a pod of another cluster by its IP address, like a pod of its own cluster. There is no NAT: the receiving pod sees the client pod's address.

Pods and services of other clusters have no DNS names. To reach an application of another cluster by name, make its service global.

Global services

A global service uses its own backends and the backends of the service with the same name in the same namespace in the neighbour clusters. Clients reach it by its name and address in their own cluster.

A service is configured with annotations:

Annotation	Value

Annotation	Value
`network.deckhouse.io/global-service-mode`	`Local`: the service is local (same as no annotation). `ImportOnly`: uses the neighbours' backends, does not offer its own. `ImportAndExport`: uses the neighbours' backends and offers its own
`network.deckhouse.io/global-service-traffic-distribution`	`Any` (default): backends of all clusters. `PreferLocalCluster`: own backends while any is ready. `PreferRemoteCluster`: the neighbours' backends while any is ready

An unknown mode means `Local`, an unknown distribution means `Any`. The distribution applies only in the `ImportOnly` and `ImportAndExport` modes. Changes apply without restarting pods; open connections are not moved.

The service name, namespace and ports (with names) must match in every cluster.

A headless service (`clusterIP: None`) can be global too: its DNS name returns the addresses of the pods of this and the neighbour clusters. The traffic distribution does not apply to it. Name the StatefulSet pods behind such a service differently in each cluster, for example with the cluster name: equal pod names from different clusters conflict in DNS.

Common tasks:

Task	What to do
Balance over the replicas of all clusters	`global-service-mode: ImportAndExport` in every cluster
Use own replicas, the neighbours as a fallback	Add `global-service-traffic-distribution: PreferLocalCluster`
Use an application that does not run in your cluster	In your cluster, a service with `ImportOnly`; in the cluster running the application, with `ImportAndExport`
Drain a cluster without stopping its replicas	In that cluster, `ImportOnly` and `PreferRemoteCluster`. After maintenance, set `ImportAndExport` back and remove the distribution

Example:

```
apiVersion: v1
kind: Service
metadata:
  name: api
  namespace: shop
  annotations:
    network.deckhouse.io/global-service-mode: ImportAndExport
    network.deckhouse.io/global-service-traffic-distribution: PreferLocalCluster
spec:
  selector:
    app: api
  ports:
  - name: http
    port: 80
    targetPort: 8080
```

When the mesh with a neighbour is torn down, its backends are removed from global services and connections to its pods break. A temporary loss of connectivity between the clusters does not tear the mesh down.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Advanced usage

> The module lifecycle stage: General Availability

Cluster peering

The module connects the pod networks of clusters peered by the `peering` module: a pod reaches a pod of another cluster by IP address, a service can use backends of other clusters (see Cluster peering in usage). The clusters only exchange the mesh settings over peering; traffic goes directly between the nodes.

Limitations:

- VXLAN mode without encryption only; pod traffic between clusters is not encrypted, so mesh clusters over trusted networks only;
- neighbours connect to control-plane nodes directly, by node addresses; a load balancer or NAT between clusters is not supported;
- the pod subnets of the clusters must not overlap;
- a cluster with all its neighbours is at most 255 clusters;

- the mesh is not transitive: if A is meshed with B and B with C, A and C are not connected;
- enabling, disabling and changing the cluster ID change the security identities of all pods: restart all pods of the cluster afterwards, in a maintenance window.

Requirements

Requirement	How to check
The `peering` module is enabled, `ClusterPeer` is `Active` on both sides	`d8 k get clusterpeers`
Cilium runs in VXLAN mode, `tunnelMode: VXLAN` is set explicitly in the ModuleConfig	`d8 k get mc cni-cilium -o jsonpath='{.spec.settings.tunnelMode}'` prints `VXLAN`
Encryption is off: `encryption.mode` is unset or `Disabled`	`d8 k get mc cni-cilium -o jsonpath='{.spec.settings.encryption.mode}'`
The same VXLAN port in all clusters	`d8 k -n d8-cni-cilium get cm cilium-config -o jsonpath='{.data.tunnel-port}'`
The pod subnet does not overlap the neighbours' pod subnets	`podSubnetCIDR` in `d8 k -n kube-system get secret d8-cluster-configuration -o jsonpath='{.data.cluster-configuration\.yaml}' | base64 -d`
The cluster ID is unique among the cluster and all its neighbours	Assign IDs from one list for all clusters that may be meshed

The module sets the VXLAN port. Clusters with different ports cannot be meshed. Enabling the `virtualization` module can change the port.

Service subnets may overlap.

Network access between clusters, by node `InternalIP` addresses, without NAT:

From	To	Port
Every node	Every node of the neighbour	UDP, the VXLAN port
Control-plane nodes	Control-plane nodes of the neighbour	TCP, the neighbour's `networkPeering.hostPort.port` (4294 by default)

Enabling

The example meshes clusters A and B. The peering is named `cluster-b` in cluster A and `cluster-a` in cluster B. Run every step in both clusters.

1. Peer the clusters by the `peering` module guide up to the `Active` phase. Do not open capabilities yet.
2. Enable NetworkPeering in the `cni-cilium` ModuleConfig (`d8 k edit mc cni-cilium`). In cluster B, `clusterID: 2`:

   ```
   spec:
     settings:
       tunnelMode: VXLAN
       networkPeering:
         enabled: true
         clusterID: 1
   ```

   The Cilium agents restart. Then restart all pods of the cluster so they get identities with the cluster ID. Do it in a maintenance window. If Cilium runs without a tunnel, switch it to VXLAN in a separate maintenance window first.

   Wait for `READY: True` in `d8 k get networkpeering cluster` and `ACCEPTED: True` in `d8 k get peeringcapability network`.
3. Add `network` to `spec.capabilities` of the `ClusterPeer`, keeping the other capabilities (`d8 k edit clusterpeer cluster-b`). The module creates a ClusterNetworkPeer named after the `ClusterPeer`, it shows the state of the mesh with the neighbour. The capability works once both sides list it: check `EFFECTIVE` in `d8 k get clusterpeer cluster-b`.
4. Wait for `PHASE: Configured` and `READY: True` in `d8 k get clusternetworkpeers`. It usually takes a minute or two.

If the ModuleConfig is rejected, fix the setting named in the message: set `networkPeering.clusterID`, an explicit `tunnelMode: VXLAN`, or turn encryption off.

Several neighbours

The cluster meshes with each neighbour separately: the `ClusterPeer` lists the `network` capability on both sides. The module keeps a ClusterNetworkPeer for every `ClusterPeer` that lists `network` and deletes it when the capability or the `ClusterPeer` is removed.

A neighbour's ID and pod subnet stay taken while the cluster has its ClusterNetworkPeer, even if the mesh with it is down. A new neighbour with a taken ID or subnet gets an error (`ClusterIDConflict`, `PodCIDROverlap`); the neighbour already meshed keeps working. To resolve the conflict, change the new neighbour's ID or remove `network` from the old neighbour's `ClusterPeer`.

ClusterNetworkPeer status

Phases:

- `Pending`: the mesh waits for the neighbour or for the peering, the reason is in the conditions;
- `Negotiating`: certificates are being exchanged;
- `Configured`: the mesh is configured;
- `Error`: a check failed, the reason is in the conditions.

To print the conditions, run:

```
d8 k get clusternetworkpeer cluster-b \
  -o jsonpath='{range .status.conditions[*]}{.type}{"\t"}{.status}{"\t"}{.reason}{"\t"}{.message}{"\n"}
{end}'
```

Reason	What to do
`PeerNotActive`	Check the peering
`CapabilityNotOffered`	On the neighbour's side, add `network` to the `ClusterPeer` and enable NetworkPeering
`CapabilityNotAccepted`	This cluster does not offer `network` to the neighbour: check the `Accepted` and `GrantsApplied` conditions in `d8 k get peeringcapability network -o yaml`
`CapabilityNotEffective`	Both sides offer `network`, the peering has not applied it yet. If it persists, check `d8 k get clusterpeer cluster-b`
`AwaitingPeer`	The neighbour has not created its ClusterNetworkPeer named in the message yet. If it persists, check `d8 k -n d8-cni-cilium logs deploy/clustermesh-controller` on the neighbour
`PeerUnreachable`, `ClusterPeerUnreadable`, `PeerAccessNotReady`	Check the peering. With `... not found`, wait until NetworkPeering is deployed on the neighbour
`TunnelModeNotVXLAN`, `VXLANPortMismatch`	Switch the neighbour to VXLAN with the same port. Clusters with different ports cannot be meshed
`ClusterIDConflict`	Change the neighbour's ID or remove `network` from the `ClusterPeer` of the neighbour named in the message
`ClusterNameConflict`	Delete the extra peering with the same cluster. A cluster cloned with its UUID cannot be meshed
`PodCIDROverlap`	The pod subnets (podCIDR) of the clusters overlap. These clusters cannot be meshed
`RemoteNotReady`	The neighbour has not published its state yet. If it persists, check `d8 k get networkpeering cluster` and the `clustermesh-apiserver` replicas on the neighbour
`AwaitingPeerSignature`	Wait for the next check. If it persists, look at the neighbour's ClusterNetworkPeer
`PeerCSRInvalid`	On the neighbour's side, remove `network` from the `ClusterPeer`, wait until its ClusterNetworkPeer is deleted, and add `network` back
`LastKnownConfiguration`	The peering is unavailable, the mesh runs on the last configuration. Restore the peering

Changing settings

- To change `networkPeering.clusterID`, check that the new ID is free among the cluster and its neighbours. Change it in a maintenance window, then restart all pods of the cluster.
- To change `networkPeering.hostPort.port`, open the new port in the neighbours' firewalls first.

Disconnecting a neighbour

To disconnect a neighbour, remove `network` from `spec.capabilities` of its `ClusterPeer` on either side (`d8 k edit clusterpeer cluster-b`). The module deletes the ClusterNetworkPeer.

The mesh is torn down on both sides, connections between the clusters break. To restore the mesh, add `network` back.

To give the ID or pod subnet of a retired cluster to another cluster, remove `network` from the retired cluster's `ClusterPeer` on all its neighbours, or delete that `ClusterPeer`.

Disabling NetworkPeering

1. Remove `network` from `spec.capabilities` of the `ClusterPeer` objects. Wait until `d8 k get clusternetworkpeers` lists none: the module deletes them within a minute.
2. Set `networkPeering.enabled: false` in the `cni-cilium` ModuleConfig in a maintenance window, then restart all pods of the cluster.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> **i** The module lifecycle stage: General Availability

Egress Gateway

Operation principle

Configuring an egress gateway requires two custom resources:

1. EgressGateway— describes the group of nodes that perform the egress gateway function in hot-standby mode:
   - Among the group of nodes match the `spec.nodeSelector`, the eligible nodes will be selected. One of them will be assigned as the active gateway. The active node is selected in alphabetical order.

     Attributes of an eligible node:

     - The node is in `Ready` state.
       - The node is not in the maintenance state (i.e., it is not cordoned).
       - The `cilium-agent` on the node is in the `Ready` state.
     - When using EgressGateway in `VirtualIP` mode, an agent is launched on the active node which emulates a “virtual” IP address using the ARP protocol. The status of this agent’s pod is also taken into account when determining the eligibility of a node.
     - Different EgressGateways can use the same nodes for operation. The active node is selected independently for each EgressGateway, which allows for load balancing between them.
2. EgressGatewayPolicy — describes the policy for routing network requests from pods in the cluster to a specific egress gateway defined using EgressGateway.

Node maintenance

To perform maintenance on a node that is currently the active egress gateway, follow these steps:

1. Remove the node label to exclude it from the egress gateway candidate pool. Egress-label is the label specified in `spec.nodeSelector` of your EgressGateway.

   ```
   d8 k label node <node-name> <egress-label>-
   ```

2. Cordon the node to prevent new pods from starting:

   ```
   d8 k cordon <node-name>
   ```

   After this, Cilium will automatically select a new active node from the remaining candidates. Traffic will continue routing through the new gateway without interruption.

3. After maintenance is complete, return the node to service:

   ```
   d8 k uncordon <node-name>
   d8 k label node <node-name> <egress-label>=<value>
   ```

> **i** Reapplying the label may cause the node to become active again (if it is first in alphabetical order among candidates).

To avoid immediate failback, temporarily reduce the number of EgressGateway replicas or adjust priorities using additional labels.

Comparison with CiliumEgressGatewayPolicy

The CiliumEgressGatewayPolicy implies configuring only one node as an egress gateway. If it fails, there are no failover mechanisms and the network connection will be broken.

Egress Gateway configuration examples

EgressGateway in PrimaryIPFromEgressGatewayNodeInterface mode (basic mode)

```
apiVersion: network.deckhouse.io/v1alpha1
kind: EgressGateway
metadata:
  name: my-egressgw
spec:
  nodeSelector:
    dedicated/egress: ""
  sourceIP:
    mode: PrimaryIPFromEgressGatewayNodeInterface
    primaryIPFromEgressGatewayNodeInterface:
      # The "public" interface must have the same name on all nodes that matching the nodeSelector.
      # If the active node fails, traffic will be redirected through the backup node and
      # the source IP address of the network packets will change.
      interfaceName: eth1
```

EgressGateway in VirtualIPAddress mode (Virtual IP mode)

```
apiVersion: network.deckhouse.io/v1alpha1
kind: EgressGateway
metadata:
  name: my-egressgw
spec:
  nodeSelector:
    dedicated/egress: ""
  sourceIP:
    mode: VirtualIPAddress
    virtualIPAddress:
      # Each node must have all the necessary routes configured to access all external public services,
      # the "public" interface must be prepared for automatic configuration of the "virtual" IP as a
secondary IP address.
      # In case of failure of the active node, traffic will be redirected through the backup node and
      # the source IP address of the network packets will not change.
      ip: 172.18.18.242
      # List of network interfaces for Virtual IP
      interfaces:
      - eth1
```

EgressGatewayPolicy

```
apiVersion: network.deckhouse.io/v1alpha1
kind: EgressGatewayPolicy
metadata:
  name: my-egressgw-policy
spec:
  destinationCIDRs:
  - 0.0.0.0/0
  egressGatewayName: my-egressgw
  selectors:
  - podSelector:
      matchLabels:
        app: backend
        io.kubernetes.pod.namespace: my-ns
```

HubbleMonitoringConfig

The cluster-scoped HubbleMonitoringConfig resource is intended to configure data export from Hubble, which runs inside Cilium agents.

HubbleMonitoringConfig configuration examples

Enabling extended metrics and flow logs export (with filters and field mask)

> ⚠ The HubbleMonitoringConfig resource must be named `hubble-monitoring-config`.

Example of enabling metrics and export:

```
apiVersion: deckhouse.io/v1alpha1
kind: HubbleMonitoringConfig
metadata:
  name: hubble-monitoring-config
spec:
  extendedMetrics:
    enabled: true
    collectors:
      - name: drop
        # Add additional labels context for the selected collector.
        contextOptions:
"labelsContext=source_ip,source_namespace,source_pod,destination_ip,destination_namespace,destination_po
d"
      - name: flow
  flowLogs:
    enabled: true
    # Allow only the specified events to be written to the log file /var/log/cilium/hubble/flow.log.
    allowFilterList:
      - verdict: ["DROPPED", "ERROR"]
    # Exclude events matching the denyFilterList from the log file.
    denyFilterList:
      - source_pod:
        - kube-system/
      - destination_pod:
        - kube-system/
    # Persist only the specified fields in each record.
    fieldMaskList:
      - time
      - verdict
    # Maximum log file size (in MB) before rotation.
    fileMaxSizeMB: 30
```

Collecting Hubble flow logs with the log-shipper module

To collect flow logs, use the `log-shipper` module.

Create a ClusterLoggingConfig resource that reads the log file from the node filesystem:

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: cilium-hubble-flow-logs
spec:
  type: File
  file:
    include:
      - /var/log/cilium/hubble/flow.log
```

Enabling BPF trace events on demand

BPF trace events (`bpf-events-trace-enabled`) are disabled cluster-wide by default. They are the dominant source of `cilium-agent` CPU and memory on nodes with high pod density: each forwarded packet (subject to `monitor-aggregation`) produces an entry in the BPF event buffer that the agent has to parse, label and feed into Hubble. `drop` and `policy verdict` events are not affected by this setting and remain available in Hubble.

When forwarded-flow visibility is required (for example, to debug a connectivity issue), enable trace events with a CiliumNodeConfig resource. The same resource can target a single node, a group of nodes, or all nodes in the cluster — depending on `spec.nodeSelector`.

Enable trace events on a single node

To enable trace on a specific node, specify its name in the `spec.nodeSelector.matchLabels` parameter:

```
apiVersion: cilium.io/v2
kind: CiliumNodeConfig
metadata:
  name: trace-debug-node-1
  namespace: d8-cni-cilium
spec:
  nodeSelector:
    matchLabels:
      kubernetes.io/hostname: <node-name>
  defaults:
    bpf-events-trace-enabled: "true"
    # Aggregation level "none" disables aggregation of trace events for packets of the
    # same session: a separate trace event is created for each packet.
    # If this line is omitted, the cluster default "medium" remains on the node.
    monitor-aggregation: "none"
```

Enable trace events cluster-wide

An empty `matchLabels` selects all nodes:

```
apiVersion: cilium.io/v2
kind: CiliumNodeConfig
metadata:
  name: trace-debug-all-nodes
  namespace: d8-cni-cilium
spec:
  nodeSelector:
    matchLabels: {}
  defaults:
    bpf-events-trace-enabled: "true"
```

Applying the change

Cilium agent at startup reads the merged configuration, so the affected `cilium-agent` pods must be restarted after the CiliumNodeConfig is created or modified (Deckhouse does not restart agents automatically on such changes):

- for single node:

  ```
  d8 k -n d8-cni-cilium delete pod \
    -l app=agent --field-selector spec.nodeName=<node-name>
  ```

- for all nodes (rolling restart):

  ```
  d8 k -n d8-cni-cilium rollout restart daemonset/agent
  ```

To revert (disable traces), delete the CiliumNodeConfig resource and restart the same pods.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The cni-flannel module

> The module lifecycle stage: General Availability

This module is responsible for providing a network between multiple nodes in a cluster using the flannel module.

Third-party components

List of third-party software used in the `cni-flannel` module:

- Flannel 0.27.4

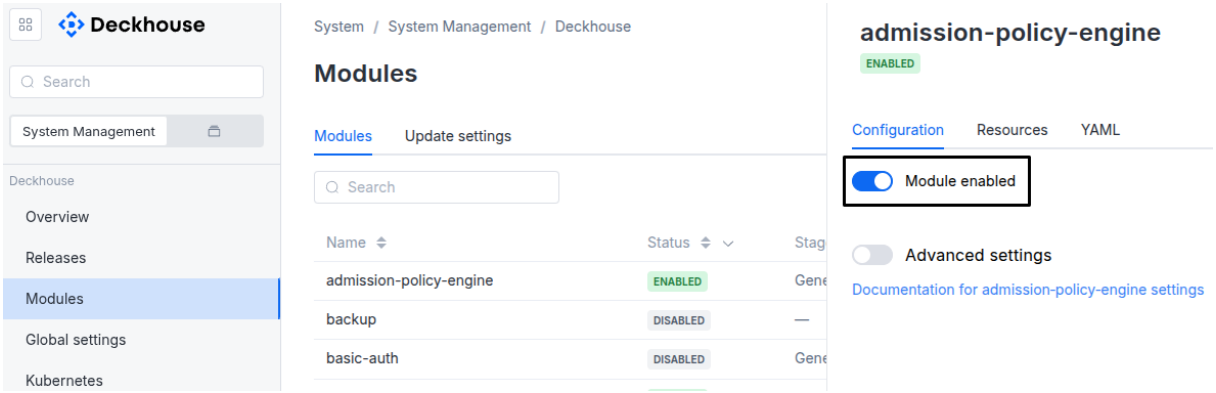
  License: Apache License 2.0

  A simple and easy way to configure a layer 3 network fabric designed for Kubernetes.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability



The module has 7 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-flannel` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

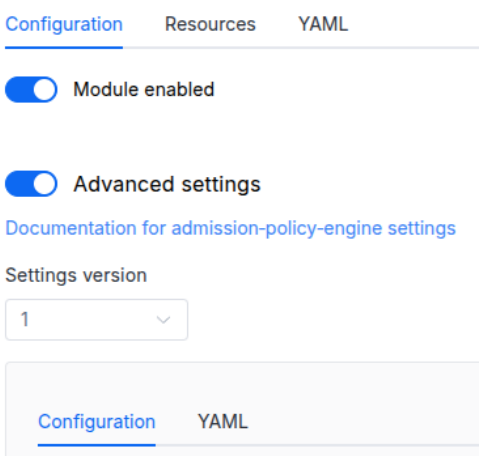
```
d8 system module enable cni-flannel
```

- **Using ModuleConfig `cni-flannel`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cni-flannel` (create it if necessary);

  Example of a manifest to enable module `cni-flannel`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cni-flannel
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-flannel` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cni-flannel` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cni-flannel`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cni-flannel` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cni-flannel
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cni-flannel` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cni-flannel`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cni-flannel
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.ipv4OptionsGuard**
    object

    Mitigation of CVE-2026-98432 (use-after-free in the Linux IPv4 TCP handshake triggered by a TCP SYN with IP options).

    A sidecar of the CNI agent installs a filter into the host network namespace and into every pod network namespace on the node, including pods started later. The filter matches IPv4 TCP SYN packets and IPv4 fragments carrying IP options.

    The filter follows the iptables mode (nft or legacy) that iptables-wrapper selects on the node, the same as the other Deckhouse components. In the nft mode, the filter uses native nftables expressions. In the legacy mode, it uses iptables with the `u32` match. No kernel modules are loaded unless `allowKernelModuleLoad` is set. If the kernel modules of the selected mode are not loaded but those of the other mode are, the filter uses the other mode, and the node is reported by the `D8IPv4OptionsGuardBackendMismatch` alert. A node that cannot be protected is reported by the `D8IPv4OptionsGuardNodeUnprotected` alert.

    To exclude a node (for example, a node with CIPSO labeled networking), set the `ipv4-options-guard.deckhouse.io/disabled: "true"` label on it: the changes are reverted on that node.

    The mitigation does not fix the vulnerability: update the node kernel as soon as a fixed version is available.

    - **settings.ipv4OptionsGuard.allowKernelModuleLoad**
      boolean

      The filter needs the `nf_tables` kernel module in the nft mode and the `ip_tables`, `iptable_raw`, `xt_tcpudp` and `xt_u32` kernel modules in the legacy mode.

      By default, kernel modules are not loaded: if a module of the mode selected by iptables-wrapper is not loaded, the filter uses the other mode when its modules are loaded, and the node is reported as unprotected otherwise. Set to `true` to load the modules of the selected mode.

      Default: `false`

    - **settings.ipv4OptionsGuard.disableMPTCP**
      boolean

      In the `Enforce` mode, set `net.mptcp.enabled=0` in the host and in every pod network namespace. This removes the precondition of the published exploit.

      Listeners opened before the change stay MPTCP until the process is restarted. After a node reboot, MPTCP on the host is disabled again once the CNI agent starts.

      Default: `true`

    - **settings.ipv4OptionsGuard.mode**
      string

      Operating mode.

If the mode is not set, it is `Enforce` in clusters installed with the mitigation and `Audit` in clusters that existed before it.

- `Audit` — matching packets are only counted (the `d8_ipv4_options_guard_matched_packets_total` metric and the `D8IPv4OptionsGuardMatchedTraffic` alert). Use it to check that no workload relies on IP options. While any node is in this mode, the `D8IPv4OptionsGuardAuditMode` alert reminds that the cluster is not protected yet.
- `Enforce` — matching packets are dropped, and MPTCP is disabled if `disableMPTCP` is set.
- `Disabled` — the filter is removed from all network namespaces, including running pods, and `net.mptcp.enabled` is restored to the value it had before.

The mode is applied without restarting the CNI agent pods.

Allowed values: `Audit`, `Enforce`, `Disabled`

- **settings.podNetworkMode**
  string

  Work mode.

  > **i** **NOTE!** All cluster nodes must be rebooted after switching work mode. You can change the parameter **only** in bare metal clusters.

  Default: `HostGW`

  Allowed values: `HostGW`, `VXLAN`

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The cni-simple-bridge module

> **i** The module lifecycle stage: General Availability

The module does not have any settings.

It is automatically enabled for the following cloud providers:

- AWS
- Azure
- GCP

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Managing control plane

> **i** The module lifecycle stage: General Availability

The `control-plane-manager` (CPM) module is responsible for managing the cluster's control plane components. It runs on all master nodes of the cluster (nodes that have the `node-role.kubernetes.io/control-plane: ""` label).

The control-plane-manager:

- **Manages certificates** required for the operation of the control plane (renews certificates and re-issues them in response to configuration changes, among other things). This feature allows the CPM to automatically maintain a secure control plane configuration and quickly add additional SANs for organizing secure access to the Kubernetes API.
- **Configures components**. The CPM module automatically creates the required configs and manifests of the control plane components.
- **Upgrades/downgrades components**. Makes sure that the versions of the components in the cluster are the same.
- **Manages the configuration of the etcd cluster** and its members. The CPM module scales master nodes and migrates the cluster from single-master to multi-master (and vice versa).
- **Configures kubeconfig**. The CPM module maintains up-to-date kubeconfig files on control-plane nodes. It generates, renews, and updates kubeconfigs for control-plane components and the admin kubeconfig (`admin.conf`). By default, it creates a symlink for the root user (`/root/.kube/config` -> `admin.conf`). When the user-authz module is enabled, the symlink can be turned off via the `rootKubeconfigSymlink` parameter in the **control-plane-manager** module (see FAQ). The CPM also hardens file permissions on `admin.conf` and `super-admin.conf`.
- **Extends scheduler functionality** by integrating external plugins via webhooks. Manages by KubeSchedulerWebhookConfiguration resource. Allows more complex logic to be used in workload scheduling tasks within the cluster. For example:
  - placing data storage application pods closer to the data itself,
  - state-based node prioritization (network load, storage subsystem status, etc.),
  - dividing nodes into zones, etc.
- **Monitors the control plane**. The CPM module organizes secure metrics collection and provides a basic set of monitoring rules for the control plane components. For details, refer to Control plane monitoring.
- **Periodic etcd defragmentation**. In clusters with three or more etcd members, this feature is enabled by default. For

more details, see the description of the `etcd.defrag` parameter.

Managing certificates

The CPM module manages certificates of the `control-plane` components, such as:

- Server certificates for `kube-apiserver` & `etcd`. These are stored in the secret `d8-pki` of the namespace `kube-system`:
  - the root CA kubernetes certificate (`ca.crt` & `ca.key`),
  - the root CA etcd certificate (`etcd/ca.crt` & `etcd/ca.key`),
  - the RSA certificate and the key for signing Service Accounts (`sa.pub` & `sa.key`),
  - the root CA certificate for the extension API servers (`front-proxy-ca.key` & `front-proxy-ca.crt`).
- Client certificates for connecting `control-plane` components to each other. The CPM module issues, renews, and re-issues if something has changed (e.g., the SAN list). These certificates are stored on the nodes only:
  - The server-side API server certificate (`apiserver.crt` & `apiserver.key`).
  - The client-side certificate for connecting `kube-apiserver` to `kubelet` (`apiserver-kubelet-client.crt` & `apiserver-kubelet-client.key`).
  - The client-side certificate for connecting `kube-apiserver` to `etcd` (`apiserver-etcd-client.crt` & `apiserver-etcd-client.key`).
  - The client-side certificate for connecting `kube-apiserver` to the extension API servers (`front-proxy-client.crt` & `front-proxy-client.key`).
  - The server-side `etcd` certificate (`etcd/server.crt` & `etcd/server.key`).
  - The client-side certificate for connecting `etcd` to other cluster members (`etcd/peer.crt` & `etcd/peer.key`).
  - The client-side certificate for connecting `kubelet` to `etcd` for performing health-checks (`etcd/healthcheck-client.crt` & `etcd/healthcheck-client.key`).

Also, the CPM module lets you add the additional SANs to certificates (this way, you can quickly and effortlessly add more “entry points” to the Kubernetes API).

The CPM module automatically updates the kubeconfig configuration when certificates are changed.

Scaling

The CPM module supports `control plane` running in a *single-master* or *multi-master* mode.

In the *single-master* mode:

- `kube-apiserver` only uses the `etcd` instance that is hosted on the same node;
- A proxy server is configured on the node that responds to localhost, `kube-apiserver` responds to the IP address of the master node.

In the *multi-master* mode, `control plane` components are automatically deployed in a fault-tolerant manner:

- `kube-apiserver` is configured to work with all etcd instances;
- The additional proxy server that processes localhost requests is set up on each master node. By default, the proxy server sends requests to the local `kube-apiserver` instance. If it is unavailable, the proxy tries to connect to other `kube-apiserver` instances.

Scaling master nodes

The `control-plane` nodes are scaled automatically using the `node-role.kubernetes.io/control-plane=""` label:

- Attaching the `node-role.kubernetes.io/control-plane=""` label to a node results in deploying `control plane` components on this node, connecting the new `etcd` node to the etcd cluster, and regenerating all the necessary certificates and config files.
- Removing the `node-role.kubernetes.io/control-plane=""` label results in deleting all `control plane` components on a node, gracefully removing it from the etcd cluster, and regenerating all the necessary config files and certificates.

⚠ Manual `etcd` actions are required when decreasing the number of nodes from two to one. In all other cases, all the necessary actions are performed automatically. Please note that when scaling from any number of master nodes to one, sooner or later at the last step, the situation of scaling nodes from two to one will arise.

Dynamic terminated pod garbage collection threshold

Automatically configures the optimal `--terminated-pod-gc-threshold` based on cluster size:

- **Small clusters** (less than 100 nodes): 1000 terminated Pods.
- **Medium clusters** (from 100 to 300 nodes): 3000 terminated Pods.
- **Large clusters** (from 300 nodes): 6000 terminated Pods.

i Note. This feature only takes effect in environments where the `--terminated-pod-gc-threshold` parameter is configurable. On managed Kubernetes services (such as EKS, GKE, AKS), this setting is controlled by managed provider.

Configuring Control Plane Resource Requests

The module allows you to configure the total CPU and memory resource requests for control plane components on each master node: `kube-apiserver`, `etcd`, `kube-controller-manager`, and `kube-scheduler`.

Use the `resourcesRequests` parameter in the `control-plane-manager` ModuleConfig:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  enabled: true
  settings:
    resourcesRequests:
      cpu: 1000m
      memory: 500Mi
```

The specified values are used as a common requests budget for control plane components on each master node. Deckhouse Platform (DP) distributes this budget between control plane static pods when rendering their manifests in the following fixed proportions:

Component	Share	Requests for `cpu: 1000m`	Requests for `memory: 500Mi`
`kube-apiserver`	45%	`450m`	`225Mi`
`etcd`	35%	`350m`	`175Mi`
`kube-controller-manager`	10%	`100m`	`50Mi`
`kube-scheduler`	10%	`100m`	`50Mi`

If CPU or memory requests are not explicitly specified, the module automatically calculates requests for the corresponding resource for each control plane component once a day based on the average usage over the previous seven days, plus a 10% margin so that actual usage stays below the request. In this mode the proportions above do not apply: each component gets a request derived from its own measured usage. Explicitly specifying the total amount of CPU or memory disables automatic request calculation for that resource for all control plane components.

i These settings do not apply if the cluster control plane is managed by a cloud provider, for example in GKE, AKS, or EKS.

Version control

Patch versions of control plane components (i.e. within the minor version, for example, from `1.31.13` to `1.31.14`) are upgraded automatically together with the DP version updates. You can't manage patch version upgrades.

Upgrading **minor versions** of control plane components (e.g. from `1.33.*` to `1.34.*`) can be managed using the `kubernetesVersion` parameter of the `control-plane-manager` ModuleConfig. It specifies tracking the DP default (if set to `Default`) or the desired minor version of the control plane. The default control plane version (to use with `kubernetesVersion: Default`) as well as a list of supported Kubernetes versions can be found in the "Supported Kubernetes and OS versions" section.

The cluster Kubernetes version is resolved in one order: `kubernetesVersion` in the `control-plane-manager` ModuleConfig, then the deprecated `ClusterConfiguration.kubernetesVersion`, then the version the current Deckhouse release defaults to. The ModuleConfig setting wins whenever it is set, `Default` included; while it is unset, the deprecated field still decides. Deckhouse raises the `D8ObsoleteKubernetesVersionFieldInClusterConfiguration` alert for as long as the deprecated field is present at all — including when ModuleConfig already owns the version — and it clears once the field is removed from `ClusterConfiguration`.

Example of pinning a Kubernetes version:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  enabled: true
  settings:
    kubernetesVersion: "1.33"
```

The control plane upgrade is performed in a safe way for both single-master and multi-master clusters. The API server may be temporarily unavailable during the upgrade. At the same time, it does not affect the operation of applications in the cluster and can be performed without scheduling a maintenance window.

If the target version (set with the kubernetesVersion parameter) does not match the current control plane version in the cluster, a smart strategy for changing component versions is applied:

- General remarks
  - Updating in different NodeGroups is performed in parallel. Within each NodeGroup, nodes are updated sequentially, one at a time.
- When upgrading:
  - Upgrades are carried out sequentially, one minor version at a time: 1.33 -> 1.34, 1.34 -> 1.35, 1.35 -> 1.36, 1.36 -> 1.37.
  - At each step, the control plane version is upgraded first, followed by kubelet upgrades on the cluster nodes.
- When downgrading:
  - Successful downgrading is only guaranteed for a single version down from the maximum minor version of the control plane ever used in the cluster.
  - kubelets on the cluster nodes are downgraded first, followed by the control plane components.

Exposing the Kubernetes API

The kube-apiserver component is only available within the internal cluster network by default. This module solves the problem of providing simple and secure external access to the Kubernetes API from outside the cluster.

Via Ingress

By configuring the `apiserver.publishAPI.ingress` parameters, you can publish the API server on a dedicated domain (for more details, see the section on service domains in the documentation).

During configuration, you can specify:

- The list of network addresses and subnets from which connections are allowed;
- The Ingress controller on which the publication occurs;
- Whether to use a manually provided TLS certificate, one obtained via cert-manager, or an automatic self-signed certificate.

By default, a special CA certificate will be generated and a kubeconfig generator will be automatically configured.

Via Gateway API

If the `alb` module is enabled in the cluster and a Gateway can be resolved for it (either a default Gateway discovered automatically, or one set explicitly via the `gatewayAPI` settings), the API server is additionally published via the Gateway API: a `ListenerSet` and an `HTTPRoute` are automatically created in the `kube-system` namespace, using the same hostname as for Ingress.

This publication method:

- Is controlled by the same `apiserver.publishAPI.ingress.enabled` parameter. There is no separate parameter to enable it.
- Requires the `global.modules.publicDomainTemplate` parameter to be set (for more details, see the section on service domains in the API documentation).
- Does not depend on whether the Ingress controller is enabled — it works as a fully independent mechanism alongside it.

> ⚠ If the Ingress controller and the `alb` module (with a resolvable Gateway) are enabled in the cluster at the same time, the API server gets published both via Ingress and via the Gateway API, under the same hostname. Only one of the two will actually be reachable by that name, depending on where its DNS record points. The other stays configured but unused. Don't disable the Ingress controller until you've confirmed that publication via the Gateway API works as expected.

Via a Service of type LoadBalancer

By configuring the `apiserver.publishAPI.loadBalancer` parameters, you can create a service of type LoadBalancer named `kube-system/d8-control-plane-apiserver`.

During configuration, you can specify:

- The list of network addresses and subnets from which connections are allowed;
- The external port of the service;
- Annotations on the service for load balancer provider settings.

Exposing the Kubernetes API over Ingress

The kube-apiserver component (without advanced configuration) is only accessible in the internal cluster network. This module enables easy and secure access to Kubernetes API from outside the cluster. The API server is exposed on a dedicated domain (for more details, see the section on service domains in the documentation).

When configuring, you can:

- list network addresses from which connection is allowed;
- list groups that are allowed to access the API server;
- specify Ingress-controller to authenticate on.

By default, a special CA certificate will be generated and the kubeconfig generator will be automatically configured.

Auditing

Kubernetes Auditing can help you if you need to keep track of operations in your Namespaces or troubleshoot the cluster. You can configure it by setting the appropriate Audit Policy. As the result you will have the log file `/var/log/kube-audit/audit.log` containing audit events according to the configured Policy.

By default, in a cluster with DP, a basic policy is created for logging events:

- related to the creation, deletion, and changing of resources;
- committed from the names of ServiceAccounts from the "system" Namespace `kube-system`, `d8-*`;
- committed with resources in the "system" Namespace `kube-system`, `d8-*`.

A basic policy can be disabled by setting the basicAuditPolicyEnabled flag to `false`.

When OIDC authentication is configured, additional user information is included in audit logs under the `user.extra` field:

- `user-authn.deckhouse.io/name` — user's display name
- `user-authn.deckhouse.io/preferred_username` — user's preferred username
- `user-authn.deckhouse.io/dex-provider` — Dex provider identifier (requires `federated:id` scope)
- `user-authn.deckhouse.io/sub` — `sub` claim of the token: the user and the Dex provider in one identifier
- `user-authn.deckhouse.io/generation` — generation of the user's Dex account the token was issued at; the `user-authn` module raises it when it revokes the user's tokens

You can find how to set up policies in a special FAQ section.

Control plane monitoring

The module organizes secure metrics collection and provides a basic set of monitoring rules for the following cluster components:

- `kube-apiserver`;
- `kube-controller-manager`;
- `kube-scheduler`;
- `kube-etcd`.

Admission plugins enabled by default

When installing the Deckhouse Platform, in addition to the standard admission plugins enabled by Kubernetes, the module enables several additional ones. For more information about admission plugins, see the Kubernetes documentation.

Standard admission plugins enabled by Kubernetes

Kubernetes enables the following standard admission plugins:

Admission plugin	Type	Short description
NamespaceLifecycle	Validating	Prevents the creation of new objects in namespaces that are in the process of being deleted (termination) or in non-existent namespaces. It also prevents the deletion of system namespaces: `default`, `kube-system`, and `kube-public`.
LimitRanger	Mutating and Validating	Monitors incoming requests and checks whether they violate the limits specified in the LimitRange object within the namespace. It is used to enforce resource limits at the container and pod levels.
ServiceAccount	Mutating and Validating	Automates the handling of ServiceAccounts. If a pod does not specify a `ServiceAccount`, it automatically assigns the `default` account from the same namespace. It also verifies that the specified ServiceAccount exists.
TaintNodesByCondition	Mutating	A standard security plugin that automatically adds taints to newly created nodes based on their status (e.g., `NotReady` or `Unreachable`). This prevents pods from being scheduled on new nodes before their labels are updated to accurately reflect their declared state.
PodSecurity	Validating	Checks new pods before they are launched and determines whether to allow them based on the requested security context and the restrictions set by the Pod Security Standards in the namespace where the pod will reside.
Priority	Mutating and Validating	Uses the `priorityClassName` field and populates the integer priority value. If the priority class is not found, the pod is rejected.
DefaultTolerationSeconds	Mutating	Sets default toleration values for Pods for the `notready:NoExecute` and `unreachable:NoExecute` taints if the Pod does not have its own tolerations. The default value is **5 minutes**.
DefaultStorageClass	Mutating	Oversees the creation of PersistentVolumeClaim objects. If a specific StorageClass is not specified in the request, it automatically adds the StorageClass labeled `default`. This ensures that users who do not specify a StorageClass will receive the default StorageClass.
StorageObjectInUseProtection	Mutating	Protects storage objects (such as PersistentVolumes) that are in use by pods from accidental deletion. Adds the `kubernetes.io/pvc-protection` or `kubernetes.io/pv-protection` finalizers, which prevent the resource from being deleted while it is in use.

Admission plugin	Type	Short description
PersistentVolumeClaimResize	Validating	Performs additional checks on incoming requests to resize a PersistentVolumeClaim. By default, it prohibits resizing of all claims, except in cases where the claim's StorageClass explicitly allows resizing by setting the `allowVolumeExpansion` parameter to `true`.
RuntimeClass	Mutating and Validating	Takes the `RuntimeClass` into account when creating pods. Sets the `pod.Spec.Overhead` field according to the selected runtime class and validates requests.
CertificateApproval	Validating	Monitors requests to approve `CertificateSigningRequests` and performs additional authorization checks to ensure the user has the rights to approve certificate requests.
CertificateSigning	Validating	Monitors updates to the `status.certificate` field in a CertificateSigningRequest and verifies that the user has the rights to sign the certificate request, using the `spec.signerName` value specified in the CertificateSigningRequest resource.
ClusterTrustBundleAttest	Validating	Analyzes and attests to the trustworthiness of the Kubernetes cluster. This may include verifying certificates, security configurations, and other parameters related to the cluster's integrity.
CertificateSubjectRestriction	Validating	Monitors the creation of CertificateSigningRequests where `spec.signerName = kubernetes.io/kube-apiserver-client`. Rejects requests that specify the `system:masters` group.
DefaultIngressClass	Mutating	Monitors the creation of Ingress objects. If no Ingress class is specified in the request, it automatically adds the Ingress class labeled as "default."
PodTopologyLabels	Mutating	Adds topology labels (e.g., availability zone) to pods bound to a node, corresponding to the labels of that node.
MutatingAdmissionPolicy	Validating and Mutating	A mechanism within the admission control system that allows objects to be modified when they are created or updated during the request admission process.
MutatingAdmissionWebhook	Mutating	Invokes all mutating webhooks that correspond to the request. Webhooks can modify the object and are invoked sequentially.
ValidatingAdmissionPolicy	Validating	Allows declarative validation to be embedded directly into the API, without using external HTTP calls. It checks the CEL for incoming requests that meet the criteria. It is enabled when both the `validatingadmissionpolicy` feature and the `admissionregistration.k8s.io/v1alpha1` group/version are active. If any of the `ValidatingAdmissionPolicy` policies fail, the request is rejected.
ValidatingAdmissionWebhook	Validating	Invokes all validating webhooks that match the request to check the object.
ResourceQuota	Validating	Monitors incoming requests and checks whether they violate the limits specified in the ResourceQuota object in the namespace. Used to limit the total consumption of resources (CPU, memory, number of objects) in the namespace.

Additional admission plugins enabled by the module

In addition to the standard admission plugins enabled by Kubernetes, the module enables the following admission plugins (which cannot be disabled):

Admission plugin	Type	Short description
EventRateLimit	Validating	Addresses the issue of API server overload caused by requests to save new events. Allows you to configure limits at the namespace, user, or global level.
ExtendedResourceToleration	Mutating	Automatically adds tolerations to pods requesting extended resources (e.g., GPU, FPGA). This allows you to allocate special nodes for such pods—nodes that are pre-tainted with the resource name—without manually adding tolerations to the pods.
NodeRestriction	Validating	Restricts the set of Node and Pod objects that the kubelet can modify. Enhances cluster security.
PodNodeSelector	Mutating and Validating	Defines and restricts which node selectors can be used within a namespace, based on reading the namespace annotation and global configuration.
PodTolerationRestriction	Mutating and Validating	Checks the pod's toleration for conflicts with tolerations specified at the namespace level. If there are no conflicts, it merges the pod's and namespace's tolerations. It also checks the pod against a "whitelist" of tolerations.

i In addition to the admission plugins listed above (which are enabled by Kubernetes and the module), you can also enable some additional ones. To do this, use the `apiserver.admissionPlugins` parameter.

The `PodNodeSelector` and `PodTolerationRestriction` plugins are still listed among the allowed values of that parameter for backward compatibility only: they are always enabled, so specifying them has no effect and causes no error.

Feature Gates

You can configure feature gates using the enabledFeatureGates parameter of the `control-plane-manager` ModuleConfig.

Changing the list of feature gates causes a restart of the corresponding component (for example, `kube-apiserver`, `kube-scheduler`, `kube-controller-manager`, `kubelet`).

The following example enables the `ComponentFlagz` and `ComponentStatusz` feature gates:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  enabled: true
  settings:
    enabledFeatureGates:
      - ComponentFlagz
      - ComponentStatusz
```

If a feature gate is not supported or is deprecated, the monitoring system generates the D8ProblematicFeatureGateInUse alert indicating that the feature gate will not be applied.

⚠ The Kubernetes version update (controlled by the kubernetesVersion parameter) will not occur if the list of enabled feature gates for the new version of Kubernetes includes deprecated feature gates.

More information about feature gates is available in the Kubernetes documentation.

▾ List of available feature gates...

Kubernetes 1.33

- `AllowParsingUserUIDFromCertAuth`
- `AllowUnsafeMalformedObjectDeletion`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `ContainerStopSignals`

- `CrossNamespaceVolumeDataSource`
- `DeploymentReplicaSetTerminatingReplicas`
- `DisableAllocatorDualWrite`
- `HPAConfigurableTolerance`
- `HPAScaleToZero`
- `ImageVolume`
- `KubeletPSI`
- `KubeletPodResourcesGet`
- `ListFromCacheSnapshot`
- `MaxUnavailableStatefulSet`
- `MemoryQoS`
- `MutatingAdmissionPolicy`
- `PodLogsQuerySplitStreams`
- `PodObservedGenerationTracking`
- `PreferSameTrafficDistribution`
- `ResourceHealthStatus`
- `SELinuxMount`
- `StrictIPCIDRValidation`

Kubernetes 1.34

- `AllowUnsafeMalformedObjectDeletion`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `ContainerRestartRules`
- `ContainerStopSignals`
- `CrossNamespaceVolumeDataSource`
- `DeploymentReplicaSetTerminatingReplicas`
- `EnvFiles`
- `HPAConfigurableTolerance`
- `HPAScaleToZero`
- `HostnameOverride`
- `ImageVolume`
- `MaxUnavailableStatefulSet`
- `MemoryQoS`
- `MutatingAdmissionPolicy`
- `PodLogsQuerySplitStreams`
- `ResourceHealthStatus`
- `SELinuxMount`
- `StrictIPCIDRValidation`

Kubernetes 1.35

- `AllowUnsafeMalformedObjectDeletion`
- `CRDObservedGenerationTracking`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `ConstrainedImpersonation`
- `ContainerStopSignals`
- `CrossNamespaceVolumeDataSource`
- `HPAScaleToZero`
- `MemoryQoS`
- `MutablePVNodeAffinity`
- `MutablePodResourcesForSuspendedJobs`
- `MutableSchedulingDirectivesForSuspendedJobs`
- `MutatingAdmissionPolicy`
- `NodeDeclaredFeatures`
- `PodLogsQuerySplitStreams`
- `ResourceHealthStatus`
- `RestartAllContainersOnContainerExits`
- `SELinuxMount`
- `StrictIPCIDRValidation`
- `TaintTolerationComparisonOperators`

Kubernetes 1.36

- `AllowUnsafeMalformedObjectDeletion`
- `CRDObservedGenerationTracking`
- `CRIListStreaming`
- `ConcurrentWatchObjectDecode`
- `ContainerStopSignals`
- `ControllerManagerReleaseLeaderElectionLockOnExit`
- `CrossNamespaceVolumeDataSource`
- `HPAScaleToZero`
- `MemoryQoS`
- `MutablePVNodeAffinity`
- `NativeHistograms`
- `PersistentVolumeClaimUnusedSinceTime`
- `PodLogsQuerySplitStreams`
- `SELinuxMount`
- `ShardedListAndWatch`
- `TaintTolerationComparisonOperators`

Kubernetes 1.37

- `AtomicWriteVolumeUserFields`
- `CRDObservedGenerationTracking`
- `CRIListStreaming`
- `ContainerStopSignals`
- `ControllerManagerReleaseLeaderElectionLockOnExit`
- `CrossNamespaceVolumeDataSource`
- `EmptyDirVolumeMode`
- `GRPCContainerProbeTLS`
- `H2CContainerProbe`
- `InPlacePodVerticalScalingMemoryBackedVolumes`
- `MutablePVNodeAffinity`
- `PodLogsQuerySplitStreams`
- `ShardedListAndWatch`
- `StatefulSetRecreateStrategy`
- `TaintTolerationComparisonOperators`

Protecting sensitive fields in custom resources

The `CRDSensitiveData` feature gate provides field-level protection for sensitive data in resources marked with the `x-kubernetes-sensitive-data: true` annotation. This feature is implemented as a patch to `kube-apiserver` (`apiextensions-apiserver`) and is supported starting from Kubernetes version 1.31.

The `x-kubernetes-sensitive-data` marker is validated by `kube-apiserver` when applying a resource:

- Marker requires the `CRDSensitiveData` feature gate to be enabled. It is enabled by default and shouldn't be specified manually.
- Marker can't be set on the root of the schema (the `openAPIV3Schema` node). To protect all fields of a resource, add the marker to the `spec` property (or a subtree below it), not to the schema root — the root also includes system fields (`apiVersion`, `kind`, `metadata`), which cannot be encrypted.
- Field type must be one of the OpenAPI v3 types: `string`, `integer`, `number`, `boolean`, `object`, or `array`. Applying the marker to `object` or `array` makes the entire subtree sensitive.
- Fields defined with `x-kubernetes-int-or-string: true` are supported.
- Marker is not allowed inside `anyOf`, `oneOf`, `allOf`, or `not` branches (this is enforced by the structural schema validator).

If at least one field in the resource schema is marked with `x-kubernetes-sensitive-data: true`, the following protection mechanisms are applied to all custom resources of this type:

- **Encryption in etcd**: Entire resource is encrypted using the same mechanism as Kubernetes Secrets. Requires enabling the `apiserver.encryptionEnabled` parameter.
- **RBAC-based field filtering**: For `get`, `list`, and `watch` requests, sensitive fields are removed from API responses if the caller does not have the corresponding permissions on the `<resource>/sensitive` subresource.
- **Audit log masking**: Values of sensitive fields are replaced with `"******"` in audit logs, regardless of RBAC permissions and audit level.

To add encryption in etcd to sensitive data protection, set the `apiserver.encryptionEnabled` parameter to `true`. The `CRDSensitiveData` feature gate is enabled by default and it shouldn't be specified manually:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  enabled: true
  settings:
    apiserver:
      encryptionEnabled: true
```

⚠ Enabling `encryptionEnabled` is irreversible and triggers a `kube-apiserver` restart.

For details, see the following sections:

- FAQ: Instructions for enabling sensitive data protection.
- Examples: Configuration examples and results.

Third-party components

List of third-party software used in the `control-plane-manager` module:

- Kubernetes 1.33+

  License: Apache License 2.0

  An open source system for managing containerized applications across multiple hosts.

- Etcd 3.6.15

  License: Apache License 2.0

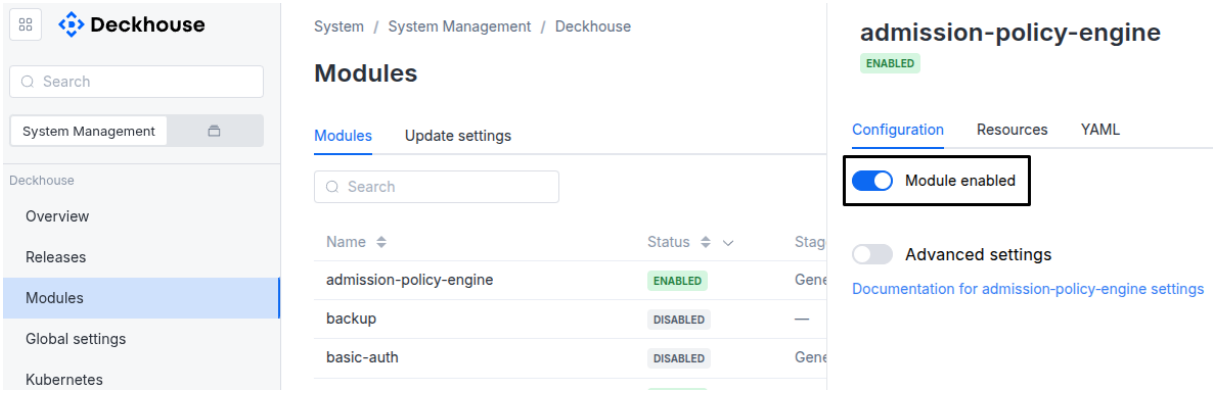
  A distributed reliable key-value store for the most critical data of a distributed system.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability

Some cluster parameters that affect control plane management historically came from the ClusterConfiguration resource. Prefer the corresponding settings in this ModuleConfig instead — for example, `kubernetesVersion`. The ClusterConfiguration fields remain only as a deprecated fallback during migration.



The module has 36 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `control-plane-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

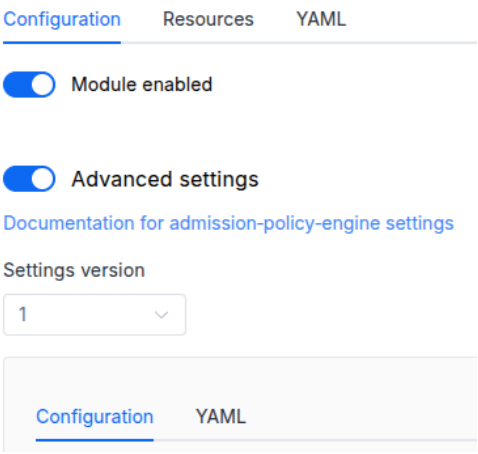
```
d8 system module enable control-plane-manager
```

- **Using ModuleConfig `control-plane-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `control-plane-manager` (create it if necessary);

  Example of a manifest to enable module `control-plane-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `control-plane-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `control-plane-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `control-plane-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `control-plane-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc control-plane-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `control-plane-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `control-plane-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: control-plane-manager
  spec:
    version: 3
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `etcd.externalMembersNames`

- Updates from version **2** to **3**:

  Replace `.apiserver.loadBalancer` with `.apiserver.publishAPI.loadBalancer`.

Parameters

Schema version: 3

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  enabled: true
  settings:
    resourcesRequests:
      cpu: 1000m
      memory: 500Mi
    apiserver:
      bindToWildcard: true
      certSANs:
      - bakery.infra
      - devs.infra
      publishAPI: {}
```

- **settings**
  object
  - **settings.apiserver**
    object

    `kube-apiserver` parameters.

    - **settings.apiserver.admissionPlugins**
      array of strings

      List of enabled additional admission plugins.

      Note, that in addition to the admission plugins enabled by default in Kubernetes, the following admission plugins are also always enabled:

      - `ExtendedResourceToleration`
      - `PodNodeSelector`
      - `PodTolerationRestriction`
      - `NodeRestriction`
      - `EventRateLimit` with the following config:

        ```
        apiVersion: eventratelimit.admission.k8s.io/v1alpha1
        kind: Configuration
        limits:
        - type: Namespace
          qps: 50
          burst: 100
          cacheSize: 2000
        ```

      > **i** Note that the `PodNodeSelector` admission plugin does not require specifying a global configuration, it relies on annotated Namespaces.

      During DP installation, Kubernetes enables the standard admission plugins. In addition to these, the module enables several more. For details, see the “Admission plugins enabled by default” section.

      The `PodNodeSelector` and `PodTolerationRestriction` values are kept in the list of allowed values for backward compatibility only: these plugins are always enabled, so specifying them has no effect and causes no error.

      Example:

      ```
      admissionPlugins:
      - AlwaysPullImages
      - NamespaceAutoProvision
      ```

      - **Element of the array**
        string

        Allowed values: `AlwaysPullImages`, `NamespaceAutoProvision`, `OwnerReferencesPermissionEnforcement`, `PodNodeSelector`, `PodTolerationRestriction`

    - **settings.apiserver.auditLog**
      object

      Audit policy settings

      Default: `{"output":"File"}`

      - **settings.apiserver.auditLog.output**
        string

        Required value

        Audit logs target stream.

Default: `File`

Allowed values: `File`, `Stdout`

Example:

```
output: Stdout
```

- **settings.apiserver.auditLog.path**
  string

  Directory path for logs if the output is “File”, otherwise ignored.

  Default: `/var/log/kube-audit`

  Pattern: `^[a-zA-Z0-9_/.-]+[a-zA-Z0-9_.-]$`

- **settings.apiserver.auditPolicyEnabled**
  boolean

  Set the audit policies using the configuration from the `kube-system/audit-policy` Secret.

  Default: `false`

- **settings.apiserver.authn**
  object

  Optional authentication parameters for Kubernetes API clients.

  By default, they are taken from user-authn module ConfigMap.

  - **settings.apiserver.authn.oidcCA**
    string

    OIDC provider CA.

  - **settings.apiserver.authn.oidcIssuerAddress**
    string

    OIDC provider network address alias.

    Examples:

    ```
    oidcIssuerAddress: 1.2.3.4
    ```

    ```
    oidcIssuerAddress: ''
    ```

  - **settings.apiserver.authn.oidcIssuerURL**
    string

    OIDC provider URL.

    Example:

    ```
    oidcIssuerURL: https://my-super-site.tech/
    ```

  - **settings.apiserver.authn.webhookCA**
    string

    Authorization webhook CA.

  - **settings.apiserver.authn.webhookCacheTTL**
    string

    The duration to cache responses from the webhook token authenticator.

    It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

    Example:

    ```
    webhookCacheTTL: 5m
    ```

  - **settings.apiserver.authn.webhookURL**
    string

    Authentication webhook URL.

    Example:

    ```
    webhookURL: https://127.0.0.1:40443/
    ```

- **settings.apiserver.authz**
  object

  Optional authorization parameters for Kubernetes API clients.

  By default, they are taken from user-authz module ConfigMap.

  - **settings.apiserver.authz.webhookCA**

string

Authorization webhook CA.

- **settings.apiserver.authz.webhookURL**
  string

  Authorization webhook URL.

  Example:

  ```
  webhookURL: https://127.0.0.1:40443/
  ```

- **settings.apiserver.basicAuditPolicyEnabled**
  boolean

  Enforce basic Deckhouse audit policies.

  Default: `true`

- **settings.apiserver.bindToWildcard**
  boolean

  Specifies whether to listen on `0.0.0.0`.

  By default, the API server listens on the hostIP. The latter usually corresponds to the Internal node address; however, the actual IP depends on the cluster type (Static or Cloud) and the layout selected.

  Default: `false`

- **settings.apiserver.certSANs**
  array of strings

  Array of SANs, with which the API server certificate will be generated.

  In addition to the passed list, the following list is always used:

  - `kubernetes`;
  - `kubernetes.default`;
  - `kubernetes.default.svc`;
  - `kubernetes.default.svc.cluster.local`;
  - Kubernetes API server address;
  - `127.0.0.1`;
  - host name;
  - host IP.

  Example:

  ```
  certSANs:
  - my-site.com
  - 192.168.67.76
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9a-zA-Z\.-]+$`

- **settings.apiserver.encryptionEnabled**
  boolean

  Enables data encryption in etcd (see Encrypting secret data at rest).

  When enabled, a Secret `kube-system/d8-secret-encryption-key` is created to store the encryption key.

  Sensitive custom resource fields marked with `x-kubernetes-sensitive-data: true` are protected by the `CRDSensitiveData` feature gate for `kube-apiserver`, which is enabled by default. Enabling this parameter adds encryption in etcd to RBAC-based field filtering with the `<resource>/sensitive` subresource and hiding values from the audit log.

  > **Warning.** Once enabled, this parameter can’t be disabled.

  Default: `false`

- **settings.apiserver.publishAPI**
  object

  Publishing access to Kubernetes API.

  - **settings.apiserver.publishAPI.ingress**
    object

    Settings for PublishAPI type Ingress.

    - **settings.apiserver.publishAPI.ingress.addKubeconfigGeneratorEntry**
      boolean

      Setting it to `false` will remove an entry in kubeconfig-generator.

      Default: `true`

    - **settings.apiserver.publishAPI.ingress.enabled**

boolean

Setting it to `true` will create an Ingress resource `kubernetes-api` in the `kube-system` namespace in the cluster (it exposes the Kubernetes API).

Default: `false`

- **settings.apiserver.publishAPI.ingress.https**
  object

  The HTTPS mode for the API server Ingress.

  Examples:

  ```
  https:
    mode: SelfSigned
  ```

  ```
  https:
    mode: Global
    global:
      kubeconfigGeneratorMasterCA: plainstring
  ```

  - **settings.apiserver.publishAPI.ingress.https.global**
    object

    An additional parameter for the `Global` mode.

    - **settings.apiserver.publishAPI.ingress.https.global.kubeconfigGeneratorMasterCA**
      string

      If there is an external load balancer in front of the Ingress that terminates HTTPS traffic using non-public CA, then you need to specify the CA so it will be included in kubectl-config.

      If you are using certificates issued by the `cert-manager` module and Let’s Encrypt in your cluster, you should set an empty string `""` as the value.

      Also, you can set the external LB’s certificate itself as a CA if you can’t get the CA that signed it for some reason. Note that after the certificate is updated on the LB, all the previously generated kubeconfigs will stop working.

  - **settings.apiserver.publishAPI.ingress.https.mode**
    string

    The mode of issuing certificates for the Ingress resource.

    In the `SelfSigned` mode, a CA-signed certificate will be issued for the Ingress resource.

    Use the following command to get the certificate: `d8 k -n kube-system get secrets kubernetes-api-ca-key-pair -oyaml`.

    In the `Global` mode, the policies specified in the `global.modules.https.mode` global parameter will be applied. Thus, if the global parameter has the `CertManager` mode set (with `letsencrypt` as the ClusterIssuer), then the Let’s Encrypt certificate will be issued for the Ingress resource.

    Default: `SelfSigned`

    Allowed values: `SelfSigned`, `Global`

  - **settings.apiserver.publishAPI.ingress.ingressClass**
    string

    The Ingress class that will be used to expose the Kubernetes API via Ingress.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  - **settings.apiserver.publishAPI.ingress.whitelistSourceRanges**
    array of strings

    An array of CIDRs that are allowed to connect to the API server.

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))?$`

- **settings.apiserver.publishAPI.loadBalancer**
  object

  Settings type LoadBalancer

  - **settings.apiserver.publishAPI.loadBalancer.annotations**
    object

    Annotations to attach to a service to fine-tune the load balancer.

> **Caution!** The module does not take into account the specifics of setting annotations in various cloud environments. If the annotations for load balancer provisioning are only applied when creating a service, you will need to delete and add the `apiserver.loadBalancer` parameter to update such parameters.

- **settings.apiserver.publishAPI.loadBalancer.enabled**
  boolean

  If set to `true`, service `kube-system/d8-control-plane-apiserver` of the LoadBalancer type will be created.

  Default: `false`

- **settings.apiserver.publishAPI.loadBalancer.port**
  integer

  External LoadBalancer TCP port.

  Default: `443`

  Allowed values: `1 <= X <= 65534`

- **settings.apiserver.publishAPI.loadBalancer.sourceRanges**
  array of strings

  A list of CIDRs that are allowed to connect to the API.

  The cloud provider may not support this option or ignore it.

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\/[0-9]+$`

- **settings.apiserver.serviceAccount**
  object

  ServiceAccount issuing settings.

  Examples:

  ```
  serviceAccount: {}
  ```

  ```
  serviceAccount:
    additionalAPIAudiences:
    - istio-ca
  ```

  - **settings.apiserver.serviceAccount.additionalAPIAudiences**
    array of strings

    A list of API audiences to add when provisioning ServiceAccount tokens.

    The default audiences list includes:

    - `serviceAccount.issuer`, if specified.
    - `serviceAccount.additionalAPIIssuers`, if specified.
    - `https://kubernetes.default.svc.${clusterDomain}`, for example, `https://kubernetes.default.svc.cluster.local` – this audience is always added for backward compatibility.

    The service account token authenticator will validate that tokens used against the API are bound to at least one of these audiences.

    This option is beneficial when migrating from one API issuer to another.

  - **settings.apiserver.serviceAccount.additionalAPIIssuers**
    array of strings

    A list of additional issuers to include when provisioning ServiceAccount tokens.

    Issuers (`iss`) are used to verify the source of the tokens, ensuring they originate from trusted entities.

    The first issuer is automatically generated based on the template `https://kubernetes.default.svc.${clusterDomain}`, for example, `https://kubernetes.default.svc.cluster.local`. When multiple issuers are specified, the first issuer is used to generate tokens, and all provided issuers are accepted for token verification.

    This option is beneficial when migrating from one API issuer to another.

  - **settings.apiserver.serviceAccount.issuer**
    string

    ServiceAccount issuer. This is the URL of the API server. The values of this field are used as the `iss` claim of the token and to verify Service Account JWT tokens.

    Note, all pods in the cluster using ServiceAccount tokens must be restarted upon changing this option.

    Example:

    ```
    issuer: https://api.example.com
    ```

- **settings.enabledFeatureGates**
  array of strings

  List of feature gates enabled in the control plane.

  More information about feature gates is available in the Kubernetes documentation. The list of feature gates supported in DP can be found on the module overview page.

  Default: `[]`

  - **Element of the array**
    string

    Pattern: `^[a-zA-Z][a-zA-Z0-9]*$`

- **settings.encryptionAlgorithm**
  string

  Asymmetric encryption algorithm used when generating keys and certificates for the following control-plane components:

  - `apiserver`;
  - `apiserver-kubelet-client`;
  - `apiserver-etcd-client`;
  - `front-proxy-client`;
  - `etcd-server`;
  - `etcd-peer`;
  - `etcd-healthcheck-client`.

  Certificates for the components listed above will be reissued using the selected algorithm and key length.

  If parameter not set, the value from `ClusterConfiguration.encryptionAlgorithm` is used (defaults to `RSA-2048`).

  > **Warning.** When reissuing certificates, the root certificate (**CA**) is not rotated. The root certificate is created with the selected algorithm only during the initial cluster bootstrap.

  Default: `RSA-2048`

  Allowed values: `RSA-2048`, `RSA-3072`, `RSA-4096`, `ECDSA-P256`

  Example:

  ```
  encryptionAlgorithm: ECDSA-P256
  ```

- **settings.etcd**
  object

  `etcd` parameters.

  - **settings.etcd.backup**
    object

    etcd backup parameters.

    - **settings.etcd.backup.cronSchedule**
      string

      Backup schedule etcd in cron format. The local time zone of the `kube-controller-manager` is used.

      Backups on different master nodes are started with a 15-minute offset from each other to avoid simultaneous disk load on all etcd members. Nodes are processed in reverse order of their names, so the node with the lowest name (for example, `master-0`) is backed up last and stores the most recent snapshot.

      Default: `0 0 * * *`

      Example:

      ```
      cronSchedule: 0 1 * * *
      ```

    - **settings.etcd.backup.enabled**
      boolean

      Enable etcd backup.

      Default: `true`

    - **settings.etcd.backup.hostPath**
      string

      Host path on masters nodes for etcd backup.

      Default: `/var/lib/etcd`

  - **settings.etcd.defrag**
    object

    etcd defragmentation parameters.

    Default: `{"cronSchedule":"0 1 * * *"}`

    - **settings.etcd.defrag.cronSchedule**

string

Defragmentation schedule in cron format (UTC).

Default: `0 1 * * *`

Pattern: `^(*(\/[0-9]+)?|[0-9]+(-[0-9]+)?(\/[0-9]+)?(,[0-9]+(-[0-9]+)?(\/[0-9]+)?)*)\s+(*(\/[0-9]+)?|[0-9]+(-[0-9]+)?(\/[0-9]+)?(,[0-9]+(-[0-9]+)?(\/[0-9]+)?)*)\s+(*(\/[0-9]+)?|[0-9]+(-[0-9]+)?(\/[0-9]+)?(,[0-9]+(-[0-9]+)?(\/[0-9]+)?)*)\s+(*(\/[0-9]+)?|[0-9]+(-[0-9]+)?(\/[0-9]+)?(,[0-9]+(-[0-9]+)?(\/[0-9]+)?)*)$`

Example:

```
cronSchedule: 0 1 * * *
```

- **settings.etcd.defrag.enabled**
  boolean

  Enable periodic etcd defragmentation.

  Defaults to `true` when the cluster has three or more etcd members (masters ≥ 3, or masters = 2 with an etcd-arbiter node); otherwise defaults to `false`. An explicit value always takes priority over the computed default.

  > **Warning.** Enabling defragmentation on a single-master cluster will cause a brief control plane unavailability while etcd is being defragmented.

- **settings.etcd.maxDbSize**
  number

  quota-backend-bytes parameter. Deckhouse automatically manages the `quota-backend-bytes` parameter. If the `maxDbSize` parameter is set, deckhouse will use this value for the `quota-backend-bytes` etcd parameter.

  Minimum: 512MB.

  Maximum: 8GB.

  Experimental. It can be removed in the future.

  Allowed values: `536870912 <= X <= 8589934592`

- **settings.failedNodePodEvictionTimeoutSeconds**
  integer

  The number of seconds after which pods will be deleted from the node with the `Unreachable` status.

  > **Note!** If you change the parameter, the pods must be restarted.

  Default: `300`

- **settings.kubernetesVersion**
  string

  Desired Kubernetes version of the control plane components.

  This is the preferred place to manage the cluster Kubernetes version. Edit with:

  ```
  d8 k edit mc control-plane-manager
  ```

  The cluster Kubernetes version is resolved in the following order: this parameter, then the deprecated `ClusterConfiguration.kubernetesVersion`, then the version the current Deckhouse release defaults to. This parameter wins whenever it is set, `Default` included; while it is unset, the deprecated field still decides.

  If `Default` is specified, DP selects the version considered stable for the current release. If that version is more than 1 minor version below the maximum version that has ever been used in the cluster, the version is not changed automatically.

  Downgrading more than 1 minor version below the highest version the cluster has ever run is forbidden.

  Allowed values: `1.33`, `1.34`, `1.35`, `1.36`, `1.37`, `Default`

  Examples:

  ```
  kubernetesVersion: '1.35'
  ```

  ```
  kubernetesVersion: Default
  ```

- **settings.network**
  object

  Cluster network parameters.

  Each parameter is resolved in the following order: this section, then the deprecated same-named field in `ClusterConfiguration`. A parameter set here wins; while it is unset, the deprecated field still decides.

> **Warning.** `podSubnetCIDR`, `serviceSubnetCIDR` and `podSubnetNodeCIDRPrefix` describe the network of a running cluster. Changing any of them after the cluster is bootstrapped is **extremely dangerous** and can lead to complete cluster failure, so it is blocked by admission. It is **strongly recommended to recreate the cluster** instead. See documentation for details. `clusterDomain` is not subject to this warning: changing it is a normal, documented procedure.

- **settings.network.clusterDomain**
  string

  Cluster domain (used for local routing).

  Set the cluster domain here. The same field in `ClusterConfiguration` is deprecated and will be removed in a future release.

  Please note: the domain must not match the domain used in the DNS name template in the publicDomainTemplate parameter. For example, you cannot set `clusterDomain: cluster.local` and `publicDomainTemplate: %s.cluster.local` at the same time.

  When moving the value from `ClusterConfiguration`, keep it exactly as it is now: a different value is rejected. To change the domain later, follow the documented procedure.

  Default: `cluster.local`

  Pattern: `^[0-9a-zA-Z._-]+$`

  Example:

  ```
  clusterDomain: cluster.local
  ```

- **settings.network.podSubnetCIDR**
  string

  Address space of the cluster's Pods.

  When migrating from the deprecated `ClusterConfiguration.podSubnetCIDR`, the value must match the one the cluster currently runs with; admission rejects a mismatch.

  Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

  Example:

  ```
  podSubnetCIDR: 10.111.0.0/16
  ```

- **settings.network.podSubnetNodeCIDRPrefix**
  string

  The prefix size of the Pod network allocated to each node.

  This parameter determines how many IP addresses are available for Pods on each individual node. For example, if `podSubnetCIDR: 10.111.0.0/16` and `podSubnetNodeCIDRPrefix: "24"`, each node will receive a `/24` subnet (e.g., `10.111.0.0/24`, `10.111.1.0/24`, etc.), providing up to 254 IP addresses per node (253 usable for Pods, accounting for network and broadcast addresses).

  Calculation examples:

  - With `/16` network and `/24` prefix: maximum **256 nodes** (2^(24-16) = 256)
  - With `/16` network and `/25` prefix: maximum **512 nodes**, but only **126 IPs per node**
  - Each Pod network IP can support up to 2 Pods (one running + one terminating)

  If the parameter is set in neither this section nor the deprecated `ClusterConfiguration.podSubnetNodeCIDRPrefix`, `24` is used.

  When migrating from the deprecated field, the value must match the one the cluster currently runs with; admission rejects a mismatch.

  Pattern: `^[0-9]{1,2}$`

  Example:

  ```
  podSubnetNodeCIDRPrefix: '24'
  ```

- **settings.network.serviceSubnetCIDR**
  string

  Address space of the cluster's services.

  When migrating from the deprecated `ClusterConfiguration.serviceSubnetCIDR`, the value must match the one the cluster currently runs with; admission rejects a mismatch.

  Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

  Example:

  ```
  serviceSubnetCIDR: 10.222.0.0/16
  ```

- **settings.nodeMonitorGracePeriodSeconds**
  integer

  The number of seconds after which the node will enter the `Unreachable` status in case of lost connection.

Default: `40`

- **settings.resourcesRequests**
  object

  The amount of CPU and memory resources allocated to control-plane components on each master node.

  If CPU or memory requests are not explicitly specified, the module automatically calculates requests for the corresponding resource for each control plane component once a day based on the average usage over the previous seven days, plus a 10% margin so that actual usage stays below the request. Explicitly specifying the total amount of CPU or memory disables automatic request calculation for that resource for all control plane components.

  The explicitly specified amount is distributed among the components in the following fixed proportions:

  - `kube-apiserver` — 45%;
  - `etcd` — 35%;
  - `kube-controller-manager` — 10%;
  - `kube-scheduler` — 10%.

  For example, `cpu: 1000m` results in requests of `450m` for `kube-apiserver`, `350m` for `etcd`, and `100m` for each of `kube-controller-manager` and `kube-scheduler`.

  These settings do not apply if the cluster control plane is managed by a cloud provider (for example, Google Kubernetes Engine or Azure Kubernetes Service). More info in the Kubernetes documentation.

  Example:

  ```
  resourcesRequests:
    cpu: 1000m
    memory: 500Mi
  ```

  - **settings.resourcesRequests.cpu**
    string or number

    The combined CPU requests for control-plane components on each master node.

    Pattern: `^[0-9]+m?$`

  - **settings.resourcesRequests.memory**
    string

    The combined memory requests for control-plane components on each master node.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.rootKubeconfigSymlink**
  boolean

  Whether to maintain a symlink from `/root/.kube/config` to `/etc/kubernetes/admin.conf` on control-plane nodes.

  When the user-authz module is enabled and this parameter is `false`, the symlink is removed and the `NODE ADMIN KUBECONFIG` environment variable is set on control-plane-manager pods accordingly. Use `d8 k` with `--kubeconfig=/etc/kubernetes/admin.conf` (or other credentials) when you need API access from the node.

  When the `user-authz` module is disabled, `control-plane-manager` ignores this parameter and keeps the default (symlink present).

  Setting the value back to `true` restores the symlink on the next reconciliation.

  Default: `true`

  Examples:

  ```
  rootKubeconfigSymlink: true
  ```

  ```
  rootKubeconfigSymlink: false
  ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The module lifecycle stage: General Availability

ControlPlaneNode

Short names: cpn

Scope: Namespaced
Version: v1alpha1

Describes the desired and observed state of control plane components on a single node: etcd, kube-apiserver, kube-controller-manager, kube-scheduler.

The resource is created and updated by the `control-plane-manager` module automatically. Users do not need to create or edit it.

Useful for diagnosing the health of the control plane on the node:

- `ETCD`, `APISERVER`, `CONTROLLERMANAGER` and `SCHEDULER` columns of `kubectl get cpn` show component readiness.
- `CERTIFICATES` column shows overall certificate health.
- `spec.components` contains desired fingerprints, while `status.components` contains the actually applied ones.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Describes the desired state of control plane components on the node.

  - **spec.caChecksum**
    string

    Checksum of the `d8-pki` Secret containing CA certificates that must be applied to all components on the node.

  - **spec.components**
    object

    Contains the desired configuration and PKI checksums for each control plane component.

    If a value in `spec.components.<component>.checksums` differs from the corresponding value in `status.components.<component>.checksums`, the module starts a ControlPlaneOperation to bring the component to the desired state.

    - **spec.components.etcd**
      object

      Desired state of the etcd component.

      - **spec.components.etcd.checksums**
        object

        Desired checksums for the component.

        - **spec.components.etcd.checksums.ca**
          string

          Checksum of the CA certificates applied to the component.

          Absent in `spec` because CA configuration is global.

          Set in `status` after the component pod restarts with the new CA certificates.

        - **spec.components.etcd.checksums.config**
          string

          Checksum of the component static pod manifest and associated configuration files.

        - **spec.components.etcd.checksums.pki**
          string

          Checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

    - **spec.components.kube-apiserver**
      object

      Desired state of the kube-apiserver component.

      - **spec.components.kube-apiserver.checksums**
        object

        Desired checksums for the component.

        - **spec.components.kube-apiserver.checksums.ca**
          string

          Checksum of the CA certificates applied to the component.

          Absent in `spec` because CA configuration is global.

          Set in `status` after the component pod restarts with the new CA certificates.

        - **spec.components.kube-apiserver.checksums.config**
          string

          Checksum of the component static pod manifest and associated configuration files.

        - **spec.components.kube-apiserver.checksums.pki**
          string

Checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

- **spec.components.kube-controller-manager**
  object

  Desired state of the kube-controller-manager component.

  - **spec.components.kube-controller-manager.checksums**
    object

    Desired checksums for the component.

    - **spec.components.kube-controller-manager.checksums.ca**
      string

      Checksum of the CA certificates applied to the component.

      Absent in `spec` because CA configuration is global.

      Set in `status` after the component pod restarts with the new CA certificates.

    - **spec.components.kube-controller-manager.checksums.config**
      string

      Checksum of the component static pod manifest and associated configuration files.

    - **spec.components.kube-controller-manager.checksums.pki**
      string

      Checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

- **spec.components.kube-scheduler**
  object

  Desired state of the kube-scheduler component.

  - **spec.components.kube-scheduler.checksums**
    object

    Desired checksums for the component.

    - **spec.components.kube-scheduler.checksums.ca**
      string

      Checksum of the CA certificates applied to the component.

      Absent in `spec` because CA configuration is global.

      Set in `status` after the component pod restarts with the new CA certificates.

    - **spec.components.kube-scheduler.checksums.config**
      string

      Checksum of the component static pod manifest and associated configuration files.

    - **spec.components.kube-scheduler.checksums.pki**
      string

      Checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

- **status**
  object

  Describes the observed state of control plane components on the node.

  - **status.caChecksum**
    string

    Actually applied checksum of CA certificates.

  - **status.components**
    object

    Contains the observed state for each component: applied checksums and certificate expiration dates.

    - **status.components.etcd**
      object

      Observed state of the etcd component.

      - **status.components.etcd.certificatesExpirationTime**
        object

        Maps each component certificate file name to its `NotAfter` timestamp.

        Populated during the `CertObserve` step.

      - **status.components.etcd.checksums**
        object

        Applied checksums for the component.

        - **status.components.etcd.checksums.ca**
          string

          Checksum of the CA certificates applied to the component.

Absent in `spec` because CA configuration is global.

Set in `status` after the component pod restarts with the new CA certificates.

- **status.components.etcd.checksums.config**
  string

  Applied checksum of the component static pod manifest and associated configuration files.

- **status.components.etcd.checksums.pki**
  string

  Applied checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

- **status.components.etcd.lastCertObserveTime**
  string

  Time of the last successful `CertObserve` step for the component.

- **status.components.kube-apiserver**
  object

  Observed state of the kube-apiserver component.

  - **status.components.kube-apiserver.certificatesExpirationTime**
    object

    Maps each component certificate file name to its `NotAfter` timestamp.

    Populated during the `CertObserve` step.

  - **status.components.kube-apiserver.checksums**
    object

    Applied checksums for the component.

    - **status.components.kube-apiserver.checksums.ca**
      string

      Checksum of the CA certificates applied to the component.

      Absent in `spec` because CA configuration is global.

      Set in `status` after the component pod restarts with the new CA certificates.

    - **status.components.kube-apiserver.checksums.config**
      string

      Applied checksum of the component static pod manifest and associated configuration files.

    - **status.components.kube-apiserver.checksums.pki**
      string

      Applied checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

  - **status.components.kube-apiserver.lastCertObserveTime**
    string

    Time of the last successful `CertObserve` step for the component.

- **status.components.kube-controller-manager**
  object

  Observed state of the kube-controller-manager component.

  - **status.components.kube-controller-manager.certificatesExpirationTime**
    object

    Maps each component certificate file name to its `NotAfter` timestamp.

    Populated during the `CertObserve` step.

  - **status.components.kube-controller-manager.checksums**
    object

    Applied checksums for the component.

    - **status.components.kube-controller-manager.checksums.ca**
      string

      Checksum of the CA certificates applied to the component.

      Absent in `spec` because CA configuration is global.

      Set in `status` after the component pod restarts with the new CA certificates.

    - **status.components.kube-controller-manager.checksums.config**
      string

      Applied checksum of the component static pod manifest and associated configuration files.

    - **status.components.kube-controller-manager.checksums.pki**
      string

      Applied checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

  - **status.components.kube-controller-manager.lastCertObserveTime**

string

Time of the last successful `CertObserve` step for the component.

- **status.components.kube-scheduler**
  object

  Observed state of the kube-scheduler component.

  - **status.components.kube-scheduler.certificatesExpirationTime**
    object

    Maps each component certificate file name to its `NotAfter` timestamp.

    Populated during the `CertObserve` step.

  - **status.components.kube-scheduler.checksums**
    object

    Applied checksums for the component.

    - **status.components.kube-scheduler.checksums.ca**
      string

      Checksum of the CA certificates applied to the component.

      Absent in `spec` because CA configuration is global.

      Set in `status` after the component pod restarts with the new CA certificates.

    - **status.components.kube-scheduler.checksums.config**
      string

      Applied checksum of the component static pod manifest and associated configuration files.

    - **status.components.kube-scheduler.checksums.pki**
      string

      Applied checksum of the component PKI settings (`certSANs`, `encryption-algorithm`).

  - **status.components.kube-scheduler.lastCertObserveTime**
    string

    Time of the last successful `CertObserve` step for the component.

- **status.conditions**
  array of objects

  List of conditions reflecting the readiness of control plane components on the node.

  Possible condition types:

  - `EtcdPodReady`, `APIServerPodReady`, `ControllerManagerPodReady`, `SchedulerPodReady`: the component's static pod is running and ready.
  - `EtcdInSync`, `APIServerInSync`, `ControllerManagerInSync`, `SchedulerInSync`: the desired configuration is applied to the component (`True` with reason `InSync`). `False` with reason `OperationInQueue` means an operation is waiting for approval, `OperationInFlight` means an operation is running (the `message` field contains the operation name(s)), `OutOfSync` means there is no active operation, but the applied configuration differs from the desired one (for example, in maintenance mode).
  - `EtcdReady`, `APIServerReady`, `ControllerManagerReady`, `SchedulerReady`: `<Component>PodReady` and `<Component>InSync` are both `True` (`ETCD`, `APISERVER`, `CONTROLLERMANAGER`, `SCHEDULER` columns). When `False`, `reason` and `message` are taken from the failing condition; a not ready pod takes precedence.
  - `CertificatesHealthy`: All component certificates are valid and have enough lifetime left (`CERTIFICATES` column).

  The `<Component>PodReady` conditions reflect only the health of the component's static pod. Whether the desired configuration is applied to the component is reported by `<Component>InSync`.

  When `status` is `False`, the cause is described in `reason` and `message`.

  - **status.conditions.lastTransitionTime**
    string

    Required value

    Time of the last condition status transition.

  - **status.conditions.message**
    string

    Required value

    Human-readable description of the current condition state.

    Maximum length: `32768`

  - **status.conditions.observedGeneration**
    integer

    The `.metadata.generation` value used to calculate the current condition state.

    Allowed values: `0 <= X`

  - **status.conditions.reason**
    string

    Required value

Machine-readable reason for the current condition state.

Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  Status of the condition.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  Type of the condition in CamelCase or in the `foo.example.com/CamelCase` format.

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

ControlPlaneOperation

Short names: cpo

Scope: Namespaced
Version: v1alpha1

ControlPlaneOperation describes a single update operation for a control plane component on a specific node — for example, certificate renewal or applying a new manifest.

The resource is created and updated by the control-plane-manager module automatically; users do not need to create or edit it.

Useful for diagnostics: shows which operation is running on the node, which step is currently active and whether the operation completed successfully (see Phase and CurrentStep columns of `kubectl get cpo`).

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Describes the desired state of an operation.

  - **spec.approved**
    boolean

    Required value

    Indicates whether the operation is allowed to run.

    Only one approved operation may run on a node at a time. The approver controller sets this automatically based on the current control plane state.

    Default: `false`

  - **spec.component**
    string

    Required value

    Control plane component the operation targets.

    Allowed values: `Etcd`, `KubeAPIServer`, `KubeControllerManager`, `KubeScheduler`

  - **spec.desiredCaChecksum**
    string

    Expected CA certificate checksum once the operation completes.

    Populated only for steps that update the root CA certificate (`SyncCA` and related).

  - **spec.desiredConfigChecksum**
    string

    Expected component configuration checksum (static pod manifest and associated configuration files) once the operation completes.

    Used to confirm that the operation actually applied the intended configuration. After the pod restarts the checksum in `ControlPlaneNode.status` must match this value.

  - **spec.desiredPkiChecksum**
    string

    Expected component PKI checksum (`certSANs`, `encryption-algorithm`) once the operation completes.

    Populated only for steps that change PKI (`RenewPKICerts` and related).

- **spec.nodeName**
  string

  Required value

  Name of the control plane node on which the operation must be executed.

- **spec.steps**
  array of strings

  Required value

  Ordered list of steps to perform within the operation.

  Possible values:

  - `Backup`: Backs up the current component configuration (static pod manifest, associated configuration files) into `/etc/kubernetes/deckhouse/backup` before any changes.
  - `SyncCA`: Synchronizes CA certificates (`ca.crt`, `ca.key`) with the current `d8-pki` Secret.
  - `RenewPKICerts`: Re-issues component certificates (`server`, `peer`, `client`).
  - `RenewKubeconfigs`: Re-issues kubeconfig files used by the component to authenticate against the API.
  - `SyncManifests`: Updates the static pod manifest and accompanying files (`/etc/kubernetes/manifests`, associated configuration files) and records changes in `/etc/kubernetes/deckhouse/diffs` and `status.changedFiles`.
  - `JoinEtcdCluster`: Joins a new member to the etcd cluster.
  - `DefragEtcd`: Defragments the etcd data store on the target node to reclaim disk space.
  - `WaitPodReady`: Waits for the component static pod to become `Ready` after a restart.
  - `CertObserve`: Collects the current certificate expiration dates for the component and publishes them to `status.observedState`.
  - `RenewSignature`: Re-issues the signature key for the kube-apiserver.
  - **Element of the array**
    string

    Name of a single step performed within an operation.

    Allowed values: `Backup`, `SyncCA`, `RenewPKICerts`, `RenewKubeconfigs`, `SyncManifests`, `JoinEtcdCluster`, `DefragEtcd`, `WaitPodReady`, `CertObserve`, `RenewSignature`

- **status**
  object

  Observed state of an operation.

  - **status.changedFiles**
    array of objects

    Files that the `SyncManifests` step changed on the node.

    Full diffs of all files are kept on the node in `/etc/kubernetes/deckhouse/diffs`.

    File changed by an operation on the node.

    - **status.changedFiles.diff**
      string

      Unified diff of the file. Not published for files that may contain sensitive data.

      A diff larger than 32 KiB is truncated at a line boundary and ends with a line that says so.

      Maximum length: `32768`

    - **status.changedFiles.path**
      string

      Required value

      Absolute path of the file on the node.

  - **status.conditions**
    array of objects

    Reflects the operation progress.

    The primary condition is `Completed`. Its `reason` field is shown in the `Phase` column of `kubectl get cpo`:

    - `InProgress`: Operation is running. The current step name is shown in the `CurrentStep` column.
    - `Succeeded`: Operation finished successfully.
    - `Failed`: Operation finished with an error. See details in `message`.
    - **status.conditions.lastTransitionTime**
      string

      Required value

      Last time the condition transitioned from one status to another.

    - **status.conditions.message**
      string

      Required value

      Human-readable description of the current condition state. If there is an error, this field contains the last error output on a step.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**

integer

The `.metadata.generation` value that the condition was set based upon.

Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  Machine-readable reason for the current condition state (for example, `InProgress`, `Succeeded`, or `Failed`).

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  Status of the condition.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  Type of condition.

  In addition to `Completed`, a separate condition is created for each executed step, where `type` equals the step name (for example, `RenewPKICerts`, `SyncManifests`).

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.observedState**
  object

  Contains the component state collected by the `CertObserve` step.

  Populated only for static pod components (etcd, kube-apiserver, kube-controller-manager, kube-scheduler).

  - **status.observedState.certificatesExpirationTime**
    object

    Maps each component certificate file name to its `NotAfter` timestamp.

    Used by the module for certificate re-issuing and alerting.

KubeSchedulerWebhookConfiguration

Scope: Cluster
Version: v1alpha1

Defines the configuration for connecting a third-party kube-scheduler extender webhook.

An external kube-scheduler webhook allows expanding the capabilities of the scheduler and consider more complex conditions when planning the load in the Kubernetes cluster.

kube-scheduler metrics and the explanations of its decisions (the `Scheduled` event text and the decision log, as `extender/<name>`) name the extender of a webhook by the name of this object; when the object has several webhooks, the name gets `/<n>`, the position of the webhook in `webhooks` starting from 1.

During a simulation, kube-scheduler evaluates which nodes could host a Pod without actually placing it. The `filter` and `prioritize` requests sent to the extender include `dryRun: true`, which is absent from regular scheduling requests. When `dryRun` is `true`, the extender must compute its response as usual without causing side effects: it must not reserve space or resources for the Pod or modify its own state. An extender that rejects unknown JSON fields (for example, Go `DisallowUnknownFields`) fails simulation requests; regular scheduling requests are unaffected.

- **webhooks**
  array of objects

  Required value

  - **webhooks.clientConfig**
    object

    Required value

    ClientConfig defines how to communicate with the webhook.

    - **webhooks.clientConfig.caBundle**
      string

      Required value

      caBundle is a PEM encoded CA bundle which will be used to validate the webhook’s server certificate.

      Pattern: `^(?:[A-Za-z0-9+\/]{4})*(?:[A-Za-z0-9+\/]{4}|[A-Za-z0-9+\/]{3}=|[A-Za-z0-9+\/]{2}={2})$`

- **webhooks.clientConfig.service**
  object

  Required value

  Access to webhook via cluster service.

  - **webhooks.clientConfig.service.name**
    string

    Required value

    Service name.

    Pattern: `^[0-9a-z\-]+$`

    Length: `1..255`

  - **webhooks.clientConfig.service.namespace**
    string

    Required value

    Service namespace.

    Pattern: `^[0-9a-z\-]+$`

    Length: `1..255`

  - **webhooks.clientConfig.service.path**
    string

    Required value

    URI path.

    Pattern: `^[0-9a-zA-Z._\/-]+$`

    Length: `1..255`

  - **webhooks.clientConfig.service.port**
    integer

    Required value

    Service port.

    Allowed values: `1 <= X <= 65535`

- **webhooks.failurePolicy**
  string

  Specifies scheduling should fail or not fail when the extender returns an error or is not reachable.

  Default: `Fail`

  Allowed values: `Fail`, `Ignore`

- **webhooks.filterVerb**
  string

  Verb appended to `URLPrefix` when issuing a `filter` call to the scheduler extender. If omitted, defaults to `filter` (for backward compatibility, avoid making changes unless necessary). Set to an empty string `""` to disable `filter` calls for this extender.

- **webhooks.preemptVerb**
  string

  Verb appended to `URLPrefix` when issuing a `preempt` call to this extender. Leave empty (`""`) to disable `preempt` calls for this extender.

- **webhooks.prioritizeVerb**
  string

  Verb appended to `URLPrefix` when issuing a `prioritize` call to this extender. If omitted, defaults to `prioritize` (for backward compatibility, avoid making changes unless necessary). Set to an empty string `""` to disable `prioritize` calls for this extender.

- **webhooks.sendPlacements**
  boolean

  Send the extender information about tentative Pod reservations on nodes and their cancellations through the `assumed` field in `prioritize` requests. Each entry has the fields `uid`, `namespace`, `name`, `node` and `forget: true` for a canceled reservation.

  Requires `prioritizeVerb`. Entries older than 30 seconds are not sent. After a failed request, entries may be sent again. The extender must handle repeated entries and `forget` notifications for Pods it does not know, and expire reservations after 30 seconds if no `forget` arrives.

  Default: `false`

- **webhooks.timeout**
  string

  Webhook timeout: an integer with the `ms` or `s` suffix, for example `500ms` or `30s`. Allowed values are from `1ms` to `60s`.

Takes precedence over `timeoutSeconds`. If omitted, the `timeoutSeconds` value is used.

Pattern: `^[0-9]+(ms|s)$`

Example:

```
timeout: 500ms
```

- **webhooks.timeoutSeconds**
  Deprecated
  integer

  Webhook timeout in seconds.

  Deprecated. Use the `timeout` parameter instead. Ignored if `timeout` is set.

  Default: `10`

  Allowed values: `1 <= X <= 60`

- **webhooks.weight**
  integer

  Required value

  The numeric multiplier for the node scores that the prioritize call generates.

  Allowed values: `1 <= X`

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> **i** The module lifecycle stage: General Availability

How do I add a master node to a static or hybrid cluster?

> **i** It is important to have an odd number of masters to ensure a quorum.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

When installing Deckhouse Platform with default settings, the NodeGroup `master` lacks the section `spec.staticInstances.labelSelector` with label filter settings for `staticInstances` resources. Because of this, after changing the number of `staticInstances` nodes in the NodeGroup `master` (parameter `spec.staticInstances.count`), when adding a regular node using Cluster API Provider Static (CAPS), it can be "intercepted" and added to the NodeGroup `master`, even if the corresponding `StaticInstance` (in `metadata`) specifies a label with a `role` different from `master`. To avoid this "interception", after installing DP, edit the NodeGroup `master` — add the section `spec.staticInstances.labelSelector` with label filter settings for `staticInstances` resources. Example of NodeGroup `master` with `spec.staticInstances.labelSelector`:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: master
spec:
  nodeType: Static
  staticInstances:
    count: 2
    labelSelector:
      matchLabels:
        role: master
```

Next, when adding master nodes to the cluster using CAPS, specify the label specified in `spec.staticInstances.labelSelector` NodeGroup `master` in the corresponding `StaticInstance`. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-master-1
  labels:
    # The label specified in spec.staticInstances.labelSelector NodeGroup master.
    role: master
spec:
  # Specify the IP address of the static node server.
  address: "<SERVER-IP>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
```

> **i** When adding new master nodes using CAPS and changing the number of master nodes in the NodeGroup `master` (parameter `spec.staticInstances.count`), please note the following:
>
> During the initial cluster installation, the configuration specifies the first master node on which the installation takes place. If, after the initial cluster installation, you need to create a multi-master cluster and add master nodes using CAPS, you must specify the number of nodes in the `spec.staticInstances.count` parameter of the NodeGroup `master` as one less than the desired number.
>
> For example, if you need to create a multi-master with three master nodes in `spec.staticInstances.count` NodeGroup `master`, specify the value `2` and create two `staticInstances` for the nodes to be added. After adding them to the cluster, the number of master nodes will be three: the master node on which the installation took place and two master nodes added using CAPS.

Otherwise, adding a master node to a static or hybrid cluster is similar to adding a regular node. To do this, use the corresponding examples. All the necessary actions to configure cluster control plane components on the new master nodes are performed automatically. Wait until the master nodes appear in `Ready` status.

How do I add master nodes to a cloud cluster?

The following describes the conversion of a single-master cluster into a multi-master.

> **i** Before adding nodes, ensure you have the required quotas in the cloud provider.
>
> It is important to have an odd number of masters to ensure a quorum.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

1. Make a backup of `etcd` and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the creation of new master nodes.
4. Make sure that Deckhouse queue is empty:

   ```
   d8 system queue list
   ```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

   > **i** When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Platform license key.

6. Run the appropriate edition and version of the Deckhouse installer container **on the local machine** (change the container registry address if necessary):

   ```
   DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
   DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]' '[:lower:]' )
   docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
     registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
   ```

7. **In the installer container**, run the following command to check the state before working:

   ```
   dhctl terraform check --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-host
   <MASTER-NODE-0-HOST>
   ```

The command output should indicate that Terraform found no inconsistencies and no changes are required.

8. **In the installer container**, run the following command and specify the required number of replicas using the `masterNodeGroup.replicas` parameter:

```
dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> \
  --ssh-host <MASTER-NODE-0-HOST>
```

> **i** For **Yandex Cloud**, when using external addresses on master nodes, the number of array elements in the masterNodeGroup.instanceClass.externalIPAddresses parameter must equal the number of master nodes. If `Auto` is used (public IP addresses are provisioned automatically), the number of array elements must still equal the number of master nodes.
>
> To illustrate, with three master nodes (`masterNodeGroup.replicas: 3`) and automatic address reservation, the `masterNodeGroup.instanceClass.externalIPAddresses` parameter would look as follows:
>
> ```
> externalIPAddresses:
> - "Auto"
> - "Auto"
> - "Auto"
> ```

9. **In the installer container**, run the following command to start scaling:

```
dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST>
```

10. Wait until the required number of master nodes are `Ready` and all `control-plane-manager` instances are up and running:

```
d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady -l app=d8-control-plane-manager
```

How do I reduce the number of master nodes in a cloud cluster?

The following describes the conversion of a multi-master cluster into a single-master.

> ⚠ The steps described below must be performed from the first in order of the master node of the cluster (master-0). This is because the cluster is always scaled in order: for example, it is impossible to delete nodes master-0 and master-1, leaving master-2.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

1. Create a backup of etcd and the `/etc/kubernetes` directory.
2. Copy the resulting archive outside the cluster (e.g., to a local machine).
3. Ensure there are no alerts in the cluster that may interfere with the master node update process.
4. Make sure the DP queue is empty:

```
d8 system queue list
```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

```
docker login registry.deckhouse.io
```

During the login process, you will need to enter your `Username` and `Password`.

> **i** When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Platform license key.

6. On the **local machine**, run the DP installer container for the corresponding edition and version (change the container registry address if needed):

```
DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]' '[:lower:]' )
docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
  registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
```

7. **In the installer container**, run the following command and set `masterNodeGroup.replicas` to `1`:

```
dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> \
  --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST>
```

> **i**
>
> For **Yandex Cloud**, if external IPs are used for master nodes, the number of items in the `masterNodeGroup.instanceClass.externalIPAddresses` array must match the number of master nodes. Even when using `Auto` (automatic public IP allocation), the number of entries must still match.
>
> For example, for a single master node (`masterNodeGroup.replicas: 1`) and automatic IP assignment, the `masterNodeGroup.instanceClass.externalIPAddresses` section would look like:
>
> ```
> externalIPAddresses:
> - "Auto"
> ```

8. **In the installer container**, run the following command to trigger the scaling operation:

```
dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST>
```

> **i**
>
> For **OpenStack** and **VK Cloud (OpenStack)**, after confirming the node deletion, it is extremely important to check the disk deletion `<prefix>kubernetes-data-N` in Openstack itself.
>
> For example, when deleting the `cloud-demo-master-2` node in the Openstack web interface or in the OpenStack CLI, it is necessary to check the absence of the `cloud-demo-kubernetes-data-2` disk.
>
> If the kubernetes-data disk remains, there may be problems with ETCD operation as the number of master nodes increases.

9. Check the Deckhouse queue and make sure that there are no errors with the command:

```
d8 system queue list
```

How do I dismiss the master role while keeping the node?

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

1. Make a backup of `etcd` and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the update of the master nodes.
4. Make sure that Deckhouse queue is empty:

```
d8 system queue list
```

5. Remove the following labels:
   - `node-role.kubernetes.io/control-plane`
   - `node-role.kubernetes.io/master`
   - `node.deckhouse.io/group`

   Use the following command to remove labels:

```
d8 k label node <MASTER-NODE-N-NAME> node-role.kubernetes.io/control-plane- node-role.kubernetes.io/master- node.deckhouse.io/group-
```

6. Make sure that the master node to be deleted is no longer listed as a member of the etcd cluster:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ member list -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

7. Exec to the node and run the following commands:

```
rm -f /etc/kubernetes/manifests/{etcd,kube-apiserver,kube-scheduler,kube-controller-manager}.yaml
rm -f /etc/kubernetes/{scheduler,controller-manager}.conf
rm -f /etc/kubernetes/authorization-webhook-config.yaml
rm -f /etc/kubernetes/admin.conf /root/.kube/config
rm -rf /etc/kubernetes/deckhouse
rm -rf /etc/kubernetes/pki/{ca.key,apiserver*,etcd/,front-proxy*,sa.*}
rm -rf /var/lib/etcd/member/
```

How do I switch to a different OS image in a multi-master cluster?

The OS change method depends on the cluster type: in a cloud cluster, nodes are replaced with `dhctl converge`; in a static cluster, nodes are replaced manually, one at a time.

In a cloud cluster

To change the OS image in a cloud cluster with multiple master nodes, follow these steps:

⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

1. Make a backup of `etcd` and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the update of the master nodes.
4. Make sure that Deckhouse queue is empty:

   ```
   d8 system queue list
   ```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

   i When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Platform license key.

6. Run the appropriate edition and version of the Deckhouse installer container **on the local machine** (change the container registry address if necessary):

   ```
   DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
   DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]' '[:lower:]' )
   docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
     registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
   ```

7. **In the installer container**, run the following command to check the state before working:

   ```
   dhctl terraform check --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> \
     --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-HOST>
   ```

   The command output should indicate that Terraform found no inconsistencies and no changes are required.

8. **In the installer container**, run the following command and specify the required OS image using the `masterNodeGroup.instanceClass` parameter (specify the addresses of all master nodes using the `--ssh-host` parameter):

   ```
   dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-
   user=<USERNAME> \
     --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-HOST>
   ```

9. **In the container with the installer**, run the following command to update the nodes:

   Carefully review the actions that converge plans to perform when it asks for confirmation.

   When the command is executed, the nodes will be replaced by new nodes with confirmation on each node. The replacement will be performed one by one in reverse order (2,1,0).

   ```
   dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> \
     --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-HOST>
   ```

   The following steps should be performed **sequentially on each** master node, starting with the node with the highest number (suffix 2) and ending with the node with the lowest number (suffix 0).

10. **On the newly created node**, check the systemd-unit log for the `bashible.service`. Wait until the node configuration is complete (you will see a message `nothing to do` in the log):

    ```
    journalctl -fu bashible.service
    ```

11. Make sure the node is listed as an etcd cluster member:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ member list -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

12. Make sure `control-plane-manager` is running on the node:

```
d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady \
  -l app=d8-control-plane-manager --field-selector spec.nodeName=<MASTER-NODE-N-NAME>
```

13. Proceed to update the next node (repeat the steps above).

In a static cluster

The following instruction describes OS replacement on master nodes that were added to the cluster **manually** using the `bootstrap.sh` script. Perform the steps for each master node, one node at a time. Do not proceed to the next node until the current node has rejoined the cluster and is healthy.

⚠ If master nodes are managed by Cluster API Provider Static (CAPS) through StaticInstance resources, do not use this instruction. First delete the StaticInstance, install the required OS, and add the node to the `master` NodeGroup again.

⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

To change the OS of a manually added master node, follow these steps:

1. Make a backup of `etcd` and the `/etc/kubernetes` directory. If the `stronghold` module is enabled, make sure its data has also been backed up.
2. Check the cluster health and make sure there are no alerts or pending Deckhouse queue tasks:

```
d8 status
```

3. Remove the master node labels from the node:

```
d8 k label node <MASTER_NODE_NAME> node-role.kubernetes.io/control-plane- \
  node-role.kubernetes.io/master- node.deckhouse.io/group-
```

   where `<MASTER_NODE_NAME>`: Name of the master node being changed.

4. Make sure the node has been removed from the etcd cluster member list:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
    --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
    --endpoints https://127.0.0.1:2379/ member list -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

5. Evict workloads from the node with `d8 k drain`:

```
d8 k drain <MASTER_NODE_NAME> --ignore-daemonsets --delete-emptydir-data
```

6. Force-delete any Pods remaining on the node:

```
d8 k delete pods --all-namespaces --field-selector spec.nodeName=<MASTER_NODE_NAME> --force
```

7. Delete the Node object:

```
d8 k delete node <MASTER_NODE_NAME>
```

8. Clean up the DP data on the removed master node. This command irreversibly removes Kubernetes and DP data from the node. Before running it, make sure you have selected the correct node and created the required backups:

```
bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
```

9. Install the required OS on the node.
10. On one of the remaining master nodes in the cluster, retrieve and decode the script for adding a master node:

```
d8 k -n d8-cloud-instance-manager get secret manual-bootstrap-for-master \
  -o jsonpath='{.data.bootstrap\.sh}' | base64 -d > bootstrap.sh
```

11. Securely copy the `bootstrap.sh` file obtained in the previous step to the node being added and run it as `root` on that node:

    ```
    bash bootstrap.sh
    ```

12. **On the node being added**, check the systemd-unit log for the `bashible.service`. Wait until the node configuration is complete (you will see a message `nothing to do` in the log):

    ```
    journalctl -fu bashible.service
    ```

13. Wait until the node reaches the `Ready` status:

    ```
    d8 k wait node <MASTER_NODE_NAME> --for=condition=Ready --timeout=10m
    ```

14. Make sure the node is listed as an etcd cluster member:

    ```
    for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
      d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
        --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
        --endpoints https://127.0.0.1:2379/ member list -w table
      if [ $? -eq 0 ]; then
        break
      fi
    done
    ```

15. Make sure `control-plane-manager` is running on the node:

    ```
    d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady \
      -l app=d8-control-plane-manager --field-selector spec.nodeName=<MASTER_NODE_NAME>
    ```

16. Make sure there are no alerts or pending queue tasks:

    ```
    d8 status
    ```

17. Repeat the procedure for the next master node.

How do I switch to a different OS image in a single-master cluster?

The method depends on the cluster type: first add extra master nodes, replace the OS in multi-master mode, then restore the original number of master nodes.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

In a cloud cluster

1. Convert your single-master cluster to a multi-master one, as described in the guide on adding master nodes to a cluster.
2. Change the OS on the master nodes according to the instructions.
3. Convert your multi-master cluster to a single-master one according to the guide on excluding master nodes from the cluster.

In a static cluster

1. Add extra master nodes according to the instructions.
2. Change the OS on the master nodes according to the instructions.
3. Remove extra master nodes from the control plane role according to the instructions. Then delete them from the cluster with `d8 k delete node <MASTER_NODE_NAME>` and power off the corresponding servers.

How to configure HA mode with two master nodes and an arbiter node?

Deckhouse Platform allows you to configure HA mode with two master nodes and an arbiter node. This approach allows you to meet HA requirements in conditions of limited resources.

Only etcd is placed on the arbiter node, without the other control plane components. This node is used to ensure the etcd quorum.

Requirements for the arbiter node:

- At least 2 CPU cores
- At least 4 GB of RAM
- At least 8 GB of disk space for etcd

The network latency requirements for the arbiter node are similar to those for the master nodes.

Configuring in a cloud cluster

The example below applies to a cloud cluster with three master nodes. To configure HA mode with two master nodes and an arbiter node in a cloud cluster, you need to remove one master node from the cluster and add one arbiter node.

To do this, follow these steps:

⚠ The following steps must be performed starting from the first master node (`master-0`) in the cluster. This is because the cluster scales in order — for example, it is not possible to remove `master-0` and `master-1` while leaving `master-2`.

⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

1. Create a backup of etcd and the `/etc/kubernetes` directory.
2. Copy the resulting archive outside the cluster (for example, to a local machine).
3. Ensure there are no alerts in the cluster that may interfere with the master node update process.
4. Make sure the DP queue is empty:

   ```
   d8 system queue list
   ```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

   i When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Platform license key.

6. On the **local machine**, run the DP installer container for the corresponding edition and version (change the container registry address if needed):

   ```
   DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
   DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]' '[:lower:]' )
   docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
     registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
   ```

7. **In the installer container**, run the following command:

   ```
   dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> \
     --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST>
   ```

   Change the cloud provider settings:

   - Set `masterNodeGroup.replicas` to `2`.
   - Create a NodeGroup for the arbiter node. The arbiter node **must have** the label `node.deckhouse.io/etcd-arbiter: ""` and a taint that prevents user workloads from being placed on it. Example of a NodeGroup description for the arbiter node:

     ```
     nodeGroups:
       - name: arbiter
         replicas: 1
         nodeTemplate:
           labels:
             node.deckhouse.io/etcd-arbiter: ""
           taints:
             - key: node.deckhouse.io/etcd-arbiter
               effect: NoSchedule
         zones:
           - europe-west3-b
         instanceClass:
           machineType: n1-standard-4
       # ... the rest of the manifest
     ```

   - Save your changes.

> **i** For **Yandex Cloud**, if external IPs are used for master nodes, the number of items in the `masterNodeGroup.instanceClass.externalIPAddresses` array must match the number of master nodes. Even when using `Auto` (automatic public IP allocation), the number of entries must still match.
>
> For example, for a single master node (`masterNodeGroup.replicas: 1`) and automatic IP assignment, the `masterNodeGroup.instanceClass.externalIPAddresses` section would look as follows:
>
> ```
> externalIPAddresses:
> - "Auto"
> ```

8. **In the installer container**, run the following command to trigger the scaling operation:

   ```
   dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST>
   ```

   > **i** **Important**. For **OpenStack** and **VK Cloud (OpenStack)**, after confirming the node deletion, it is extremely important to check the disk deletion `<prefix>kubernetes-data-N` in OpenStack itself.
   >
   > For example, when deleting the `cloud-demo-master-2` node in the OpenStack web interface or in the OpenStack CLI, it is necessary to check the absence of the `cloud-demo-kubernetes-data-2` disk.
   >
   > If the `kubernetes-data` disk remains, there may be problems with etcd operation as the number of master nodes increases.

9. Check the Deckhouse queue with the following command and make sure there are no errors:

   ```
   d8 system queue list
   ```

Configuring in a static cluster

To configure HA mode with two master nodes and an arbiter node in a static cluster, follow these steps:

1. Create a NodeGroup for the arbiter node. The arbiter node **must have** the label `node.deckhouse.io/etcd-arbiter: ""` and a taint that prevents user workloads from being placed on it. Example of a NodeGroup description for the arbiter node:

   ```
   apiVersion: deckhouse.io/v1
     kind: NodeGroup
     metadata:
       name: arbiter
     spec:
       nodeType: Static
       nodeTemplate:
         labels:
           node.deckhouse.io/etcd-arbiter: ""
         taints:
           - key: node.deckhouse.io/etcd-arbiter
             effect: NoSchedule
     # ... the rest of the manifest
   ```

2. Add a node to the cluster that will be used as an arbiter node in a way that is convenient for you.
3. Ensure that the added arbiter node is in the list of etcd cluster members.
4. Remove one master node from the cluster.

How do I view the list of etcd members?

Option 1

Use the `etcdctl member list` command.

Example:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ member list -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

Warning. The last parameter in the output table shows etcd member is in `learner` state, is not in `leader` state.

Option 2

To obtain information about etcd cluster nodes in tabular form, use the `etcdctl endpoint status` command. For the leader, the `IS LEADER` column will show `true`.

Example:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ endpoint status --cluster -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

What if something went wrong?

During its operation, `control-plane-manager` automatically creates backups of configurations and data that may be useful in case of issues. These backups are stored in the `/etc/kubernetes/deckhouse/backup` directory. If errors or unforeseen situations occur during operation, you can use these backups to restore to the previous stable state.

What if the etcd cluster fails?

If the etcd cluster is not functioning and it cannot be restored from a backup, you can attempt to rebuild it from scratch by following the steps below.

1. First, on all nodes that are part of your etcd cluster, except for one, remove the `etcd.yaml` manifest located in the `/etc/kubernetes/manifests/` directory. This last node will serve as a starting point for the new multi-master cluster.
2. On the last node, edit etcd manifest `/etc/kubernetes/manifests/etcd.yaml` and add the parameter `--force-new-cluster` to `spec.containers.command`.
3. After the new cluster is ready, remove the `--force-new-cluster` parameter.

> ⚠ This operation is unsafe and breaks the guarantees given by the consensus protocol. Note that it brings the cluster to the state that was saved on the node. Any pending entries will be lost.

What if etcd restarts with an error?

This method may be necessary if the `--force-new-cluster` option doesn't restore etcd work. Such a scenario can occur during an unsuccessful converge of master nodes, where a new master node was created with an old etcd disk, changed its internal address, and other master nodes are absent. Symptoms indicating the need for this method include: the etcd container being stuck in an endless restart with the log showing the error: `panic: unexpected removal of unknown remote peer`.

1. Find the `etcdutl` utility on the master node and copy the executable to `/usr/local/bin/`:

   ```
   ETCD_PID=$(crictl inspect $(crictl ps --name etcd -q | head -1) | jq .info.pid)
   cp /proc/${ETCD_PID}/root/usr/bin/etcdutl /usr/local/bin/etcdutl
   chmod +x /usr/local/bin/etcdutl
   ```

2. Create a new etcd database snapshot from the current local snapshot (`/var/lib/etcd/member/snap/db`):

   ```
   etcdutl snapshot restore /var/lib/etcd/member/snap/db --name <HOSTNAME> \
   --initial-cluster=<HOSTNAME>=https://<ADDRESS>:2380 --initial-advertise-peer-urls=https://<ADDRESS>:2380 \
   --skip-hash-check=true --data-dir /var/lib/etcdtest
   ```

   where:

   - `<HOSTNAME>`: Name of the master node.
   - `<ADDRESS>`: Address of the master node.

3. Execute the following commands to use the new snapshot:

   ```
   cp -r /var/lib/etcd /tmp/etcd-backup
   rm -rf /var/lib/etcd
   mv /var/lib/etcdtest /var/lib/etcd
   ```

4. Locate the `etcd` and `api-server` containers:

   ```
   crictl ps -a | egrep "etcd|apiserver"
   ```

5. Remove the `etcd` and `api-server` containers:

   ```
   crictl rm <CONTAINER-ID>
   ```

6. Restart the master node.

What to do if the database volume of etcd reaches the limit set in quota-backend-bytes?

When the database volume of etcd reaches the limit set by the `quota-backend-bytes` parameter, it switches to "read-only"

mode. This means that the etcd database stops accepting new entries but remains available for reading data. You can tell that you are facing a similar situation by executing the command:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name | sed -n 1p) -- \
  etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt \
  --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ \
  endpoint status -w table --cluster
```

If you see a message like `alarm:NOSPACE` in the `ERRORS` field, you need to take the following steps:

1. On **each master node** (from the list of the etcd cluster members obtained earlier), find the line with `--quota-backend-bytes` in the etcd pod manifest at `/etc/kubernetes/manifests/etcd.yaml` and double the value. If there is no such line, add one, for example: `- --quota-backend-bytes=8589934592`. This sets the limit to 8 GB.
2. Disarm the active alarm that occurred due to reaching the limit. To do this, execute the command:

   ```
   d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name | sed -n 1p)
   -- \
   etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
   --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
   --endpoints https://127.0.0.1:2379/ alarm disarm
   ```

3. Change the maxDbSize parameter in the `control-plane-manager` settings to match the value specified in the manifest.

How to compact etcd storage

> ⚠ Before compacting etcd storage, back up etcd.

To view the size of the etcd database on a specific node before and after compaction, use the command (where `NODE_NAME` is the name of the master node):

```
d8 k -n kube-system exec -it etcd-NODE_NAME -- /usr/bin/etcdctl \
  --cert=/etc/kubernetes/pki/etcd/server.crt \
  --key=/etc/kubernetes/pki/etcd/server.key \
  --cacert=/etc/kubernetes/pki/etcd/ca.crt \
  endpoint status --cluster -w table
```

Output example (the size of the etcd database on the node is specified in the `DB SIZE` column):

```
+----------------------------+------------------+---------+-----------------+---------+--------+-------
---------------+--------+------------+------------+-----------+------------+--------------------+------
--+----------------------------+-------------------+
|          ENDPOINT          |        ID        | VERSION | STORAGE VERSION | DB SIZE | IN USE |
PERCENTAGE NOT IN USE | QUOTA  | IS LEADER  | IS LEARNER | RAFT TERM | RAFT INDEX | RAFT APPLIED INDEX |
ERRORS | DOWNGRADE TARGET VERSION | DOWNGRADE ENABLED |
+----------------------------+------------------+---------+-----------------+---------+--------+-------
---------------+--------+------------+------------+-----------+------------+--------------------+------

```

How to compact etcd storage on a node in a single-master cluster

> ⚠ Compacting etcd storage is a resource-intensive operation that temporarily blocks etcd from running on that node. Keep this in mind when choosing a time to perform the operation in a cluster with a single master node.

To compact etcd storage in a cluster with a single master node, use the following command (where `NODE_NAME` is the name of the master node):

```
d8 k -n kube-system exec -ti etcd-NODE_NAME -- /usr/bin/etcdctl \
  --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt \
  --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ defrag --command-timeout=30s
```

Example output when the operation is successful:

```
Finished defragmenting etcd member[https://localhost:2379]. took 848.948927ms
```

> **i** If a timeout error occurs, increase the value of the `—command-timeout` parameter from the command above until compaction completes successfully.

How to compact etcd storage in a cluster with multiple master nodes

To compact etcd storage in a cluster with multiple master nodes:

1. Get a list of etcd pods. To do this, use the following command:

   ```
   d8 k -n kube-system get pod -l component=etcd -o wide
   ```

   Example output:

   ```
   NAME           READY    STATUS    RESTARTS   AGE     IP              NODE        NOMINATED NODE
   READINESS GATES
   etcd-master-0   1/1     Running   0          3d21h   192.168.199.80  master-0    <none>
   <none>
   etcd-master-1   1/1     Running   0          3d21h   192.168.199.81  master-1    <none>
   <none>
   etcd-master-2   1/1     Running   0          3d21h   192.168.199.82  master-2    <none>
   <none>
   ```

2. Identify the leader master node. To do this, contact any etcd pod and get a list of nodes participating in the etcd cluster using the command (where `NODE_NAME` is the name of the master node):

   ```
   d8 k -n kube-system exec -it etcd-NODE_NAME -- /usr/bin/etcdctl \
     --cert=/etc/kubernetes/pki/etcd/server.crt \
     --key=/etc/kubernetes/pki/etcd/server.key \
     --cacert=/etc/kubernetes/pki/etcd/ca.crt \
     endpoint status --cluster -w table
   ```

   Output example (the leader in the `IS LEADER` column will have the value `true`):

   ```
   +----------------------------+------------------+---------+-----------------+---------+--------+--
   --------------------+--------+------------+------------+-----------+------------+-----------------
   ---+--------+--------------------------+-------------------+
   |          ENDPOINT          |        ID        | VERSION | STORAGE VERSION | DB SIZE | IN USE |
   PERCENTAGE NOT IN USE | QUOTA  | IS LEADER  | IS LEARNER | RAFT TERM | RAFT INDEX | RAFT APPLIED
   INDEX | ERRORS | DOWNGRADE TARGET VERSION | DOWNGRADE ENABLED |
   +----------------------------+------------------+---------+-----------------+---------+--------+--
   --------------------+--------+------------+------------+-----------+------------+-----------------
   ---+--------+--------------------------+-------------------+
   | https://192.168.199.80:2379 | 489a8af1e7acd7a0 |   3.6.1 |           3.6.0 |   76 MB |  62 MB |
   20% | 2.1 GB |       true |      false |        56 |  258054684 |          258054684 |        |
   |             false |
   +----------------------------+------------------+---------+-----------------+---------+--------+--
   --------------------+--------+------------+------------+-----------+------------+-----------------
   ---+--------+--------------------------+-------------------+
   | https://192.168.199.81:2379 | 589a8ad1e7ccd7b0 |   3.6.1 |           3.6.0 |   76 MB |  62 MB |
   20% | 2.1 GB |      false |      false |        56 |  258054685 |          258054685 |        |
   |             false |
   +----------------------------+------------------+---------+-----------------+---------+--------+--
   --------------------+--------+------------+------------+-----------+------------+-----------------
   ---+--------+--------------------------+-------------------+
   | https://192.168.199.82:2379 | 229a8cd1e7bcd7a0 |   3.6.1 |           3.6.0 |   76 MB |  62 MB |
   20% | 2.1 GB |      false |      false |        56 |  258054685 |          258054685 |        |
   |             false |
   +----------------------------+------------------+---------+-----------------+---------+--------+--
   --------------------+--------+------------+------------+-----------+------------+-----------------
   ---+--------+--------------------------+-------------------+
   ```

3. Compact etcd storage on the etcd cluster member nodes one by one. Use the following command (where `NODE_NAME` is the name of the master node):

   > **i** Important: compact the leader node last.
   >
   > Restoring etcd on a node after compaction may take some time. It is recommended to wait at least a minute before proceeding to compact etcd storage on the next node.

   ```
   d8 k -n kube-system exec -ti etcd-NODE_NAME -- /usr/bin/etcdctl \
     --cacert /etc/kubernetes/pki/etcd/ca.crt \
     --cert /etc/kubernetes/pki/etcd/ca.crt \
     --key /etc/kubernetes/pki/etcd/ca.key \
     --endpoints https://127.0.0.1:2379/ defrag --command-timeout=30s
   ```

   Example output when the operation is successful:

   ```
   Finished defragmenting etcd member[https://localhost:2379]. took 848.948927ms
   ```

   > **i** If a timeout error occurs, increase the value of the `—command-timeout` parameter from the command above until compaction completes successfully.

Cluster admin access model

The control-plane-manager module maintains several kubeconfig files on master nodes. Understanding their purpose is important for secure cluster administration.

Kubeconfig files on master nodes

File	Identity	Purpose
`/etc/kubernetes/admin.conf`	`kubernetes-admin` (`kubeadm:cluster-admins` group)	Machine kubeconfig for control-plane-manager operations (kubeconfig renewal, cluster administration). The group is bound to the built-in wildcard `cluster-admin` role.
`/etc/kubernetes/super-admin.conf`	`kubernetes-super-admin` (`system:masters` group)	Break-glass emergency credential. Bypasses RBAC entirely. Restrict access to this file to trusted recovery scenarios.
`/etc/kubernetes/controller-manager.conf`	`system:kube-controller-manager`	Used by kube-controller-manager.
`/etc/kubernetes/scheduler.conf`	`system:kube-scheduler`	Used by kube-scheduler.

RBAC-based admin access

`admin.conf` is generated with the `kubeadm:cluster-admins` group instead of `system:masters`. This provides RBAC-controlled admin access that can be revoked by removing the RBAC binding objects for `kubeadm:cluster-admins`.

Deckhouse binds the `kubeadm:cluster-admins` group to the built-in wildcard ClusterRole `cluster-admin` (the same effective model as a standard Kubernetes cluster without extra RBAC), regardless of whether the user-authz module is enabled. For full unrestricted access that also bypasses RBAC, use `super-admin.conf`.

Recommended admin access

The following options are available for administrative access:

- Personalized OIDC-based kubeconfig obtained through the DP web interface. This provides individual accountability and audit trail.
- Administrators can explicitly use the admin kubeconfig on a master node:

  ```
  d8 k --kubeconfig=/etc/kubernetes/admin.conf <command>
  ```

How to generate a kubeconfig to access the Kubernetes API?

`kubeconfig` for remote cluster access via `d8` (`kubectl`) can be generated in the DP web interface.

To publish the Kubernetes API and generate `kubeconfig`, configure the `apiserver.publishAPI` parameter of the `control-plane-manager` module:

- Open the `control-plane-manager` module settings (create the ModuleConfig `control-plane-manager` resource if there is none):

  ```
  d8 k edit mc control-plane-manager
  ```

- Add the following section to the `settings` block and save:

```
apiserver:
  publishAPI:
    ingress:
      enabled: true
```

Root kubeconfig symlink

By default, the CPM module creates a symlink `/root/.kube/config` -> `/etc/kubernetes/admin.conf` on master nodes, allowing root to run `d8 k` without specifying `--kubeconfig`.

When the **user-authz** module is enabled, you can disable this symlink by setting `rootKubeconfigSymlink: false` in the **control-plane-manager** module configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  enabled: true
  settings:
    rootKubeconfigSymlink: false
```

If **user-authz** is disabled, CPM does not apply this setting and keeps the default symlink behavior.

When the symlink is disabled (and **user-authz** is enabled), the symlink is removed when it pointed to `admin.conf`. Use personalized credentials or pass `--kubeconfig` explicitly.

Security hardening

The CPM module automatically restricts file permissions on `admin.conf` and `super-admin.conf` to `0600` (owner read/write only) during every reconciliation cycle. This prevents unauthorized users from reading these sensitive credentials.

Break-glass access

In emergency situations (RBAC misconfiguration, webhook failures), use `super-admin.conf`:

```
d8 k --kubeconfig=/etc/kubernetes/super-admin.conf <command>
```

This credential bypasses all RBAC checks. Use it only as a last resort and restrict who can read the file.

How do I configure additional audit policies?

1. Enable the auditPolicyEnabled flag in the module configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  settings:
    apiserver:
      auditPolicyEnabled: true
```

2. Create the `kube-system/audit-policy` Secret containing a Base64 encoded YAML file:

```
apiVersion: v1
kind: Secret
metadata:
  name: audit-policy
  namespace: kube-system
data:
  audit-policy.yaml: <base64>
```

   The minimum viable example of the `audit-policy.yaml` file looks as follows:

```
apiVersion: audit.k8s.io/v1
kind: Policy
rules:
- level: Metadata
  omitStages:
  - RequestReceived
```

You can find detailed information on how to configure `audit-policy.yaml` file here:

- The official Kubernetes documentation;
- The code of the generator script used in GCE.

How to omit Deckhouse built-in policy rules?

Set the apiserver.basicAuditPolicyEnabled module parameter to `false`.

An example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  settings:
    apiserver:
      auditPolicyEnabled: true
      basicAuditPolicyEnabled: false
```

How to stream audit log to stdout instead of files?

Set the apiserver.auditLog.output parameter to `Stdout`.

An example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  settings:
    apiserver:
      auditPolicyEnabled: true
      auditLog:
        output: Stdout
```

How to deal with the audit log?

There must be some `log scraper` on master nodes *(log-shipper, promtail, filebeat)* that will monitor the log file:

```
/var/log/kube-audit/audit.log
```

The following fixed parameters of log rotation are in use:

- The maximum disk space is limited to `1000 Mb`.
- Logs older than `30 days` will be deleted.

Depending on the `Policy` settings and the number of requests to the `apiserver`, the amount of logs collected may be high. Thus, in some cases, logs can only be kept for less than 30 minutes.

> ⚠ The current implementation of this feature isn't safe and may lead to a temporary failure of the control plane.
>
> The `apiserver` will not be able to start if there are unsupported options or a typo in the Secret.

If `apiserver` is unable to start, you have to manually disable the `--audit-log-*` parameters in the `/etc/kubernetes/manifests/kube-apiserver.yaml` manifest and restart apiserver using the following command:

```
docker stop $(docker ps | grep kube-apiserver- | awk '{print $1}')
# Or (depending on your CRI).
crictl stopp $(crictl pods --name=kube-apiserver -q)
```

After the restart, you will be able to fix the Secret or delete it:

```
d8 k -n kube-system delete secret audit-policy
```

How do I speed up the restart of Pods if the connection to the node has been lost?

By default, a node is marked as unavailable if it does not report its state for 40 seconds. After another 5 minutes, its Pods will be rescheduled to other nodes. Thus, the overall application unavailability lasts approximately 6 minutes.

In specific cases, if an application cannot run in multiple instances, there is a way to lower its unavailability time:

1. Reduce the period required for the node to become `Unreachable` if the connection to it is lost by setting the

`nodeMonitorGracePeriodSeconds` parameter.
2. Set a lower timeout for evicting Pods on a failed node using the `failedNodePodEvictionTimeoutSeconds` parameter.

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 3
  settings:
    nodeMonitorGracePeriodSeconds: 10
    failedNodePodEvictionTimeoutSeconds: 50
```

In this case, if the connection to the node is lost, the applications will be restarted in about 1 minute.

Both these parameters directly impact the CPU and memory resources consumed by the control plane. By lowering timeouts, we force system components to send statuses more frequently and check the resource state more often.

When deciding on the appropriate threshold values, consider resources consumed by the control nodes (graphs can help you with this). Note that the lower parameters are, the more resources you may need to allocate to these nodes.

etcd backup and restore

What is done automatically

CronJob `kube-system/d8-etcd-backup-*` is automatically started at 00:00 UTC+0. Master nodes are backed up one by one with a 15-minute offset in reverse order of node names, so the node with the lowest name (for example, `master-0`) is backed up last and stores the most recent snapshot. The result is saved in `/var/lib/etcd/etcd-backup.tar.gz` on all nodes with `control-plane` in the cluster (master nodes). `/var/lib/etcd` is the default directory, it can be changed in the etcd.backup.hostPath parameter.

The archives on different nodes can contain snapshots taken at different times. If a backup job fails on a node, its archive can be even older. To restore, use the snapshot with the highest revision. To find out the revision, unpack the archive and run:

```
tar -xzf etcd-backup.tar.gz
etcdutl snapshot status etcd-backup.snapshot -w table
```

How to manually backup etcd

Using Deckhouse CLI (Deckhouse Platform v1.65+)

Starting with Deckhouse Platform v1.65, a new `d8 backup etcd` tool is available for taking snapshots of etcd state.

```
d8 backup etcd ./etcd-backup.snapshot
```

Using bash (Deckhouse Platform v1.64 and older)

Login into any control-plane node with `root` user and use next script:

```
#!/usr/bin/env bash
set -e

pod=etcd-`hostname`
d8 k -n kube-system exec "$pod" -- /usr/bin/etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt --cert
/etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key --endpoints https://127.0.0.1:2379/ snapshot save
/var/lib/etcd/${pod##*/}.snapshot && \
mv /var/lib/etcd/"${pod##*/}.snapshot" etcd-backup.snapshot && \
cp -r /etc/kubernetes/ ./ && \
tar -cvzf kube-backup.tar.gz ./etcd-backup.snapshot ./kubernetes/
rm -r ./kubernetes ./etcd-backup.snapshot
```

In the current directory etcd snapshot file `kube-backup.tar.gz` will be created from one of an etcd cluster members. From this file, you can restore the previous etcd cluster state in the future.

Also, we recommend making a backup of the `/etc/kubernetes` directory, which contains:

- manifests and configurations of control-plane components;
- Kubernetes cluster PKI.

This directory will help to quickly restore a cluster in case of complete loss of control-plane nodes without creating a new cluster and without rejoin the remaining nodes into the new cluster.

We recommend encrypting etcd snapshot backups as well as backup of the directory `/etc/kubernetes/` and saving them outside the Deckhouse cluster. You can use one of third-party files backup tools, for example: Restic, Borg, Duplicity, etc.

You can see documentation for learn about etcd disaster recovery procedures from snapshots.

How do perform a full recovery of the cluster state from an etcd backup?

The following steps will be described to restore to the previous state of the cluster from a backup in case of complete data loss.

Restoring a single-master cluster

Follow these steps to restore a single-master cluster on master node:

1. Find `etcdutl` utility on the master-node and copy the executable to `/usr/local/bin/`:

   ```
   ETCD_PID=$(crictl inspect $(crictl ps --name etcd -q | head -1) | jq .info.pid)
   cp /proc/${ETCD_PID}/root/usr/bin/etcdutl /usr/local/bin/etcdutl
   chmod +x /usr/local/bin/etcdutl
   ```

   Check the version of `etcdutl` using the command:

   ```
   etcdutl version
   ```

   The result must be a correct output of `etcdutl version` command without errors.

   Alternatively, you can download etcdutl executable to the node (preferably its version is the same as the etcd version in the cluster):

   ```
   wget "https://github.com/etcd-io/etcd/releases/download/v3.6.1/etcd-v3.6.1-linux-amd64.tar.gz"
   tar -xzvf etcd-v3.6.1-linux-amd64.tar.gz && mv etcd-v3.6.1-linux-amd64/etcdutl /usr/local/bin/etcdutl
   ```

   You can check current `etcd` version using following command (might not work, if etcd and Kubernetes API are already unavailable):

   ```
   d8 k -n kube-system exec -ti etcd-$(hostname) -- etcdutl version
   ```

2. Stop the etcd.

   ```
   mv /etc/kubernetes/manifests/etcd.yaml ~/etcd.yaml
   ```

3. Save the current etcd data.

   ```
   cp -r /var/lib/etcd/member/ /var/lib/deckhouse-etcd-backup
   ```

4. Copy or move the `etcd-backup.snapshot` file to the current user’s (root) home directory:

   ```
   cp /path/to/backup/etcd-backup.snapshot ~/etcd-backup.snapshot
   ```

5. Clean the etcd directory.

   ```
   rm -rf /var/lib/etcd
   ```

6. Restore the etcd database.

   ```
   ETCDCTL_API=3 etcdutl snapshot restore ~/etcd-backup.snapshot  --data-dir=/var/lib/etcd
   ```

7. Run etcd. The process may take some time.

   ```
   mv ~/etcd.yaml /etc/kubernetes/manifests/etcd.yaml
   crictl ps --label io.kubernetes.pod.name=etcd-$HOSTNAME
   ```

   To verify that etcd is running, use the command:

   ```
   crictl ps --label io.kubernetes.pod.name=etcd-$HOSTNAME
   ```

   Output example:

   ```
   CONTAINER        IMAGE            CREATED              STATE     NAME      ATTEMPT     POD ID
   POD
   4b11d6ea0338f    16d0a07aa1e26    About a minute ago   Running   etcd      0
   ee3c8c7d7bba6   etcd-gs-test
   ```

8. Restart the master node.

Restoring a multi-master cluster

To properly restore a multi-master cluster, follow these steps:

1. Enable High Availability (HA) mode. This is necessary to preserve at least one Prometheus replica and its PVC, since HA is disabled by default in single-master clusters.
2. Switch the cluster to single-master mode:
   - In a cloud cluster, follow the instructions.
   - In a static cluster, remove any unnecessary master nodes from the `control-plane` role by following the instructions and then remove them from the cluster.
   - In a static cluster with the configured HA mode based on two master nodes and an arbiter node, remove the arbiter node and additional master nodes.
   - In a cloud cluster with the configured HA mode based on two master nodes and an arbiter node, use the instructions to remove the additional master nodes and the arbiter node.
3. Restore etcd from the backup on the only remaining master node. Follow the instructions for restoring a cluster with a single master node.
4. Once etcd is restored, remove the records of the previously deleted master nodes from the cluster using the following command (replace with the actual node name):

   ```
   d8 k delete node <MASTER_NODE_NAME>
   ```

   > **Warning.** If the `d8 k` or `kubectl` commands are unavailable on the node, check the `/etc/kubernetes/kubernetes-api-proxy/nginx.conf` configuration file. It should only specify your current API server. If the configuration contains lines with IP addresses of old master nodes, remove them. Edit the configuration in a similar way on all other nodes.
5. Reboot the master node. Ensure that the other nodes transition to the `Ready` state.
6. Wait for Deckhouse to process all tasks in the queue:

   ```
   d8 system queue main
   ```
7. Switch the cluster back to multi-master mode. Follow the respective instructions for cloud clusters and static clusters.

Once you go through these steps, the cluster will be successfully restored in the multi-master configuration.

How do I restore a Kubernetes object from an etcd backup?

To get cluster objects data from an etcd backup, you need:

1. Start an temporary instance of etcd.
2. Fill it with data from the backup.
3. Get desired objects using `auger`.

Example of steps to restore objects from an etcd backup

In the example below, `etcd-backup.snapshot` is an etcd snapshot, `infra-production` is the namespace in which objects need to be restored.

- To decode objects from `etcd` you would need auger. It can be built from source on any machine that has Docker installed (it cannot be done on cluster nodes).

  ```
  git clone -b v1.0.1 --depth 1 https://github.com/etcd-io/auger
  cd auger
  make release
  build/auger -h
  ```
- Resulting executable `build/auger`, and also the `snapshot` from the backup copy of etcd must be uploaded on master-node, on which following actions would be performed.

Following actions are performed on a master node, to which `etcd snapshot` file and `auger` tool were copied:

1. Set the correct access permissions for the backup file:

   ```
   chmod 644 etcd-backup.snapshot
   ```
2. Set full path for snapshot file and for the tool into environmental variables:

   ```
   SNAPSHOT=/root/etcd-restore/etcd-backup.snapshot
   AUGER_BIN=/root/auger
   chmod +x $AUGER_BIN
   ```
3. Run a Pod with temporary instance of `etcd`.
   - Create Pod manifest. It should schedule on current master node by `$HOSTNAME` variable, and mounts snapshot file by `$SNAPSHOT` variable, which it then restores in temporary `etcd` instance:

```
cat <<EOF >etcd.pod.yaml
apiVersion: v1
kind: Pod
metadata:
  name: etcdrestore
  namespace: default
spec:
  nodeName: $HOSTNAME
  tolerations:
  - operator: Exists
  initContainers:
  - command:
    - etcdutl
    - snapshot
    - restore
    - "/tmp/etcd-snapshot"
    - --data-dir=/default.etcd
    image: $(kubectl -n kube-system get pod -l component=etcd -o jsonpath="
{.items[*].spec.containers[*].image}" | cut -f 1 -d ' ')
    imagePullPolicy: IfNotPresent
    name: etcd-snapshot-restore
    # Uncomment the fragment below to set limits for the container if the node does not have
enough resources to run it.
    # resources:
    #   requests:
    #     ephemeral-storage: "200Mi"
    #   limits:
    #     ephemeral-storage: "500Mi"
    volumeMounts:
    - name: etcddir
      mountPath: /default.etcd
    - name: etcd-snapshot
      mountPath: /tmp/etcd-snapshot
      readOnly: true
  containers:
  - command:
    - etcd
    image: $(kubectl -n kube-system get pod -l component=etcd -o jsonpath="
{.items[*].spec.containers[*].image}" | cut -f 1 -d ' ')
    imagePullPolicy: IfNotPresent
    name: etcd-temp
    volumeMounts:
    - name: etcddir
      mountPath: /default.etcd
  volumes:
  - name: etcddir
    emptyDir: {}
    # Use the snippet below instead of emptyDir: {} to set limits for the container if the
node's resources are insufficient to run it.
    # emptyDir:
    #  sizeLimit: 500Mi
  - name: etcd-snapshot
    hostPath:
      path: $SNAPSHOT
      type: File
EOF
```

- Create Pod from the resulting manifest:

```
d8 k create -f etcd.pod.yaml
```

4. Set environment variables. In this example:
   - `infra-production` - namespace which we will search resources in.
   - `/root/etcd-restore/output` - path for outputting recovered resource manifests.
   - `/root/auger` - path to `auger` executable.

```
FILTER=infra-production
BACKUP_OUTPUT_DIR=/root/etcd-restore/output
mkdir -p $BACKUP_OUTPUT_DIR && cd $BACKUP_OUTPUT_DIR
```

5. Commands below will filter needed resources by `$FILTER` and output them into `$BACKUP_OUTPUT_DIR` directory:

```
files=($(d8 k -n default exec etcdrestore -c etcd-temp -- etcdctl  --endpoints=localhost:2379 get / --prefix --
keys-only | grep "$FILTER"))
for file in "${files[@]}"
do
  OBJECT=$(d8 k -n default exec etcdrestore -c etcd-temp -- etcdctl  --endpoints=localhost:2379 get "$file" --
print-value-only | $AUGER_BIN decode)
  FILENAME=$(echo $file | sed -e "s#/registry/##g;s#/#_#g")
  echo "$OBJECT" > "$BACKUP_OUTPUT_DIR/$FILENAME.yaml"
  echo $BACKUP_OUTPUT_DIR/$FILENAME.yaml
done
```

6. From resulting `yaml` files, delete `creationTimestamp`, `UID`, `status` and other operational fields, and then restore the objects:

   ```
   d8 k create -f deployments_infra-production_supercronic.yaml
   ```

7. Delete the Pod with a temporary instance of etcd:

   ```
   d8 k -n default delete pod etcdrestore
   ```

How the node to run the Pod on is selected

The Kubernetes scheduler component selects the node to run the Pod on.

The selection process involves two phases, namely `Filtering` and `Scoring`. They are supposed to efficiently distribute the Pods between the nodes.

Although there are some additional phases, such as `pre-filtering`, `post-filtering`, and so on, you can safely narrow them down to the global phases mentioned above, as they merely increase flexibility and help to optimize things.

The structure of the Kubernetes scheduler

The Scheduler comprises plugins that function in either or both phases.

Example of plugins:

- **ImageLocality** — favors nodes that already have the container images that the Pod runs. Phase: `Scoring`.
- **TaintToleration** — implements taints and tolerations. Phases: `Filtering`, `Scoring`.
- **NodePorts** - checks whether the ports required for the Pod to run are available on the node. Phase: `Filtering`.

The full list of plugins is available in the Kubernetes documentation.

Working logic

Scheduler profiles

There are two predefined scheduler profiles:

- `default-scheduler`: The default profile that distributes pods to nodes with the lowest load;
- `high-node-utilization`: A profile that places pods on nodes with the highest load.

To specify a scheduler profile, use the `spec.schedulerName` parameter in the pod manifest.

Example of using a profile:

```
apiVersion: v1
kind: Pod
metadata:
  name: scheduler-example
  labels:
    name: scheduler-example
spec:
  schedulerName: high-node-utilization
  containers:
  - name: example-pod
    image: registry.k8s.io/pause:2.0
```

Pod scheduling stages

The selection process starts with the `Filtering` phase. During it, `filter` plugins select nodes that satisfy filter conditions such as `taints`, `nodePorts`, `nodeName`, `unschedulable`, etc. If the nodes are in different zones, the scheduler alternates zones when selecting to ensure that all Pods will not end up in the same zone.

Suppose there are two zones with the following nodes:

```
Zone 1: Node 1, Node 2, Node 3, Node 4
Zone 2: Node 5, Node 6
```

In this case, the nodes will be selected in the following order:

```
Node 1, Node 5, Node 2, Node 6, Node 3, Node 4.
```

Note that Kubernetes limits the number of nodes to calculate their scores during scheduling. This optimizes the selection process and prevents unnecessary scoring. By default, the threshold is linear. For clusters with less than or equal to 50 nodes, 100% of nodes are considered for scheduling; for clusters with 100 nodes, a 50%-threshold is used; and for clusters with 5000 nodes, a 10%-threshold is used. The minimum threshold value is 5% for clusters with more than 5000 nodes. Therefore, even if all the conditions are met, a node may not be included in the list of candidates for scheduling if the default settings are used.

This logic can be changed (read more about the parameter `percentage Of Nodes To Score` in the Kubernetes documentation), but Deckhouse does not provide such an option.

The `Scoring` phase follows once the nodes that meet the conditions are selected. Each plugin evaluates the filtered node list and assigns a score to each node based on available resources: `pod capacity`, `affinity`, `volume provisioning`, and other factors. The scores from the different plugins are then summed up and the node with the highest score is selected. If several nodes have the same score, the node is selected at random.

Finally, the scheduler assigns the Pod to the node with the highest ranking.

Documentation

- General description of the scheduler.
- Plugin system.
- Node Filtering Details.
- Scheduler source code.

How to change or extend the scheduler logic

To change the logic of the scheduler it is possible to use the extension mechanism Extenders.

Each plugin is a webhook that must satisfy the following requirements:

- Use of TLS.
- Accessibility through a service within the cluster.
- Support for standard `Verbs` (`filterVerb = filter`, `prioritizeVerb = prioritize`).
- It is also assumed that all plugins can cache node information (`nodeCacheCapable: true`).

You can connect an `extender` using KubeSchedulerWebhookConfiguration resource.

✖ When using the `failurePolicy: Fail` option, in case of an error in the webhook's operation, the scheduler will stop working and new pods will not be able to start.

kube-scheduler pauses an extender with `failurePolicy: Ignore` if 10 `filter` or `prioritize` requests in a row fail: a time-out, a connection error or an invalid response. For 30 seconds it sends no `filter` and `prioritize` requests to this extender, then it sends one probe request. If the probe succeeds, the requests resume; if it fails, the pause starts again. A response with an error in its body is not a failure: the extender has answered. During the pause, Pods are scheduled without the filter and the scores of this extender. `bind` and `preempt` requests are always sent, and extenders with `failurePolicy: Fail` are never paused.

An extender that scores nodes by their load can receive the Pods that kube-scheduler has just placed. To enable it, set `sendPlacements: true` in KubeSchedulerWebhookConfiguration. kube-scheduler then adds these Pods to the next `prioritize` request, and the extender takes them into account when it scores a burst of Pods.

How to check which node a Pod would be scheduled to

kube-scheduler can simulate the scheduling of a Pod. It evaluates the Pod with the same plugins and extenders as in a real scheduling cycle, but does not place the Pod and does not change the cluster. The answer lists every node: whether the Pod fits it, which filter or extender rejected the node and why, and the score that each plugin and extender gave the node.

The simulation is available at `POST /scheduler/simulate` of the Service `control-plane-proxy` in the `kube-system` namespace (port `8080`, HTTPS). Access is granted by the ClusterRole `d8:control-plane-manager:scheduler-simulate`. Deckhouse Platform does not bind this ClusterRole to users: bind it to the users or ServiceAccounts that call the simulation.

The request body contains the following fields:

- `namespace` and `name`: Namespace and name of an existing Pod to simulate. Instead of them, you can pass the full Pod manifest in the `pod` field.
- `excludeNodes`: Names of the nodes to skip, for example, the node that the Pod is about to leave. Optional.
- `removePods`: Pods to treat as already deleted, as objects with the `namespace`, `name` and optional `uid` fields. Optional.

The request accepts the following query parameters:

- `weights=true`: Show the weight behind every score.
- `filters=all`: List every filter that a node fails. Without the parameter, the answer contains the first filter only. A simulation with this parameter takes longer; use it for debugging.

To simulate the scheduling of a Pod, run the following commands from a Pod in the cluster:

```
d8 k create token <SERVICE_ACCOUNT> -n <SERVICE_ACCOUNT_NAMESPACE> > token
curl -sk \
  -X POST \
  -H "Authorization: Bearer $(cat token)" \
  -H "Content-Type: application/json" \
  -d '{"namespace": "<POD_NAMESPACE>", "name": "<POD_NAME>"}' \
  "https://control-plane-proxy.kube-system.svc:8080/scheduler/simulate?weights=true"
```

In the commands:

- `<SERVICE_ACCOUNT>` and `<SERVICE_ACCOUNT_NAMESPACE>`: ServiceAccount that is bound to the ClusterRole `d8:control-plane-manager:scheduler-simulate`, and its namespace.
- `<POD_NAMESPACE>` and `<POD_NAME>`: Pod to simulate.
- `-k`: Skips the verification of the `control-plane-proxy` certificate.

The response contains the `bestNodes` list with the nodes that the Pod would get now. The `nodes` list contains the verdict for each node (`Feasible`, `Rejected` or `NotEvaluated`), the rejection reasons, and the scores of plugins (`plugin/<name>`) and extenders (`extender/<name>`). The `leader` field shows whether the answer came from the kube-scheduler leader: another replica may not yet know about the Pods that the leader has just placed.

⚠ While a simulation runs, real scheduling on the same kube-scheduler replica waits for it, extender calls included (up to 30 seconds). A replica runs one simulation at a time and answers `429` to a concurrent request. Do not call the simulation in a loop without a pause.

Extenders receive the `filter` and `prioritize` requests of a simulation with the `"dryRun": true` field. On such a request, an extender must compute its answer without side effects, such as reservations. An extender that rejects unknown JSON fields fails the requests of a simulation; its requests of real scheduling are not affected.

The `descheduler` module uses the simulation in the `LowNodeUtilization` strategy: it evicts a Pod only if kube-scheduler would place it on an underutilized node.

How to monitor the scheduler

The “Scheduling” dashboard in the “Kubernetes Cluster” folder of Grafana shows how kube-scheduler works: scheduling attempts and their results, the plugin or extender that decided the node of a Pod, the number of feasible nodes, requests to extenders (duration, errors, paused extenders) and requests to the simulation.

kube-scheduler exports the following metrics:

- `scheduler_decision_deciding_plugin_total{profile, plugin}`: What decided the node of a Pod. `plugin` is `plugin/<name>` (a score plugin), `extender/<name>` (an extender), `scheduler/single-node` (only one node fit), `scheduler/tie` (the best nodes have equal scores), `scheduler/nominated-node` or `scheduler/node-hint`.
- `scheduler_extender_request_duration_seconds{extender, verb, result}`: Requests to extenders and their results: `success`, `extender_error`, `timeout`, `error`, `status`, `decode`, `skipped`. `extender` is the name of the KubeSchedulerWebhookConfiguration, with `/<n>` if it has several webhooks.
- `scheduler_extender_circuit_open{extender}`: `1` if the extender is paused now.
- `scheduler_simulate_requests_total{code}` and `scheduler_simulate_duration_seconds`: Requests to the simulation and the time that real scheduling waited for them.

How does kubelet certificate rotation work?

In Deckhouse Platform, kubelet certificate rotation is automatic.

The kubelet uses a client TLS certificate (`/var/lib/kubelet/pki/kubelet-client-current.pem`) with which it can request a new client certificate or a new server certificate (`/var/lib/kubelet/pki/kubelet-server-current.pem`) from kube-apiserver.

When there is 5-10% (random value from the range) of time left before the certificate expires, kubelet requests a new certificate from kube-apiserver. For a description of the algorithm, see the official Kubernetes documentation.

Certificates lifetime

By default, lifetime of certificates is 1 year (8760 hours).

⚠ If the client certificate lifetime has expired, kubelet will not be able to make requests to kube-apiserver and will not be able to renew certificates. In this case, the node will be marked as `NotReady` and recreated.

Specifics of working with kubelet server certificates in Deckhouse Platform

Deckhouse Platform uses IP addresses for kubelet API requests. The kubelet configuration does not use the `tlsCertFile` and `tlsPrivateKeyFile` fields, but uses a dynamic certificate that kubelet generates itself. Also, the CIS benchmark `AVD-KCV-0088` and `AVD-KCV-0089` checks, which track whether the `--tls-cert-file` and `--tls-private-key-file` arguments were passed to kubelet, are disabled in the Deckhouse Platform (in the `operator-trivy` module).

Information about the logic of working with server certificates in Kubernetes

Kubelet handles server certificates using the following logic:

- If `tlsCertFile` and `tlsPrivateKeyFile` are not empty, kubelet will use them as the default certificate and key.
  - When a client requests the kubelet API by specifying an IP address (e.g., `https://10.1.1.2:10250/`), the default private key (`tlsPrivateKeyFile`) will be used to establish a TLS connection. In this case, certificate rotation will not work.

    - When a client requests the kubelet API by specifying a host name (e.g., `https://k8s-node:10250/`), a dynamically generated private key from the `/var/lib/kubelet/pki/` directory will be used to establish a TLS connection. In this case, certificate rotation will work.
- If `tlsCertFile` and `tlsPrivateKeyFile` are empty, a dynamically generated private key from the `/var/lib/kubelet/pki/` directory will be used to establish the TLS connection. In this case, certificate rotation will work.

How to manually update control plane component certificates?

There may be a situation when the cluster's master nodes are powered off for an extended period. During this time, the control plane component certificates may expire.

Automatic renewal (normal operation): `control-plane-manager` monitors certificate expiry and automatically renews control-plane certificates when they are within 30 days of their expiry date. No manual action is required while the cluster is running.

When nodes come back online after extended downtime: Once the master nodes start and the Kubernetes API becomes available, `control-plane-manager` detects expired or soon-to-expire certificates and creates renewal operations automatically. To confirm that renewal has completed, check that the cert-renewal `ControlPlaneOperation` objects show `Phase=OperationCompleted`:

```
d8 k get cpo -o wide
```

The `ControlPlaneNode` object's `CERTIFICATES` column also shows `True` once all certificates are healthy:

```
d8 k get cpn
```

How do I protect sensitive fields in custom resources?

To protect sensitive fields (such as passwords, tokens, or keys) in resource schemas from unauthorized access via the API, unencrypted storage in etcd, or exposure in audit logs, use the `CRDSensitiveData` feature gate together with the `x-kubernetes-sensitive-data` schema marker.

To enable field protection, do the following:

1. Enable etcd encryption using the `apiserver.encryptionEnabled` parameter in the module settings. The `CRDSensitiveData` feature gate is enabled by default and shouldn't be specified manually.

   ⚠ Enabling `apiserver.encryptionEnabled` is irreversible and triggers a `kube-apiserver` restart.

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: control-plane-manager
   spec:
     version: 3
     enabled: true
     settings:
       apiserver:
         encryptionEnabled: true
   ```

2. Mark sensitive fields in the resource schema with `x-kubernetes-sensitive-data: true`.

   The marker can be applied to the fields of the following types: `string`, `integer`, `number`, `boolean`, `object` and `array` (applying the marker to an `object` or `array` makes the entire subtree sensitive). Fields marked with `x-kubernetes-int-or-string: true` are supported as well.

   The marker can't be set on the schema root (the `openAPIV3Schema` node) and inside `anyOf`, `oneOf`, `allOf`, or `not` branches.

3. For users and ServiceAccounts that require access to full data, grant RBAC permissions for the `<resource>/sensitive` subresource.

Protection mechanisms

Protection	Description
Encryption in etcd	The entire resource is encrypted using the same AES-CBC transformer as Kubernetes Secrets.
API field filtering	Sensitive fields are removed from responses to `get`, `list`, and `watch` requests if the caller does not have permissions on the `<resource>/sensitive` subresource.
Audit log masking	Values of sensitive fields are replaced with `"******"` in all audit events, regardless of RBAC permissions and audit level.

A complete configuration example and results are available in the Examples section.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Built-in audit rules

> The module lifecycle stage: General Availability

What is Audit Policy

Audit Policy is a YAML file that defines which events the API server should record. When a request occurs, Kubernetes checks it against the rules in the file. The **first matching rule** determines the logging level.

Policy structure

Kubernetes documentation Policy resource field structure

In Kubernetes, an audit policy is defined as a YAML file and consists of a set of rules that determine which events are logged and at what level of detail. The file has the following structure:

```
apiVersion: audit.k8s.io/v1  # API version used for the audit policy
kind: Policy              # Resource type — always Policy
rules:                   # Set of audit rules
  - level:                 # Log detail level. Required field
    users:                 # List of users whose actions are logged
    userGroups:             # User groups (for example, system:serviceaccounts)
    verbs:                 # Logged actions/operations (create, update, delete, etc.)
    resources:              # Kubernetes resources this rule applies to
    namespaces:             # Namespaces covered by this rule
```

The `rules` array defines audit rules. Each rule contains the following fields:

- `level` — the level of detail for logged events. Possible values (from most detailed to least detailed):
  - `None` — do not log,
  - `Metadata` — only request metadata (who, when, what, from where; without object content),
  - `Request` — also stores the request body (for write operations),
  - `RequestResponse` — stores both request and response bodies.
- `users` — a list of user names the rule applies to (for example, `["admin"]`). If these are service accounts, the name usually looks like `system:serviceaccount:<namespace>:<serviceaccount-name>`. For regular users, the name depends on the authentication system configuration. For `deckhouse.io/v1` objects, `Users` uses `email` as the name.
- `userGroups` — user groups (for example, `["system:authenticated"]`). After authentication, kube-apiserver assigns each user a list of groups (for example, all authenticated users are part of `system:authenticated`, service accounts belong to additional groups). If a request comes from a user who belongs to at least one group listed in `userGroups`, the rule is applied to that request.

  Built-in Kubernetes groups:

  - `system:authenticated` — all authenticated users.
  - `system:unauthenticated` — requests from anonymous users.
  - `system:serviceaccounts` — all service accounts in all namespaces.
  - `system:serviceaccounts:<namespace>` — service accounts in a specific namespace.
- `verbs` — list of API operations (`get`, `list`, `create`, `delete`, etc.).
- `resources` — array of target resources:
  - `group` — API group (for example, `"apps"`, `"batch"`, `""` for core),
  - `resources` — resource kinds (for example, `["pods", "deployments"]`). You can get the full list of resources and groups with `kubectl api-resources`.
- `namespaces` — array of namespaces where the rule applies.
- `nonResourceURLs` —— set of URL paths to audit. The `*` symbol is allowed only as a full, final path segment. Examples:
  - `/metrics` — log requests to apiserver metrics,
  - `/healthz*` — log all health check requests.

Built-in audit rules

Deckhouse Platform (DP) deploys a basic audit policy by default, which can be extended with user-defined rules.

The policy implements the following rules:

Do not log health probes (`/readyz`, `/livez`, `/healthz`). This rule does not apply to requests that fail authentication.

```
level: None
userGroups:
  - system:authenticated
  - system:unauthenticated
nonResourceURLs:
  - /readyz
  - /readyz/*
  - /livez
  - /livez/*
  - /healthz
  - /healthz/*
```

Do not log frequent updates for `Endpoints`, `EndpointSlices`, and `Events`.

```
level: None
resources:
  - resources:
      - endpoints
      - endpointslices
      - events
```

Do not log leader election operations on `Lease` resources.

```
level: None
resources:
  - group: coordination.k8s.io
    resources:
      - leases
```

Do not log cert-manager leader election ConfigMaps.

```
level: None
resources:
  - resources:
      - configmaps
    resourceNames:
      - cert-manager-cainjector-leader-election
      - cert-manager-controller
```

Do not log VerticalPodAutoscalerCheckpoints resources.

```
level: None
resources:
  - group: autoscaling.k8s.io
    resources:
      - verticalpodautoscalercheckpoints
```

Do not log PATCH operations on `VerticalPodAutoscaler` from recommender.

```
level: None
users:
  - system:serviceaccount:kube-system:d8-vertical-pod-autoscaler-recommender
verbs:
  - patch
resources:
  - group: autoscaling.k8s.io
    resources:
      - verticalpodautoscalers
```

Do not log UpmeterHookProbes resources.

```
level: None
resources:
  - group: deckhouse.io
    resources:
      - upmeterhookprobes
```

Do not log any operations in `d8-upmeter` namespace.

```
level: None
namespaces:
  - d8-upmeter
```

Do not log ingress-nginx leader election updates in ConfigMaps.

```
level: None
users:
  - system:serviceaccount:d8-ingress-nginx:ingress-nginx
verbs:
  - update
resources:
  - resources:
     - configmaps
namespaces:
  - d8-ingress-nginx
```

Do not log dex health-check create/delete operations on `AuthRequest` resources.

```
level: None
users:
  - system:serviceaccount:d8-user-authn:dex
verbs:
  - create
  - delete
resources:
  - group: dex.coreos.com
    resources:
     - authrequests
namespaces:
  - d8-user-authn
```

Log create and delete operations for Node resources with request/response payload.

```
level: RequestResponse
verbs:
  - create
  - delete
resources:
  - resources:
     - nodes
```

Log kubectl logs requests (pods/log) at Metadata level.

```
level: Metadata
resources:
  - resources:
     - pods/log
```

Log create/update/patch/delete operations from system service accounts (`kube-system`, `d8-*`).

```
level: Metadata
users:
  - system:serviceaccount:d8-cert-manager:cainjector
  - system:serviceaccount:d8-cert-manager:cert-manager
  - system:serviceaccount:d8-cert-manager:webhook
  - system:serviceaccount:d8-cert-manager:yandex-dns-webhook

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

The module lifecycle stage: General Availability

The connection of an external scheduler plugin

Example of connecting an external scheduler plugin via webhook.

```
apiVersion: deckhouse.io/v1alpha1
kind: KubeSchedulerWebhookConfiguration
metadata:
  name: sds-replicated-volume
webhooks:
- weight: 5
  failurePolicy: Ignore
  clientConfig:
    service:
      name: scheduler
      namespace: d8-sds-replicated-volume
      port: 8080
      path: /scheduler
    caBundle: ABCD=
  timeout: 5s
```

Protecting resources with sensitive fields

The following example demonstrates how to protect sensitive fields in resources using the `CRDSensitiveData` feature gate and the `x-kubernetes-sensitive-data` schema marker.

For instructions on enabling this feature, see FAQ.

1. Enabling etcd encryption with the `encryptionEnabled` parameter. The `CRDSensitiveData` feature gate for `kube-apiserver` is enabled by default.

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: control-plane-manager
   spec:
     version: 3
     enabled: true
     settings:
       apiserver:
         encryptionEnabled: true
   ```

2. Defining sensitive fields in the resource schema.

   Fields marked with `x-kubernetes-sensitive-data: true` are encrypted in etcd and removed from API responses for callers that do not have access to the `<resource>/sensitive` subresource.

   ```
   apiVersion: apiextensions.k8s.io/v1
   kind: CustomResourceDefinition
   metadata:
     name: dbconfigs.example.com
   spec:
     group: example.com
     scope: Namespaced
     names:
       plural: dbconfigs
       singular: dbconfig
       kind: DbConfig
     versions:
       - name: v1
         served: true
         storage: true
         schema:
           openAPIV3Schema:
             type: object
             properties:
               spec:
                 type: object
                 properties:
                   host:
                     type: string
                   username:
                     type: string
                   password:
                     type: string
                     x-kubernetes-sensitive-data: true
   ```

3. Creating a custom resource with values filled in sensitive fields.

```
apiVersion: example.com/v1
kind: DbConfig
metadata:
  name: primary
  namespace: default
spec:
  host: db.example.com
  username: admin
  password: s3cr3t
```

Once saved, the entire object is encrypted in etcd and the `password` value is hidden in the audit log and removed from the API responses of the caller has no permissions to the `dbconfigs/sensitive` subresource.

4. Configuring access to sensitive fields using RBAC and the `<resource>/sensitive` subresource.

```
# Regular role: can read the resource, but sensitive fields are removed from responses.
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: dbconfig-reader
rules:
- apiGroups: ["example.com"]
  resources: ["dbconfigs"]
  verbs: ["get", "list", "watch"]
---
# Privileged role: can read full data, including sensitive fields.
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: dbconfig-sensitive-reader
rules:
- apiGroups: ["example.com"]
  resources: ["dbconfigs"]
  verbs: ["get", "list", "watch"]
- apiGroups: ["example.com"]
  resources: ["dbconfigs/sensitive"]
  verbs: ["get", "list", "watch"]
```

5. A result of sensitive field protection.
   - A user with the `dbconfig-reader` role who runs `d8 k get dbconfig primary -o json` can see the resource with sensitive fields removed:

     ```
     {
       "spec": {
         "host": "db.example.com",
         "username": "admin"
       }
     }
     ```

   - A user with the `dbconfig-sensitive-reader` role can see the full data:

     ```
     {
       "spec": {
         "host": "db.example.com",
         "username": "admin",
         "password": "s3cr3t"
       }
     }
     ```

   - In audit logs, values of sensitive fields are always masked, regardless of caller permissions:

     ```
     {
       "spec": {
         "host": "db.example.com",
         "username": "admin",
         "password": "******"
       }
     }
     ```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The csi-vsphere module

Included in extensions: **Storage Integration**

The module lifecycle stage: Deprecated

The `csi-vsphere` module provides Container Storage Interface (CSI) support for VMware vSphere environments, enabling dynamic provisioning and management of persistent storage volumes in Kubernetes clusters running on vSphere infrastructure.

This module is specifically designed for **static Kubernetes clusters** (non-cloud) deployed on VMware vSphere and works independently from the cloud-provider-vsphere module. It integrates with vSphere datastores to provide persistent storage capabilities through the vSphere CSI driver.

Use the `csi-vsphere` module when the cluster cannot use the `cloud-provider-vsphere` module but still requires dynamic volume provisioning on vSphere infrastructure.

Main Features

- Provides dynamic persistent volume provisioning for static Kubernetes clusters on VMware vSphere.
- Automatically discovers vSphere datastores and creates StorageClass resources.
- Supports topology-aware volume placement using vSphere region and zone tags.
- Handles volume creation, deletion, attachment, detachment, and online resizing (Default mode).
- Supports Legacy, Default, and Migration compatibility modes for smooth driver transitions.

The module deploys the VMware vSphere CSI driver components that:

- **Automatically discover vSphere datastores**: Reads discovery data from the `d8-cloud-provider-discovery-data` secret to identify available datastores and their topology.
- **Create StorageClasses**: Automatically generates StorageClass resources for each discovered datastore, filtered by the exclude list if configured.
- **Provision persistent volumes**: Dynamically creates persistent volumes on vSphere datastores when PersistentVolumeClaims are created.
- **Support volume operations**: Handles volume creation, deletion, attachment, detachment, and online resizing (in Default mode).
- **Implement topology awareness**: Uses zone and region labels for proper volume placement according to vSphere cluster topology.

System requirements

To use the module in a cluster, the following system requirements must be met:

- All cluster nodes must be virtual machines created with vSphere tooling.
- The vSphere VM name must **exactly match** the node hostname in the Deckhouse Platform cluster.
- Each VM must have `disk.EnableUUID:TRUE` set so the platform can identify attached volumes reliably.

Architecture

The CSI driver consists of components:

1. **CSI Controller** (runs on master nodes):
   - **vsphere-csi-controller**: Main controller managing volume lifecycle operations;
   - **csi-provisioner**: Watches for PVCs and triggers volume creation;
   - **csi-attacher**: Handles volume attachment to nodes;
   - **csi-resizer**: Manages online volume expansion;
   - **vsphere-syncer**: Synchronizes metadata between Kubernetes and vSphere every 30 minutes;
   - **liveness-probe**: Monitors controller health.
2. **CSI Node** (DaemonSet on all nodes):
   - **vsphere-csi-node**: Node-level CSI driver handling volume mounting/unmounting;
   - **node-driver-registrar**: Registers the CSI driver with kubelet;
   - **liveness-probe**: Monitors node driver health.

Compatibility modes

The module supports the following operational modes (the mode is set via the `compatibilityFlag` parameter):

- **Default mode** (used by default, `compatibilityFlag` not set or empty):
  - uses the current vSphere CSI driver (`csi.vsphere.vmware.com`);
  - supports CNS (Cloud Native Storage) volumes;
  - enables online volume resizing;
  - recommended for new deployments.
- **Legacy mode** (`compatibilityFlag: "Legacy"`):
  - uses the older vSphere CSI driver (`vsphere.csi.vmware.com`);
  - works with FCD (First Class Disk) volumes only;
  - no online volume resizing support;
  - used for backward compatibility.
- **Migration mode** (`compatibilityFlag: "Migration"`):
  - runs both driver versions simultaneously,
  - facilitates migration from Legacy to Default mode,
  - allows gradual transition of workloads.

Storage discovery and provisioning

The module automatically:

1. **Discovers datastores** from the cloud provider discovery data.
2. **Generates StorageClass names** by sanitizing datastore names to meet Kubernetes DNS naming requirements.
3. **Filters excluded storage** based on storageClass.exclude configuration (supports regex patterns).
4. **Creates StorageClasses** with appropriate parameters:
   - `allowVolumeExpansion: true` (Default mode only).
   - `volumeBindingMode: WaitForFirstConsumer`: Ensures volumes are created in the same zone as the pod.
   - Topology constraints matching vSphere regions and zones.

Default StorageClass and exclusions

The module automatically creates a StorageClass for each Datastore and DatastoreCluster from the zones.

To set the default StorageClass for a cluster, use the global parameter `defaultClusterStorageClass`. To filter out unwanted StorageClass objects, specify exclusion patterns in the `storageClass.exclude` parameter.

Volume lifecycle

When a pod requests storage:

1. A PVC is created referencing a StorageClass managed by this module.
2. The CSI provisioner creates a volume on the specified vSphere datastore.
3. The CSI attacher attaches the volume to the appropriate node.
4. The CSI node driver mounts the volume into the pod.
5. The vsphere-syncer periodically synchronizes metadata to ensure consistency.

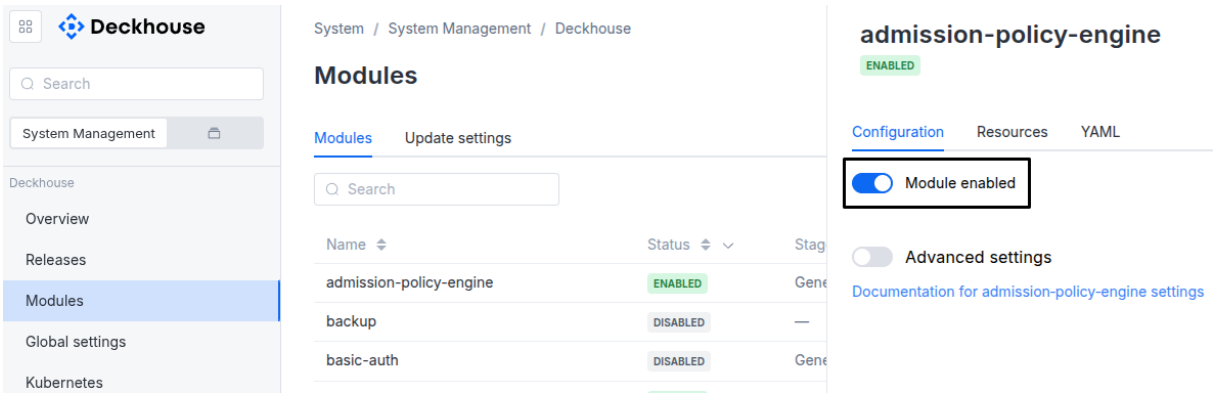
Limitations

- This module is designed exclusively for static (non-cloud) Kubernetes clusters on vSphere.
- Legacy mode does not support online volume resizing.
- Volume expansion requires the current CSI driver (`csi.vsphere.vmware.com`).
- StorageClasses are automatically managed — manual modifications may be overwritten.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Included in extensions: **Storage Integration**



> The module lifecycle stage: Deprecated

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `csi-vsphere` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

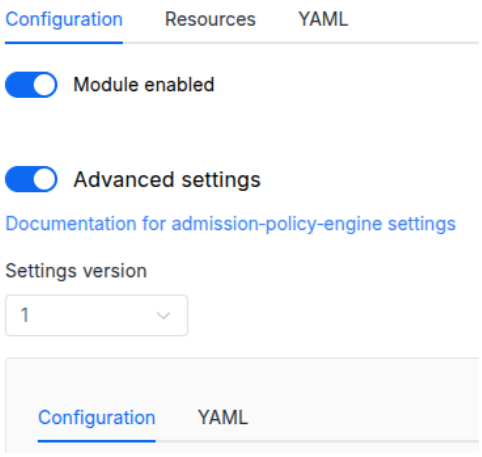
```
d8 system module enable csi-vsphere
```

- **Using ModuleConfig `csi-vsphere`.**

Set `spec.enabled` to `true` or `false` in ModuleConfig `csi-vsphere` (create it if necessary);

Example of a manifest to enable module `csi-vsphere`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: csi-vsphere
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `csi-vsphere` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `csi-vsphere` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `csi-vsphere`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `csi-vsphere` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc csi-vsphere
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `csi-vsphere` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `csi-vsphere`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: csi-vsphere
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.disableTimesync**
    boolean

Disable time synchronization on the vSphere side.

> **Warning.** This parameter does not disable NTP daemons in the guest OS; it only disables time correction on the ESXi side.

- **settings.host**
  string

  Required value

  The domain of the vCenter server.

  Example:

  ```
  host: myhost
  ```

- **settings.insecure**
  boolean

  Set to `true` if vCenter has a self-signed certificate.

- **settings.password**
  string

  Required value

  The user's password.

  Example:

  ```
  password: myPaSsWd
  ```

- **settings.region**
  string

  Required value

  Is a tag added to the vSphere Datacenter where all actions will occur: provisioning VirtualMachines, storing virtual disks on datastores, connecting to the network.

  Example:

  ```
  region: myreg
  ```

- **settings.regionTagCategory**
  string

  Required value

  The name of the tag category used to identify the region (vSphere Datacenter).

  Example:

  ```
  regionTagCategory: myregtagcat
  ```

- **settings.storageClass**
  object
  - **settings.storageClass.compatibilityFlag**
    string

    A flag allowing the use of the old CSI version:

    - `Legacy` — use the old version of the driver. FCD discs only, no online-resizing;
    - `Migration` — in this case, both drivers will be available in the cluster at the same time. This mode is used to migrate from an old driver.

    Allowed values: `Legacy`, `Migration`

  - **settings.storageClass.exclude**
    array of strings

    A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

    Example:

    ```
    exclude:
    - ".*-lun101-.*"
    - slow-lun103-1c280603
    ```

- **settings.username**
  string

  Required value

  The login.

  Example:

```
username: myuname
```

- **settings.vmFolderPath**
  string

  Required value

  The path to the VirtualMachine Folder where the cloned VMs will be created.

  Example:

  ```
  vmFolderPath: dev/test
  ```

- **settings.zoneTagCategory**
  string

  Required value

  The name of the tag category used to identify the zone (vSphere Cluster).

  Example:

  ```
  zoneTagCategory: myzonetagcat
  ```

- **settings.zones**
  array of strings

  Required value

  The globally restricted set of zones that this Cloud Provider works with.

  Example:

  ```
  zones:
  - zonea
  - zoneb
  ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Preparing environment

> The module lifecycle stage: Deprecated

This section describes how to prepare vCenter and vSphere for the `csi-vsphere` module.

Required resources

The following resources are required for the module to function:

- User with the required permissions.
- Network with DHCP and internet access.
- Datacenter tagged as `k8s-region`.
- Cluster tagged as `k8s-zone`.
- One or more Datastores with the appropriate tags.

Installing govc

Use the vSphere CLI govc.

Set environment variables for vCenter access:

```
export GOVC_URL=example.com
export GOVC_USERNAME=<username>@vsphere.local
export GOVC_PASSWORD=<password>
export GOVC_INSECURE=1
```

Create tags and tag categories

`csi-vsphere` maps Kubernetes topology to vSphere objects: a **region** is a vSphere Datacenter, and a **zone** is a vSphere Cluster. The relationship between these objects is defined using tags.

To link Cluster and Datacenter objects, follow these steps:

1. Create tag categories:

```
govc tags.category.create -d "Kubernetes Region" k8s-region
govc tags.category.create -d "Kubernetes Zone" k8s-zone
```

2. Create tags in each category. If you use several zones (Cluster), create one tag per cluster:

```
govc tags.create -d "Kubernetes Region" -c k8s-region test-region
govc tags.create -d "Kubernetes Zone Test 1" -c k8s-zone test-zone-1
govc tags.create -d "Kubernetes Zone Test 2" -c k8s-zone test-zone-2
```

3. Attach the region tag to the Datacenter:

```
govc tags.attach -C k8s-region test-region /<DatacenterName>
```

4. Attach zone tags to Cluster objects:

```
govc tags.attach -C k8s-zone test-zone-1 /<DatacenterName>/host/<ClusterName1>
govc tags.attach -C k8s-zone test-zone-2 /<DatacenterName>/host/<ClusterName2>
```

Datastore configuration

> **i** For dynamic PersistentVolume provisioning, each Datastore must be reachable from every ESXi host (shared datastore).

Attach region and zone tags to Datastore objects so the module can create StorageClass resources automatically:

```
govc tags.attach -C k8s-region test-region /<DatacenterName>/datastore/<DatastoreName1>
govc tags.attach -C k8s-zone test-zone-1 /<DatacenterName>/datastore/<DatastoreName1>

govc tags.attach -C k8s-region test-region /<DatacenterName>/datastore/<DatastoreName2>
govc tags.attach -C k8s-zone test-zone-2 /<DatacenterName>/datastore/<DatastoreName2>
```

Create and assign the role

> **i** Due to the variety of SSO providers connected to csi-vsphere, the steps for creating a user are not covered in this article.
>
> The role to be created below includes all possible privileges for all DP components. For a detailed list of privileges, refer to the `cloud-provider-vsphere` documentation.

Create the role:

```
govc role.create deckhouse \
   Cns.Searchable Datastore.AllocateSpace Datastore.Browse Datastore.FileManagement \
   Global.GlobalTag Global.SystemTag Network.Assign StorageProfile.View \
   $(govc role.ls Admin | grep -F -e 'Folder.' -e 'InventoryService.' -e 'Resource.' -e 'VirtualMachine.')
```

Grant the role on the `vCenter` root object:

```
govc permissions.set -principal <username>@vsphere.local -role deckhouse /
```

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The deckhouse module

> **i** Included in extensions: **Billing, Cluster Union**

> **i** The module lifecycle stage: General Availability

In Deckhouse, this module sets up:

- **The logging level**;
- **The set of modules enabled by default**;

  Usually, the `Default` set is used (it is suitable for most cases).

  Regardless of the set of modules enabled by default, any module can be explicitly enabled or disabled in the Deckhouse configuration (learn more about enabling and disabling a module).

- **The release channel**;

  Deckhouse has a built-in mechanism for automatic updates. This mechanism uses 5 release channels with various stability and frequency of releases. Learn more about how the automatic update mechanism works and how you can set the desired release channel

- **The update mode** and **update windows**;

  Deckhouse supports **manual** and **automatic** update modes.

  In the manual upgrade mode, only critical fixes (patch releases) are automatically applied, and upgrading to a more current Deckhouse release requires manual confirmation.

  In the automatic update mode, Deckhouse switches to a newer release as soon as it is available in the corresponding release channel unless update windows are **configured** for the cluster. If update windows are **configured** for the cluster, Deckhouse will upgrade to a newer release during the next available update window.

- **Service for validating Custom Resources**.

  The validation service prevents creating Custom Resources with invalid values or adding such values to the existing Custom Resources. Note that it only tracks Custom Resources managed by Deckhouse modules.

Deckhouse releases update

Get Deckhouse releases status

You can get Deckhouse releases list via the command `d8 k get deckhousereleases`. By default, a cluster keeps the last 10 Superseded releases and all deployed/pending releases.

Every release can have one of the following statuses:

- `Pending` - release is waiting to be deployed: waiting for update window, canary deployment, etc. You can see the detailed status via the `d8 k describe deckhouserelease $name` command.
- `Deployed` - release is applied. It means that the image tag of the Deckhouse Pod was changed, but the update process of all components is going asynchronously and could not have been finished yet.
- `Superseded` - release is outdated and not used anymore.
- `Suspended` - release was suspended (for example, due to an error found). A release can have this status if it was suspended before being deployed in the cluster.

Update process

When release status is changed to `Deployed` state, release is updating only a tag of the Deckhouse image. Deckhouse will start checking and updating process of the all modules, which were changed from the last release. Duration of an update could be different and connected to cluster size, enabled modules count and settings. Foe example: if you cluster have a lot of `NodeGroup` resources, it will take some time to update them because these resources are updated one by one `IngressNginxControllers` also updating one by one.

Manual release deployment

If you have a manual update mode enabled and have a few Pending releases, you can approve them all at once. In that case Deckhouse will update in series keeping a release order and changing their status during the update.

Pin a release

To pin a release means fully or partially disable the automatic Deckhouse version update.

There are three options to limit the automatic update of Deckhouse:

- Enable a manual update mode.

  In this case, Deckhouse holds on a current version and able to receive updates. But to apply the update, a manual action will need to be performed. This applies to both patch versions and minor versions.

  To enable manual update mode, you need to set the parameter settings.update.mode in ModuleConfig `deckhouse` to `Manual`:

  ```
  d8 k patch mc deckhouse --type=merge -p='{"spec":{"settings":{"update":{"mode":"Manual"}}}}'
  ```

- Set the automatic update mode for patch versions.

  In this case, Deckhouse holds on a current version and will automatically update to patch versions of the current release (taking into account the update windows). To apply a minor version update, a manual action will need to be performed.

  For example: the current version of DP is `v1.70.1`, after setting the automatic update mode for patch versions, Deckhouse can be updated to version `v1.70.2`, but will not update to version `v1.71.*` or higher.

  To set the automatic update mode for patch versions, you need to set the parameter settings.update.mode to `AutoPatch` in the ModuleConfig `deckhouse`:

  ```
  d8 k patch mc deckhouse --type=merge -p='{"spec":{"settings":{"update":{"mode":"AutoPatch"}}}}'
  ```

- Set a specified image tag for Deployment `deckhouse` and remove releaseChannel parameter from `deckhouse` module configuration.

  In that case, DP holds on a current version, and no information about new available versions in the cluster (DeckhouseRelease objects) will be received.

  An example of installing version `v1.66.3` for DP EE and removing the `releaseChannel` parameter from the configuration of the `deckhouse` module:

```
d8 k -ti -n d8-system exec svc/deckhouse-leader -c deckhouse -- kubectl set image deployment/deckhouse
deckhouse=registry.deckhouse.io/deckhouse/ee:v1.66.3
d8 k patch mc deckhouse --type=json -p='[{"op": "remove", "path": "/spec/settings/releaseChannel"}]'
```

Priority Classes

This module creates a set of priority classes and assigns them to components installed by Deckhouse and applications in the cluster.

Priority classes are utilized by the scheduler to determine a Pod's priority based on the class it belongs to during scheduling.

For example, when deploying Pods with `priorityClassName: production-low`, if the cluster lacks sufficient resources, Kubernetes will start evicting Pods with the lowest priority to accommodate the `production-low` Pods. That is, Kubernetes will first evict all Pods with `priorityClassName: develop` Pods, then proceed to `cluster-low` Pods, and so on.

When setting the priority class, it is crucial to understand the type of application and the environment it operates in. Assigning any priority class does not lower a Pod's priority because Pods without a specified priority class are considered to have the lowest priority.

Practical examples of creating and using PriorityClass, preemption demos, and troubleshooting are described in the Examples section.

⚠ You cannot use the following priority classes: `system-node-critical`, `system-cluster-critical`, `cluster-medium`, `cluster-low`.

Below is the list of priority classes set by the module (sorted by the priority from highest to lowest):

Priority class	Description	Value
`system-node-critical`	Cluster components that must be present on the node. This priority class fully protects components against eviction by kubelet. Examples: `node-exporter`, `csi`, and others.	2000001000
`system-cluster-critical`	Cluster components that are critical to its correct operation. This PriorityClass is mandatory for MutatingWebhooks and Extension API servers. It also fully protects components against eviction by kubelet. Examples: `kube-dns`, `kube-proxy`, `cni-flannel`, `cni-cilium`, and others.	2000000000
`production-high`	Stateful applications in the production environment. Their unavailability leads to service downtime or data loss. Examples: `PostgreSQL`, `Memcached`, `Redis`, `MongoDB`, and others.	9000
`cluster-medium`	Cluster components responsible for monitoring (alerts, diagnostic tools) and autoscaling. Without monitoring, assessing the scale of incidents is impossible; without autoscaling, applications cannot receive necessary resources. Examples: `deckhouse`, `node-local-dns`, `grafana`, `upmeter`, and others.	7000
`production-medium`	Main stateless applications in the production environment that are responsible for operating the service for end-users.	6000
`deployment-machinery`	Cluster components that are responsible for deploying/building.	5000
`production-low`	Non-critical, secondary applications in the production environment (crons, admin dashboards, batch processing). For important batch or cron jobs, consider assigning them the `production-medium` priority.	4000
`staging`	Staging environments for applications.	3000
`cluster-low`	Cluster components that are desirable but not essential for proper cluster operation. Examples: `dashboard`, `cert-manager`, `prometheus`, and others.	2000
`develop` (default)	Develop environments for applications. The default class for a component (if other priority classes aren't set).	1000

Priority class	Description	Value
`standby`	This class is not intended for applications. It is used for system purposes (reserving nodes).	-1

Monitoring

The module provides monitoring and observability for Deckhouse Platform (DP). It collects platform performance metrics, provides pre-configured alerting rules and dashboards for DP status monitoring.

The module uses features provided by `prometheus` and `observability` modules for collecting and storing metrics.

It deploys monitoring resources that:

- **Collect DP metrics**: Collects metrics from the `deckhouse` Pod using a PodMonitor resource, including:
  - Self metrics on port `4222` via the `/metrics` endpoint.
  - Custom hook-generated metrics via the `/metrics/hooks` endpoint.
  - Module execution metrics, hook performance, and system health indicators.
- **Define alerting rules**: Provides Prometheus alerting rules organized into several categories:
  - **DP availability**: Monitors Pod health, readiness, and uptime.
  - **DP malfunctioning**: Detects excessive restarts, registry access issues, and hung processes.
  - **Release management**: Tracks release channel subscriptions, pending updates, and manual approvals.
  - **Module management**: Monitors module state, validation errors, and deprecated configurations.
  - **CNI checks**: Detects multiple CNI configurations and misconfigurations.
  - **OS requirements**: Identifies nodes running deprecated operating system versions.
- **Provide Grafana dashboards**: Includes pre-built Grafana dashboards for visualizing:
  - DP performance metrics.
  - Module execution statistics.
  - Hook run times and resource usage.
  - Queue processing and convergence status.

Metrics collection

A PodMonitor scrapes two endpoints from the `deckhouse` Pod:

1. **DP metrics** (`/metrics`): Core DP operational metrics, including the following:
   - `deckhouse_live_ticks`: Health indicator incrementing every 10 seconds.
   - `deckhouse_registry_check_errors_total`: Failed registry checks.
   - `deckhouse_module_hook_run_seconds`: Module hook execution duration.
   - `deckhouse_tasks_queue_action_duration_seconds`: Task queue processing times.
   - Other operational metrics.
2. **Hook metrics** (`/metrics/hooks`): Custom metrics generated by DP hooks with `honorLabels: true` to preserve hook-specific labels.

The PodMonitor is created only when the `operator-prometheus` module is enabled, and the alerting rules and dashboards are processed by the `prometheus` module.

Integration with the observability module

When the `observability` module is enabled, the following resources are created automatically:

- ClusterObservabilityMetricsRulesGroup: For Prometheus rules.
- ClusterObservabilityDashboard: For Grafana dashboards.

This enables centralized monitoring resource management via the `observability` module interfaces.

Third-party components

List of third-party software used in the `deckhouse` module:

- Shell operator 1.9.3

  License: Apache License 2.0

  A tool for running event-driven scripts in a Kubernetes cluster

- JQ 1.7.1

  License: Mixed (https://github.com/stedolan/jq/blob/master/COPYING)

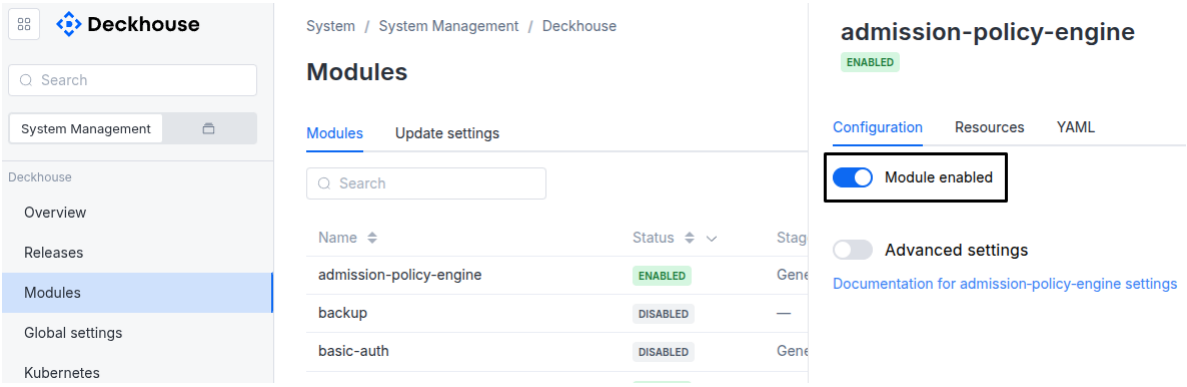
  A lightweight and flexible command-line JSON processor.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Included in extensions: **Billing, Cluster Union**

> The module lifecycle stage: General Availability



The module has 67 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

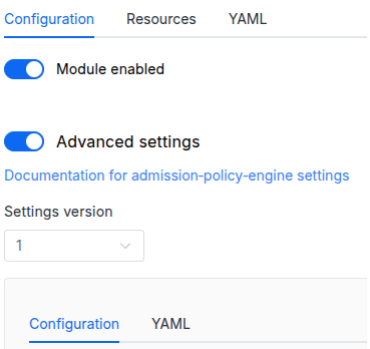
```
d8 system module enable deckhouse
```

- **Using ModuleConfig `deckhouse`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `deckhouse` (create it if necessary);

  Example of a manifest to enable module `deckhouse`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `deckhouse` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `deckhouse`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `deckhouse` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc deckhouse
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `deckhouse` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `deckhouse`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.allowExperimentalModules**
    boolean

    Allows the use of experimental modules (modules in the `Experimental` lifecycle stage).

    Experimental modules can be unstable and are not supported under the Deckhouse SLA. Use them with caution.

    Default: `false`

    Example:

    ```
    allowExperimentalModules: false
    ```
  - **settings.allowedExperimentalModules**
    array of strings

    A list of experimental module names allowed to be enabled even when `allowExperimentalModules` is `false`.

    Lets you opt into specific experimental modules without allowing all of them.

    If `allowExperimentalModules` is `true`, all experimental modules are allowed and this list is ignored.

    Default: `[]`

    Example:

    ```
    allowedExperimentalModules:
    - r-b-test
    ```
  - **settings.bundle**
    string

    The set of DP modules that are enabled by default.

    Changing the parameter value in an already deployed cluster is not possible.

    Possible values:

    - `Default`: Recommended set of modules for cluster operation. Includes modules for monitoring, authorization control, networking, and other basic platform needs.
    - `Managed`: Set of modules for managed clusters from cloud providers.
    - `Minimal`: Minimum possible set, which includes a single module (this one).

      Warning. Several basic platform modules (for example, the CNI module) are not included in the `Minimal` module set. Without the basic modules, DP can only operate in an already deployed cluster. Read the “Things to keep in mind when working with the Minimal module set” section for more details.

    Default: `Default`

    Allowed values: `Default`, `Minimal`, `Managed`

    Example:

    ```
    bundle: Default
    ```
  - **settings.enableModuleV2**
    boolean

    Enables the experimental Module v2 controller and installs the Module v2 CRD instead of the legacy Module CRD.

    The feature is experimental and not supported under the Deckhouse SLA. Use it with caution.

    Default: `false`

    Example:

    ```
    enableModuleV2: false
    ```
  - **settings.highAvailability**
    boolean

    Manually enable the high availability mode.

    By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

    Example:

    ```
    highAvailability: true
    ```
  - **settings.license**
    object

    Edition settings of the Deckhouse Platform.

    - **settings.license.edition**
      string

      Edition of the Deckhouse Platform:

      - `CE` — Community Edition.
      - `BE` - Basic edition.
      - `EE` — Enterprise Edition.

- `SE` — Standard Edition.
- `SE-plus` — Standard Edition+.
- `CSE` — Certified Security Edition.

Default: `CE`

Example:

```
edition: CE
```

- **settings.logLevel**
  string

  Deckhouse logging level.

  Default: `Info`

  Allowed values: `Trace`, `Debug`, `Info`, `Error`

  Example:

  ```
  logLevel: Info
  ```

- **settings.nodeSelector**
  object

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, `nodeSelector` will be determined automatically.

  Caution! Deckhouse will stop working if there is a nonexistent label in `nodeSelector`. You need to change the values to the correct ones in `ModuleConfig/deckhouse` and `deployment/deckhouse` to get Deckhouse back on track.

- **settings.registry**
  object

  Settings for accessing the container registry with Deckhouse images.

  This parameter allows configuring how DP connects to the container registry to pull its own component images. Settings are processed by the internal registry module. In clusters where this configuration is not supported, the registry connection setup is done manually using the `change-registry` helper script.

  Examples:

  ```
  registry:
    mode: Unmanaged
  ```

  ```
  registry:
    mode: Unmanaged
    unmanaged:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
  ```

  ```
  registry:
    mode: Direct
    direct:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
  ```

  - **settings.registry.direct**
    object

    Parameters for the `Direct` access mode. These parameters are required when `mode` is set to `Direct`.

    Examples:

    ```
    direct:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
    ```

    ```
    direct:
      imagesRepo: my-private-registry.com/deckhouse
      username: user
      password: password
      scheme: HTTPS
      ca: |
        -----BEGIN CERTIFICATE-----
        MIIC...
        -----END CERTIFICATE-----
    ```

    - **settings.registry.direct.ca**
      string

      The root CA certificate (in PEM format) for validating the container registry's server certificate. This is necessary if the registry uses a self-signed certificate or a certificate issued by a private Certificate Authority. If not provided, the system's trusted root CAs will be used.

    - **settings.registry.direct.checkMode**
      string

      Mode for checking the container registry:

      - `Default` — checks for the presence of all critical components in the container registry.
      - `Relax` — checks only for the presence of the Deckhouse image tag in the container registry (used for switching between Deckhouse editions).

      Default: `Default`

      Allowed values: `Default`, `Relax`

    - **settings.registry.direct.imagesRepo**
      string

      Required value

      The address of the container registry repository where Deckhouse images are stored.

      In firewalled environments, this might be a private registry address that mirrors the public one.

      Default: `registry.deckhouse.io/deckhouse/ce`

      Pattern: `^[0-9a-zA-Z\.\-]+(\:[0-9]{1,5})?(\/[0-9a-zA-Z\.\-\_]+)*$`

      Examples:

```
imagesRepo: registry.deckhouse.io/deckhouse/ee
```

```
imagesRepo: private-registry:5000/deckhouse/ce
```

- **settings.registry.direct.license**
  string

  The license key for accessing the Deckhouse container registry. This key is used as a password with the username `license-token`. This field is mutually exclusive with `username/password`.

  Example:

  ```
  license: DECKHOUSE_LICENSE_KEY
  ```

- **settings.registry.direct.password**
  string

  The password for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  password: registry-password
  ```

- **settings.registry.direct.scheme**
  string

  The protocol to use for connecting to the registry.

  Use `HTTP` only for insecure, trusted registries (e.g., in a firewalled environment). Defaults to `HTTPS` for secure communication.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

  Example:

  ```
  scheme: HTTPS
  ```

- **settings.registry.direct.username**
  string

  The username for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  username: registry-user
  ```

- **settings.registry.mode**
  string

  The mode for accessing the container registry with Deckhouse images.

  - `Unmanaged`: The default mode. In this mode, the `registry` module does not run an internal registry. To configure it, set the parameters in the `unmanaged` section. **Important.** Changing the registry in `Unmanaged` mode will result in a full restart of all DP components.
  - `Direct`: A mode for direct access to the registry. It uses a “virtual” registry address that is overwritten on the fly to the real registry address. This allows for registry changes without a full component restart. **Important.** The first switch from `Unmanaged` to `Direct` mode will result in a full restart of all DP components.
  - `Proxy` and `Local`: Deprecated and will be removed in a future release. These are modes of the v1 implementation of the `registry` module (DP up to and including 1.77), and they have no effect: the installer refuses them, and they cannot be set in a running cluster. To run an in-cluster cache or to operate an air-gapped cluster, use the `registry` module.

  Default: `Unmanaged`

  Allowed values: `Unmanaged`, `Direct`, `Proxy`, `Local`

- **settings.registry.proxy**
  Deprecated
  object

  Deprecated. Parameters for the `Proxy` mode of the v1 implementation of the `registry` module. The mode has no effect, see the `mode` parameter.

  - **settings.registry.proxy.ca**
    string

    The root CA certificate (in PEM format) for validating the container registry’s server certificate. This is necessary if the registry uses a self-signed certificate or a certificate issued by a private Certificate Authority. If not provided, the system’s trusted root CAs will be used.

  - **settings.registry.proxy.checkMode**
    string

    Mode for checking the container registry:

    - `Default` — checks for the presence of all critical components in the container registry.
    - `Relax` — checks only for the presence of the Deckhouse image tag in the container registry (used for switching between Deckhouse editions).

    Default: `Default`

    Allowed values: `Default`, `Relax`

  - **settings.registry.proxy.imagesRepo**
    string

    Required value

    The address of the container registry repository where Deckhouse images are stored.

    In firewalled environments, this might be a private registry address that mirrors the public one.

    Default: `registry.deckhouse.io/deckhouse/ce`

    Pattern: `^[0-9a-zA-Z\.\-]+(\:[0-9]{1,5})?(\/[0-9a-zA-Z\.\-\_]+)*$`

    Examples:

    ```
    imagesRepo: registry.deckhouse.io/deckhouse/ee
    ```

    ```
    imagesRepo: private-registry:5000/deckhouse/ce
    ```

  - **settings.registry.proxy.license**
    string

    The license key for accessing the Deckhouse container registry. This key is used as a password with the username `license-token`. This field is mutually exclusive with `username/password`.

    Example:

```
license: DECKHOUSE_LICENSE_KEY
```

- **settings.registry.proxy.password**
  string

  The password for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  password: registry-password
  ```

- **settings.registry.proxy.scheme**
  string

  The protocol to use for connecting to the registry.

  Use `HTTP` only for insecure, trusted registries (e.g., in a firewalled environment). Defaults to `HTTPS` for secure communication.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

  Example:

  ```
  scheme: HTTPS
  ```

- **settings.registry.proxy.ttl**
  string

  TTL determines the lifetime of cached images. Once the TTL expires, the images will be automatically removed from the cache. If not set, the TTL defaults to 7 days (168 hours).

  Supported units: `h` (hours), `m` (minutes), `s` (seconds). The minimum allowable value is 5 minutes.

  Pattern: `^(?:(\d+)h)?(?:(\d+)m)?(?:(\d+)s)?$`

- **settings.registry.proxy.username**
  string

  The username for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  username: registry-user
  ```

- **settings.registry.unmanaged**
  object

  Parameters for the `Unmanaged` access mode.

  Examples:

  ```
  unmanaged:
    imagesRepo: registry.deckhouse.io/deckhouse/ee
    license: DECKHOUSE_LICENSE_KEY
  ```

  ```
  unmanaged:
    imagesRepo: my-private-registry.com/deckhouse
    username: user
    password: password
    scheme: HTTPS
    ca: |
      -----BEGIN CERTIFICATE-----
      MIIC...
      -----END CERTIFICATE-----
  ```

  - **settings.registry.unmanaged.ca**
    string

    The root CA certificate (in PEM format) for validating the container registry's server certificate. This is necessary if the registry uses a self-signed certificate or a certificate issued by a private Certificate Authority. If not provided, the system's trusted root CAs will be used.

  - **settings.registry.unmanaged.checkMode**
    string

    Mode for checking the container registry:

    - `Default` — checks for the presence of all critical components in the container registry.
    - `Relax` — checks only for the presence of the Deckhouse image tag in the container registry (used for switching between Deckhouse editions).

    Default: `Default`

    Allowed values: `Default`, `Relax`

  - **settings.registry.unmanaged.imagesRepo**
    string

    Required value

    The address of the container registry repository where Deckhouse images are stored.

    In firewalled environments, this might be a private registry address that mirrors the public one.

    Default: `registry.deckhouse.io/deckhouse/ce`

    Pattern: `^[0-9a-zA-Z\.\-]+(\:[0-9]{1,5})?(\/[0-9a-zA-Z\.\-\_]+)*$`

    Examples:

    ```
    imagesRepo: registry.deckhouse.io/deckhouse/ee
    ```

    ```
    imagesRepo: private-registry:5000/deckhouse/ce
    ```

  - **settings.registry.unmanaged.license**
    string

    The license key for accessing the Deckhouse container registry. This key is used as a password with the username `license-token`. This field is mutually exclusive with `username`/`password`.

    Example:

    ```
    license: DECKHOUSE_LICENSE_KEY
    ```

  - **settings.registry.unmanaged.password**

string

The password for authenticating with the container registry. This field is required if `license` is not provided.

Example:

```
password: registry-password
```

- **settings.registry.unmanaged.scheme**
  string

  The protocol to use for connecting to the registry.

  Use `HTTP` only for insecure, trusted registries (e.g., in a firewalled environment). Defaults to `HTTPS` for secure communication.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

  Example:

  ```
  scheme: HTTPS
  ```

- **settings.registry.unmanaged.username**
  string

  The username for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  username: registry-user
  ```

- **settings.releaseChannel**
  string

  Target Deckhouse release channel (Deckhouse will switch to it when such an opportunity appears).

  The order in which the stability of the release channel increases (from **less** stable to **more** stable): `Alpha`, `Beta`, `EarlyAccess`, `Stable`, `RockSolid`.

  Allowed values: `Alpha`, `Beta`, `EarlyAccess`, `Stable`, `RockSolid`

  Example:

  ```
  releaseChannel: Stable
  ```

- **settings.reservedPublicHosts**
  object

  Settings of the reservation that keeps the hostnames of the DP web interfaces from being claimed by a workload.

  DP renders those hostnames from the `global.modules.publicDomainTemplate` global parameter and reserves them cluster-wide: an Ingress, or a Gateway, GRPCRoute, HTTPRoute, ListenerSet or TLSRoute of the Gateway API, created outside a system namespace cannot name one of them. Using the settings in `reservedPublicHosts`, you can expand the set of reserved names (using the `additionalHosts` parameter) or reduce it (using the `excludedServices` parameter).

  The reservation is per hostname and applies to every namespace. To exempt a whole namespace from the reservation instead, label the namespace with `security.deckhouse.io/reserved-hosts-bypass: "true"`.

  Example:

  ```
  reservedPublicHosts:
    mode: List
    additionalHosts:
    - admin.example.com
    excludedServices:
    - grafana
  ```

  - **settings.reservedPublicHosts.additionalHosts**
    array of strings

    Hostnames to reserve on top of the ones DP publishes.

    Every entry is a complete hostname, matched exactly and case-insensitively, the same way the built-in ones are. Wildcards are not supported.

    The hostname specified in `additionalHosts` is reserved, even if the name of the corresponding service is listed in `excludedServices`.

    Default: `[]`

    Example:

    ```
    additionalHosts:
    - admin.example.com
    ```

    - **Element of the array**
      string

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  - **settings.reservedPublicHosts.excludedServices**
    array of strings

    Service names whose hostname must not be reserved.

    Use it for a cluster where a workload outside a system namespace legitimately serves a path under one of those hostnames.

    A name is the part `global.modules.publicDomainTemplate` substitutes, `grafana` for `grafana.example.com`, not the hostname itself. The hostname it renders to is published in the `excludedHosts` key of the `d8-reserved-public-hosts` ConfigMap in the `d8-system` namespace, which is where to check that the name did what was meant.

    Under `mode: Template` any name works, because the reservation covers the whole domain and not only what Deckhouse publishes. Under `mode: List` only a name Deckhouse actually publishes has an effect, because only those are reserved there; the rest are listed in the `unknownExcludedServices` key of the same ConfigMap, which is where to look if a hostname stayed reserved unexpectedly.

    Specifying a service name in `excludedServices` prevents the corresponding hostname from being reserved in all namespaces, including those where the platform itself hosts it.

    Default: `[]`

    Example:

    ```
    excludedServices:
    - grafana
    ```

    - **Element of the array**
      string

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **settings.reservedPublicHosts.mode**
  string

  How much of the platform's domain is reserved.

  Set `Template` to reserve every hostname the template can render.

  Possible values:

  - `Template`: Every hostname `global.modules.publicDomainTemplate` can render, plus its wildcard form where the template's `%s` is the whole first label. A module never has to ask to be covered, and a hostname is reserved as soon as the template can produce it, whether or not any Deckhouse module publishes it today. A hostname that a workload legitimately serves is given back with `excludedServices` below, or with the per-namespace label. The wildcard form is the exception: it is reserved by exact match and `excludedServices` cannot free it, so a workload that serves it needs the per-namespace label or `List` below.
  - `List`: Only the hostnames of the services DP knows it publishes. The hostnames in the list are hard-specified in the `reservedNames` parameter of the Helm template, which is included with the release and maintained manually. Any public domain not included in the list—which DP will begin publishing later—remains unreserved until the list is updated in a DP release.

  `Template` applies when `%s` is the whole first label (`%s.example.com`) or a suffix of it (`kube-%s.example.com`). A template where `%s` is only a prefix of the first label (`%s-cluster.example.com`) is reserved as `List` instead: that shape can render every hostname sharing the rest of the label, including tenant Ingresses named the same way.

  The hostnames workloads already serve are recorded once, when `Template` first takes effect, and stay allowed. Switching from `List` to `Template` later takes that record then, so a workload that appeared while `List` was in force is grandfathered too.

  The record is taken once and is not taken again. Switching to `List` and back to `Template` keeps the record of the first time, so a workload that claimed a reserved hostname in between is denied on its next write. Recording again on every return would make the reservation avoidable by switching to `List`, claiming the hostname and switching back.

  Ecosystem applications are unaffected either way: `global.applications.publicDomainTemplate` puts the application name and its namespace in two different labels, so an application hostname has one label more than anything this reservation covers.

  Default: `List`

  Allowed values: `Template`, `List`

  Examples:

  ```
  mode: Template
  ```

  ```
  mode: List
  ```

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, `tolerations` will be determined automatically.

  Caution! Deckhouse will stop working if `tolerations` specified are incorrect. You need to change the values to the correct ones in `ModuleConfig/deckhouse` and `deployment/deckhouse` to get Deckhouse back on track.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string
- **settings.update**
  object

  Settings of the Deckhouse update mode and windows.

  Example:

  ```
  update:
    windows:
    - from: '8:00'
      to: '15:00'
      days:
      - Tue
      - Sat
    disruptionApprovalMode: Manual
    notification:
      webhook: https://release-webhook.mydomain.com
      minimalNotificationTime: 6h
      auth:
        basic:
          username: user
          password: password
  ```

  - **settings.update.blockOnAlerts**
    object
    - **settings.update.blockOnAlerts.enabled**
      boolean

      If enabled, the update will be blocked if there are any alerts in the cluster with severity level greater than or equal to the specified severity level.

      Default: `false`

    - **settings.update.blockOnAlerts.severity**
      integer

      The severity level of the alerts that will block the update. The severity level is a number from 0 to 9, where 0 is the highest severity and 9 is the lowest severity.

      Default: `4`

      Allowed values: `0 <= X <= 9`

  - **settings.update.disruptionApprovalMode**
    Deprecated
    string

    Update mode for disruptive Deckhouse releases:

    - `Auto` — a disruptive release is approved automatically.
    - `Manual` — requires a manual release confirmation (set the `release.deckhouse.io/disruption-approved=true` annotation on the appropriate DeckhouseRelease resource to apply the update).

    Default: `Auto`

    Allowed values: `Auto`, `Manual`

- **settings.update.mode**
  string

  Update mode of Deckhouse on the selected release channel.

  - `AutoPatch` — automatic update mode for patch releases.

    To change a minor version (for example, from `v1.69.*` to `v1.70.*`), confirmation is required.

    A patch version update (for example, from `v1.70.1` to `v1.70.2`) is applied taking into account the update windows, if they are set.

  - `Auto` — automatic update mode for all versions.

    A minor version updates (for example, from `v1.69.*` to `v1.70.*`) and patch version updates (for example, from `v1.70.1` to `v1.70.2`) are applied taking into account the update windows, if they are set.

  - `Manual` — manual update mode for all versions.

    Confirmation is required for updating both minor and patch versions.

  To confirm the version update, it is necessary to set the `approved` field to `true` in the corresponding resource DeckhouseRelease.

  Default: `AutoPatch`

  Allowed values: `AutoPatch`, `Auto`, `Manual`

- **settings.update.notification**
  object

  Settings for notifications of scheduled Deckhouse updates.

  Has the effect **only** when the automatic update mode is set.

  Example:

  ```
  notification:
    webhook: https://release-webhook.mydomain.com
    minimalNotificationTime: 8h
    retryMinTime: 2s
  ```

  - **settings.update.notification.auth**
    object

    Authentication settings for the webhook.

    If the parameter is omitted, the webhook will be called without authentication.

    - **settings.update.notification.auth.basic**
      object

      Basic authentication settings for the webhook.

      If the parameter is omitted, the webhook will be called without authentication.

      - **settings.update.notification.auth.basic.password**
        string

        Required value

        The password for the webhook.

        The username and password will be sent in the `Authorization` header in the format `Basic <base64(username:password)>`.

      - **settings.update.notification.auth.basic.username**
        string

        Required value

        The username for the webhook.

        The username and password will be sent in the `Authorization` header in the format `Basic <base64(username:password)>`.

    - **settings.update.notification.auth.bearerToken**
      string

      The token for the webhook.

      The token will be sent in the `Authorization` header in the format `Bearer <token>`.

  - **settings.update.notification.minimalNotificationTime**
    string

    The minimum time that must pass before updating from the moment a new minor version appears on the release channel used.

    It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    The update mechanism ensures that Deckhouse will not be updated until a specified period of time has passed.

    When using update windows, the Deckhouse update will happen at the nearest possible update window but not before the time specified in `minimalNotificationTime` expires.

    Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

    Example:

    ```
    minimalNotificationTime: 6h
    ```

  - **settings.update.notification.releaseType**
    string

    Defines the type of version for which the notification will be sent:

    - `Minor` — only for updating the minor version.
    - `All` — for any updates, including updating a patch version.

    Default: `Minor`

    Allowed values: `All`, `Minor`

    Example:

    ```
    releaseType: All
    ```

  - **settings.update.notification.retryMinTime**
    string

    The minimum time between webhook retry attempts when the webhook request fails.

    It is specified as a string containing the time unit in hours, minutes, or seconds: 30s, 1m, 2m30s, 1h, 2h30m.

    The retry mechanism uses exponential backoff: each subsequent retry attempt waits twice as long as the previous one. For example, if `retryMinTime` is set to `2s`, the retry delays will be: 2s, 4s, 8s, 16s, 32s.

    Default value is 2 seconds if not specified.

Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m|[0-9]+s)$`

Example:

```
retryMinTime: 2s
```

- **settings.update.notification.tlsSkipVerify**
  boolean

  Skip TLS certificate verification while webhook request.

  Default: `false`

- **settings.update.notification.webhook**
  string

  URL for an external webhook handler.

  The POST request will be sent to the webhook URL after a new minor version of Deckhouse appears on the release channel before it is applied to the cluster.

  > **Caution!** If you specify an invalid webhook address, Deckhouse update will be blocked.

  > Use the minimalNotificationTime parameter if necessary to set the minimum time that must pass before updating from the moment a new minor version appears on the release channel used.

  Example of the POST request payload (`Content-Type: application/json`):

  ```
  {
    "subject":"Deckhouse",
    "version": "1.36.0",
    "requirements":  {"k8s": "1.20.0"},
    "changelogLink": "https://github.com/deckhouse/deckhouse/changelog/1.36.md",
    "applyTime": "2023-01-01T14:30:00Z00:00",
    "message": "New Deckhouse Release 1.36.0 is available. Release will be applied at: Friday, 01-Jan-23 14:30:00 UTC"
  }
  ```

  Description of POST request fields:

  - `subject` — string, the update event type. Possible values: `Deckhouse`, `Module`;
  - `moduleName` — string, the name of the module. Set only if `subject: Module`.
  - `version` - string, x.y.z (semantic versioning);
  - `requirements` - object, version requirements;
  - `changelogLink` - string, a URL to the minor version changelog;
  - `applyTime` - string, date and time of the scheduled update (taking into account the configured update windows) in RFC3339 format;
  - `message` - string, a text message about the availability of the new minor version and the scheduled update time.

  Pattern: `^https?://[^\s/$.?#].[^\s]*$`

  Example:

  ```
  webhook: https://webhook.site/#!/bc8f71ac-c182-4181-9159-6ba6950afffa
  ```

- **settings.update.windows**
  array of objects

  List of update windows during the day.

  - **settings.update.windows.days**
    array of strings

    The days of the week on which the update window is applied.

    Example:

    ```
    days:
    - Mon
    - Wed
    ```

    - **Element of the array**
      string

      Day of the week.

      Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

      Example:

      ```
      Mon
      ```

  - **settings.update.windows.from**
    string

    Required value

    Start time of the update window (UTC timezone).

    Should be less than the end time of the update window.

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    from: '13:00'
    ```

  - **settings.update.windows.to**
    string

    Required value

    End time of the update window (UTC timezone).

    Should be more than the start time of the update window.

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    to: '18:30'
    ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

ConversionWebhook

Short names: cwhc

Scope: Cluster
Version: `v1alpha1`

ConversionWebhook is the Schema for the conversionwebhooks API

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **context**
  array of objects

  Run a hook on a Kubernetes object changes.

  - **context.kubernetes**
    object
    - **context.kubernetes.allowFailure**
      boolean

      If `true`, Shell-operator skips the hook execution errors. If `false` or the parameter is not set, the hook is restarted after a 5 seconds delay in case of an error.

    - **context.kubernetes.apiVersion**
      string

      Is an optional group and version of object API. For example, it is `v1` for core objects (Pod, etc.), `rbac.authorization.k8s.io/v1beta1` for ClusterRole and `monitoring.coreos.com/v1` for prometheus-operator.

    - **context.kubernetes.fieldSelector**
      object
      - **context.kubernetes.fieldSelector.matchExpressions**
        array of objects

        Required value

        - **context.kubernetes.fieldSelector.matchExpressions.field**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.operator**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.value**
          string

    - **context.kubernetes.includeSnapshotsFrom**
      array of strings

      An array of names of kubernetes bindings in a hook. When specified, a list of monitored objects from that bindings will be added to the binding context in a snapshots field. Self-include is also possible.

    - **context.kubernetes.jqFilter**
      string

      An optional parameter that specifies event filtering using jq syntax. The hook will be triggered on the “Modified” event only if the filter result is changed after the last event.

    - **context.kubernetes.kind**
      string

      Required value

      Is the type of a monitored Kubernetes resource. This field is required.

    - **context.kubernetes.labelSelector**
      object

      A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

      - **context.kubernetes.labelSelector.matchExpressions**
        array of objects

        matchExpressions is a list of label selector requirements. The requirements are ANDed.

        A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

        - **context.kubernetes.labelSelector.matchExpressions.key**
          string

          Required value

          key is the label key that the selector applies to.

        - **context.kubernetes.labelSelector.matchExpressions.operator**
          string

          Required value

          operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

        - **context.kubernetes.labelSelector.matchExpressions.values**
          array of strings

          values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

      - **context.kubernetes.labelSelector.matchLabels**

object

matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **context.kubernetes.nameSelector**
  object
  - **context.kubernetes.nameSelector.matchNames**
    array of strings

    Required value
- **context.kubernetes.namespace**
  object

  Filters to choose namespaces.
  - **context.kubernetes.namespace.labelSelector**
    object

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.
    - **context.kubernetes.namespace.labelSelector.matchExpressions**
      array of objects

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.
      - **context.kubernetes.namespace.labelSelector.matchExpressions.key**
        string

        Required value

        key is the label key that the selector applies to.
      - **context.kubernetes.namespace.labelSelector.matchExpressions.operator**
        string

        Required value

        operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.
      - **context.kubernetes.namespace.labelSelector.matchExpressions.values**
        array of strings

        values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.
    - **context.kubernetes.namespace.labelSelector.matchLabels**
      object

      matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.
  - **context.kubernetes.namespace.nameSelector**
    object
    - **context.kubernetes.namespace.nameSelector.matchNames**
      array of strings

      Required value
- **context.kubernetes.queue**
  string

  A name of a separate queue. It can be used to execute long-running hooks in parallel with hooks in the “main” queue.

- **context.name**
  string

  Required value

  It is used to distinguish different bindings during runtime.

- **conversions**
  array of objects

  Required value

  This binding transforms a hook into a handler for conversions defined in CustomResourceDefinition. The Shell-operator updates a CRD with `.spec.conversion`, starts HTTPS server, and runs hooks to handle ConversionReview requests.

  - **conversions.from**
    string

    Required value

    A version of a custom resource that hook can convert.
  - **conversions.handler**
    object

    Required value

    Code of the conversion handler.
    - **conversions.handler.python**
      string

      Python script handler for object.
  - **conversions.includeSnapshotsFrom**
    array of strings

    An array of names of Kubernetes bindings in a hook. When specified, a list of monitored objects from these bindings will be added to the binding context in the snapshots field.
  - **conversions.to**
    string

    Required value

    A version of a custom resource that hook can produce.
- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds
- **metadata**
  object
- **status**
  object

Status defines the observed state of ConversionWebhook.

ValidationWebhook

Short names: vwhc

Scope: Cluster
Version: v1alpha1

ValidationWebhook is the Schema for the validationwebhooks API

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **context**
  array of objects

  Run a hook on a Kubernetes object changes.

  - **context.kubernetes**
    object
    - **context.kubernetes.allowFailure**
      boolean

      If `true`, Shell-operator skips the hook execution errors. If `false` or the parameter is not set, the hook is restarted after a 5 seconds delay in case of an error.

    - **context.kubernetes.apiVersion**
      string

      Is an optional group and version of object API. For example, it is `v1` for core objects (Pod, etc.), `rbac.authorization.k8s.io/v1beta1` for ClusterRole and `monitoring.coreos.com/v1` for prometheus-operator.

    - **context.kubernetes.fieldSelector**
      object
      - **context.kubernetes.fieldSelector.matchExpressions**
        array of objects

        Required value

        - **context.kubernetes.fieldSelector.matchExpressions.field**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.operator**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.value**
          string

    - **context.kubernetes.includeSnapshotsFrom**
      array of strings

      An array of names of kubernetes bindings in a hook. When specified, a list of monitored objects from that bindings will be added to the binding context in a snapshots field. Self-include is also possible.

    - **context.kubernetes.jqFilter**
      string

      An optional parameter that specifies event filtering using jq syntax. The hook will be triggered on the “Modified” event only if the filter result is changed after the last event.

    - **context.kubernetes.kind**
      string

      Required value

      Is the type of a monitored Kubernetes resource. This field is required.

    - **context.kubernetes.labelSelector**
      object

      A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

      - **context.kubernetes.labelSelector.matchExpressions**
        array of objects

        matchExpressions is a list of label selector requirements. The requirements are ANDed.

        A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

        - **context.kubernetes.labelSelector.matchExpressions.key**
          string

          Required value

          key is the label key that the selector applies to.

        - **context.kubernetes.labelSelector.matchExpressions.operator**
          string

          Required value

          operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

        - **context.kubernetes.labelSelector.matchExpressions.values**
          array of strings

          values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

      - **context.kubernetes.labelSelector.matchLabels**
        object

        matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

    - **context.kubernetes.nameSelector**
      object
      - **context.kubernetes.nameSelector.matchNames**
        array of strings

        Required value

    - **context.kubernetes.namespace**
      object

      Filters to choose namespaces.

- **context.kubernetes.namespace.labelSelector**
  object

  A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

  - **context.kubernetes.namespace.labelSelector.matchExpressions**
    array of objects

    matchExpressions is a list of label selector requirements. The requirements are ANDed.

    A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

    - **context.kubernetes.namespace.labelSelector.matchExpressions.key**
      string

      Required value

      key is the label key that the selector applies to.

    - **context.kubernetes.namespace.labelSelector.matchExpressions.operator**
      string

      Required value

      operator represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

    - **context.kubernetes.namespace.labelSelector.matchExpressions.values**
      array of strings

      values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

  - **context.kubernetes.namespace.labelSelector.matchLabels**
    object

    matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is "key", the operator is "In", and the values array contains only "value". The requirements are ANDed.

- **context.kubernetes.namespace.nameSelector**
  object
  - **context.kubernetes.namespace.nameSelector.matchNames**
    array of strings

    Required value

- **context.kubernetes.queue**
  string

  A name of a separate queue. It can be used to execute long-running hooks in parallel with hooks in the "main" queue.

- **context.name**
  string

  Required value

  It is used to distinguish different bindings during runtime.

- **handler**
  object

  Required value

  Code of the ValidatingWebhook handler

  - **handler.cel**
    string

    CEL rules handler for object.

  - **handler.python**
    string

    Python script handler for object.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **status**
  object

  Status defines the observed state of ValidationWebhook.

- **validationObject**
  object

  Required value

  ValidatingWebhook describes an webhook and the resources and operations it applies to.

  - **validationObject.failurePolicy**
    string

    Defines how errors from the hook are handled.

  - **validationObject.group**
    string

    A key to include snapshots from a group of schedule and Kubernetes bindings. See grouping.

  - **validationObject.labelSelector**
    object

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

    - **validationObject.labelSelector.matchExpressions**
      array of objects

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **validationObject.labelSelector.matchExpressions.key**
        string

        Required value

        key is the label key that the selector applies to.

      - **validationObject.labelSelector.matchExpressions.operator**
        string

Required value

operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

- **validationObject.labelSelector.matchExpressions.values**
  array of strings

  values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **validationObject.labelSelector.matchLabels**
  object

  matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **validationObject.matchConditions**
  array of objects

  An optional list of match conditions for fine-grained request filtering. Available only since v1.27 of Kubernetes.

  MatchCondition represents a condition which must by fulfilled for a request to be sent to a webhook.

  - **validationObject.matchConditions.expression**
    string

    Required value

    Expression represents the expression which will be evaluated by CEL. Must evaluate to bool. CEL expressions have access to the contents of the AdmissionRequest and Authorizer, organized into CEL variables:

    ‘object’ - The object from the incoming request. The value is null for DELETE requests. ‘oldObject’ - The existing object. The value is null for CREATE requests. ‘request’ - Attributes of the admission request(/pkg/apis/admission/types.go#AdmissionRequest). ‘authorizer’ - A CEL Authorizer. May be used to perform authorization checks for the principal (user or service account) of the request. See https://pkg.go.dev/k8s.io/apiserver/pkg/cel/library#Authz ‘authorizer.requestResource’ - A CEL ResourceCheck constructed from the ‘authorizer’ and configured with the request resource. Documentation on CEL: https://kubernetes.io/docs/reference/using-api/cel/

    Required.

  - **validationObject.matchConditions.name**
    string

    Required value

    Name is an identifier for this match condition, used for strategic merging of MatchConditions, as well as providing an identifier for logging purposes. A good name should be descriptive of the associated expression. Name must be a qualified name consisting of alphanumeric characters, *‘-’, ‘.’ or ‘.’, and must start and end with an alphanumeric character (e.g. ‘MyName’, or ‘my.name’, or ‘123-abc’, regex used for validation is ‘([A-Za-z0-9][-A-Za-z0-9.]*)?[A-Za-z0-9]’)* with an optional DNS subdomain prefix and ‘/’ (e.g. ‘example.com/MyName’)

    Required.

- **validationObject.name**
  string

  Required value

  Name should be a domain with at least three segments separated by dots.

- **validationObject.namespace**
  object

  Namespace filtering. Only labelSelector is supported (not nameSelector). To filter by namespace name, use labelSelector with kubernetes.io/metadata.name label.

  - **validationObject.namespace.labelSelector**
    object

    labelSelector is a selector to filter namespaces by labels. Use kubernetes.io/metadata.name label to filter by namespace name.

    - **validationObject.namespace.labelSelector.matchExpressions**
      array of objects

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **validationObject.namespace.labelSelector.matchExpressions.key**
        string

        Required value

        key is the label key that the selector applies to.

      - **validationObject.namespace.labelSelector.matchExpressions.operator**
        string

        Required value

        operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

      - **validationObject.namespace.labelSelector.matchExpressions.values**
        array of strings

        values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

    - **validationObject.namespace.labelSelector.matchLabels**
      object

      matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **validationObject.rules**
  array of objects

  A required list of rules used to determine if a request to the Kubernetes API server should be sent to the hook.

  RuleWithOperations is a tuple of Operations and Resources. It is recommended to make sure that all the tuple expansions are valid.

  - **validationObject.rules.apiGroups**
    array of strings

    APIGroups is the API groups the resources belong to. *‘ ’ is all groups. If ‘’* is present, the length of the slice must be one. Required.

  - **validationObject.rules.apiVersions**
    array of strings

    APIVersions is the API versions the resources belong to. *‘ ’ is all versions. If ‘’* is present, the length of the slice must be one. Required.

  - **validationObject.rules.operations**
    array of strings

    Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or * for all of those operations and any future admission operations that are added. If ‘*’ is present, the length of the slice must be one. Required.

    - **Element of the array**

string

OperationType specifies an operation for a request.

- **validationObject.rules.resources**
  array of strings

  Resources is a list of resources this rule applies to.

  For example: ‘pods’ means pods. ‘pods/log’ means the log subresource of pods. ‘ *’ means all resources, but not subresources. ‘pods/*’* means all subresources of pods. *‘/scale’ means all scale subresources. ‘/*’* means all resources and their subresources.

  If wildcard is present, the validation rule will ensure resources do not overlap with each other.

  Depending on the enclosing object, subresources might not be allowed. Required.

- **validationObject.rules.scope**
  string

  scope specifies the scope of this rule. Valid values are “Cluster”, “Namespaced”, and “ *” “Cluster” means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. “Namespaced” means that only namespaced resources will match this rule. “”* means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is “*”.

- **validationObject.sideEffects**
  string

  Determines whether the hook is dryRun-aware.

- **validationObject.timeoutSeconds**
  integer

  Seconds API server should wait for a hook to respond before treating the call as a failure. Default is 10 (seconds).

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Usage

> The module lifecycle stage: General Availability

Setting up the update mode

You can manage DP updates in the following ways:

- Using the `settings.update` parameter of the ModuleConfig `deckhouse` resource.
- Using the `disruptions` parameters section of the NodeGroup resource.

Update windows configuration

You can configure the time windows when Deckhouse will automatically install updates in the following ways:

- For general update management, in the `update.windows` parameter of the `deckhouse` ModuleConfig resource.
- For managing disruptive updates, in the `disruptions.automatic.windows` and `disruptions.rollingUpdate.windows` parameters of the NodeGroup resource.

An example of setting up two daily update windows — from 8 a.m. to 10 a.m. and from 8 p.m. to 10 p.m. (UTC):

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    releaseChannel: EarlyAccess
    update:
      windows:
        - from: "8:00"
          to: "10:00"
        - from: "20:00"
          to: "22:00"
```

You can also set up updates on certain days, for example, on Tuesdays and Saturdays from 6 p.m. to 7:30 p.m. (UTC):

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    releaseChannel: Stable
    update:
      windows:
        - from: "18:00"
          to: "19:30"
          days:
            - Tue
            - Sat
```

Manual update confirmation

Manual confirmation of Deckhouse version updates is provided in the following cases:

- The Deckhouse update confirmation mode is enabled.

  This means that the parameter settings.update.mode in the ModuleConfig `deckhouse` is set to `Manual` (confirmation for both patch and minor versions of Deckhouse) or `AutoPatch` (confirmation for the minor version of Deckhouse). Run the following command to confirm the update (use the corresponding Deckhouse version):

  ```
  d8 k patch DeckhouseRelease <VERSION> --type=merge -p='{"approved": true}'
  ```

- If automatic application of disruptive updates is disabled for a node group.

  This means that the corresponding NodeGroup has the parameter `spec.disruptions.approvalMode` set to `Manual`.

For updating **each** node in such a group, the node must have `update.node.deckhouse.io/disruption-approved=` annotation. Example:

```
d8 k annotate node ${NODE_1} update.node.deckhouse.io/disruption-approved=
```

Deckhouse update notifications

In the `Auto` update mode, you can configure a webhook call to receive a notification about an upcoming minor Deckhouse version update.

In addition, notifications are generated not only for Deckhouse updates but also for updates of any modules, including their individual updates. In some cases, the system may initiate the sending of multiple notifications at once (10–20 notifications) at approximately 15-second intervals.

> **i** Notifications are available only in the `Auto` update mode; in the `Manual` mode they are not generated.

> **i** Specifying a webhook is optional: if the `update.notification.webhook` parameter is not set but the `update.notification.minimalNotificationTime` parameter is specified, the update will still be postponed for the specified period. In this case, the appearance of a DeckhouseRelease resource in the cluster with the name of the new version can be considered the notification of its availability.

Notifications are sent only once for a specific update. If something goes wrong (for example, the webhook receives incorrect data), they will not be resent automatically. To resend the notification, you must delete the corresponding DeckhouseRelease resource.

Example of notification configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    update:
      releaseChannel: Stable
      mode: Auto
      notification:
        webhook: https://release-webhook.mydomain.com
```

After a new minor Deckhouse version appears on the selected release channel, but before it is applied in the cluster, a POST request will be sent to the configured webhook address.

The minimalNotificationTime parameter allows you to postpone the update installation for the specified period, providing time to react to the notification while respecting update windows. If the webhook is unavailable, each failed attempt to send the notification will postpone the update by the same duration, which may lead to the update being deferred indefinitely.

> **⚠** If your webhook returns any status code out of 2xx range, DP retries sending the notification up to five times with exponential backoff. If all attempts fail, the release is blocked until the webhook becomes available again.

For easier error handling and debugging, when returning error codes the webhook should return a JSON response with the following structure:

- `code` — optional internal error code for programmatic handling;
- `message` — a human-readable description of what went wrong.

If the webhook returns a successful HTTP status (2xx), DP treats the notification as successful regardless of the response body.

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    update:
      releaseChannel: Stable
      mode: Auto
      notification:
        webhook: https://release-webhook.mydomain.com
        minimalNotificationTime: 8h
```

Minimal Go webhook example...

```
package main

import (
  "encoding/json"
  "fmt"
  "log"
  "net/http"
)

// Payload structure Deckhouse sends in POST body.
type WebhookData struct {
  Subject      string          `json:"subject"`
  Version      string          `json:"version"`
  Requirements  map[string]string `json:"requirements,omitempty"`
  ChangelogLink string          `json:"changelogLink,omitempty"`
  ApplyTime    string          `json:"applyTime,omitempty"`
  Message      string          `json:"message"`
}

// Response structure that Deckhouse expects from webhook on error
type ResponseError struct {
  Code   string `json:"code,omitempty"`
  Message string `json:"message"`
}

func handler(w http.ResponseWriter, r *http.Request) {
  if r.Method != http.MethodPost {
    w.WriteHeader(http.StatusMethodNotAllowed)
    return
  }
  defer r.Body.Close()

  var data WebhookData
  if err := json.NewDecoder(r.Body).Decode(&data); err != nil {
    log.Printf("failed to decode payload: %v", err)
    w.WriteHeader(http.StatusInternalServerError)
    return
  }

  // Print payload fields
  log.Printf("subject=%s version=%s applyTime=%s changelog=%s requirements=%v",
    data.Subject, data.Version, data.ApplyTime, data.ChangelogLink, data.Requirements)
  log.Printf("message=%s", data.Message)

  // Example conditional logic: fail intentionally for testing
  if data.Version == "v0.0.0-fail" {
    // Return structured error response with error status code
    errorResp := ResponseError{
      Code:   "TEST_FAILURE",
      Message: "intentional failure for testing",
    }

    w.WriteHeader(http.StatusBadRequest)
    json.NewEncoder(w).Encode(errorResp)
    return
  }

  // Return success response with 2xx status code
  w.WriteHeader(http.StatusOK)
  w.Write([]byte("Notification processed successfully"))
}

func main() {
  mux := http.NewServeMux()
  mux.HandleFunc("/webhook", handler)

  addr := ":8080"
  fmt.Printf("listening on %s, POST to http://localhost%s/webhook\n", addr, addr)
  if err := http.ListenAndServe(addr, mux); err != nil {
    log.Fatal(err)
  }
}
```

Reserving the hostnames of the platform web interfaces

DP publishes its own web interfaces under hostnames rendered from the `publicDomainTemplate` global parameter: the API, the web interface, Grafana, Dex, the kubeconfig generator and others. Those hostnames are reserved cluster-wide. An Ingress, HTTPRoute, GRPCRoute, TLSRoute, ListenerSet or Gateway resource created outside a namespace labeled `heritage: deckhouse` cannot claim such a name, and such a request is rejected with a message naming the hostname:

```
Hostname console.example.com is reserved for Deckhouse platform services
and cannot be claimed outside a system namespace
```

Only resource creation and modification are checked. An object that already claims a reserved hostname keeps serving traffic until it is modified.

Reserved hostnames

The reserved set is controlled by the `settings.reservedPublicHosts.mode` parameter of the ModuleConfig `deckhouse`:

- `Template` (by default): Every hostname the template can render are reserved.
- `List`: Only the hostnames of the services DP knows it publishes.

For details on each reservation method, refer to the parameter description.

Excluding a name from reservation

Under `Template` mode, the reservation covers not only the hostnames used by DP but also others matching the template. A workload that requires such a hostname can be excluded from reservation in one of the following ways:

- Free a single hostname with the `settings.reservedPublicHosts.excludedServices` parameter.

  The parameter includes not the entire hostname, only the service name (the value included in the template). For example, for the `%s.example.com` template, the `grafana` value excludes `grafana.example.com` from reservation.
- Exclude a whole namespace with the `security.deckhouse.io/reserved-hosts-bypass: "true"` label.

The label is set on the namespace, not on the object, so a tenant who is allowed to manage resources only in their own namespaces can't set it.

- Return to the previous reservation by setting `mode: List`.

The following is an example that frees `grafana.example.com` from reservation and additionally reserves `admin.corp.example.org` that doesn't match the template:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    reservedPublicHosts:
      mode: Template
      excludedServices:
        - grafana
      additionalHosts:
        - admin.corp.example.org
```

The `settings.reservedPublicHosts.additionalHosts` parameter lets you reserve additional hostnames regardless of the `excludedServices` value.

⚠ The `excludedServices` parameter accepts service names only, therefore it can't be used to exclude a wildcard name from reservation.

To allow a workload to use a wildcard name (such as `*.example.com`), disable the checking for its namespace using the above-mentioned label or use the `List` mode.

Excluding the shared Gateway

The Gateway to which DP module ListenerSet resources are attached is automatically excluded from reservation, regardless of the hostnames specified in its listeners.

The following Gateway is considered the shared Gateway:

- The Gateway specified in the global `gatewayAPIGateway` parameter.
- If the parameter is not set, the Gateway specified in the `default-gateway` ConfigMap in the `d8-alb` namespace.

The exclusion applies by name and namespace and only to the Gateway resource. It does not apply to other resources using the same hostnames, such as Ingress, HTTPRoute, or another Gateway.

This exclusion is necessary because such a Gateway typically has a listener with a wildcard hostname and wildcard certificate and is often located in a dedicated namespace without the `heritage: deckhouse` label. Without the exclusion, the Gateway could not be modified after hostname reservation is enabled, even though the attached DP routes continue to depend on it.

Any other Gateway with a `*.example.com` listener is rejected, even if that hostname was already in use when reservation was enabled. To use such a Gateway, add the `security.deckhouse.io/reserved-hosts-bypass: "true"` label to its namespace or enable `List` mode.

If the shared Gateway is neither specified in the `gatewayAPIGateway` parameter nor defined through the `default-gateway` ConfigMap, no automatic exclusion is applied.

Reservation with existing applications in the cluster

When hostname reservation takes effect, hostnames already used by applications are automatically added to the list of allowed hostnames. Otherwise, the next modification of the corresponding resources would be rejected.

The list is stored in the `grandfatheredHosts` key of the `d8-reserved-public-hosts` ConfigMap in the `d8-system` namespace, separately from hostnames manually excluded from reservation.

The list is created only when `Template` mode is enabled for the first time and is not updated afterward. This prevents reservation from being bypassed: an application cannot claim a reserved hostname after reservation has been enabled and then have that hostname allowed through subsequent regeneration of the list.

If an application that used a hostname allowed this way is removed and the hostname is no longer needed, remove the corresponding entry from `grandfatheredHosts`.

Before being stored, hostnames are converted to lowercase and any trailing dot is removed. Invalid values, such as a URL instead of a hostname, are ignored. If a resource uses the corresponding reserved hostname, its next modification will be rejected.

Wildcard hostnames, such as `*.example.com`, are not added to `grandfatheredHosts`. Otherwise, an application could use any hostname matching the template, including hostnames of services that DP may publish in the future. To allow an application to use a wildcard hostname in the platform domain, add the `security.deckhouse.io/reserved-hosts-bypass: "true"` label to its namespace or enable `List` mode.

This restriction does not apply to the Gateway to which DP is attached. This Gateway is automatically excluded from the check.

Switching from `Template` mode to `List` mode and back does not regenerate `grandfatheredHosts`. Therefore, hostnames that applications start using while `List` mode is enabled are not added to the list of allowed hostnames after switching back to `Template` mode. When the corresponding resources are modified, these hostnames are checked according to the standard reservation rules.

Checking reservation status

Information about the current reservation status is stored in the `d8-reserved-public-hosts` ConfigMap in the `d8-system` namespace.

To view the ConfigMap, run the following command:

```
d8 k -n d8-system get configmap d8-reserved-public-hosts -o yaml
```

The ConfigMap contains the following keys:

Key	Description
`mode`	Current reservation mode. If `publicDomainTemplate` does not match the schema, the value is `List`
`hostPattern`	Regular expression describing the hostnames that can be generated from the template. The value is empty in `List` mode
`hosts`	Hostnames matched exactly. In `Template` mode, contains the values from `additionalHosts` and the wildcard domain name; in `List` mode, contains the hostnames of platform services
`allowedHosts`	Hostnames excluded from matching against `hostPattern`: hostnames from `excludedServices` and `grandfatheredHosts`
`excludedHosts`	Hostnames excluded from reservation using `excludedServices`
`grandfatheredHosts`	Hostnames that were already used by applications when reservation was enabled and were automatically added to the list of allowed hostnames
`sharedGateway`	Gateway to which DP is attached, in the `<NAMESPACE>/<NAME>` format. The value is empty if no such Gateway is configured or detected
`platformHosts`	Hostnames of services published by DP. Used as a reference in both reservation modes

Key	Description
`unknownExcludedServices`	Names from `excludedServices` that are not published by any module. A value in this key most likely indicates a typo in the service name

Collect debug info

Read the FAQ to learn more about collecting debug information.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

How to run kube-bench in my cluster?

First, you have to exec in Deckhouse Pod:

```
d8 k -n d8-system exec -ti svc/deckhouse-leader -c deckhouse -- bash
```

Then you have to select which node you want to run kube-bench.

- Run on random node:

  ```
  curl -s https://raw.githubusercontent.com/aquasecurity/kube-bench/main/job.yaml | d8 k create -f -
  ```

- Run on specific node, e.g. control-plane node:

  ```
  curl -s https://raw.githubusercontent.com/aquasecurity/kube-bench/main/job.yaml | d8 k apply -f - --dry-run=client -o json | jq
  '.spec.template.spec.tolerations=[{"operator": "Exists"}] | .spec.template.spec.nodeSelector={"node-role.kubernetes.io/control-
  plane": ""}' | d8 k create -f -
  ```

Then you can check report:

```
d8 k logs job.batch/kube-bench
```

> ⚠ Deckhouse set the log retention period to 7 days. However, according to the security requirements specified in kube-bench, logs should be retained for at least 30 days. Use separate storage for logs if you need to keep logs for more than 7 days.

How to collect debug info?

1. Create a diagnostic archive with the `d8` utility, redirecting its output (stdout) to a file:

   ```
   d8 system collect-debug-info > deckhouse-debug-$(date +"%Y_%m_%d").tar.gz
   ```

2. Send the resulting archive to the Deckhouse team for further debugging.

> The `--exclude` flag omits the specified items from the archive. Example:

```
d8 system collect-debug-info --exclude=queue global-values > deckhouse-debug-$(date +"%Y_%m_%d").tar.gz
```

> The `--list-exclude` flag prints the list of items available for exclusion. Example:

```
d8 system collect-debug-info --list-exclude
```

The following information is produced when creating the archive. Names in the “File in archive” column correspond to top-level items inside the resulting `tar.gz` archive. Certain sensitive values (e.g., `kubeRBACProxyCA` and `registry.dockercfg`) are excluded.

Category	Collected data	File in archive
Deckhouse	Deckhouse queue state	`queue`
	Deckhouse values (excluding `kubeRBACProxyCA` and `registry.dockercfg`)	`global-values`
	Current `deckhouse` pod version	`deckhouse-version`
	All `DeckhouseRelease` objects	`deckhouse-releases`
	Deckhouse pod logs	`deckhouse-logs`
	Manifests of controllers and pods from all Deckhouse namespaces	`d8-all`
Cluster objects	`NodeGroup`	`node-groups`
	`NodeGroupConfiguration`	`node-group-configuration`
	`Node`	`nodes`
	`Machine`	`machines`
	`Instance`	`instances`
	`StaticInstance`	`staticinstances`
	`MachineDeployment`	`cloud-machine-deployment`, `static-machine-deployment`
	`ClusterAuthorizationRule`	`cluster-authorization-rules`
	`AuthorizationRule`	`authorization-rules`
	`ModuleConfig`	`module-configs`
	Events (all namespaces)	`events`

Category	Collected data	File in archive
Modules and states	List of enabled modules	`deckhouse-enabled-modules`
	`ModuleSource` objects in the cluster	`deckhouse-module-sources`
	`ModulePullOverride` objects in the cluster	`deckhouse-module-pull-overrides`
	Modules in `maintenance` mode	`deckhouse-maintenance-modules`
Controller logs and manifests	`machine-controller-manager` logs	`mcm-logs`
	`cloud-controller-manager` logs	`ccm-logs`
	`csi-controller` logs	`csi-controller-logs`
	`cluster-autoscaler` logs	`cluster-autoscaler-logs`
	Vertical Pod Autoscaler admission controller logs	`vpa-admission-controller-logs`
	Vertical Pod Autoscaler recommender logs	`vpa-recommender-logs`
	Vertical Pod Autoscaler updater logs	`vpa-updater-logs`
	`capi-controller-manager` YAML	`capi-controller-manager`
	`caps-controller-manager` YAML	`caps-controller-manager`
	`machine-controller-manager` YAML	`machine-controller-manager`
Monitoring and alerts	Prometheus logs	`prometheus-logs`
	Active (firing) Prometheus alerts	`alerts`
	Pods not in `Running` (excluding `Completed` and `Evicted`)	`bad-pods`
	List of Audit Policies	`audit-policy`
Network	All objects in the `d8-istio` namespace	`d8-istio-resources`
	All `istio` custom resources	`d8-istio-custom-resources`
	Envoy configuration for `istio`	`d8-istio-envoy-config`
	`istio` logs	`d8-istio-system-logs`
	`istio` ingress gateway logs	`d8-istio-ingress-logs`
	`istio` users logs	`d8-istio-users-logs`
	Cilium connection status (`cilium health status`)	`cilium-health-status`

How to debug pod problems with ephemeral containers?

Run the following command:

```
d8 k -n <namespace_name> debug -it <pod_name> --image=ubuntu <container_name>
```

More info in official documentation.

An ephemeral container cannot be added to a Pod labeled `heritage: deckhouse`, see the next section.

Who can run exec into Deckhouse Platform pods and scale Deckhouse Platform objects?

Only Deckhouse Platform system users. For all other users, including those with the `ClusterAdmin` and `SuperAdmin` roles, the `deckhouse` module prohibits the following operations in any namespace:

- `kubectl exec`, `kubectl attach`, `kubectl cp`, `kubectl port-forward` and `kubectl debug` into a Pod labeled `heritage: deckhouse`. The restriction also applies to `kubectl port-forward` to Services if the request is directed to a protected Pod.
- `kubectl scale` of Deployment, StatefulSet, ReplicaSet or ReplicationController resources labeled `heritage: deckhouse`, unless the object is under maintenance, that is, labeled `maintenance.deckhouse.io/no-resource-reconciliation`.

The `heritage: deckhouse` label is checked on the object itself. For example, if a Deployment has this label but a Pod created by it does not, the access restrictions do not apply to that Pod.

These restrictions do not apply to the following users and components:

- `system:sudouser`.
- `dhctl` and `observability`.
- Service accounts from `d8-*` and `kube-*` namespaces (`system:serviceaccount:d8-*`, `system:serviceaccount:kube-*`), including the Deckhouse Platform controllers and the Horizontal Pod Autoscaler from `kube-controller-manager`.
- Kubernetes control plane components (`system:apiserver`, `system:kube-controller-manager`, `system:kube-scheduler`, `system:volume-scheduler`) and nodes belonging to the `system:nodes` group.
- Members of the `system:masters` group, that is, when using `super-admin.conf` on a master node. The restrictions still apply when using `admin.conf` (the `kubeadm:cluster-admins` group).

Except for `system:masters`, these are the same users that are allowed to modify resources with the `heritage: deckhouse` label. The restrictions apply regardless of whether the `admission-policy-engine` module is enabled in the cluster.

Requests are validated by the `webhook-handler` Pods in the `d8-system` namespace. If these Pods are unavailable, requests are rejected. In this case, the following operations are blocked in all namespaces for all users except those listed above, regardless of whether the `heritage: deckhouse` label is present:

- `kubectl exec`, `kubectl attach`, `kubectl cp`, and `kubectl port-forward` for any Pod.
- `kubectl scale` for any Deployment, StatefulSet, ReplicaSet, or ReplicationController resource.

To access a Pod for diagnostics, you can use `system:sudouser` or `super-admin.conf` on a master node.

Example of executing a command in a Pod as `system:sudouser`:

```
d8 k --as=system:sudouser -n d8-system exec -it <POD_NAME> -- sh
```

⚠ You must have permission to impersonate the `system:sudouser` user.

How to debug node problems with ephemeral containers?

Run the following command:

```
d8 k debug node/mynode -it --image=ubuntu
```

More info in official documentation.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The deckhouse-tools module

> The module lifecycle stage: General Availability

> Web interfaces associated with the module: deckhouse-tools

The module creates a web UI with links to download Deckhouse CLI tool for various operating systems.

The web interface address is composed based on the publicDomainTemplate template of the Deckhouse global configuration parameter (the `%s` key is replaced with `tools`).

For example, if `publicDomainTemplate` is set to `%s-kube.company.my`, the tools web interface will be exposed at `tools-kube.company.my`.

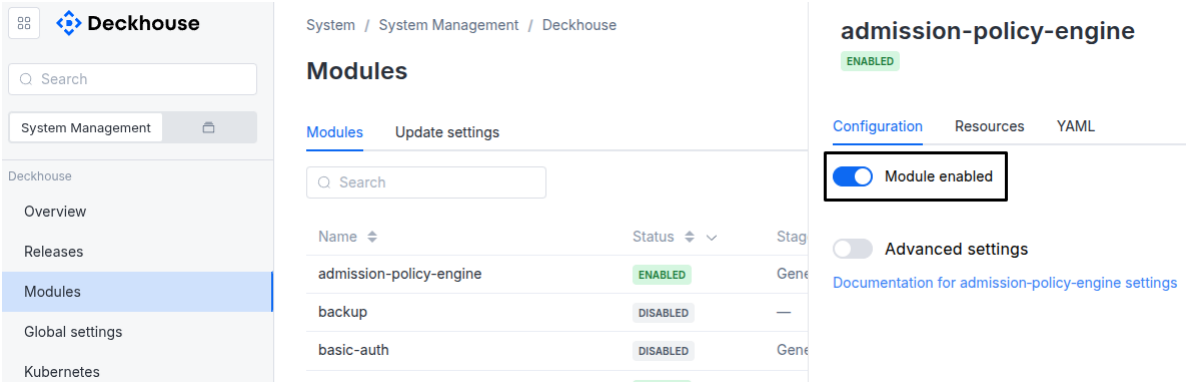
> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability

The module does not have any mandatory parameters.

An example of the configuration



```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse-tools
spec:
  enabled: true
  version: 1
```

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse-tools` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

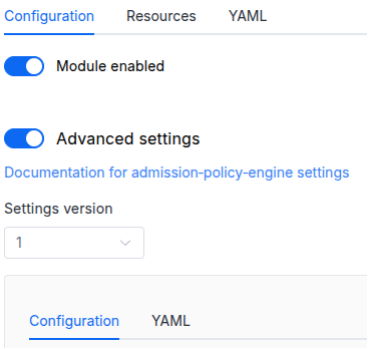
  ```
  d8 system module enable deckhouse-tools
  ```

- **Using ModuleConfig `deckhouse-tools`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `deckhouse-tools` (create it if necessary);

  Example of a manifest to enable module `deckhouse-tools`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: deckhouse-tools
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse-tools` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `deckhouse-tools` on the "YAML" tab in the module settings window ("System" → "System Management" → "Deckhouse" → "Modules", open the module `deckhouse-tools`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `deckhouse-tools` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc deckhouse-tools
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `deckhouse-tools` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `deckhouse-tools`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: deckhouse-tools
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.auth**
    object

    Parameters to authenticate and authorize access to the module's web interface.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module's public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

      An array of groups whose users can browse the module's web interface.

      This parameter is used if the `user-authn` module is enabled or if the `externalAuthentication` parameter is set.

      > **Caution!** Note that you must add those groups to the appropriate field in the `DexProvider` config if this module is used together with the `user-authn` one.

      Default: `[]`

      Examples:

      ```
      allowedUserGroups:
      - admin
      - users
      ```

      ```
      allowedUserGroups: []
      ```

    - **settings.auth.externalAuthentication**
      object

      Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

      > External authentication is enabled automatically if the user-authn module is enabled.

      - **settings.auth.externalAuthentication.authSignInURL**
        string

        The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response).

        Default:

        Example:

        ```
        authSignInURL: https://$host/dex-authenticator/sign_in
        ```

      - **settings.auth.externalAuthentication.authURL**
        string

The URL of the authentication service.

If the user is authenticated, the service should return an HTTP 200 response code.

Default:

Example:

```
authURL: https://deckhouse-tools-dex-authenticator.d8-system.svc.cluster.local/dex-authenticator/auth
```

- **settings.https**
  object

  What certificate type to use.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: Disabled
  ```

  ```
  https:
    mode: OnlyInURI
  ```

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object

    Parameters for certmanager.

    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are supported; you can also define your own).

      Default: `letsencrypt`

      Example:

      ```
      clusterIssuerName: letsencrypt
      ```

  - **settings.https.customCertificate**
    object

    Parameters for custom certificate usage.

    - **settings.https.customCertificate.secretName**
      string

      The name of the secret in the `d8-system` namespace to use with the module's web interface.

      Note that this secret must conform to the kubernetes.io/tls format.

  - **settings.https.mode**
    string

    The HTTPS usage mode:

    - `CertManager` — the web UI is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate` — the web UI is accessed over HTTPS using a certificate from the `d8-system` namespace.
    - `Disabled` — in this mode, the module's web interface can only be accessed over HTTP.
    - `OnlyInURI` — the module's web interface will work over HTTP (implies there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. The load balancer should provide redirection from HTTP to HTTPS.

    Default: `CertManager`

    Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller of the module web interface.

  An optional parameter; by default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

```
tolerations:
- key: key1
  operator: Equal
  value: value1
  effect: NoSchedule
```

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The descheduler module

The module lifecycle stage: General Availability

Every 15 minutes, the module analyzes the cluster state and performs pod eviction according to the conditions described in the active strategies. Evicted pods go through the scheduling process again, considering the current state of the cluster. This helps redistribute workloads according to the chosen strategy.

The module is based on the descheduler project.

Features of the module

- The module can take into account the pod priority class (parameter spec.priorityClassThreshold), restricting its operation to only those pods that have a priority class lower than the specified threshold;
- The module does not evict pods in the following cases:
  - a pod is in the `d8-*` or `kube-system` namespaces;
  - a pod has a `priorityClassName` `system-cluster-critical` or `system-node-critical`;
  - a pod is associated with a local storage;
  - a pod is associated with a DaemonSet;
  - pod eviction will violate Pod Disruption Budget (PDB);
  - there are no available nodes to run the evicted pod.
- Pods with the `Best effort` priority class are evicted before those with `Burstable` and `Guaranteed`.

Descheduler uses parameters with the `labelSelector` syntax from Kubernetes to filter pods and nodes:

- `podLabelSelector` — limits pods by labels;
- `namespaceLabelSelector` — filters pods by namespaces;
- `nodeLabelSelector` — selects nodes by labels.

Metrics provider

If the cluster has a registered `metrics.k8s.io` API group (for example, when metrics-server is installed), the module automatically detects it and enables the **KubernetesMetrics** metrics provider in the `descheduler` policy. This allows to use the **actual** resource consumption data from the Metrics API instead of relying solely on pod requests and limits when the `LowNodeUtilization` strategy is set. Accordingly, the values in thresholds and targetThresholds are then interpreted as a percentage of actual consumption, not of pod requests. The `HighNodeUtilization` strategy is not affected: it always uses pod requests and limits.

No user action is required: the module discovers the `metrics.k8s.io` API group by watching APIService resources and configures the policy accordingly. If metrics-server is installed **after** the module is already running, the `descheduler` Pod will be automatically restarted with the updated policy.

If the `metrics.k8s.io` API group is not registered in the cluster, the module estimates resource usage from pod requests and limits.

Evictions in background

The module runs the descheduler with the upstream `EvictionsInBackground` feature gate enabled (`--feature-gates EvictionsInBackground=true`). There is no module setting for it: the behavior is part of the module and requires no configuration.

By default, the descheduler expects every eviction to complete immediately: the eviction API request either succeeds or is rejected. Some workloads cannot be evicted that way — for example, a pod backing a virtual machine has to be live-migrated first, which may take minutes and may need retries.

With the feature gate enabled, an eviction of a pod annotated with `descheduler.alpha.kubernetes.io/request-evict-only` is treated as a *request* to start the eviction. The controller that owns the pod rejects the eviction API call with `429 Too Many Requests` and marks the pod with the `descheduler.alpha.kubernetes.io/eviction-in-progress` annotation while it performs the actual eviction (for example, a live migration). The descheduler keeps track of such pods and counts them against its eviction limits until the pod is gone or the annotation is removed, so it doesn't start more evictions than allowed while the previous ones are still in progress.

Pods without the `descheduler.alpha.kubernetes.io/request-evict-only` annotation are evicted as usual, so nothing changes for clusters where no workload implements its own eviction policy.

The feature gate is in the alpha stage in the upstream descheduler project (see KEP-1397). It changes nothing on its own: without a controller that answers the eviction request as described above, the descheduler behaves exactly as it did before.

Strategies

HighNodeUtilization

More compactly places pods. Requires scheduler configuration and enabling auto-scaling.

To use `HighNodeUtilization`, you must explicitly specify the high-node-utilization scheduler profile for each pod (this profile cannot be set as the default).

This strategy identifies *under utilized nodes* and evicts pods from them to redistribute them more compactly across fewer nodes.

Under utilized node — A node whose resource usage is below all the threshold values specified in the strategies.highNodeUtilization.thresholds section.

The strategy is enabled by the parameter spec.strategies.highNodeUtilization.enabled.

⚠ In GKE, you cannot configure the default scheduler, but you can use the `optimize-utilization` strategy or deploy a second custom scheduler.

⚠ Node resource usage takes into account extended resources and is calculated based on pod requests and limits (requests and limits), not actual consumption. This approach ensures consistency with the kube-scheduler, which uses a similar principle when scheduling pods on nodes.

This strategy always uses pod requests and limits, regardless of whether the `metrics.k8s.io` API is available in the cluster (see Metrics provider).

LowNodeUtilization

ℹ Loads the nodes more evenly.

This strategy identifies *under utilized nodes* and evicts pods from other *over utilized nodes*. The strategy assumes that the evicted pods will be recreated on the under utilized nodes (following normal scheduler behavior).

Under utilized node — A node whose resource usage is below all the threshold values specified in the strategies.lowNodeUtilization.thresholds section.

Over utilized node — A node whose resource usage exceeds at least one of the threshold values specified in the strategies.lowNodeUtilization.targetThresholds section.

Nodes with resource usage in the range between `thresholds` and `targetThresholds` are considered optimally utilized. Pods on these nodes will not be evicted.

The strategy is enabled by the parameter spec.strategies.lowNodeUtilization.enabled.

By default, `thresholds` and `targetThresholds` are absolute percentages. If spec.strategies.lowNodeUtilization.useDeviationThresholds is `true`, they are counted from the average utilization of all Ready nodes of the cluster: a node is under utilized if its usage is at or below the average minus `thresholds`, and over utilized if its usage is above the average plus `targetThresholds`. For example, with an average CPU utilization of 40%, `thresholds: {cpu: 5}` and `targetThresholds: {cpu: 5}` make nodes at or below 35% under utilized and nodes above 45% over utilized, so the strategy keeps the nodes within the corridor of ±5% around the average.

To evict pods gradually, set spec.strategies.lowNodeUtilization.evictionLimits.node: the maximum number of pods the strategy evicts from one node in one descheduling cycle. A virtual machine that is still migrating from the node takes a place in the limit in every cycle, so for virtual machines the parameter effectively limits how many of them migrate from one node at the same time.

⚠ If the `metrics.k8s.io` API group is **not** registered in the cluster, node resource usage takes into account extended resources and is calculated based on pod requests and limits (requests and limits), not actual consumption. This approach ensures consistency with the kube-scheduler, which uses a similar principle when scheduling pods on nodes.

If the `metrics.k8s.io` API group **is** registered (for details, see “Metrics provider”), the strategy uses the **actual** resource consumption from the Metrics API *instead of* requests and limits. In this case the values used by the descheduler are close to what `kubectl top` shows, but they no longer match the kube-scheduler’s view: a node whose requests are exhausted may still be considered under utilized, and its pods will not be evicted.

CPU utilization averaged over 15 minutes

The momentary values from the Metrics API or pod requests react to short load spikes. To balance nodes by their sustained load, set spec.strategies.lowNodeUtilization.metricsSource to `Prometheus`. The strategy then uses the node CPU utilization averaged over the last 15 minutes, which the cluster Prometheus calculates from the node-exporter data.

How the strategy works in this mode:

1. Only the `cpu` key of `thresholds` and `targetThresholds` is used, as a percentage of the node CPU. The key is required in both sections, other keys are ignored.
2. The `prometheus` module must be enabled. If it is disabled, the strategy works as with `Default`, and the Deckhouse log shows a warning.
3. With `useDeviationThresholds: true` the strategy keeps the nodes within a corridor around the 15-minute average CPU utilization of the cluster.
4. The strategy cannot estimate how much one pod adds to the average, so it evicts one pod from each over utilized node in a cycle. With `evictionLimits.node` set, it evicts up to that number of pods from each over utilized node: in this mode the parameter raises the number of evictions instead of limiting it. Do not set `evictionLimits.node` with this source.
5. The average reflects the evictions with a delay of up to 15 minutes. With the `Frequent` descheduling interval a node stays over utilized for several cycles after the evictions and loses pods again. Use the `Moderate` (15 minutes, default) or `Rare` (30 minutes) interval with this source.
6. If Prometheus is unavailable or has no data for at least one Ready node (node-exporter does not run on it or fails to be scraped, or the node has just joined and has not been scraped twice yet), the strategy of this Descheduler skips the cycle. Other Descheduler resources keep working.

The descheduler reads the metrics through `aggregating-proxy` in the `d8-monitoring` namespace with its ServiceAccount token. The module grants the read access only while at least one Descheduler uses this mode. An example is on the “Examples” page.

Eviction target check

Since Deckhouse 1.78, in clusters with the `control-plane-manager` module enabled, the strategy requests the expected target node from kube-scheduler before evicting a pod. kube-scheduler runs a dry-run scheduling cycle for the pod, with the source node excluded, and returns the nodes with the top score.

How the strategy uses the answer:

1. The pod is evicted only if every node with the top score is under utilized in this cycle by this Descheduler’s own `thresholds`. With `useDeviationThresholds: true` this means at or below the average minus `thresholds`. The check has no thresholds of its own.
2. The pod stays on the node, and the strategy tries the next pod of the same node, if kube-scheduler would place the pod on a node that is not under utilized or has no node for it.
3. The pod also stays if kube-scheduler does not answer or answers with an error: the strategy does not evict a pod without the check.
4. kube-scheduler pauses the real scheduling while a check runs, so the checks are limited. After 5 checks of one over utilized node that did not allow an eviction, the node waits for the next cycle. After 100 checks in a cycle, this Descheduler resource stops evicting pods until the next cycle. If the check finds no feasible node or any top-scoring node is not underutilized, other pods of the same controller on the source node are skipped for this cycle.

The check applies to every Descheduler with `lowNodeUtilization` and cannot be turned off. On managed Kubernetes (the `control-plane-manager` module is disabled) the strategy works without it. The `descheduler_simulate_target_check_total` metric counts the checks by result.

RemoveDuplicates

ℹ Prevents multiple pods from the same controller (ReplicaSet, ReplicationController, StatefulSet) or the same Job from running on the same node.

The strategy ensures that no more than one pod of a ReplicaSet, ReplicationController, StatefulSet, or pods of a single Job is running on the same node. If there are two or more such pods, the module evicts the excess pods so that they are better distributed across the cluster.

The situation can occur if some nodes in the cluster have failed for any reason, and the pods from those nodes have been moved to other nodes. Once the failed nodes become available again to accept load, this strategy can be used to evict duplicate pods from other nodes.

The strategy is enabled by the parameter strategies.removeDuplicates.enabled.

RemovePodsHavingTooManyRestarts

The strategy evicts pods having too many restarts from nodes. Pods become eviction candidates when the total number of restarts across all containers, including init containers, exceeds the `podRestartThreshold` threshold. This strategy is useful for evicting pods in the `CrashLoopBackOff` state or with repeated failures, as well as for freeing up resources and allowing fresh pods to be scheduled on potentially healthier nodes.

RemovePodsViolatingInterPodAntiAffinity

ℹ Evicts pods violating inter-pod affinity and anti-affinity rules to ensure compliance.

The strategy ensures that pods violating inter-pod affinity and anti-affinity rules are evicted from nodes.

For example, if there is **podA** on a node and **podB** and **podC** (running on the same node) have anti-affinity rules which prohibit them to run on the same node, then **podA** will be evicted from the node so that **podB** and **podC** could run. This issue could happen, when the anti-affinity rules for **podB** and **podC** are created when they

are already running on node.

The strategy is enabled by the parameter spec.strategies.highNodeUtilization.enabled.

RemovePodsViolatingNodeAffinity

> i Evicts pods violating node affinity rules to ensure compliance.

The strategy makes sure all pods violating node affinity are eventually removed from nodes.

Essentially, depending on the settings of the parameter strategies.removePodsViolatingNodeAffinity.nodeAffinityType, the strategy temporarily implement the rule `requiredDuringSchedulingIgnoredDuringExecution` of the pod's node affinity as the rule `requiredDuringSchedulingRequiredDuringExecution`, and the rule `preferredDuringSchedulingIgnoredDuringExecution` as the rule `preferredDuringSchedulingPreferredDuringExecution`.

Example for `nodeAffinityType: requiredDuringSchedulingIgnoredDuringExecution`. There is a pod scheduled to a node which satisfies the node affinity rule `requiredDuringSchedulingIgnoredDuringExecution` at the time of scheduling. If over time this node no longer satisfies the node affinity rule, and there is another node available that satisfies the node affinity rule, the strategy evicts the pod from the node it was originally scheduled to.

Example for `nodeAffinityType: preferredDuringSchedulingIgnoredDuringExecution`. There is a pod scheduled to a node because at the time of scheduling there were no other nodes that satisfied the node affinity rule `preferredDuringSchedulingIgnoredDuringExecution`. If over time an available node that satisfies this rule appears in the cluster, the strategy evicts the pod from the node it was originally scheduled to.

The strategy is enabled by the parameter strategies.removePodsViolatingNodeAffinity.enabled.

RemovePodsViolatingTopologySpreadConstraint

The strategy ensures that pods violating topology spread constraints are evicted from nodes. It evicts the minimum number of pods required to balance topology domains to within each constraint's `maxSkew`. This is useful for rebalancing pods across zones after a zone outage recovery.

Third-party components

List of third-party software used in the `descheduler` module:

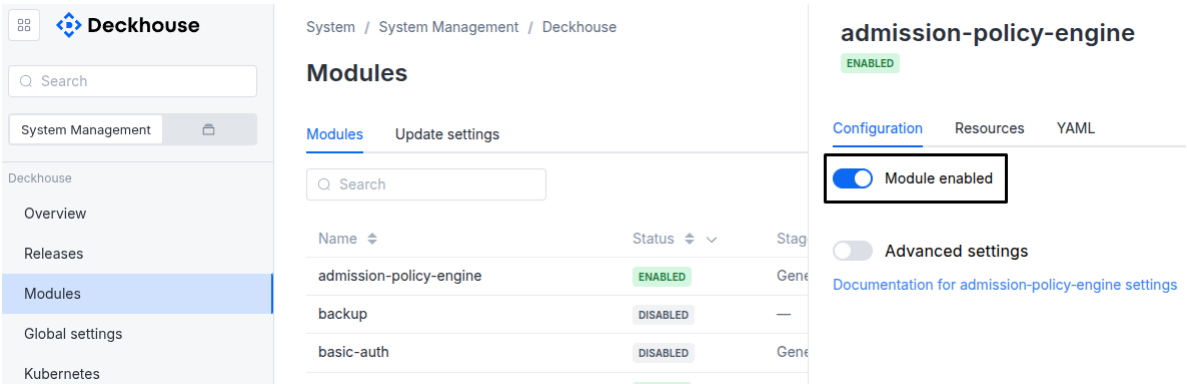
- Descheduler 0.37.0

  License: Apache License 2.0

  A tool to auto-fix scheduling issues Kubernetes does not cover itself.

> i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> i The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `descheduler` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

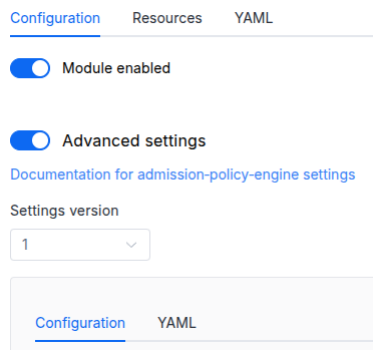
```
d8 system module enable descheduler
```

- **Using ModuleConfig `descheduler`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `descheduler` (create it if necessary);

  Example of a manifest to enable module `descheduler`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: descheduler
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `descheduler` module and enable the "Advanced Settings" switch. Fill in the required fields in the "Configuration" tab or specify the module settings in YAML format on the "YAML" tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `descheduler` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `descheduler`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `descheduler` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc descheduler
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `descheduler` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `descheduler`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: descheduler
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `settings`.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.deschedulingInterval**
    string

    Interval between pod redistribution runs.

    Supported values:

    - `Frequent`: Runs every 5 minutes. Suitable for clusters where faster pod redistribution is important.
    - `Moderate`: Runs every 15 minutes (default).
    - `Rare`: Runs every 30 minutes. Suitable for clusters where it’s important to minimize the number of pod redistributions.

    Default: `Moderate`

    Allowed values: `Frequent`, `Moderate`, `Rare`
  - **settings.logLevel**
    string

    Descheduler logging level.

    Each level includes the messages of the less detailed levels. Some informational messages and warnings, such as startup messages, are logged at any level.

    Supported values:

    - `Error`: Errors only.
    - `Warning`: Configuration warnings, evicted pods, and descheduling cycle results (default).
    - `Info`: The progress of each descheduling cycle, such as the nodes being processed.
    - `Debug`: Detailed information on eviction decisions, such as why a pod was not evicted, and every request to the Kubernetes API. Produces a very large volume of logs, so use it for troubleshooting only.

    Default: `Warning`

    Allowed values: `Debug`, `Info`, `Warning`, `Error`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

Descheduler

Scope: Cluster

- v1alpha2
- v1alpha1

Descheduler is a description of a single descheduler instance.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
  - **metadata.name**
    string
- **spec**
  object

  Required value

  Defines the behavior of a descheduler instance.

  - **spec.evictLocalStoragePods**
    boolean

    Allows Pods using local storage to be evicted.

    Default: `false`

  - **spec.namespaceLabelSelector**
    object

    Limiting the pods which are processed by namespace labels.

    - **spec.namespaceLabelSelector.matchExpressions**
      array of objects

      List of label expressions that a node should have to qualify for the filter condition.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      - key: tier
        operator: NotIn
        values:
        - production
      ```

      - **spec.namespaceLabelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.namespaceLabelSelector.matchExpressions.operator**
        string

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.namespaceLabelSelector.matchExpressions.values**
        array of strings

        A label value.

        - **Element of the array**
          string

          Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

          Length: `1..63`

    - **spec.namespaceLabelSelector.matchLabels**
      object
  - **spec.nodeLabelSelector**
    object

    Limiting the pods which are processed to fit evicted pods by labels in set representation. If set, `nodeSelector` must not be set.

    - **spec.nodeLabelSelector.matchExpressions**
      array of objects

      List of label expressions that a node should have to qualify for the filter condition.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      - key: tier
        operator: NotIn
        values:
        - production
      ```

      - **spec.nodeLabelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.nodeLabelSelector.matchExpressions.operator**
        string

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

        - **spec.nodeLabelSelector.matchExpressions.values**
          array of strings

          A label value.

          - **Element of the array**
            string

            Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

            Length: `1..63`
      - **spec.nodeLabelSelector.matchLabels**
        object
  - **spec.podLabelSelector**
    object

    Limiting the pods which are processed by labels.

    - **spec.podLabelSelector.matchExpressions**
      array of objects

      List of label expressions that a node should have to qualify for the filter condition.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      - key: tier
        operator: NotIn
        values:
        - production
      ```

      - **spec.podLabelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.podLabelSelector.matchExpressions.operator**
        string

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.podLabelSelector.matchExpressions.values**
        array of strings

        A label value.

        - **Element of the array**
          string

          Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

          Length: `1..63`
    - **spec.podLabelSelector.matchLabels**
      object
  - **spec.priorityClassThreshold**
    object

    Limiting the pods which are processed by priority class. Only pods under the threshold can be evicted.

    You can specify either the name of the priority class (priorityClassThreshold.name), or the actual value of the priority class (priorityThreshold.value).

    By default, this threshold is set to the value of `system-cluster-critical` priority class.

    - **spec.priorityClassThreshold.name**
      string

      Name of the priority class.

    - **spec.priorityClassThreshold.value**
      integer

      Value of the priority class.

  - **spec.protectedStorageClasses**
    array of strings

    A list of StorageClass names whose Pods must not be evicted.

    If a Pod refers to a PersistentVolumeClaim provisioned by one of the listed StorageClasses, the descheduler will never evict such a Pod.

    Note the following:

    - An empty list (or an omitted parameter) keeps the current behavior: Pods with PVCs are evicted as usual.
    - A Pod whose PersistentVolumeClaim cannot be resolved (the PVC is missing or has an empty `storageClassName`) is considered protected as well.

    Example:

    ```
    protectedStorageClasses:
    - local-path
    - local-storage-class
    ```

    - **Element of the array**
      string

      A StorageClass name.

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

      Length: `1..253`
  - **spec.strategies**
    object

    Required value

    Settings of strategies for the Descheduler instances.

    - **spec.strategies.highNodeUtilization**
      object

      The strategy evicts pods from under utilized nodes to concentrate workloads on fewer nodes. It is intended for use with node autoscaling and a scheduler using `MostAllocated`.

Node resource usage takes into account extended resources and is based on pod requests and limits, not actual consumption.

Detailed description of the strategy is provided in the HighNodeUtilization section.

- **spec.strategies.highNodeUtilization.enabled**
  boolean

  Makes the strategy active.

  Default: `false`

- **spec.strategies.highNodeUtilization.thresholds**
  object

  Sets threshold values to identify to identify under utilized nodes.

  If the resource usage of the node is below **all** threshold values, then the node is considered under utilized.

  If a resource threshold is not specified, it is treated as 100% and does not participate in node utilization calculations.

  - **spec.strategies.highNodeUtilization.thresholds.cpu**
    integer

    CPU fraction in percents

    Allowed values: `0 <= X <= 100`

  - **spec.strategies.highNodeUtilization.thresholds.memory**
    integer

    Memory fraction in percents

    Allowed values: `0 <= X <= 100`

  - **spec.strategies.highNodeUtilization.thresholds.pods**
    integer

    Pods count in percents

    Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization**
  object

  The strategy evicts pods from over utilized nodes, assuming they will be rescheduled on under utilized nodes.

  By default, a node is under utilized when its resource usage is below all values in `thresholds`, and over utilized when it exceeds at least one value in `targetThresholds`.

  Node resource usage takes into account extended resources and is based on pod requests and limits, not actual consumption.

  The utilization data source is determined by `metricsSource`.

  Detailed description of the strategy is provided in the LowNodeUtilization section.

  - **spec.strategies.lowNodeUtilization.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

  - **spec.strategies.lowNodeUtilization.evictionLimits**
    object

    Limits the number of pods the strategy evicts from one node.

    Example:

    ```
    evictionLimits:
      node: 2
    ```

    - **spec.strategies.lowNodeUtilization.evictionLimits.node**
      integer

      The maximum number of pods the strategy evicts from one node in one descheduling cycle.

      The limit also counts pods evicted in the background, such as a virtual machine pod that leaves the node through a live migration. Such a pod takes a place in the limit in every cycle until it leaves the node, and no new eviction request is sent for it. So for virtual machines the parameter effectively limits how many of them migrate from one node at the same time.

      If the parameter is not set, the strategy evicts pods from a node until the node stops being over utilized or the under utilized nodes run out of free resources.

      With metricsSource `Prometheus` the strategy evicts one pod from each over utilized node in a cycle without the parameter and up to the set number of pods with it, so in that mode the parameter raises the number of evictions instead of limiting it.

      Allowed values: `1 <= X`

  - **spec.strategies.lowNodeUtilization.metricsSource**
    string

    Source of node utilization data for the strategy.

    - `Default` — Pod resource requests or actual consumption from the Metrics API if the `metrics.k8s.io` API group is registered in the cluster.
    - `Prometheus` — node CPU utilization averaged over 15 minutes using cluster Prometheus data (node-exporter).

    With `Prometheus`, the `cpu` key is required in both thresholds and targetThresholds; other keys are ignored. The `prometheus` module must be enabled. Otherwise, the strategy uses `Default`, and the Deckhouse log shows a warning.

    Together with useDeviationThresholds, the strategy keeps nodes within a corridor around the 15-minute average CPU utilization of the cluster. If evictionLimits.node is set, the parameter increases the number of evictions in this mode instead of limiting it.

    If Prometheus is unavailable or has no data for at least one Ready node, the strategy skips balancing in that cycle.

    Detailed description of this mode is provided in the CPU utilization section.

    Default: `Default`

    Allowed values: `Default`, `Prometheus`

  - **spec.strategies.lowNodeUtilization.targetThresholds**
    object

    Sets threshold values to identify to identify over utilized nodes.

    If the resource usage of the node exceeds at least one of the threshold values, then the node is considered over utilized.

    If a resource threshold is not specified, it is treated as 100% and does not participate in node utilization calculations.

    - **spec.strategies.lowNodeUtilization.targetThresholds.cpu**
      integer

      CPU fraction in percents

      Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.targetThresholds.memory**
  integer

  Memory fraction in percents

  Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.targetThresholds.pods**
  integer

  Pods count in percents

  Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.thresholds**
  object

  Sets threshold values to identify to identify under utilized nodes.

  If the resource usage of the node is below **all** threshold values, then the node is considered under utilized.

  If a resource threshold is not specified, it is treated as 100% and does not participate in node utilization calculations.

  - **spec.strategies.lowNodeUtilization.thresholds.cpu**
    integer

    CPU fraction in percents

    Allowed values: `0 <= X <= 100`

  - **spec.strategies.lowNodeUtilization.thresholds.memory**
    integer

    Memory fraction in percents

    Allowed values: `0 <= X <= 100`

  - **spec.strategies.lowNodeUtilization.thresholds.pods**
    integer

    Pods count in percents

    Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.useDeviationThresholds**
  boolean

  Counts thresholds and targetThresholds from the average utilization of the nodes instead of using them as absolute values.

  The average is calculated over all Ready nodes of the cluster for every resource listed in `thresholds`, regardless of nodeLabelSelector.

  A node is considered under utilized if its usage of **all** listed resources is at or below the average minus the `thresholds` value. A node is considered over utilized if its usage of **at least one** listed resource is above the average plus the `targetThresholds` value. The resulting bounds are limited to the range from 0 to 100%.

  In this mode, a `thresholds` value may be greater than the `targetThresholds` value of the same resource. Both sections must still list the same resources.

  For example, `thresholds: {cpu: 5}` and `targetThresholds: {cpu: 5}` keep the CPU utilization of the nodes within the corridor of ±5% around the average.

  Default: `false`

- **spec.strategies.removeDuplicates**
  object

  The strategy ensures that no more than one pod of a ReplicaSet, ReplicationController, StatefulSet, or pods of a single Job is running on the same node. If there are two or more such pods, the module evicts the excess pods so that they are better distributed across the cluster.

  - **spec.strategies.removeDuplicates.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

- **spec.strategies.removePodsHavingTooManyRestarts**
  object

  The strategy evicts pods having too many restarts from nodes.

  Pods become eviction candidates when the total number of restarts across all containers, including init containers, exceeds the `podRestartThreshold` threshold.

  This strategy is useful for evicting pods in the `CrashLoopBackOff` state or with repeated failures, as well as for freeing up resources and allowing fresh pods to be scheduled on potentially healthier nodes.

  - **spec.strategies.removePodsHavingTooManyRestarts.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

  - **spec.strategies.removePodsHavingTooManyRestarts.podRestartThreshold**
    integer

    Threshold for the total number of restarts across all pod containers, including init containers.

    If the number of restarts exceeds this value, the pod is considered unhealthy and becomes a candidate for eviction.

    Default: `100`

    Allowed values: `1 <= X`

- **spec.strategies.removePodsViolatingInterPodAntiAffinity**
  object

  The strategy ensures that pods violating inter-pod affinity and anti-affinity rules are evicted from nodes.

  - **spec.strategies.removePodsViolatingInterPodAntiAffinity.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

- **spec.strategies.removePodsViolatingNodeAffinity**
  object

  The strategy evicts pods that violate node affinity rules according to the configured nodeAffinityType.

  - **spec.strategies.removePodsViolatingNodeAffinity.enabled**
    boolean

    Makes the strategy active.

Default: `false`

- **spec.strategies.removePodsViolatingNodeAffinity.nodeAffinityType**
  array of strings

  Defines the list of node affinity rules used.

  Default: `["requiredDuringSchedulingIgnoredDuringExecution"]`

  - **Element of the array**
    string

    Allowed values: `requiredDuringSchedulingIgnoredDuringExecution`, `preferredDuringSchedulingIgnoredDuringExecution`

- **spec.strategies.removePodsViolatingTopologySpreadConstraint**
  object

  The strategy ensures that pods violating topology spread constraints are evicted from nodes. It evicts the minimum number of pods required to balance topology domains to within each constraint's `maxSkew`.

  This is useful for rebalancing pods across zones after a zone outage recovery.

  - **spec.strategies.removePodsViolatingTopologySpreadConstraint.constraints**
    array of strings

    List of topology spread constraint types to consider when deciding which pods to evict.

    Topology spread constraints control how pods are distributed across your cluster topology (e.g. regions, zones, nodes).

    By default, only `DoNotSchedule` (hard constraints) are considered — these are constraints that the scheduler strictly enforces: a pod will NOT be placed if doing so would violate the constraint. `Descheduler` will evict pods that are currently violating such constraints (e.g. due to node failures or cluster topology changes after initial scheduling).

    Optionally, `ScheduleAnyway` (soft constraints) can also be included — these are constraints that the scheduler tries to satisfy but does not strictly enforce: a pod WILL be placed even if the constraint cannot be satisfied, though the scheduler will attempt to minimize the imbalance. Including this type causes `descheduler` to also evict pods that violate soft constraints.

    Default: `["DoNotSchedule"]`

    - **Element of the array**
      string

      Allowed values: `DoNotSchedule`, `ScheduleAnyway`

  - **spec.strategies.removePodsViolatingTopologySpreadConstraint.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

  - **spec.strategies.removePodsViolatingTopologySpreadConstraint.topologyBalanceNodeFit**
    boolean

    If set to `true`, the strategy will consider whether the pods can fit on other nodes when balancing topology domains.

    Default: `true`

Deprecated resource. Support for the resource might be removed in a later release.

Descheduler is a description of a single descheduler instance.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
  - **metadata.name**
    string
- **spec**
  object

  Required value

  Defines the behavior of a descheduler instance.

  - **spec.deploymentTemplate**
    object

    Defines Template of a descheduler Deployment.

    - **spec.deploymentTemplate.nodeSelector**
      object
    - **spec.deploymentTemplate.tolerations**
      array of objects
      - **spec.deploymentTemplate.tolerations.effect**
        string
      - **spec.deploymentTemplate.tolerations.key**
        string
      - **spec.deploymentTemplate.tolerations.operator**
        string
      - **spec.deploymentTemplate.tolerations.tolerationSeconds**
        integer
      - **spec.deploymentTemplate.tolerations.value**
        string
  - **spec.deschedulerPolicy**
    object

    `globalParameters` and `strategies` follow the descheduler's documentation.

    - **spec.deschedulerPolicy.globalParameters**
      object

      Parameters that apply to all policies.

      - **spec.deschedulerPolicy.globalParameters.evictFailedBarePods**
        boolean

        Allows Pods without `ownerReferences` and in `failed` phase to be evicted.

      - **spec.deschedulerPolicy.globalParameters.evictLocalStoragePods**
        boolean

        Allows Pods using local storage to be evicted.

      - **spec.deschedulerPolicy.globalParameters.evictSystemCriticalPods**
        boolean

        Allows eviction of Pods of any priority (including Kubernetes system Pods).

      - **spec.deschedulerPolicy.globalParameters.ignorePvcPods**
        boolean

        Prevents Pods with PVCs from being evicted.

- **spec.deschedulerPolicy.globalParameters.maxNoOfPodsToEvictPerNamespace**
  integer

  Restricts maximum of Pods to be evicted per namespace.

- **spec.deschedulerPolicy.globalParameters.maxNoOfPodsToEvictPerNode**
  integer

  Restricts maximum of Pods to be evicted per node.

- **spec.deschedulerPolicy.globalParameters.nodeSelector**
  string

- **spec.deschedulerPolicy.strategies**
  object

  List of strategies with corresponding parameters for a given Descheduler instances.

  - **spec.deschedulerPolicy.strategies.highNodeUtilization**
    object

    This strategy finds nodes that are under utilized and evicts Pods from the nodes in the hope that these Pods will be scheduled compactly into fewer nodes.

    - **spec.deschedulerPolicy.strategies.highNodeUtilization.enabled**
      boolean

      Required value

    - **spec.deschedulerPolicy.strategies.highNodeUtilization.namespaceFilter**
      object

      Restricts Namespaces to which this strategy applies.

    - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter**
      object

      Filters Nodes to which the strategy applies.

      - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter.labelSelector**
        object
        - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter.labelSelector.matchExpressions**
          array of objects

          List of label expressions that a node should have to qualify for the filter condition.

          Example:

          ```
          matchExpressions:
          - key: tier
            operator: In
            values:
            - production
            - staging
          - key: tier
            operator: NotIn
            values:
            - production
          ```

          - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter.labelSelector.matchExpressions.key**
            string

            A label name.

          - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter.labelSelector.matchExpressions.operator**
            string

            A comparison operator.

            Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

          - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter.labelSelector.matchExpressions.values**
            array of strings

            A label value.

            - **Element of the array**
              string

              Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

              Length: `1..63`

        - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter.labelSelector.matchLabels**
          object

    - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFit**
      boolean

      If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

    - **spec.deschedulerPolicy.strategies.highNodeUtilization.priorityFilter**
      object

      Only Pods with priority lower than this will be descheduled.

  - **spec.deschedulerPolicy.strategies.lowNodeUtilization**
    object

    This strategy finds nodes that are under utilized and evicts Pods, if possible, from other nodes in the hope that recreation of evicted Pods will be scheduled on these underutilized nodes.

    - **spec.deschedulerPolicy.strategies.lowNodeUtilization.enabled**
      boolean

      Required value

    - **spec.deschedulerPolicy.strategies.lowNodeUtilization.namespaceFilter**
      object

      Restricts Namespaces to which this strategy applies.

    - **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter**
      object

      Filters Nodes to which the strategy applies.

      - **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter.labelSelector**
        object
        - **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter.labelSelector.matchExpressions**
          array of objects

          List of label expressions that a node should have to qualify for the filter condition.

          Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter.labelSelector.matchExpressions.key**
  string

  A label name.

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter.labelSelector.matchExpressions.operator**
  string

  A comparison operator.

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter.labelSelector.matchExpressions.values**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter.labelSelector.matchLabels**
  object

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFit**
  boolean

  If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.priorityFilter**
  object

  Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removeDuplicates**
  object

  This strategy makes sure that there is only one Pod associated with a ReplicaSet (RS), ReplicationController (RC), StatefulSet, or Job running on the same node.

  - **spec.deschedulerPolicy.strategies.removeDuplicates.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removeDuplicates.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

    - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter.labelSelector**
      object
      - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter.labelSelector.matchExpressions**
        array of objects

        List of label expressions that a node should have to qualify for the filter condition.

        Example:

        ```
        matchExpressions:
        - key: tier
          operator: In
          values:
          - production
          - staging
        - key: tier
          operator: NotIn
          values:
          - production
        ```

        - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter.labelSelector.matchExpressions.key**
          string

          A label name.

        - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter.labelSelector.matchExpressions.operator**
          string

          A comparison operator.

          Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

        - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter.labelSelector.matchExpressions.values**
          array of strings

          A label value.

          - **Element of the array**
            string

            Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

            Length: `1..63`

      - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter.labelSelector.matchLabels**
        object

    - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFit**
      boolean

      If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.removeDuplicates.priorityFilter**
  object

  Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removeFailedPods**
  object

  This strategy evicts Pods that are in `failed` status phase.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removeFailedPods.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

    - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter.labelSelector**
      object
      - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter.labelSelector.matchExpressions**
        array of objects

        List of label expressions that a node should have to qualify for the filter condition.

        Example:

        ```
        matchExpressions:
        - key: tier
          operator: In
          values:
          - production
          - staging
        - key: tier
          operator: NotIn
          values:
          - production
        ```

        - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter.labelSelector.matchExpressions.key**
          string

          A label name.

        - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter.labelSelector.matchExpressions.operator**
          string

          A comparison operator.

          Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

        - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter.labelSelector.matchExpressions.values**
          array of strings

          A label value.

          - **Element of the array**
            string

            Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

            Length: `1..63`

      - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter.labelSelector.matchLabels**
        object

  - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts**
  object

  This strategy makes sure that Pods having too many restarts are removed from nodes.

  - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

    - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter.labelSelector**
      object
      - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter.labelSelector.matchExpressions**
        array of objects

        List of label expressions that a node should have to qualify for the filter condition.

        Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter.labelSelector.matchExpressio**
  string

  A label name.

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter.labelSelector.matchExpressio**
  string

  A comparison operator.

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter.labelSelector.matchExpressio**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter.labelSelector.matchLabels**
  object

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFit**
  boolean

  If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.priorityFilter**
  object

  Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity**
  object

  This strategy makes sure that Pods violating interpod anti-affinity are removed from nodes.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

    - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter.labelSelector**
      object
      - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter.labelSelector.matchExpressio**
        array of objects

        List of label expressions that a node should have to qualify for the filter condition.

        Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

        - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter.labelSelector.matchExpr**
          string

          A label name.

        - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter.labelSelector.matchExpr**
          string

          A comparison operator.

          Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

        - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter.labelSelector.matchExpr**
          array of strings

          A label value.

          - **Element of the array**
            string

            Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

            Length: `1..63`

      - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter.labelSelector.matchLabels**
        object

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.priorityFilter**

object

Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity**
object

This strategy makes sure all Pods violating node affinity are eventually removed from nodes.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.enabled**
boolean

Required value

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.namespaceFilter**
object

Restricts Namespaces to which this strategy applies.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter**
object

Filters Nodes to which the strategy applies.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter.labelSelector**
object
- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter.labelSelector.matchExpressions**
array of objects

List of label expressions that a node should have to qualify for the filter condition.

Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter.labelSelector.matchExpressions.**
string

A label name.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter.labelSelector.matchExpressions.**
string

A comparison operator.

Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter.labelSelector.matchExpressions.**
array of strings

A label value.

- **Element of the array**
string

Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

Length: `1..63`

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter.labelSelector.matchLabels**
object

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFit**
boolean

If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.priorityFilter**
object

Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints**
object

This strategy makes sure that Pods violating `NoSchedule` taints on nodes are removed.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.enabled**
boolean

Required value

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.namespaceFilter**
object

Restricts Namespaces to which this strategy applies.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter**
object

Filters Nodes to which the strategy applies.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter.labelSelector**
object
- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter.labelSelector.matchExpressions**
array of objects

List of label expressions that a node should have to qualify for the filter condition.

Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter.labelSelector.matchExpressions.k**
  string

  A label name.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter.labelSelector.matchExpressions.o**
  string

  A comparison operator.

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter.labelSelector.matchExpressions.v**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter.labelSelector.matchLabels**
  object

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFit**
  boolean

  If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.priorityFilter**
  object

  Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint**
  object

  This strategy makes sure that Pods violating topology spread constraints are evicted from nodes.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

    - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter.labelSelector**
      object
      - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter.labelSelector.matchExp**
        array of objects

        List of label expressions that a node should have to qualify for the filter condition.

        Example:

        ```
        matchExpressions:
        - key: tier
          operator: In
          values:
          - production
          - staging
        - key: tier
          operator: NotIn
          values:
          - production
        ```

        - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter.labelSelector.matc**
          string

          A label name.

        - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter.labelSelector.matc**
          string

          A comparison operator.

          Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

        - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter.labelSelector.matc**
          array of strings

          A label value.

          - **Element of the array**
            string

            Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

            Length: `1..63`

      - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter.labelSelector.matchLab**
        object

  - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

- **status**
  object

  Most recently observed status of a descheduler instance.

  - **status.ready**
    boolean

    Required value

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Configuring the pod redistribution interval

To set how often the `descheduler` module runs the pod redistribution cycle, use the `deschedulingInterval` parameter.

For example, to run `descheduler` every 5 minutes, set `deschedulingInterval: Frequent`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: descheduler
spec:
  enabled: true
  settings:
    deschedulingInterval: Frequent
```

Supported values:

- `Frequent`: Runs every 5 minutes. Suitable for clusters where faster pod redistribution is important.
- `Moderate`: Runs every 15 minutes (default).
- `Rare`: Runs every 30 minutes. Suitable for clusters where it's important to minimize the number of pod redistributions.

Example LowNodeUtilization strategy

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: low-node-utilization
spec:
  strategies:
    lowNodeUtilization:
      enabled: true
      thresholds:
        cpu: 20
      targetThresholds:
        cpu: 50
```

Example LowNodeUtilization strategy with thresholds relative to the average

The strategy keeps the CPU utilization of the nodes within the corridor of ±5% around the average utilization of the cluster nodes and evicts at most two pods from one node per descheduling cycle. A virtual machine that is still migrating from the node takes one of the two places:

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: low-node-utilization-deviation
spec:
  strategies:
    lowNodeUtilization:
      enabled: true
      useDeviationThresholds: true
      thresholds:
        cpu: 5
      targetThresholds:
        cpu: 5
      evictionLimits:
        node: 2
```

Example LowNodeUtilization strategy on the 15-minute CPU average

The strategy keeps the nodes within the corridor of ±5% around the cluster average of the CPU utilization averaged over 15 minutes, so short load spikes do not trigger evictions. It evicts one pod from each over utilized node per descheduling cycle; keep `evictionLimits.node` unset in this mode, since it raises that number. Use the default `Moderate` descheduling interval (15 minutes). The `prometheus` module must be enabled:

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: low-node-utilization-prometheus
spec:
  strategies:
    lowNodeUtilization:
      enabled: true
      metricsSource: Prometheus
      useDeviationThresholds: true
      thresholds:
        cpu: 5
      targetThresholds:
        cpu: 5
```

Example HighNodeUtilization strategy

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: high-node-utilization
spec:
  strategies:
    highNodeUtilization:
      enabled: true
      thresholds:
        cpu: 50
        memory: 50
```

Protecting pods by StorageClass

Use the `protectedStorageClasses` parameter to forbid evicting pods that use PersistentVolumeClaims provisioned by specific StorageClasses. This is useful for storage that is bound to a node (for example, `local-path`), where evicting a pod either loses the data locality or leaves the pod unschedulable.

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: protect-local-storage
spec:
  protectedStorageClasses:
    - local-path
  strategies:
    lowNodeUtilization:
      enabled: true
      thresholds:
        cpu: 20
      targetThresholds:
        cpu: 50
```

With this configuration, the descheduler can still evict every other pod, but a pod with a PersistentVolumeClaim from the `local-path` StorageClass is never evicted.

Keep the following in mind:

- If the parameter is omitted or empty, the behavior does not change: pods with PersistentVolumeClaims are evicted as usual.
- A pod is also considered protected when its PersistentVolumeClaim cannot be resolved, that is, the PVC does not exist or its `storageClassName` is empty. Such pods are never evicted while the parameter is set.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Module documentation

> **i** The module lifecycle stage: General Availability

> **i** Web interfaces associated with the module: documentation

The `documentation` module creates a web interface for access to the documentation of the Deckhouse Platform version running in the cluster and to the documentation of the available modules.

To get the web interface address, in the publicDomainTemplate template of the Deckhouse Platform global configuration parameter, replace the `%s` key with `documentation`. For example, if `publicDomainTemplate` is set as `%s-kube.company.my`, then the documentation web interface will be available at `documentation-kube.company.my`.

Main features

The module provides the following features:

- The documentation of the Deckhouse Platform version running in the cluster, without access to the Internet
- The documentation of the modules of every ModuleSource of the cluster, enabled or not
- Search throughout the platform documentation and the modules
- The pages in Markdown, an `llms.txt` index and a `corpus.json` file for AI tools
- Authentication through the `user-authn` module, an external authentication service or basic authentication with a generated password: see the usage page
- Keeping the prepared versions in the system S3 storage or in an S3 storage of your own, and a high availability mode with two replicas

How the module works

The documentation of the Deckhouse Platform version the module is part of is built into the module.

The documentation of a specific module version is prepared on demand and cached:

1. A user opens a page of a module version that is not prepared yet.
2. The module downloads the documentation from the image of the version in the container registry and builds its pages.
3. The prepared version is kept on the volume of the documentation pod. When keeping versions in S3 is on, the version is kept in S3 too, and after a restart of the pod the module opens it without preparing it again.
4. One version of every module is kept always. For an enabled module it is the installed version. For the other modules it is the version of the most stable channel: stable when it exists. The search index and the AI tool files (`llms.txt`, `corpus.json`) of all modules are built from these versions.

When a module has a ModuleRelease in the `Pending` phase, the module prepares the documentation of that version in advance. The module reads the list of versions from the container registry every 30 minutes. A version published later shows up in the list within 30 minutes.

Limitations

Each documentation pod keeps the prepared versions on a 4 GiB volume, in two parts of 2 GiB:

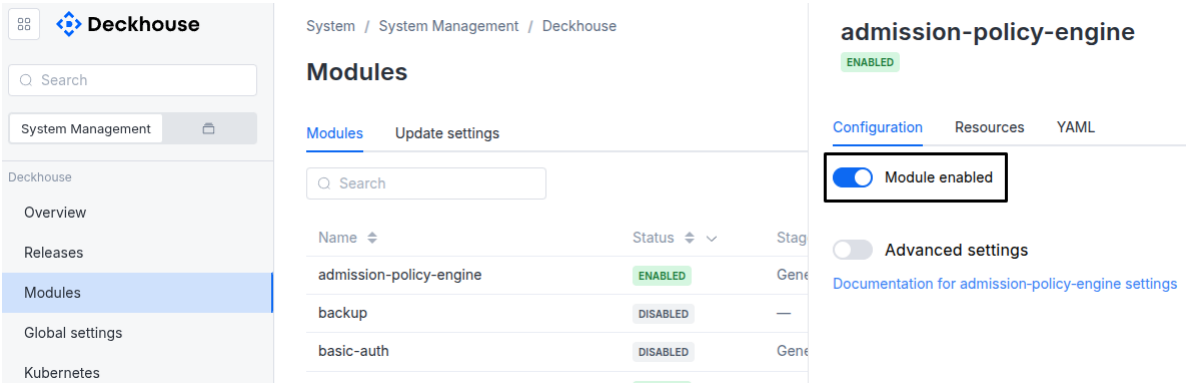
Part	Content	Room	Removal
The versions users open	A version takes about 1.3 MB	About 1500 versions	Above 2 GiB the version opened longest ago goes first; a version not opened for 7 days goes anyway and is prepared again when opened
The versions the search uses	One version of each module, with its search and AI files; about 3.5 MB each	About 600 versions	Never removed; the `D8DocumentationPinnedVersionsTooLarge` alert fires when they take more than 2 GiB

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The documentation module: configuration

> The module lifecycle stage: General Availability

The module does not have any mandatory parameters.



The module has 9 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `documentation` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

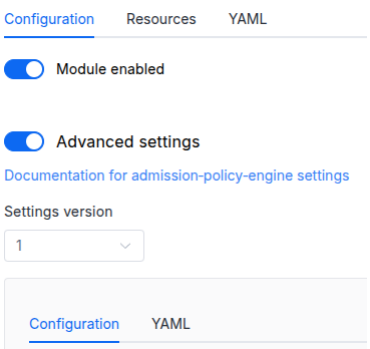
```
d8 system module enable documentation
```

- **Using ModuleConfig `documentation`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `documentation` (create it if necessary);

  Example of a manifest to enable module `documentation`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: documentation
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `documentation` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `documentation` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `documentation`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `documentation` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc documentation
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `documentation` using the example below. Fill in the `spec.settings` section with the required module

parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `documentation`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: documentation
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.auth**
    object

    Parameters to authenticate and authorize access to the documentation web interface.

    - **settings.auth.allowedUserEmails**
      array of strings

      Array of emails of users that can access module's public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

      Array of groups whose users can browse the documentation.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

      > **Caution!** If the module works together with the `user-authn` module, add the allowed groups to the DexProvider configuration.

      Default: `[]`

      Examples:

      ```
      allowedUserGroups:
      - admin
      - users
      ```

      ```
      allowedUserGroups: []
      ```

    - **settings.auth.externalAuthentication**
      object

      Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

      > External authentication is enabled automatically if the user-authn module is enabled.

      - **settings.auth.externalAuthentication.authSignInURL**
        string

        URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response).

        Default:

        Example:

        ```
        authSignInURL: https://$host/dex-authenticator/sign_in
        ```

      - **settings.auth.externalAuthentication.authURL**
        string

        URL of the authentication service.

        If the user is authenticated, the service should return an HTTP 200 response code.

        Default:

        Example:

        ```
        authURL: https://documentation-dex-authenticator.d8-system.svc.cluster.local/dex-authenticator/auth
        ```

  - **settings.highAvailability**
    boolean

    Manually enable the high availability mode.

    By default, Deckhouse Platform automatically decides whether to enable the HA mode. Learn more about the high availability mode for modules.

    In the HA mode the documentation runs in two replicas on different nodes; the "High availability mode" section of the usage page of the module tells what it needs and why S3 helps.

    Examples:

    ```
    highAvailability: true
    ```

    ```
    highAvailability: false
    ```

  - **settings.https**
    object

    What certificate type to use.

    This parameter completely overrides the `global.modules.https` settings.

    Examples:

```
https:
  mode: Disabled
```

```
https:
  mode: OnlyInURI
```

```
https:
  mode: CustomCertificate
  customCertificate:
    secretName: foobar
```

```
https:
  mode: CertManager
  certManager:
    clusterIssuerName: letsencrypt
```

- **settings.https.certManager**
  object

  Parameters for certmanager.

  - **settings.https.certManager.clusterIssuerName**
    string

    What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

    Default: `letsencrypt`

    Example:

    ```
    clusterIssuerName: letsencrypt
    ```

- **settings.https.customCertificate**
  object

  Parameters for custom certificate usage.

  - **settings.https.customCertificate.secretName**
    string

    Name of the Secret in the `d8-system` namespace to use with the documentation web UI.

    This secret must have the kubernetes.io/tls format.

- **settings.https.mode**
  string

  HTTPS usage mode:

  - `CertManager` — the web UI is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate` — the web UI is accessed over HTTPS using a certificate from the `d8-system` namespace.
  - `Disabled` — in this mode, the documentation web UI can only be accessed over HTTP.
  - `OnlyInURI` — HTTP access with an external HTTPS balancer. The balancer terminates HTTPS, and all links in `user-authn` are generated with the HTTPS scheme. The balancer must provide redirection from HTTP to HTTPS.

  Default: `CertManager`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  Class of the Ingress controller of the documentation web UI.

  An optional parameter; by default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.moduleStorage**
  object

  Storage of the documentation of module versions, prepared when a version is opened for the first time.

  - **settings.moduleStorage.s3**
    object

    Where the prepared documentation of module versions is kept besides the cache of the documentation pod.

    - **settings.moduleStorage.s3.external**
      object

      S3 storage of your own for `type: External`. The connection and the keys are taken from a Secret; the keys it holds are listed in the “S3 storage of your own” section of the usage page of the module.

      - **settings.moduleStorage.s3.external.prefix**
        string

        Part of the bucket the module uses: every object it reads, writes or deletes has a key starting with this prefix. Other objects of the bucket stay untouched, so the bucket may be shared.

        Default: `documentation/`

        Pattern: `^([A-Za-z0-9][A-Za-z0-9._-]*/)+$`

        Examples:

        ```
        prefix: documentation/
        ```

        ```
        prefix: clusters/main/documentation/
        ```

      - **settings.moduleStorage.s3.external.secretRef**
        object

        Required value

        Secret with the connection and the keys of the S3 storage, in any namespace.

        Deckhouse Platform copies it into the `documentation-s3-connection` Secret in `d8-system`. The documentation pod uses that Secret. After the Secret is created or changed, the documentation pod restarts within 5 minutes. Until the Secret appears, the versions are kept in the pod only.

        - **settings.moduleStorage.s3.external.secretRef.name**
          string

          Required value

Name of the Secret.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

Maximum length: `253`

Example:

```
name: documentation-s3
```

- **settings.moduleStorage.s3.external.secretRef.namespace**
  string

  Required value

  Namespace of the Secret.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

  Maximum length: `63`

  Examples:

  ```
  namespace: d8-system
  ```

  ```
  namespace: documentation-storage
  ```

- **settings.moduleStorage.s3.external.size**
  string

  How much of the bucket the module may take under the prefix. Above 80% of it the module deletes stored versions until 60% is left, in this order:

  1. Copies replaced after an update of the documentation template.
  2. Versions opened by readers.
  3. Versions used by the search.

  Within each group the versions stored longest ago go first.

  Default: `5Gi`

  Pattern: `^[1-9][0-9]*(Mi|Gi|Ti)$`

  Examples:

  ```
  size: 5Gi
  ```

  ```
  size: 20Gi
  ```

- **settings.moduleStorage.s3.type**
  string
  - `Disabled` — only in the pod: after a restart of the pod the versions are prepared again when opened. In the high availability mode each replica prepares and keeps the versions on its own, with twice the CPU and the requests to the registry; turn S3 on for that mode.
  - `System` — also in the system S3 storage of the system-s3 module: after a restart of the pod the versions open from it in a fraction of a second. The module creates a 5 GiB bucket for it. Requires the `system-s3` module to be enabled: without it the versions are kept in the pod only, and the `D8DocumentationSystemS3Disabled` alert fires.
  - `External` — also in an S3 storage of your own, set in the `external` section.

  Default: `Disabled`

  Allowed values: `Disabled`, `System`, `External`

- **settings.nodeSelector**
  object

  Same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.tolerations**
  array of objects

  Same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

The documentation module: usage

> The module lifecycle stage: General Availability

An example of the module configuration

The module runs on the system nodes, authenticates users through an external authentication service and lets in the users of the `admins` group:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: documentation
spec:
  version: 1
  enabled: true
  settings:
    nodeSelector:
      node-role/system: ""
    tolerations:
    - key: dedicated.deckhouse.io
      operator: Equal
      value: system
    auth:
      externalAuthentication:
        authURL: "https://<applicationDomain>/auth"
        authSignInURL: "https://<applicationDomain>/sign-in"
      allowedUserGroups:
      - admins
```

Authentication

The user-authn module provides authentication by default. Also, an external authentication service can be set in the auth.externalAuthentication parameter. When the `user-authn` module is disabled and the `auth.externalAuthentication` parameter is not set, the module uses basic authentication with the user `admin` and an auto-generated password.

Use `d8 k` to see the password:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values documentation -o json | jq '.internal.auth.password'
```

Delete the Secret to re-generate the password:

```
d8 k -n d8-system delete secret/documentation-basic-auth
```

S3 storage of your own

With `moduleStorage.s3.type: External` the module keeps the prepared documentation of module versions in an S3 bucket of your own. Create a Secret in any namespace with these keys. Deckhouse Platform copies it into the `documentation-s3-connection` Secret in `d8-system`. After the Secret is created or changed, the documentation pod restarts within 5 minutes. Keep only the connection keys in the Secret: all of its keys are copied.

Key	Required	Value
`S3_ENDPOINT`	yes	The address of the storage, `https://` only.
`S3_BUCKET`	yes	The name of the bucket.
`S3_REGION`	yes	The region of the bucket, for example `us-east-1`.
`AWS_ACCESS_KEY_ID`	yes	The access key.
`AWS_SECRET_ACCESS_KEY`	yes	The secret key.
`S3_CA_CERT`	no	The CA certificate of the storage in PEM format, when the system ones do not trust it.

The key needs the rights to read, write, list and delete objects under the prefix from moduleStorage.s3.external.prefix (`documentation/` by default). The module reads, writes and deletes no object outside of the prefix, so the S3 bucket may be shared with other data.

An example of the Secret and of the module configuration that uses it:

```
apiVersion: v1
kind: Secret
metadata:
  name: documentation-s3
  namespace: documentation-storage
stringData:
  S3_ENDPOINT: https://s3.example.com
  S3_BUCKET: documentation
  S3_REGION: us-east-1
  AWS_ACCESS_KEY_ID: <access key>
  AWS_SECRET_ACCESS_KEY: <secret key>
---
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: documentation
spec:
  version: 1
  settings:
    moduleStorage:
      s3:
        type: External
        external:
          secretRef:
            namespace: documentation-storage
            name: documentation-s3
```

While the Secret does not exist or the storage does not answer, the versions are kept in the pod only. After a restart of the pod the module prepares them again. The `docs_builder ondemand_s3_ready` metric of the documentation pod is 0 then. A mistake in the Secret (a missing or misnamed key, an `http://` address) is written to the log of the `builder` container of the documentation pod. When the storage stays not ready for 15 minutes, the `D8DocumentationS3NotReady` alert fires.

High availability mode

The high availability mode is turned on by the highAvailability parameter; when the parameter is not set, the HA mode of the cluster applies. In this mode the documentation runs in two replicas on different nodes, so two nodes the module can run on are needed (the system nodes by default). With one such node the second replica stays `Pending`, and the PodDisruptionBudget blocks draining the node with the running replica until the second replica runs on another node. The authenticator of the documentation (DexAuthenticator), if it is deployed, also runs in two replicas.

A user stays on one replica: the `d8-documentation-affinity` cookie picks it. Through an Ingress the cookie lives 24 hours, also after the browser is closed; through the Gateway API it lives until the browser is closed. That replica prepares and keeps the module versions the user opens.

Turn on keeping versions in S3 (moduleStorage.s3.type: `System` or `External`): then a version prepared by one replica is opened by the other from S3 without

preparing it again, and a user moved to the other replica when theirs restarts does not wait for the versions again. Without S3 each replica reads the container registry on its own and prepares on its own the versions the search uses and the versions its users open. In this case the documentation takes twice the CPU and sends twice the requests to the registry, and a user moved to the other replica waits for a version they already opened once more.

With S3 one replica, picked through a Lease, reads the container registry and prepares the versions the search uses; the other takes them from S3 within a minute and prepares only the versions its users open. A replica starts taking users once it has received the versions from S3, at most 5 minutes after its start.

After an update of Deckhouse Platform that changes the look of the documentation, the versions kept in S3 open as they were and are prepared again in the background, one at a time, when no user waits for a version. A version that the new look can not prepare stays as it was.

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The infra-provider-baremetal module

⚠ The module lifecycle stage: Experimental

The module has requirements for installation

Before enabling the module, you need to allow the use of experimental modules in the `deckhouse` ModuleConfig. To do this, set the allowExperimentalModules parameter to `true`.

The `infra-provider-baremetal` module allows `node-manager` to create CloudEphemeral nodes on physical servers. It manages servers through their baseboard management controllers (BMCs), installs an operating system on them over the network, and joins them to the cluster. The module is based on components of the Metal3 project and the Ironic service.

Key features

The module allows you to perform the following tasks:

- Register physical servers by BMC address and credentials with automatic selection of the Redfish or IPMI protocol
- Create and delete nodes in node groups with the `CloudEphemeral` type, including scaling groups from zero with cluster autoscaler
- Install an operating system image on servers and clean disk metadata when a server is released
- Deploy Ironic in the cluster or connect to an existing Ironic instance
- Protect server boot traffic with TLS

How it works

A node on a physical server appears in the cluster in the following order:

1. The administrator describes the server in a BareMetalInstance resource. The module connects to the BMC, finds the server by its UUID, and creates a Metal3 BareMetalHost resource for it.
2. Ironic boots the server over the network, collects hardware information, and moves the server to the `available` state.
3. When a node group with a BareMetalInstanceClass instance class needs a new node, Cluster API picks a free server by labels, and Ironic writes the image from the BareMetalImage resource to its disk.
4. The server boots the installed operating system, runs the initial configuration script, and joins the cluster as a node of the group.
5. When the node is deleted, Ironic cleans the server disk metadata by default, and the server becomes available for new nodes again.

Requirements

The module requires the following:

- A static cluster with no `cloud-provider-*` cloud provider modules enabled
- Servers whose BMC supports the Redfish or IPMI protocol and is reachable over the network from the cluster
- A provisioning network where servers boot over PXE and cluster nodes connected to it where Ironic can start if it runs in the cluster
- An operating system image with cloud-init and `python3`, where cloud-init configures network interfaces by itself, for example, over DHCP
- A storage module whose CSI driver runs on the created nodes

A storage module is required because Deckhouse Platform does not place workloads on a new node until a CSI driver registers on it.

Limitations

The module has the following limitations:

- Node groups use a single `default` zone.
- A BMC CA certificate in the `spec.bmc.tls.caCertRef` parameter can be set only if Ironic runs in the cluster.
- TLS for server boot is available only if Ironic runs in the cluster and uses the built-in DHCP server.

Third-party components

List of third-party software used in the `infra-provider-baremetal` module:

- Cluster API Provider Metal3 v1.9.5

  License: Apache License 2.0

  Infrastructure provider for Kubernetes Cluster API backed by Metal3.

- Metal3 Bare Metal Operator v0.13.1

  License: Apache License 2.0

  Kubernetes operator for provisioning bare metal hosts with Ironic.

- Ironic Standalone Operator v0.10.0

  License: Apache License 2.0

  Kubernetes operator managing standalone Ironic deployments for Metal3.

- Metal3 Ironic Image v39.0.0

  License: Apache License 2.0

  Container image to run OpenStack Ironic as part of Metal3.

- OpenStack Ironic 752100ac7ff8774510a34963839aaed93bbe8589

  License: Apache License 2.0

  Bare metal provisioning service.

- OpenStack Ironic Python package 39.0.0

  License: Apache License 2.0

  Python distribution version of the pinned Ironic source commit.

- Ironic Python Agent ramdisk ipa-centos9-stable-2026.1

  License: Apache License 2.0

  Default IPA deployment kernel and initramfs.

- pip 25.3

License: MIT

Python package installer used during the Ironic build.

- setuptools 84.2.1

  License: MIT

  Python packaging tools used during the Ironic build.

- wheel 0.38.4

  License: MIT

  Python wheel builder used during the Ironic build.

- pbr 7.1.3

  License: Apache License 2.0

  OpenStack Python build backend used for Ironic.

- Python wheels 0.19

  License: MIT

  Python dependency wheels supplied by the Deckhouse package manager.

- RPM rpm-4.20.1-release

  License: GPL-2.0-or-later

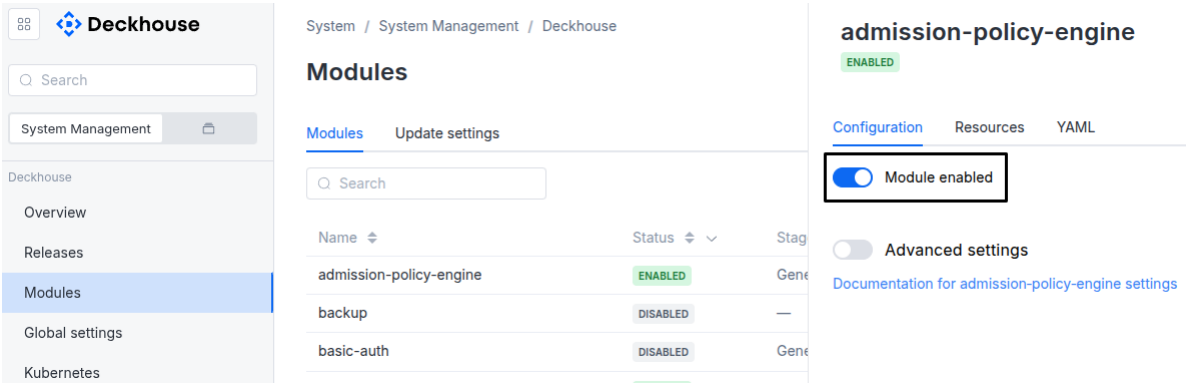
  Upstream rpm2cpio script used to extract signed EFI boot loaders during the Ironic build.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: Experimental
>
> The module has requirements for installation
>
> Before enabling the module, you need to allow the use of experimental modules in the `deckhouse` ModuleConfig. To do this, set the allowExperimentalModules parameter to `true`.

The module is disabled by default. To enable it, create the `infra-provider-baremetal` ModuleConfig and set the `nodes.parameters.ironic` parameter in it. Until the parameter is set, the module components are not started.



Choosing the Ironic mode and the setup procedure are described on the “Usage” page.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `infra-provider-baremetal` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

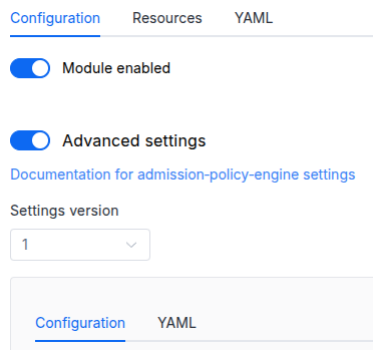
```
d8 system module enable infra-provider-baremetal
```

- **Using ModuleConfig `infra-provider-baremetal`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `infra-provider-baremetal` (create it if necessary);

  Example of a manifest to enable module `infra-provider-baremetal`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: infra-provider-baremetal
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `infra-provider-baremetal` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `infra-provider-baremetal` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `infra-provider-baremetal`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `infra-provider-baremetal` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc infra-provider-baremetal
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `infra-provider-baremetal` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `infra-provider-baremetal`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: infra-provider-baremetal
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the Deckhouse version: 1.68.0 and above.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.nodes**
    object

    Settings for creating cluster nodes on physical servers.

    - **settings.nodes.parameters**
      object

      Required value

      Parameters for creating cluster nodes on physical servers.

      - **settings.nodes.parameters.ironic**
        object

        Required value

        Settings of the Ironic service that the module uses to manage servers and install the operating system on them.

        To connect to Ironic deployed outside the cluster, set the `externalInstance` parameter. To deploy Ironic in the cluster, set the `provisioningNetwork` and `dhcp` parameters.

        - **settings.nodes.parameters.ironic.bmcProbeTimeoutSeconds**
          integer

          Timeout of a single protocol check when connecting to a baseboard management controller (BMC), in seconds.

          Default: `15`

          Allowed values: `1 <= X <= 300`
        - **settings.nodes.parameters.ironic.dhcp**
          object

          DHCP settings in the provisioning network.

          Set either the `internal` or the `external` parameter.

          - **settings.nodes.parameters.ironic.dhcp.external**
            object

            Settings of an external DHCP server in the provisioning network.

            The module does not deploy a DHCP server and does not configure the external one. Configure PXE boot of servers on the external DHCP server yourself.

            - **settings.nodes.parameters.ironic.dhcp.external.pxeBootFile**
              object

              Boot file names configured on the external DHCP server.

              - **settings.nodes.parameters.ironic.dhcp.external.pxeBootFile.bios**
                string

Boot file name for servers in legacy BIOS mode.

Length: `1..1024`

- **settings.nodes.parameters.ironic.dhcp.external.pxeBootFile.uefi**
  string

  Boot file name for servers in UEFI mode.

  Length: `1..1024`

- **settings.nodes.parameters.ironic.dhcp.external.pxeBootServer**
  string

  Required value

  IPv4 address of the PXE server that the external DHCP server passes to servers.

- **settings.nodes.parameters.ironic.dhcp.internal**
  object

  Settings of the built-in DHCP server that Ironic runs in the provisioning network.

  - **settings.nodes.parameters.ironic.dhcp.internal.disableDNS**
    boolean

    Disables the built-in DNS server and prevents DHCP from passing a DNS server address to servers.

    By default, DHCP passes `dnsAddress` if specified. Otherwise, Ironic serves DNS and forwards queries using the resolver configuration of its pod.

    Set to `true` for an isolated provisioning network that does not need DNS.

    When `true`, cannot be used with the `dnsAddress` parameter.

    Default: `false`

  - **settings.nodes.parameters.ironic.dhcp.internal.dnsAddress**
    string

    DNS server address that the DHCP server passes to servers.

    Cannot be used if the `disableDNS` parameter is `true`.

  - **settings.nodes.parameters.ironic.dhcp.internal.gatewayAddress**
    string

    Default gateway address that the DHCP server passes to servers.

  - **settings.nodes.parameters.ironic.dhcp.internal.networkCIDR**
    string

    Required value

    Provisioning network subnet in CIDR format.

  - **settings.nodes.parameters.ironic.dhcp.internal.rangeBegin**
    string

    Required value

    First IPv4 address of the range the DHCP server assigns to servers.

  - **settings.nodes.parameters.ironic.dhcp.internal.rangeEnd**
    string

    Required value

    Last IPv4 address of the range the DHCP server assigns to servers.

- **settings.nodes.parameters.ironic.externalInstance**
  object

  Settings for connecting to Ironic deployed outside the cluster.

  If the parameter is set, the module does not deploy Ironic or a DHCP server. Cannot be used with the `provisioningNetwork`, `dhcp`, `ramdiskImageRef`, `ipxeFirmwareRef`, and `provisioningTLS` parameters.

  - **settings.nodes.parameters.ironic.externalInstance.credentialsRef**
    object

    Reference to the Secret with credentials for the external Ironic API.

    The Secret must contain the `identity` key with the user name and the `secret` key with the password.

    - **settings.nodes.parameters.ironic.externalInstance.credentialsRef.kind**
      string

      Required value

      Kind of the resource with external Ironic API credentials.

      Allowed values: `Secret`

    - **settings.nodes.parameters.ironic.externalInstance.credentialsRef.name**
      string

      Required value

      Name of the Secret with external Ironic API credentials.

      Length: `1..253`

    - **settings.nodes.parameters.ironic.externalInstance.credentialsRef.namespace**
      string

      Required value

      Namespace of the Secret with external Ironic API credentials.

      Only the `d8-infra-provider-baremetal` namespace is supported.

      Pattern: `^d8-infra-provider-baremetal$`

  - **settings.nodes.parameters.ironic.externalInstance.endpoint**
    string

    Required value

    URL of the external Ironic API.

    The URL must end with `/v1` or `/v1/` and be reachable from the cluster.

    Pattern: `^https?://.+/v1/?$`

    Maximum length: `2048`

  - **settings.nodes.parameters.ironic.externalInstance.tls**

object

TLS settings for connecting to the external Ironic.

- **settings.nodes.parameters.ironic.externalInstance.tls.caCertRef**
  object

  Reference to the Secret key with the CA certificate that issued the external Ironic API certificate.

  - **settings.nodes.parameters.ironic.externalInstance.tls.caCertRef.key**
    string

    Required value

    Key in the Secret that holds the external Ironic CA certificate.

    Length: `1..253`
  - **settings.nodes.parameters.ironic.externalInstance.tls.caCertRef.kind**
    string

    Required value

    Kind of the resource with the external Ironic CA certificate.

    Allowed values: `Secret`
  - **settings.nodes.parameters.ironic.externalInstance.tls.caCertRef.name**
    string

    Required value

    Name of the Secret with the external Ironic CA certificate.

    Length: `1..253`
  - **settings.nodes.parameters.ironic.externalInstance.tls.caCertRef.namespace**
    string

    Required value

    Namespace of the Secret with the external Ironic CA certificate.

    Only the `d8-infra-provider-baremetal` namespace is supported.

    Pattern: `^d8-infra-provider-baremetal$`
- **settings.nodes.parameters.ironic.externalInstance.tls.clientCertRef**
  object

  Reference to the Secret with the client certificate and private key for mutual TLS authentication.

  - **settings.nodes.parameters.ironic.externalInstance.tls.clientCertRef.certKey**
    string

    Required value

    Key in the Secret that holds the client certificate.

    Length: `1..253`
  - **settings.nodes.parameters.ironic.externalInstance.tls.clientCertRef.kind**
    string

    Required value

    Kind of the resource with the client certificate.

    Allowed values: `Secret`
  - **settings.nodes.parameters.ironic.externalInstance.tls.clientCertRef.name**
    string

    Required value

    Name of the Secret with the client certificate and private key.

    Length: `1..253`
  - **settings.nodes.parameters.ironic.externalInstance.tls.clientCertRef.namespace**
    string

    Required value

    Namespace of the Secret with the client certificate and private key.

    Only the `d8-infra-provider-baremetal` namespace is supported.

    Pattern: `^d8-infra-provider-baremetal$`
  - **settings.nodes.parameters.ironic.externalInstance.tls.clientCertRef.privateKey**
    string

    Required value

    Key in the Secret that holds the client private key.

    Length: `1..253`
- **settings.nodes.parameters.ironic.externalInstance.tls.insecure**
  boolean

  Disables verification of the external Ironic API certificate.

  Do not use in production environments.

  Default: `false`

- **settings.nodes.parameters.ironic.ipxeFirmwareRef**
  object

  Reference to the BareMetalIPXEFirmware resource with iPXE firmware for server boot over TLS.

  Used only together with the `provisioningTLS` parameter. If the parameter is set without `provisioningTLS`, the module does not create Ironic.

  - **settings.nodes.parameters.ironic.ipxeFirmwareRef.kind**
    string

    Required value

    Kind of the resource with iPXE firmware.

    Allowed values: `BareMetalIPXEFirmware`
  - **settings.nodes.parameters.ironic.ipxeFirmwareRef.name**
    string

Required value

Name of the BareMetalIPXEFirmware resource.

Length: `1..253`

- **settings.nodes.parameters.ironic.provisioningNetwork**
  object

  Settings of the provisioning network where servers boot over PXE.

  Used only if the module deploys Ironic in the cluster.

  - **settings.nodes.parameters.ironic.provisioningNetwork.interface**
    string

    Required value

    Name of the network interface connected to the provisioning network on the node where Ironic runs.

    Pattern: `^[A-Za-z0-9_.:-]{1,15}$`

  - **settings.nodes.parameters.ironic.provisioningNetwork.ipAddress**
    string

    Required value

    Free IPv4 address in the provisioning network.

    Ironic assigns this address to the interface from the `interface` parameter and accepts server connections on it.

- **settings.nodes.parameters.ironic.provisioningTLS**
  object

  Enables TLS for the Ironic API and for file downloads by servers.

  Supported only with the built-in DHCP server (`dhcp.internal`). Requires the `ramdiskImageRef` and `ipxeFirmwareRef` parameters. The module creates Ironic only when the Secret and the resources from these parameters are ready.

  - **settings.nodes.parameters.ironic.provisioningTLS.certificateRef**
    object

    Required value

    Reference to the Secret with the Ironic TLS certificate in the `d8-infra-provider-baremetal` namespace.

    The Secret must have the `kubernetes.io/tls` type, contain the `tls.crt`, `tls.key`, and `ca.crt` keys, and have the `environment.metal3.io/ironic-standalone-operator: "true"` label.

    - **settings.nodes.parameters.ironic.provisioningTLS.certificateRef.name**
      string

      Required value

      Name of the Secret with the Ironic TLS certificate.

      Length: `1..253`

- **settings.nodes.parameters.ironic.ramdiskImageRef**
  object

  Reference to the BareMetalRamdiskImage resource with the Ironic Python Agent (IPA) image for server boot.

  If the parameter is not set, the built-in IPA image is used. The parameter is required if the `provisioningTLS` parameter is set.

  - **settings.nodes.parameters.ironic.ramdiskImageRef.kind**
    string

    Required value

    Kind of the resource with the IPA image.

    Allowed values: `BareMetalRamdiskImage`

  - **settings.nodes.parameters.ironic.ramdiskImageRef.name**
    string

    Required value

    Name of the BareMetalRamdiskImage resource.

    Length: `1..253`

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom resources

i The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

⚠ The module lifecycle stage: Experimental

The module has requirements for installation

Before enabling the module, you need to allow the use of experimental modules in the `deckhouse` ModuleConfig. To do this, set the allowExperimentalModules parameter to `true`.

BareMetalImage

Scope: Cluster
Version: v1

- **metadata**
  object
- **spec**
  object

  Required value

  Operating system disk image installed on physical servers.

  - **spec.direct**
    object

    Required value

Image source and data for its integrity check.

Cannot be changed after creation. To update the operating system image, create a BareMetalImage with a new name and update the imageRef in BareMetalInstanceClass.

- **spec.direct.checksum**
  string

  Required value

  Image checksum in hexadecimal format.

  Its length must match the algorithm in the `checksumType` parameter.

  Pattern: `^[a-fA-F0-9]+$`

  Length: `1..128`
- **spec.direct.checksumType**
  string

  Required value

  Checksum algorithm.

  Allowed values: `md5`, `sha256`, `sha512`
- **spec.direct.format**
  string

  Required value

  Disk image format.

  Allowed values: `qcow2`, `raw`
- **spec.direct.url**
  string

  Required value

  Image URL.

  The image must be available at this URL to Ironic and to servers during operating system installation.

  Pattern: `^https?://`

  Maximum length: `2048`

BareMetalInstance

Short names: bmi

Scope: Cluster
Version: v1

- **metadata**
  object
- **spec**
  object

  Required value

  Cluster-wide physical server and settings for access to its baseboard management controller (BMC).

  - **spec.bmc**
    object

    Required value

    Settings for connecting to the server BMC.

    - **spec.bmc.allowHTTP**
      boolean

      Allows connecting to the BMC using Redfish over HTTP if the HTTPS connection fails.

      In this case, BMC credentials are sent in plain text. Cannot be used with the `tls.caCertRef` parameter.

      Default: `false`
    - **spec.bmc.credentialsRef**
      object

      Required value

      Reference to the Secret with BMC credentials. If namespace is omitted, the Secret is read from `d8-infra-provider-baremetal`.

      The Secret must have the `cloud-provider.deckhouse.io/credentials` type and contain the following keys:

      - `authScheme` set to `userPassword`
      - `identity` with the BMC user name
      - `secret` with the BMC user password
      - **spec.bmc.credentialsRef.kind**
        string

        Required value

        Kind of the resource with BMC credentials.

        Allowed values: `Secret`
      - **spec.bmc.credentialsRef.name**
        string

        Required value

        Name of the Secret with BMC credentials.

        Length: `1..253`
      - **spec.bmc.credentialsRef.namespace**
        string

        Namespace of the Secret with BMC credentials.

        Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

        Length: `1..63`
    - **spec.bmc.insecure**
      boolean

      Disables BMC certificate verification.

      Cannot be used with the `tls.caCertRef` parameter.

Default: `false`

- **spec.bmc.ipAddress**
  string

  Required value

  BMC IPv4 address.

- **spec.bmc.port**
  integer

  BMC port.

  If the parameter is set, the module connects to the BMC on this port over all protocols. If the parameter is not set, the module uses the standard ports:

  - `443` for Redfish over HTTPS
  - `80` for Redfish over HTTP if the `allowHTTP` parameter is enabled
  - `623` for IPMI

  Allowed values: `1 <= X <= 65535`

- **spec.bmc.systemUUID**
  string

  Required value

  Server UUID reported by its BMC.

  Over Redfish, the module compares this value with the system UUID returned by the BMC, and over IPMI with the system identifier (System GUID).

- **spec.bmc.tls**
  object

  Settings for verifying the BMC certificate when connecting over Redfish.

  - **spec.bmc.tls.caCertRef**
    object

    Reference to the Secret key with the PEM-encoded CA certificate that issued the BMC certificate.

    The Secret must be in the `d8-infra-provider-baremetal` namespace.

    Supported only if Ironic runs in the cluster. If the module is connected to an external Ironic, an error appears in the resource status, and the module does not create a BareMetalHost for it.

    - **spec.bmc.tls.caCertRef.key**
      string

      Required value

      Key in the Secret that holds the PEM-encoded BMC CA certificate.

      Length: `1..253`

    - **spec.bmc.tls.caCertRef.kind**
      string

      Required value

      Kind of the resource with the BMC CA certificate.

      Allowed values: `Secret`

    - **spec.bmc.tls.caCertRef.name**
      string

      Required value

      Name of the Secret with the BMC CA certificate.

      Length: `1..253`

- **spec.bootMACAddress**
  string

  Required value

  MAC address of the server network interface used for PXE boot.

  Pattern: `^([0-9a-fA-F]{2}:){5}[0-9a-fA-F]{2}$`

- **spec.online**
  boolean

  Desired power state of the server.

  Applied when the physical host is created and when this parameter changes on a host that is not used for a node.

  While the server is used for a node, CAPM3 controls its power; changes to this parameter are ignored. After node deletion, the module preserves the power state requested by CAPM3 until this parameter is changed explicitly.

  Default: `false`

- **spec.rootDeviceHints**
  object

  Root disk hints.

  If the parameter is not set, Ironic selects the root disk by itself based on the hardware information.

  - **spec.rootDeviceHints.deviceName**
    string

    Linux disk name, for example, `/dev/vda`, or a path to the disk in the `/dev/disk/by-path/` directory.

    Only a disk with exactly the same value matches.

    Maximum length: `256`

  - **spec.rootDeviceHints.hctl**
    string

    Disk address on the SCSI bus, for example, `0:0:0:0`.

    Only a disk with exactly the same address matches.

    Maximum length: `256`

  - **spec.rootDeviceHints.minSizeGigabytes**
    integer

    Minimum disk size in gigabytes.

    Allowed values: `0 <= X`

  - **spec.rootDeviceHints.model**
    string

Disk model.

A disk matches if its model name contains the specified string. For example, `860 EVO` matches the `Samsung SSD 860 EVO 500GB` model.

Maximum length: `256`

- **spec.rootDeviceHints.rotational**
  boolean

  Disk type.

  If `true`, a hard disk drive (HDD) is selected. If `false`, a solid-state drive, for example, SSD or NVMe, is selected.

- **spec.rootDeviceHints.serialNumber**
  string

  Disk serial number.

  Only a disk with exactly the same serial number matches.

  Maximum length: `256`

- **spec.rootDeviceHints.vendor**
  string

  Disk vendor.

  A disk matches if its vendor name contains the specified string. For example, `Samsung` matches the `Samsung Electronics` vendor.

  Maximum length: `256`

- **spec.rootDeviceHints.wwn**
  string

  World Wide Name (WWN) of the disk.

  Only a disk with exactly the same WWN matches.

  Maximum length: `256`

- **spec.rootDeviceHints.wwnVendorExtension**
  string

  Vendor extension of the disk WWN.

  Only a disk with exactly the same value matches.

  Maximum length: `256`

- **spec.rootDeviceHints.wwnWithExtension**
  string

  Disk WWN together with the vendor extension.

  Only a disk with exactly the same value matches.

  Maximum length: `256`

- **status**
  object

  Current server state and the result of processing the resource by the module.

  - **status.conditions**
    array of objects

    Conditions that describe the resource state.

    Each time the module processes the resource, it sets the `BMCResolved` condition. The condition is `True` if the module connected to the BMC, found the server with the UUID from the `spec.bmc.systemUUID` parameter, and created or updated the BareMetalHost resource for it.

    If the module failed to complete one of these steps, the condition is `False`. The `reason` field identifies the step, and the `message` field explains the error.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      Time when the condition value or reason last changed.

    - **status.conditions.message**
      string

      Required value

      Explanation of the condition value.

      The message is empty if the condition is `True`. The main messages for the `False` value are described in the Checking server state section.

    - **status.conditions.observedGeneration**
      integer

      Resource generation (`metadata.generation`) for which the condition was set.

    - **status.conditions.reason**
      string

      Required value

      Code of the reason why the condition has its current value.

      If the condition is `True`, the reason is `BMCResolved`. If the condition is `False`, the reason identifies the step that the module failed to complete, for example `CredentialsInvalid` or `BMCResolutionFailed`.

    - **status.conditions.status**
      string

      Required value

      Condition value.

      The value is `True` or `False`.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Condition type.

  - **status.host**
    object

    Server state according to the BareMetalHost resource with the same name in the `d8-cloud-instance-manager` namespace.

    The field is filled in only if the last processing of the resource succeeded.

        - **status.host.desiredOnline**
          boolean

          Desired power state of the server.

        - **status.host.error**
          string

          Error message if an operation on the server failed.

          The error details are in the `status.errorMessage` field of the BareMetalHost resource with the same name.

        - **status.host.poweredOn**
          boolean

          Actual power state of the server.

        - **status.host.state**
          string

          Current server state according to the BareMetalHost resource, for example, `available` or `provisioned`.

    - **status.message**
      string

      Error message if the module failed to process the resource.

    - **status.observedGeneration**
      integer

      Resource generation (`metadata.generation`) last processed by the module.

BareMetalInstanceClass

Scope: Cluster
Version: v1

- **metadata**
  object
- **spec**
  object

  Required value

  Parameters of CloudEphemeral nodes created on physical servers.

    - **spec.capacity**
      object

      Node resources that cluster autoscaler takes into account when scaling the group from zero.

        - **spec.capacity.cpu**
          integer or string

          Required value

          Node CPU resources available for workloads.

          Pattern: `^[0-9]+m?$`

          Example:

          ```
          cpu: 4000m
          ```

        - **spec.capacity.memory**
          integer or string

          Required value

          Node memory available for workloads.

          Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

          Example:

          ```
          memory: 8Gi
          ```

    - **spec.disableAutomatedCleaning**
      boolean

      Disables automatic disk cleaning on servers used for the group nodes.

      By default, Ironic cleans disk metadata.

      Default: `false`

    - **spec.hostSelector**
      object

      Selector that picks servers by the labels of BareMetalInstance resources.

      If the parameter is not set, nodes are created on any free servers.

        - **spec.hostSelector.matchExpressions**
          array of objects

          Selects servers using Kubernetes label selector expressions.

            - **spec.hostSelector.matchExpressions.key**
              string

              Required value

              Label key.

              Maximum length: `253`

            - **spec.hostSelector.matchExpressions.operator**
              string

              Required value

              Operator that compares the label value with the values from the `values` parameter.

              Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

            - **spec.hostSelector.matchExpressions.values**
              array of strings

              Label values for the `In` and `NotIn` operators.

              Do not set for the `Exists` and `DoesNotExist` operators.

                - **Element of the array**

string

Maximum length: `63`

- **spec.hostSelector.matchLabels**
  object

  Selects servers that have all the listed labels with the specified values.

- **spec.imageRef**
  object

  Required value

  Reference to the BareMetalImage resource with the operating system image for the nodes.

  - **spec.imageRef.kind**
    string

    Required value

    Kind of the resource with the operating system image.

    Allowed values: `BareMetalImage`

  - **spec.imageRef.name**
    string

    Required value

    Name of the BareMetalImage resource.

    Length: `1..253`

- **spec.nodeReuse**
  boolean

  Allows reusing the same servers when the group nodes are updated.

  Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

    NodeGroups that use this instance class.

BareMetalIPXEFirmware

Scope: Cluster
Version: v1

- **metadata**
  object
- **spec**
  object

  Required value

  iPXE firmware for booting servers if TLS is enabled for Ironic in the cluster.

  - **spec.direct**
    object

    Required value

    Firmware files and their SHA-256 checksums for the supported boot modes.

    - **spec.direct.bios**
      object

      Required value

      iPXE firmware for legacy BIOS boot.

      - **spec.direct.bios.sha256**
        string

        Required value

        SHA-256 checksum of the iPXE firmware for BIOS.

        Pattern: `^[a-f0-9]{64}$`

      - **spec.direct.bios.url**
        string

        Required value

        URL of the iPXE firmware for BIOS.

        Only HTTPS is supported.

        Pattern: `^https://`

        Maximum length: `2048`

    - **spec.direct.uefiArm64**
      object

      iPXE firmware for UEFI boot on ARM64.

      If the parameter is not set, the built-in firmware is used.

      - **spec.direct.uefiArm64.sha256**
        string

        Required value

        SHA-256 checksum of the iPXE firmware for UEFI on ARM64.

        Pattern: `^[a-f0-9]{64}$`

      - **spec.direct.uefiArm64.url**
        string

        Required value

        URL of the iPXE firmware for UEFI on ARM64.

        Only HTTPS is supported.

        Pattern: `^https://`

        Maximum length: `2048`

- **spec.direct.uefiX86_64**
  object

  Required value

  iPXE firmware for UEFI boot on x86_64.

  - **spec.direct.uefiX86_64.sha256**
    string

    Required value

    SHA-256 checksum of the iPXE firmware for UEFI on x86_64.

    Pattern: `^[a-f0-9]{64}$`

  - **spec.direct.uefiX86_64.url**
    string

    Required value

    URL of the iPXE firmware for UEFI on x86_64.

    Only HTTPS is supported.

    Pattern: `^https://`

    Maximum length: `2048`

BareMetalRamdiskImage

Scope: Cluster
Version: v1

- **metadata**
  object
- **spec**
  object

  Required value

  Ironic Python Agent (IPA) image that servers boot from while Ironic collects hardware information and installs the operating system.

  - **spec.direct**
    object

    Required value

    URLs of the IPA kernel and initramfs.

    - **spec.direct.architecture**
      string

      CPU architecture the image is built for.

      Default: `x86_64`

      Allowed values: `x86_64`, `aarch64`

    - **spec.direct.initramfsURL**
      string

      Required value

      URL of the IPA initramfs.

      The file must be available at this URL to Ironic and to servers.

      Pattern: `^https?://`

      Maximum length: `2048`

    - **spec.direct.kernelURL**
      string

      Required value

      URL of the IPA kernel.

      The file must be available at this URL to Ironic and to servers.

      Pattern: `^https?://`

      Maximum length: `2048`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Usage

> The module lifecycle stage: Experimental
>
> The module has requirements for installation
>
> Before enabling the module, you need to allow the use of experimental modules in the `deckhouse` ModuleConfig. To do this, set the allowExperimentalModules parameter to `true`.

Choosing the Ironic mode

Ironic manages server power through their baseboard management controllers (BMCs) and installs an operating system on servers. The module can deploy Ironic in the cluster by itself or connect to Ironic deployed outside the cluster. The Ironic mode is set in the `nodes.parameters.ironic` parameter.

To deploy Ironic in the cluster, set the `provisioningNetwork` and `dhcp` parameters. To connect to an external Ironic, set the `externalInstance` parameter. Parameters of different modes cannot be set at the same time.

Ironic in the cluster

Ironic uses the network interfaces of the node it runs on. The module does not pin Ironic to a specific node, so every node where Ironic can start must be connected to the provisioning network where servers boot over PXE. Specify the name of the network interface connected to this network in the `provisioningNetwork.interface` parameter.

In the `provisioningNetwork.ipAddress` parameter, specify a free IPv4 address in the provisioning network. Ironic assigns this address to the interface by itself and accepts connections on it on the following TCP ports:

Port	Purpose
`6180`	HTTP server with images for server boot
`6385`	Ironic API
`6183`	Virtual media HTTPS server if TLS is enabled
`8084`	HTTPS server for iPXE if TLS is enabled

For PXE boot, servers get network settings from a DHCP server. To have Ironic assign addresses to servers by itself, set the `dhcp.internal` parameter with the subnet and the address range. If a DHCP server already runs in the provisioning network, set the `dhcp.external` parameter and configure PXE boot on that DHCP server yourself.

During preparation, servers boot from the Ironic Python Agent (IPA) service image. By default, the built-in IPA image is used, referenced by the `baremetal-default-ramdisk` BareMetalRamdiskImage resource. The module creates this resource by itself. To use a different image, create your own BareMetalRamdiskImage resource and set its name in the `ramdiskImageRef` parameter.

External Ironic

In this mode, the module does not deploy Ironic or a DHCP server in the cluster, and network boot of servers is provided by the external Ironic. Set its API address in the `externalInstance.endpoint` parameter. The address must end with `/v1` or `/v1/`.

If the API requires authentication, create a Secret with credentials in the `d8-infra-provider-baremetal` namespace and specify it in the `externalInstance.credentialsRef` parameter.

To have the Ironic API certificate verified on connection, specify the CA certificate in the `externalInstance.tls.caCertRef` parameter. If Ironic requires a client certificate, specify it in the `externalInstance.tls.clientCertRef` parameter.

The module does not pass BMC CA certificates to the external Ironic, and for BareMetalInstance resources with the `spec.bmc.tls.caCertRef` parameter it reports an error and does not create a BareMetalHost. Configure trust for BMC certificates in the external Ironic itself.

Initializing Kubernetes nodes

The module deploys its Cloud Controller Manager for both managed and external Ironic. It matches each Node to its CAPI Machine, Metal3Machine, and BareMetalHost, sets the Metal3 providerID, and removes `node.cloudprovider.kubernetes.io/uninitialized` after initialization. It does not remove the bashible initialization taint.

A module bashible step publishes the installed operating system's internal IP address for CCM. On first boot, it uses the source address of the route to the control plane. Addresses collected by IPA during inspection are not used as node addresses, since the provisioning network can differ from the node network. OS images must support cloud-init and apply the hostname supplied by Metal3DataTemplate.

Registering physical servers

To make a server available for nodes, describe it in a BareMetalInstance resource. BareMetalInstance is cluster-scoped: omit `metadata.namespace` from its manifest. Specify the namespace of the BMC credentials Secret in `spec.bmc.credentialsRef.namespace`. If omitted, `d8-infra-provider-baremetal` is used.

The requirements for the credentials Secret are listed in the description of the `spec.bmc.credentialsRef` parameter.

Connecting to the BMC

The BMC address is set in the `spec.bmc.ipAddress` parameter. The module connects to the BMC over the Redfish or IPMI protocol. It checks the protocols in the following order and uses the first one through which the server is found:

1. Redfish over HTTPS
2. Redfish over HTTP if the `spec.bmc.allowHTTP` parameter is set to `true`
3. IPMI

By default, the module uses port `443` for Redfish over HTTPS, port `80` for Redfish over HTTP, and port `623` for IPMI. If the BMC accepts connections on a different port, specify it in the `spec.bmc.port` parameter. In this case, the module uses the specified port for all protocols. The timeout of each check is set by the `bmcProbeTimeoutSeconds` parameter in the module settings.

In the `spec.bmc.systemUUID` parameter, specify the server UUID reported by its BMC. The module uses this UUID to select the server among all servers managed by the BMC. If there is no server with this UUID, the module reports an error and does not register the server.

The module verifies the BMC certificate against the system root certificates. If the BMC certificate is issued by a private CA, create a Secret with the PEM-encoded CA certificate in the `d8-infra-provider-baremetal` namespace and specify it in the `spec.bmc.tls.caCertRef` parameter. Ironic in the cluster uses a common set of CA certificates from all BareMetalInstance resources, so a CA certificate specified for one server is trusted when connecting to the BMC of any server.

Server parameters

In the `spec.bootMACAddress` parameter, specify the MAC address of the network interface the server boots from over PXE. If the server has several disks, specify the root disk hints in the `spec.rootDeviceHints` parameter.

Add labels to the BareMetalInstance resource so that an instance class can select the server for nodes. The selection rules are set in the `hostSelector` parameter of the instance class.

Checking server state

To check the server state, run the following command:

```
d8 k get baremetalinstances
```

Example output:

```
NAME        BMC              BOOT MAC            STATE       DESIRED ONLINE   POWERED ON   ERROR   AGE
worker-01   192.168.201.32   f0:3f:03:01:1d:22   available   false            false                15m
```

The server is ready for a node when the `STATE` column shows `available`. If the module fails to connect to the BMC or to prepare resources for the server, the `ERROR` column shows an error message. The main error messages:

Message	Description
`BMC credentials are invalid or unavailable.`	The credentials Secret is not found, has a different type, or lacks the required keys
`Unable to resolve the BMC endpoint.`	The BMC is unreachable over all protocols, rejects the credentials, or does not report a server with the specified `systemUUID`
`Unable to synchronize the BMC CA certificate.`	The CA certificate Secret is not found or does not contain a PEM-encoded CA certificate, or Ironic in the cluster has not been created yet
`BMC CA certificates are not supported with an external Ironic instance.`	The `spec.bmc.tls.caCertRef` parameter is set while connected to an external Ironic
`Unable to synchronize the BMC credentials Secret.`	Failed to create or update the service Secret with BMC credentials
`Unable to synchronize the physical host.`	Failed to create or update the BareMetalHost resource for the server
`A generated resource with the required name is owned by another object.`	The BareMetalHost resource or the service Secret for this server already exists and belongs to another BareMetalInstance resource or was created manually

Creating nodes

The `node-manager` module creates nodes on physical servers in node groups with the `CloudEphemeral` type. Such groups need a BareMetalImage resource with the operating system image and a BareMetalInstanceClass resource with node parameters.

Ironic installs the image from the BareMetalImage resource on the server, so the image must meet the module requirements. The instance class refers to the image and selects servers by the labels of BareMetalInstance resources.

The `spec.direct` parameters of BareMetalImage are immutable. To update the operating system image, create a BareMetalImage with a new name and change `imageRef` in the instance class. This change starts a rollout for groups using that instance class.

If the node group can scale from zero (the `minPerZone` parameter is `0`), specify the server CPU and memory in the `capacity` parameter of the instance class. Cluster autoscaler uses these values while the group has no nodes. Without them, the `Capacity calculation failed` error appears in the node group status.

To create nodes, create a node group (NodeGroup) with the `CloudEphemeral` type and specify the instance class in the `cloudInstances.classReference` parameter. Physical servers use a single `default` zone, so you can omit the `cloudInstances.zones` parameter.

Nodes of the group are recreated if you change one of the following parameters:

- The image reference in the `imageRef` parameter
- The `hostSelector` parameter
- The `disableAutomatedCleaning` parameter
- The `nodeReuse` parameter

Enabling TLS for server boot

By default, servers download images and access Ironic over HTTP. You can protect this traffic with TLS only in the Ironic in the cluster mode with the built-in DHCP server (the `dhcp.internal` parameter). If you set the TLS parameters together with the `dhcp.external` parameter, the module does not create Ironic.

Prepare the following resources for TLS:

- A Secret with the Ironic certificate. The Secret requirements are listed in the description of the `provisioningTLS.certificateRef` parameter. The certificate must be issued for the address from the `provisioningNetwork.ipAddress` parameter.
- A BareMetalRamdiskImage resource with the IPA image.
- A BareMetalIPXEFirmware resource with iPXE firmware for BIOS and UEFI x86_64. The firmware must trust the CA from the `ca.crt` key of the Secret, because iPXE downloads files from Ironic over HTTPS. The firmware itself must be available over HTTPS on a server whose certificate is issued by the same CA.

Specify these resources in the `provisioningTLS.certificateRef`, `ramdiskImageRef`, and `ipxeFirmwareRef` parameters. The module creates Ironic only when all three resources exist and the Secret meets the requirements.

⚠ Do not delete the resources specified in the TLS parameters while these parameters are set. If any of the resources becomes unavailable, the module deletes Ironic, and server boot stops.

An example of TLS setup is provided on the “Examples” page.

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

⚠ The module lifecycle stage: Experimental

The module has requirements for installation

Before enabling the module, you need to allow the use of experimental modules in the `deckhouse` ModuleConfig. To do this, set the allowExperimentalModules parameter to `true`.

Creating a node with Ironic in the cluster

In this example, Ironic runs in the cluster with the built-in DHCP server, and one CloudEphemeral node is created on a physical server. Replace the addresses, credentials, server UUID, and image data with values of your environment.

1. Enable the module and configure Ironic:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: infra-provider-baremetal
spec:
  enabled: true
  version: 1
  settings:
    nodes:
      parameters:
        ironic:
          provisioningNetwork:
            interface: enp7s0
            ipAddress: 192.168.223.85
          dhcp:
            internal:
              networkCIDR: 192.168.223.0/24
              rangeBegin: 192.168.223.160
              rangeEnd: 192.168.223.171
              gatewayAddress: 192.168.223.254
              dnsAddress: 192.168.223.1
```

2. Create a Secret with credentials of the server baseboard management controller (BMC) and a BareMetalInstance resource that describes the server:

```
apiVersion: v1
kind: Secret
metadata:
  name: worker-01-bmc
  namespace: d8-infra-provider-baremetal
type: cloud-provider.deckhouse.io/credentials
stringData:
  authScheme: userPassword
  identity: <BMC_USER>
  secret: <BMC_PASSWORD>
---
apiVersion: deckhouse.io/v1
kind: BareMetalInstance
metadata:
  name: worker-01
  labels:
    pool: workers
spec:
  bootMACAddress: "f0:3f:03:01:1d:22"
  bmc:
    ipAddress: 192.168.201.32
    systemUUID: "00583f1d-2903-e203-0010-d21de0c7571b"
    credentialsRef:
      namespace: d8-infra-provider-baremetal
      kind: Secret
      name: worker-01-bmc
```

Replace `<BMC_USER>` and `<BMC_PASSWORD>` with the BMC user name and password. The instance class from the fourth step selects the server by the `pool: workers` label.

3. Wait until the server moves to the `available` state:

```
d8 k get baremetalinstances worker-01
```

4. Create a BareMetalImage resource with the operating system image and a BareMetalInstanceClass resource with node parameters:

```
apiVersion: deckhouse.io/v1
kind: BareMetalImage
metadata:
  name: ubuntu-24-04-amd64
spec:
  direct:
    url: http://images.example.com/ubuntu-24.04-amd64.qcow2
    checksum: 6695ad25a7a930accfd1e004f151578c4152338191eb7598fd89745ab93d3160
    checksumType: sha256
    format: qcow2
---
apiVersion: deckhouse.io/v1
kind: BareMetalInstanceClass
metadata:
  name: workers
spec:
  imageRef:
    kind: BareMetalImage
    name: ubuntu-24-04-amd64
  hostSelector:
    matchLabels:
      pool: workers
  capacity:
    cpu: "4"
    memory: 8Gi
```

5. Create a NodeGroup with the `CloudEphemeral` node type:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: workers
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    minPerZone: 1
    maxPerZone: 1
    classReference:
      kind: BareMetalInstanceClass
      name: workers
```

6. Check that the node has appeared in the cluster:

```
d8 k get nodes -l node.deckhouse.io/group=workers
```

Once Ironic installs the operating system and the server joins the cluster, the node appears in the command output.

Connecting to an external Ironic

In this example, the module connects to Ironic deployed outside the cluster, with password authentication and API certificate verification.

1. Create a Secret with Ironic API credentials and a Secret with the CA certificate:

```
d8 k -n d8-infra-provider-baremetal create secret generic ironic-credentials \
  --from-literal=identity=<IRONIC_USER> \
  --from-literal=secret=<IRONIC_PASSWORD>
d8 k -n d8-infra-provider-baremetal create secret generic ironic-ca \
  --from-file=ca.crt=<CA_FILE>
```

Replace `<IRONIC_USER>` and `<IRONIC_PASSWORD>` with the Ironic API user name and password, and `<CA_FILE>` with the path to the file with the CA certificate that signed the API certificate.

2. Enable the module and set the connection settings in the `externalInstance` parameter:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: infra-provider-baremetal
spec:
  enabled: true
  version: 1
  settings:
    nodes:
      parameters:
        ironic:
          externalInstance:
            endpoint: https://ironic.example.com:6385/v1/
            credentialsRef:
              kind: Secret
              name: ironic-credentials
              namespace: d8-infra-provider-baremetal
            tls:
              caCertRef:
                kind: Secret
                name: ironic-ca
                namespace: d8-infra-provider-baremetal
                key: ca.crt
```

Servers and nodes in this mode are created in the same way as in the previous example, starting from the second step.

Enabling TLS for server boot

In this example, the module protects server boot traffic with TLS. The example extends the settings from the first example.

1. Create a Secret with the Ironic certificate and add a label to it:

   ```
   d8 k -n d8-infra-provider-baremetal create secret generic ironic-tls \
     --type=kubernetes.io/tls \
     --from-file=tls.crt=<CERT_FILE> \
     --from-file=tls.key=<KEY_FILE> \
     --from-file=ca.crt=<CA_FILE>
   d8 k -n d8-infra-provider-baremetal label secret ironic-tls \
     environment.metal3.io/ironic-standalone-operator=true
   ```

   Replace `<CERT_FILE>` and `<KEY_FILE>` with the paths to the Ironic certificate and its private key, and `<CA_FILE>` with the path to the CA certificate that issued the Ironic certificate.

2. Create a BareMetalRamdiskImage resource with the Ironic Python Agent (IPA) image and a BareMetalIPXEFirmware resource with iPXE firmware:

   ```
   apiVersion: deckhouse.io/v1
   kind: BareMetalRamdiskImage
   metadata:
     name: ipa-tls
   spec:
     direct:
       kernelURL: https://images.example.com/ipa/ironic-python-agent.kernel
       initramfsURL: https://images.example.com/ipa/ironic-python-agent.initramfs
   ---
   apiVersion: deckhouse.io/v1
   kind: BareMetalIPXEFirmware
   metadata:
     name: ipxe-tls
   spec:
     direct:
       bios:
         url: https://images.example.com/ipxe/undionly.kpxe
         sha256: <BIOS_FIRMWARE_SHA256>
       uefiX86_64:
         url: https://images.example.com/ipxe/snponly.efi
         sha256: <UEFI_FIRMWARE_SHA256>
   ```

   Replace `<BIOS_FIRMWARE_SHA256>` and `<UEFI_FIRMWARE_SHA256>` with the lowercase SHA-256 checksums of the firmware files.

3. Add the `provisioningTLS`, `ramdiskImageRef`, and `ipxeFirmwareRef` parameters to the module settings:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: infra-provider-baremetal
   spec:
     enabled: true
     version: 1
     settings:
       nodes:
         parameters:
           ironic:
             provisioningNetwork:
               interface: enp7s0
               ipAddress: 192.168.223.85
             dhcp:
               internal:
                 networkCIDR: 192.168.223.0/24
                 rangeBegin: 192.168.223.160
                 rangeEnd: 192.168.223.171
             provisioningTLS:
               certificateRef:
                 name: ironic-tls
             ramdiskImageRef:
               kind: BareMetalRamdiskImage
               name: ipa-tls
             ipxeFirmwareRef:
               kind: BareMetalIPXEFirmware
               name: ipxe-tls
   ```

4. Check that the module has created Ironic:

   ```
   d8 k -n d8-infra-provider-baremetal get ironics.ironic.metal3.io
   ```

   If the output has no `ironic` resource, check that all three resources from the TLS parameters are created and the Secret meets the requirements.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The istio module

> Available with limitations in: **Open/CE, Core, BE, SE, SE+, Certified Core/CSE Lite (1.73)**
>
> Available without limitations in: **Ultimate/EE**

> Included with limitations in extensions: **Advanced Networking, Advanced Infrastructure Security, Cluster Union, Multitenancy, Network Security**

> The module lifecycle stage: General Availability
>
> The module has requirements for installation

> Web interfaces associated with the module: istio

Compatibility table for supported versions

The table below shows Istio versions and their support status in Deckhouse Platform (DP).

Istio version	Kubernetes versions supported by Istio	Status in DP
1.29	1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36	Supported
1.27	1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36	Supported
1.25	1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36	Deprecated and will be deleted

> ⚠ Istio 1.21 is no longer supported. Before upgrading to this DP release, migrate every global and additional Istio 1.21 revision to a supported version using a previous DP release that supports both versions. The DP upgrade is blocked while Istio 1.21 remains configured.

Problems Istio helps to solve

Istio is a framework for managing network traffic on a centralized basis that implements the Service Mesh approach.

Istio solves the tasks for applications:

- Using Mutual TLS.
- Access authorization between services.
- Request routing.
- Managing request balancing between service Endpoints.
- Improving Observability.
- Organizing a multi-datacenter cluster by joining clusters into a single Service Mesh (multicluster).
- Grouping isolated clusters into a federation with the ability to provide native (in the Service Mesh sense) access to selected services .
- Joining the mesh without per-pod sidecars using ambient mode.

Mutual TLS

Mutual TLS is the main method of mutual service authentication. It is based on the fact that all outgoing requests are verified using the server certificate, and all incoming requests are verified using the client certificate. After the verification is complete, the sidecar-proxy can identify the remote node and use these data for authorization or auxiliary purposes.

Each service gets its own identifier of the following format: `<TrustDomain>/ns/<Namespace>/sa/<ServiceAccount>` where `TrustDomain` is the cluster domain in our case. You can assign your own ServiceAccount to each service or use the regular “default” one. The service ID can be used for authorization and other purposes. This is the identifier used as a name to validate against in TLS certificates.

You can redefine this settings at the Namespace level.

Authorization

The AuthorizationPolicy resource is responsible for managing authorization. Once this resource is created for the service, the following algorithm is used for determining the fate of the request:

- The request is denied if it falls under the DENY policy.
- The request is allowed if there are no ALLOW policies for the service.
- The request is allowed if it falls under the ALLOW policy.
- In all other cases, the request is denied.

In other words, if you explicitly deny something, then only this restrictive rule will work. On the other hand, if you explicitly allow something, only explicitly authorized requests would be allowed (however, restrictions will have precedence).

You can use the following arguments for defining authorization rules:

- Service IDs and wildcard expressions based on them (`mycluster.local/ns/myns/sa/myapp` or `mycluster.local/*`)
- Namespace
- IP ranges
- HTTP headers
- JWT tokens

Request routing

VirtualService is the main resource for routing control; it allows you to override the destination of an HTTP or TCP request. Routing decisions can be based on the following parameters:

- Host or other headers
- URI
- Method (GET, POST, etc.)
- Pod labels or the namespace of the request source
- dst-IP or dst-port for non-HTTP requests

Managing request balancing between service Endpoints

DestinationRule is the main resource for managing request balancing; it allows you to configure the details of requests leaving the Pods:

- Limits/timeouts for TCP
- Balancing algorithms between Endpoints
- Rules for detecting problems on the Endpoint side to take it out of balancing
- Encryption details

> ⚠ All customizable limits apply to each client Pod individually (on a per Pod basis)! Suppose you limited a service to one TCP connection. In this case, if you have three client Pods, the service will get three incoming connections.

Observability

Tracing

Istio makes it possible to collect application traces and inject trace headers if there are none. In doing so, however, you have to keep in mind the following:

- If a request initiates secondary requests for a service, they must inherit the trace headers by means of the application.
- You will need to install Jaeger to collect and display traces.

Grafana

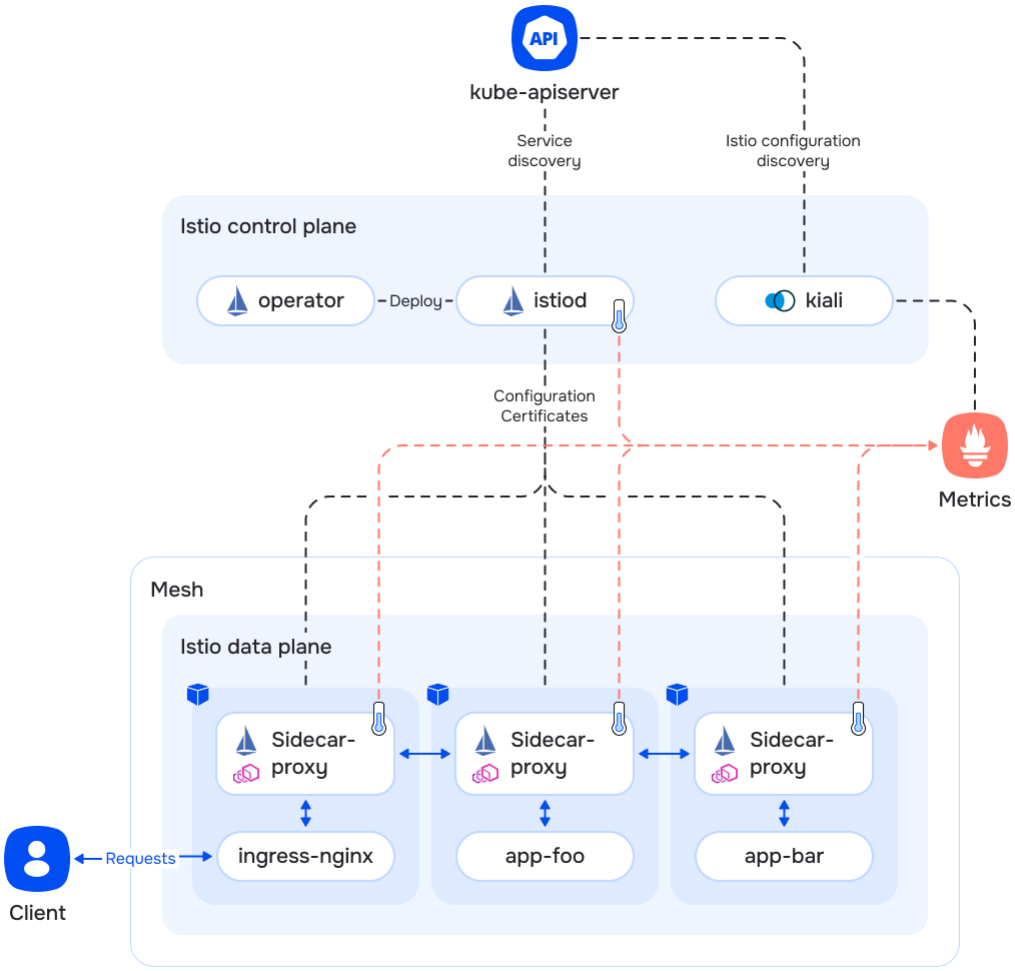
The standard module bundle includes the following additional dashboards:

- Dashboard for evaluating the throughput and success of requests/responses between applications.
- Dashboard for evaluating control plane performance and load.
- **Istio Configuration Health** (EE) — periodic configuration analysis findings: issue counts by type/severity/namespace, trends over time, and the current issue list (filterable by revision and namespace). Requires `configAnalysis.enabled`.

Kiali

Kiali is a tool for visualizing your application's service tree. It allows you to quickly assess the situation in the network connectivity by visualizing the requests and their quantitative characteristics directly on the scheme.

Mesh metrics and access logs (Telemetry API)



Metrics for Grafana workloads graphs and quantitative in Kiali on Prometheus scraping metrics `istio_*` series from `istio-proxy`. For the supported Istio versions, Istio exposes those using Telemetry API mesh defaults instead of legacy `telemetry.v2` filters alone.

DP configures `telemetryAPI.enabled`: when `false` you keep the legacy stack; when `true` you switch to `meshConfig.defaultProviders`, bundled `Telemetry` resources, and the `dataPlane.accessLog` template wired into access logs. Step-by-step examples, readiness checks, optional extra `Telemetry` policies, and tracing (`spec.tracing`) are in Telemetry API for mesh metrics, tracing, and access logs.

Architecture of the cluster with Istio enabled

The cluster components are divided into two categories:

- Control plane — managing and maintaining services; "control-plane" usually refers to istiod pods;
- Data plane — mediating and controlling all network communication between microservices, it is composed of a set of sidecar-proxy containers.

All data plane services are grouped into a mesh with the following features:

- It has a common namespace for generating service ID in the form `<TrustDomain>/ns/<Namespace>/sa/<ServiceAccount>`. Each mesh has a TrustDomain ID (in our case, it is the same as the cluster domain), e.g. `mycluster.local/ns/myns/sa/myapp`.
- Services within a single mesh can authenticate each other using trusted root certificates.

Control plane components:

- `istiod` — the main service with the following tasks:
  - Continuous connection to the Kubernetes API and collecting information about services.
  - Processing and validating all Istio-related Custom Resources using the Kubernetes validating-webhook mechanism.
  - Configuring each sidecar proxy individually:
    - Generating authorization, routing, balancing rules, etc..
    - Distributing information about other application services in the cluster.
    - Issuing individual client certificates for implementing Mutual TLS. These certificates are unrelated to the certificates that Kubernetes uses for its own service needs.
  - Automatic tuning of manifests that describe application pods via the Kubernetes mutating-webhook mechanism:
    - Injecting an additional sidecar-proxy service container.
    - Injecting an additional init container for configuring the network subsystem (configuring DNAT to intercept application traffic).
    - Routing readiness and liveness probes through the sidecar-proxy.
- `operator` — installs all the resources required to operate a specific version of the control plane.
- `kiali` — dashboard for monitoring and controlling Istio resources as well as user services managed by Istio that allows you:
  - Visualize inter-service connections.
  - Diagnose problem inter-service connections.
  - Diagnose the control plane state.

The Ingress controller must be refined to receive user traffic:

- You need to add sidecar-proxy to the controller pods. It only handles traffic from the controller to the application services (the `enableIstioSidecar` parameter of the `IngressNginxController` resource).
- Services not managed by Istio continue to function as before, requests to them are not intercepted by the controller sidecar.
- Requests to services running under Istio are intercepted by the sidecar and processed according to Istio rules (read more about activating Istio to work with the application).

The istiod controller and sidecar-proxy containers export their own metrics that the cluster-wide Prometheus collects.

Application service architecture with Istio enabled

Details

- Each service pod gets a sidecar container — sidecar-proxy. From the technical standpoint, this container contains two applications:
  - Envoy proxies service traffic. It is responsible for implementing all the Istio functionality, including routing, authentication, authorization, etc.
  - pilot-agent is a part of Istio. It keeps the Envoy configurations up to date and has a built-in caching DNS server.
- Each pod has a DNAT configured for incoming and outgoing service requests to the sidecar-proxy. The additional init container is used for that. Thus, the traffic is routed transparently for applications.
- Since incoming service traffic is redirected to the sidecar-proxy, this also applies to the readiness/liveness traffic. The Kubernetes subsystem that does this doesn't know how to probe containers under Mutual TLS. Thus, all the existing probes are automatically reconfigured to use a dedicated sidecar-proxy port that routes traffic to the application unchanged.
- You have to configure the Ingress controller to receive requests from outside the cluster:
  - The controller's pods have additional sidecar-proxy containers.
  - Unlike application Pods, the Ingress controller's sidecar-proxy intercepts only outgoing traffic from the controller to the services. The incoming traffic from the users is handled directly by the controller itself;
- Ingress resources require refinement in the form of adding annotations:
  - `nginx.ingress.kubernetes.io/service-upstream: "true"` — the Ingress controller will use the service's ClusterIP as upstream instead of the Pod addresses. In this case, traffic balancing between the Pods is handled by the sidecar-proxy. Use this option only if your service has a ClusterIP.
  - `nginx.ingress.kubernetes.io/upstream-vhost: "myservice.myns.svc"` — the Ingress controller's sidecar-proxy makes routing decisions based on the Host header. If this annotation is omitted, the controller will leave a header with the site address (e.g. `Host: example.com`).
- Resources of the Service type do not require any adaptation and continue to function properly. Just like before, applications have access to service addresses like `servicename`, `servicename.myns.svc`, etc;
- DNS requests from within the pods are transparently redirected to the sidecar-proxy for processing:
  - This way, domain names of the services in the neighboring clusters can be disassociated from their addresses.

Native sidecars

By default, Istio 1.27 and newer inject sidecar-proxy as a Kubernetes native sidecar. The `istio-proxy` container is placed in `spec.initContainers` and has `restartPolicy: Always`. By default, Istio 1.25 injects a regular sidecar: `istio-proxy` is an ordinary container in `spec.containers`.

A native sidecar is tied to the Pod lifecycle:

- It starts before the application init containers, so they can use the Mesh network.
- It delays the start of the application containers until the proxy is ready.
- It stops only after the application containers have exited, so the application keeps network access while shutting down.
- It doesn't prevent Job Pods from completing.

Since the proxy is already running, the traffic of the application init containers goes through it and follows the same rules as the rest of the Pod's traffic: `outboundTrafficPolicyMode`, Sidecar egress settings, AuthorizationPolicy and mTLS. With a regular sidecar in the `InitContainer` traffic redirection mode, the application init containers run before the redirection is set up and bypass the mesh.

When a Pod moves from a regular sidecar to a native one, for example after an upgrade from Istio 1.25, check its init containers that connect to services outside the mesh. With `outboundTrafficPolicyMode: RegistryOnly`, register these services with a ServiceEntry.

To set the sidecar type for a specific Pod, add the `sidecar.istio.io/nativeSidecar` annotation (`"true"` or `"false"`) to the Pod template.

User request lifecycle

Application with Istio turned off

Application with Istio turned on

Activating Istio to work with the application

The main purpose of the activation is to add a sidecar container to the application pods so that Istio can manage the traffic.

The sidecar-injector is a recommended way to add sidecars. Istio can inject sidecar containers into user pods using the Admission Webhook mechanism. You can configure it using labels and annotations:

- A label attached to a namespace allows the sidecar-injector to identify a group of pods to inject sidecar containers into:
  - `istio-injection=enabled` — use the global version of Istio (`spec.settings.globalVersion` in `ModuleConfig`);
  - `istio.io/rev=v1x29` — use the specific Istio version for a given namespace;
  - `istio.io/rev=default` — use the global version of Istio (`spec.settings.globalVersion` in `ModuleConfig`).
- The `sidecar.istio.io/inject` (`"true"` or `"false"`) pod annotation lets you redefine the `sidecarInjectorPolicy` policy locally. These annotations work only in namespaces to which the above labels are attached.

It is also possible to add the sidecar to an individual pod in a namespace without the `istio-injection` and `istio.io/rev` labels by setting the `sidecar.istio.io/inject=true` Pod label. The same applies to the `istio.io/rev=vXxYZ` Pod label — it selects the Istio version for an individual pod, but only in a namespace that carries neither the `istio-injection` nor the `istio.io/rev` label.

The `istio-injection` and `istio.io/rev` namespace labels are mutually exclusive. A namespace carrying both of them, or carrying `istio-injection` with a value other than `enabled`, gets no sidecars injected at all — neither namespace-wide nor per-pod.

Istio-proxy, running as a sidecar container, consumes resources and adds the following overhead:

- Any incoming DNAT request is forcibly intercepted by the Envoy proxy. Envoy analyzes the request and forwards it by establishing a new connection. On the receiver side, the process is identical: traffic first reaches the "receiving" Envoy and only then is passed to the application itself.
- Each Envoy instance stores information about all services in the cluster; therefore, scaling the cluster leads to a linear increase in Envoy's RAM consumption due to storing the full service map. Using the Sidecar CustomResource, the configuration is filtered, and only the necessary minimum of data is delivered to Envoy.

> ⚠ The EnvoyFilter interface can be controlled by Lua plugins, but it is an internal control mechanism for implementing the Istio functionality. It must not be used in a user configuration, as doing so would compromise the integrity of the system.

It is also important to get the Ingress controller and the application's Ingress resources ready:

- Enable `enableIstioSidecar` of the `IngressNginxController` resource.
- Add annotations to the application's Ingress resources:
  - `nginx.ingress.kubernetes.io/service-upstream: "true"` — the Ingress controller will use the service's ClusterIP as upstream instead of the Pod addresses. In this case, traffic balancing between the Pods is now handled by the sidecar-proxy. Use this option only if your service has a ClusterIP.
  - `nginx.ingress.kubernetes.io/upstream-vhost: "myservice.myns.svc"` — the Ingress controller's sidecar-proxy makes routing decisions based on the Host header. If this annotation is omitted, the controller will leave a header with the site address (e.g. `Host: example.com`).

Federation and multicluster

DP supports two schemes of inter-cluster interaction:

- federation
- multicluster

Below are their fundamental differences:

- The federation aggregates multiple sovereign (independent) clusters:
  - Each cluster has its own namespace (for Namespace, Service, etc.);
  - Access to individual services between clusters is clearly defined.
- The multicluster aggregates co-dependent clusters:
  - Cluster namespaces are shared — each service is available to neighboring clusters as if it were running in a local cluster (unless authorization rules prohibit that).

Federation

Requirements for clusters

- Each cluster must have a unique domain set in the `clusterDomain` parameter of the `control-plane-manager` module. None of the clusters should use the default `cluster.local`.
- Pod and Service subnets in the `podSubnetCIDR` and `serviceSubnetCIDR` parameters of the `control-plane-manager` module may overlap.

Istio uses traffic analysis as follows:

- HTTP and HTTPS traffic — identification and routing or blocking decisions are based on headers.
- TCP traffic — decisions are based only on the destination IP address and port number.

⚠ `cluster.local` is an unmodified alias for the local cluster domain. Using `cluster.local` as a principal in `AuthorizationPolicy` always refers to the local cluster, even if another cluster in the mesh has `clusterDomain` explicitly set to `cluster.local` (Istio trust domain migration best practices).

ℹ Istio operates in the multi-network mode: pods from different clusters can only communicate through the Istio ingress gateway. Direct communication between pods of different clusters is not supported.

⚠ Only sidecar-mode workloads can take part in a federation. For details, refer to Ambient mesh limitations.

General principles of federation

- Federation requires mutual trust between clusters. Thereby, to use federation, you have to make sure that both clusters (say, A and B) trust each other. This is achieved by a mutual exchange of root certificates.
- You also need to share information about public services to use the federation. You can do that using the `ServiceEntry` resource. A `ServiceEntry` defines the public `ingressgateway` address of the B cluster so that services of the A cluster can communicate with the bar service in the B cluster.

Enabling the federation

Enabling federation (via the `istio.federation.enabled = true` module parameter) results in the following activities:

- The `ingressgateway` service is added to the cluster. Its task is to proxy mTLS traffic coming from outside of the cluster to application services.
- A service gets added to the cluster that exports the following cluster metadata to the outside:
  - Istio root certificate (accessible without authentication).
  - List of public services in the cluster (available only for authenticated requests from neighboring clusters).
  - List of public addresses of the `ingressgateway` service (available only for authenticated requests from neighboring clusters).

Managing the federation

To establish a federation, you must:

- Create a set of `IstioFederation` resources in each cluster that describe all the other clusters.
  - After successful auto-negotiation between clusters, the status of `IstioFederation` resource will be filled with neighbour's public and private metadata (`status.metadataCache.public` and `status.metadataCache.private`).
- Add the `federation.istio.deckhouse.io/public-service: ""` label to each Service that is considered public within the federation.
  - In the other federation clusters, corresponding `ServiceEntry` and DestinationRule resources will be created for each such Service, leading to the `ingressgateway` of the original cluster.
  - The label value must be empty. You do not need to label other resources, such as Deployment, Pod, or VirtualService, to publish a service in the federation.

⚠ Federation publishing does not support `ExternalName` services, services without `.spec.ports`, or services with ports missing the `name` field.

Each port name must start with a supported Istio prefix: `http`, `http2`, `https`, `tcp`, `tls`, `grpc`, or `grpc-web`. The module uses the port name to determine the protocol in the generated `ServiceEntry`. If the prefix is not recognized, the port will be handled as TCP.

Example of a public service:

```
apiVersion: v1
kind: Service
metadata:
  name: reviews
  namespace: bookinfo
  labels:
    federation.istio.deckhouse.io/public-service: ""
spec:
  selector:
    app: reviews
  ports:
  - name: http
    port: 9080
    targetPort: 9080
```

To troubleshoot service publishing in the federation, follow these checks:

Check which services are marked as public in the local cluster:

```
d8 k get svc -A -l federation.istio.deckhouse.io/public-service=
```

Check metadata exchange status with remote clusters:

```
d8 k get istiofederation
d8 k get istiofederation <name> -o jsonpath='{.status.conditions}'
```

Check that the remote cluster provided its public services list:

```
d8 k get istiofederation <name> -o jsonpath='{.status.metadataCache.private.publicServices}'
```

Check that local routing resources were created from the received metadata:

```
d8 k -n d8-istio get serviceentry,destinationrule
```

In the IstioFederation `status.conditions`, the `PublicMetadataExchangeReady`, `PrivateMetadataExchangeReady`, and `DataplaneConnectionReady` conditions should become `True`. If metadata exchange does not work, check the `D8IstioFederationMetadataEndpointDoesntWork` alert and the availability of the remote cluster `spec.metadataEndpoint`.

Multicluster

Requirements for clusters

- Cluster domains in the `clusterDomain` parameter of the `control-plane-manager` module must be the same for all multicluster members. The default value is `cluster.local`.
- Pod and Service subnets in the `podSubnetCIDR` and `serviceSubnetCIDR` parameters of the `control-plane-manager` module must be unique for each multicluster member.

Istio uses traffic analysis as follows:

- HTTP and HTTPS traffic — identification and routing or blocking decisions are based on headers.
- TCP traffic — decisions are based only on the destination IP address and port number.

> ⚠ If service or pod IP addresses overlap between clusters, requests from pods in other clusters may unintentionally match Istio's routing, allow, or deny rules. Overlapping service and pod subnets is not recommended (Istio network models).

By default, pods from different clusters communicate through the Istio ingress gateway (multi-network mode). If the pods of two clusters are directly reachable from each other (flat network), set `spec.enableIngressGateway` to `false` in both clusters, in the IstioMulticluster that describes the other cluster.

> ⚠ Only sidecar-mode workloads can take part in a multicluster. For details, refer to Ambient mesh limitations.

General principles

- Multicluster requires mutual trust between clusters. Thereby, to use multiclustering, you have to make sure that both clusters (say, A and B) trust each other. From a technical point of view, this is achieved by a mutual exchange of root certificates.
- Istio connects directly to the API server of the neighboring cluster to gather information about its services. This DP module takes care of the corresponding communication channel.

Enabling the multicluster

Enabling the multicluster (via the `istio.multicluster.enabled = true` module parameter) results in the following activities:

- A proxy is added to the cluster to publish access to the API server via the standard Ingress resource:
  - Access through this public address is secured by authorization based on Bearer tokens signed with trusted keys. DP automatically exchanges trusted public keys during the mutual configuration of the multicluster.
  - The proxy itself has read-only access to a limited set of resources.
- A service gets added to the cluster that exports the following cluster metadata to the outside:
  - Istio root certificate (accessible without authentication).
  - The public API server address (available only for authenticated requests from neighboring clusters).
  - List of public addresses of the `ingressgateway` service (available only for authenticated requests from neighboring clusters).
  - Server public keys to authenticate requests to API server and to private metadata.

Managing the multicluster

To create a multicluster, you need to create a set of `IstioMulticluster` resources in each cluster that describe all the other clusters.

In case of issues when working with a multi-cluster, it is necessary to check in each cluster:

1. The conditions of the IstioMulticluster objects. To view them, run the following command:

   ```
   d8 k get istiomulticluster <NAME> -o jsonpath='{range .status.conditions[*]}{.type}: {.status}: {.reason}: {.message}{"\n"}{end}'
   ```

   Here, `<NAME>` is the name of the IstioMulticluster. Check every IstioMulticluster in the cluster. The `d8 k get istiomulticluster` command lists them.

   All conditions must be `True`. If a condition is not `True`, its `reason` and `message` say what is wrong.

2. Using the `istioctl` utility from the DP debug container, ensure that remote clusters have the `synced` status and a specified `istiod` instance (for details, refer to Debugging Istio with istioctl from the debug container):

   ```
   istioctl remote-clusters -i d8-istio
   ```

   Example output:

   ```
   NAME                        SECRET                                      STATUS     ISTIOD
   cluster-local-2451237693    d8-istio/istio-remote-secret-cluster-b      synced     istiod-v1x29-5c57d85b54-k8pl7
   ```

Ambient mesh

Besides the classic sidecar mode, Istio can run the data plane in *ambient* mode. In this mode, the mesh functionality is split into two layers, and application pods no longer get a per-pod `istio-proxy` sidecar container:

- A node-level component (`ztunnel`) handles L4 functionality (mutual TLS, identity, basic authorization) for all mesh workloads on the node.
- An optional per-namespace component (a *waypoint* proxy) handles L7 functionality (HTTP routing, L7 authorization, telemetry).

Compared to the sidecar mode, ambient mode reduces per-pod overhead (no sidecar container injected into every pod) and lets you adopt mesh features incrementally — first L4 via `ztunnel`, then L7 only for the namespaces that need it.

Components

The following components are used in the ambient mode:

- `ztunnel`: A DaemonSet that runs one pod per node and transparently tunnels traffic of the ambient workloads on that node over HTTP-Based Overlay Network Encapsulation (HBONE) with mutual TLS. It provides L4 features without a sidecar.
- **Waypoint proxy**: An optional L7 proxy deployed per namespace (or for a subset of its workloads and services). In DP, it is provisioned through the WaypointInstance custom resource, which is a DP abstraction on top of the native Istio waypoint provisioning. It adds declarative management of replicas (`Static`/`HPA`), resources (`Static`/`VPA`), node placement, and disruption budgets (PDB) per waypoint instance.

Prerequisites

To use the ambient mode, make sure to follow these requirements:

- Use Istio 1.25 or newer (ambient mode is available starting with Istio 1.25).
- Set `dataPlane.trafficRedirectionSetupMode` to `CNIPlugin`. Ambient mode requires the CNI plugin to set up traffic redirection.
- Enable ambient mode via the `ambient.enabled` module parameter.

Ambient mesh limitations

Ambient mode is compatible with federation and multicluster at the cluster level: you can enable ambient mode in a cluster that is a federation or multicluster member, and the existing inter-cluster interaction keeps working.

The limitation applies to individual workloads: federation and multicluster cover sidecar-mode workloads only. Cross-cluster traffic to and from a workload enrolled in ambient mode does not work in either direction.

⚠ To let a workload take part in a federation or a multicluster, keep it in sidecar mode — do not add the `istio.io/dataplane-mode=ambient` label to the workload or its namespace.

Both data plane modes can coexist in the same cluster, so you can keep cross-cluster workloads in sidecar mode and enroll the rest of them in ambient mode.

Enrolling workloads

The module installs and runs the ambient infrastructure (`ztunnel` and the waypoint controller for WaypointInstance resources), but it **does not** enroll your workloads automatically.

To enroll workloads, use the standard Istio labels:

1. Add the `istio.io/dataplane-mode=ambient` label to a namespace (or pod) to capture its traffic with `ztunnel` (L4).
2. Create a WaypointInstance resource in the namespace, then point workloads or services at it with the `istio.io/use-waypoint` label to enable L7 features.

See the “Examples” section for step-by-step configuration.

⚠ Delete all WaypointInstance resources before disabling ambient mode. With ambient mode disabled, the waypoint controller is not running and cannot reconcile or clean up waypoint resources.

Authentication

By default, the `user-authn` module provides authentication for Kiali. External authentication can also be configured via `externalAuthentication`. If both are disabled, the module uses basic auth with an auto-generated password.

To view the generated password:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values istio -o json | jq '.istio.internal.auth.password'
```

To re-generate the password, delete the Secret:

```
d8 k -n d8-istio delete secret/kiali-basic-auth
```

⚠ The `auth.password` parameter is deprecated.

Estimating overhead

Using Istio will incur additional resource costs for both control-plane (istiod controller) and data-plane (istio-sidecars).

control-plane

The istiod controller continuously monitors the cluster configuration, compiles the settings for the istio-sidecars and distributes them over the network. Accordingly, the more applications and their instances, the more services, and the more frequently this configuration changes, the more computational resources are required and the greater the load on the network. Two approaches are supported to reduce the load on controller instances:

- horizontal scaling (module configuration `controlPlane.replicasManagement`) — the more controller instances, the fewer instances of istio-sidecars to serve for each controller and the less CPU and network load.
- data-plane segmentation using the Sidecar resource (recommended approach) — the smaller the scope of an individual istio-sidecar, the less data in the data-plane needs to be updated and the less CPU and network overhead.

A rough estimate of overhead for a control-plane instance that serves 1000 services and 2000 istio-sidecars is 1 vCPU and 1.5 GB RAM.

data-plane

The consumption of data-plane resources (istio-sidecar) is affected by many factors:

- number of connections,
- the intensity of requests,
- size of requests and responses,
- protocol (HTTP/TCP),
- number of CPU cores,
- complexity of Service Mesh configuration.

A rough estimate of the overhead for an istio-sidecar instance is 0.5 vCPU for 1000 requests/sec and 50 MB RAM. istio-sidecars also increase latency in network requests — about 2.5ms per request.

Third-party components

List of third-party software used in the `istio` module:

- Istio 1.25.2

  License: Apache License 2.0

  An open platform to connect, manage, and secure microservices.

- Istio 1.27.9

  License: Apache License 2.0

  An open platform to connect, manage, and secure microservices.

- Istio 1.29.6

  License: Apache License 2.0

  An open platform to connect, manage, and secure microservices.

- Kiali 2.7.1

  License: Apache License 2.0

  Visualisation tool for the istio service mesh topology, and features like circuit breakers or request rates.

- Kiali 2.12.0

License: Apache License 2.0

Visualisation tool for the istio service mesh topology, and features like circuit breakers or request rates.

- Kiali 2.21.0

  License: Apache License 2.0

  Visualisation tool for the istio service mesh topology, and features like circuit breakers or request rates.

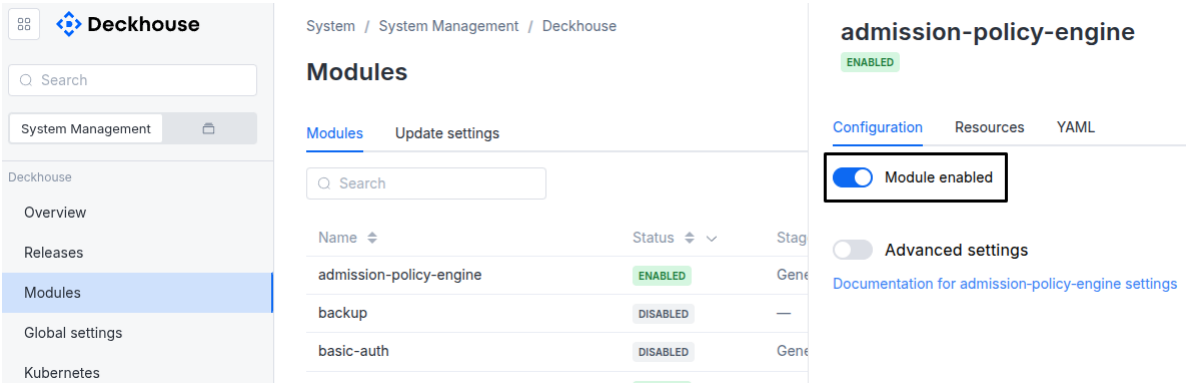
> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Available with limitations in: **Open/CE, Core, BE, SE, SE+, Certified Core/CSE Lite (1.73)**
>
> Available without limitations in: **Ultimate/EE**

> Included with limitations in extensions: **Advanced Networking, Advanced Infrastructure Security, Cluster Union, Multitenancy, Network Security**

> The module lifecycle stage: General Availability
>
> The module has requirements for installation



The module has 34 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `istio` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

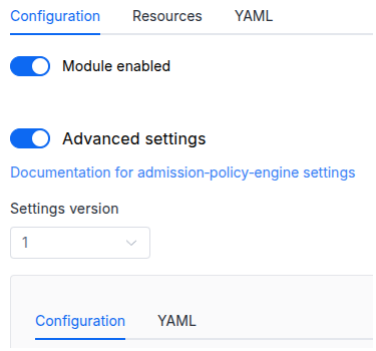
```
d8 system module enable istio
```

- **Using ModuleConfig `istio`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `istio` (create it if necessary);

  Example of a manifest to enable module `istio`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `istio` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `istio` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `istio`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `istio` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc istio
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `istio` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `istio`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: istio
  spec:
    version: 3
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the Deckhouse version: 1.72.0 and above.

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `.settings.auth.password`.

- Updates from version **2** to **3**:
  - Move `.settings.enableHTTP10` to `.settings.dataPlane.enableHTTP10`.
  - Move `.settings.proxyConfig` to `.settings.dataPlane.proxyConfig`.

Parameters

Schema version: 3

- **settings**
  object
  - **settings.additionalVersions**
    array of strings

    Additional versions of Istio control plane to install. You can use specific namespace labels (`istio.io/rev=`) to switch between installed revisions.

    Default: `[]`

    Example:

    ```
    additionalVersions:
    - '1.25'
    ```

    - **Element of the array**
      string

      Allowed values: `1.25`, `1.27`, `1.29`

  - **settings.alliance**
    object

    Available in editions: Ultimate/EE

    Common options both for federation and multicluster.

    - **settings.alliance.ingressGateway**
      object

      Available in editions: Ultimate/EE

      Ingress gateway settings.

      - **settings.alliance.ingressGateway.advertise**
        array of objects

        Available in editions: Ultimate/EE

        The actual addresses that will be announced to remote clusters for organizing intercluster application requests. If not specified, the addresses will be discovered automatically.

        Default: `[]`

Examples:

```
advertise:
- address: 172.16.0.5
  port: 15443
```

```
advertise:
- address: somehost.example.com
  port: 15443
```

- **settings.alliance.ingressGateway.advertise.address**
  string

  Required value

  Pattern: `^([a-z0-9]([a-z0-9-]{0,61}[a-z0-9])?\.)+[a-z]{2,}$`

  Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  Examples:

  ```
  address: somehost.example.com
  ```

  ```
  address: 172.16.0.5
  ```

- **settings.alliance.ingressGateway.advertise.port**
  integer

  Required value

  Allowed values: `1024 <= X <= 65535`

- **settings.alliance.ingressGateway.gatewayPodAnnotations**
  object

  Available in editions: Ultimate/EE

  Additional annotations for the ingress gateway DaemonSet pods.

  Example:

  ```
  gatewayPodAnnotations:
    checksum/config: xyz-123
  ```

- **settings.alliance.ingressGateway.inlet**
  string

  Available in editions: Ultimate/EE

  Method for exposing the ingress gateway:

  - `LoadBalancer`: For clusters whose cloud provider or infrastructure supports load balancers.
  - `NodePort`: For clusters without a load balancer.

  Default: `LoadBalancer`

  Allowed values: `LoadBalancer`, `NodePort`

  Example:

  ```
  inlet: LoadBalancer
  ```

- **settings.alliance.ingressGateway.loadBalancerClass**
  string

  Available in editions: Ultimate/EE

  Class of the load balancer for incoming network requests (passed to the `spec.loadBalancerClass` parameter of the provisioned service with the `LoadBalancer` type).

  Applies only when `inlet` is `LoadBalancer`.

- **settings.alliance.ingressGateway.nodePort**
  object

  Available in editions: Ultimate/EE

  Special settings for NodePort inlet.

  Examples:

  ```
  nodePort: {}
  ```

  ```
  nodePort:
    port: 30001
  ```

  - **settings.alliance.ingressGateway.nodePort.port**
    integer

    Static port number for NodePort-type Service. Must be in range, set by kube-apiserver –service-node-port-range argument (default is 30000-32767).

    Allowed values: `1024 <= X <= 65535`

- **settings.alliance.ingressGateway.nodeSelector**
  object

  Available in editions: Ultimate/EE

  Ingress gateway DaemonSet nodeSelector.

  The same as the `spec.nodeSelector` pod parameter in Kubernetes.

  Example:

  ```
  nodeSelector:
    type: ingress
  ```

- **settings.alliance.ingressGateway.serviceAnnotations**
  object

  Available in editions: Ultimate/EE

  Additional service annotations. They can be used, e.g., for configuring a local LB in the Yandex Cloud (using the `yandex.cpi.flant.com/listener-subnet-id` annotation).

Example:

```
serviceAnnotations:
  yandex.cpi.flant.com/listener-subnet-id: xyz-123
```

- **settings.alliance.ingressGateway.tolerations**
  array of objects

  Available in editions: Ultimate/EE

  Ingress gateway DaemonSet tolerations.

  The same as `spec.tolerations` for the Kubernetes pod.

  Example:

  ```
  tolerations:
  - operator: Exists
  ```

  - **settings.alliance.ingressGateway.tolerations.effect**
    string
  - **settings.alliance.ingressGateway.tolerations.key**
    string
  - **settings.alliance.ingressGateway.tolerations.operator**
    string
  - **settings.alliance.ingressGateway.tolerations.tolerationSeconds**
    integer
  - **settings.alliance.ingressGateway.tolerations.value**
    string

- **settings.ambient**
  object

  Available in editions: Ultimate/EE

  Ambient mesh related settings.

  Default: `{"enabled":false}`

  - **settings.ambient.enabled**
    boolean

    Enable ambient mesh.

    Ambient-mode workloads cannot take part in federation or multicluster. Both remain functional for sidecar-mode workloads. See ambient mesh limitations.

    Default: `false`

    Example:

    ```
    enabled: true
    ```

  - **settings.ambient.waypointController**
    object

    Available in editions: Ultimate/EE

    Settings for CPU and memory requests and limits by waypoint-controller pods.

    - **settings.ambient.waypointController.resourcesManagement**
      object

      Settings for CPU and memory requests and limits by waypoint-controller pods.

      Examples:

      ```
      resourcesManagement:
        mode: VPA
        vpa:
          mode: InPlaceOrRecreate
          cpu:
            min: 25m
            max: 1
            limitRatio: 1.5
          memory:
            min: 64Mi
            max: 1Gi
            limitRatio: 1.5
      ```

      ```
      resourcesManagement:
        mode: Static
        static:
          requests:
            cpu: 25m
            memory: 64Mi
          limits:
            cpu: '1'
            memory: 1Gi
      ```

      - **settings.ambient.waypointController.resourcesManagement.mode**
        string

        Resource management mode for waypoint-controller pods.

        Possible values:

        - `Static`: Lets you set requests and limits manually in the `static` parameter section.
        - `VPA`: Lets VPA manage resources automatically. The mode is configured in the `vpa` parameter section.

        Default: `VPA`

        Allowed values: `VPA`, `Static`

      - **settings.ambient.waypointController.resourcesManagement.static**
        object

        Resource management options for the `Static` mode.

        - **settings.ambient.waypointController.resourcesManagement.static.limits**
          object

          Configuring CPU and memory limits.

          - **settings.ambient.waypointController.resourcesManagement.static.limits.cpu**
            string

Configuring CPU limits.

Pattern: `^[0-9]+m?$`

- **settings.ambient.waypointController.resourcesManagement.static.limits.memory**
  string or number

  Configuring memory limits.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.ambient.waypointController.resourcesManagement.static.requests**
  object

  Resource requests settings for pods.

  - **settings.ambient.waypointController.resourcesManagement.static.requests.cpu**
    string

    Configuring CPU requests.

    Pattern: `^[0-9]+m?$`

  - **settings.ambient.waypointController.resourcesManagement.static.requests.memory**
    string or number

    Configuring memory requests.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.ambient.waypointController.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.ambient.waypointController.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.ambient.waypointController.resourcesManagement.vpa.cpu.limitRatio**
      number

      The CPU limits/requests ratio.

      This ratio is used for calculating the initial CPU limits for a pod.

      If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

    - **settings.ambient.waypointController.resourcesManagement.vpa.cpu.max**
      string or number

      The maximum value that the VPA can set for the CPU requests.

      Default: `1`

      Pattern: `^[0-9]+m?$`

    - **settings.ambient.waypointController.resourcesManagement.vpa.cpu.min**
      string or number

      The minimum value that the VPA can set for the CPU requests.

      Default: `25m`

      Pattern: `^[0-9]+m?$`

  - **settings.ambient.waypointController.resourcesManagement.vpa.memory**
    object

    Memory-related VPA settings.

    - **settings.ambient.waypointController.resourcesManagement.vpa.memory.limitRatio**
      number

      The memory limits/requests ratio.

      This ratio is used for calculating the initial memory limits for a pod.

      If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

    - **settings.ambient.waypointController.resourcesManagement.vpa.memory.max**
      string or number

      The maximum memory requests the VPA can set.

      Default: `1Gi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.ambient.waypointController.resourcesManagement.vpa.memory.min**
      string or number

      The minimum memory requests the VPA can set.

      Default: `64Mi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.ambient.waypointController.resourcesManagement.vpa.mode**
    string

    VPA operating mode.

    Possible values:

    - `Initial`: VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
    - `InPlaceOrRecreate`: VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.

    Default: `InPlaceOrRecreate`

    Allowed values: `Initial`, `InPlaceOrRecreate`

- **settings.auth**
  object

  Options related to authentication or authorization in the application.

  Example:

```
auth:
  externalAuthentication:
    authURL: https://dex.d8.svc.cluster.local/dex/auth
    authSignInURL: https://example.com/dex/sign_in
  allowedUserGroups:
  - admins
```

- **settings.auth.allowedUserEmails**
  array of strings

  An array of emails of users that can access module's public web interfaces.

  This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

- **settings.auth.allowedUserGroups**
  array of strings

  An array of user groups that can access module's public web interfaces.

  This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

  Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

- **settings.auth.externalAuthentication**
  object

  Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

  > **i** External authentication is enabled automatically if the user-authn module is enabled.

  - **settings.auth.externalAuthentication.authSignInURL**
    string

    The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

    Example:

    ```
    authSignInURL: https://example.com/dex/sign_in
    ```

  - **settings.auth.externalAuthentication.authURL**
    string

    The URL of the authentication service.

    If the user is authenticated, the service should return an HTTP 200 response code.

    Example:

    ```
    authURL: https://example.com/dex/auth
    ```

- **settings.auth.satisfyAny**
  boolean

  Enables single authentication.

  If used together with the whitelistSourceRanges parameter, it authorizes all the users from above networks (no need to enter a username and password).

  Default: `false`

  Example:

  ```
  satisfyAny: true
  ```

- **settings.auth.whitelistSourceRanges**
  array of strings

  An array if CIDRs that are allowed to authenticate in module's public web interfaces.

  Example:

  ```
  whitelistSourceRanges:
  - 1.1.1.1/32
  ```

- **settings.ca**
  object

  Explicitly specified root certificate. It signs individual service certificates to use in mutual TLS connections.

  The certificate can be provided in one of two ways:

  - inline via the `cert` and `key` fields (with optional `chain` and `root`);
  - by referencing an existing Secret via the `secretRef` field.

  These two ways are mutually exclusive.

  Regardless of how it is provided, the CA is validated the same way: the signing certificate must be a single CA certificate (`basicConstraints = CA:TRUE`) whose key matches it, and, when an intermediate CA is used, the `root` must actually anchor the `cert` through the `chain`. Invalid material hard-blocks the module rather than being pushed to istiod.

  Removing `cert/secretRef` from the configuration does **not** revert the mesh to an auto-generated self-signed CA: the module keeps the last-published CA so an already-working mesh is never rotated implicitly — rotating the mesh root breaks mTLS cluster-wide until every workload re-trusts it. To deliberately return to a self-signed CA, remove the `cert/secretRef` configuration, delete the `d8-istio/cacerts` Secret **and** restart the Deckhouse pod. The module then generates a fresh self-signed CA. This is a mesh-wide trust change and triggers a rollout.

  - **settings.ca.cert**
    string

    The root or intermediate certificate in PEM format.

  - **settings.ca.chain**
    string

    A certificate chain in PEM format if `cert` is an intermediate certificate.

  - **settings.ca.key**
    string

    The key to the root certificate in PEM format.

  - **settings.ca.root**
    string

    The root certificate in PEM format if `cert` is an intermediate certificate. Setting `root` to the same certificate as `cert` explicitly anchors mesh trust at that certificate; this is allowed even for a non-self-signed intermediate, but rotating it later changes the mesh root (a mesh-wide trust event).

- **settings.ca.secretRef**
  object

  Reference to an existing Secret that contains the CA certificate and key.

  The Secret may be in one of the following formats (auto-detected):

  - a cert-manager `kubernetes.io/tls` Secret with the `tls.crt`, `tls.key` and `ca.crt` keys — this allows issuing the CA with any preferred tooling (cert-manager self-signed issuer, Vault issuer, etc.);
  - a native Istio `cacerts` Secret with the `ca-cert.pem`, `ca-key.pem`, `cert-chain.pem` and `root-cert.pem` keys.

  The signing certificate must be a single CA certificate (`basicConstraints = CA:TRUE`) whose key matches it. For cert-manager, issue it with `isCA: true`.

  If the referenced Secret is missing or malformed (not valid PEM, not a CA certificate, or a mismatched key pair) on the first resolution of this `secretRef`, the module will not render until the issue is fixed (it will not silently fall back to a self-signed CA or to any previously-used CA). If the same `secretRef` was already resolved successfully and later becomes unavailable or invalid, the module keeps using that last successfully-resolved CA so an already-working mesh is not regressed. Changing `secretRef` to point at a different Secret is treated as a first resolution: if the new target cannot be resolved, the module hard-blocks instead of keeping the old CA.

  Example:

  ```
  secretRef:
    name: my-istio-ca
    namespace: my-pki
  ```

  - **settings.ca.secretRef.name**
    string

    Required value

    Name of the Secret containing the CA certificate and key.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  - **settings.ca.secretRef.namespace**
    string

    Namespace of the Secret. If not specified, the Secret is looked up in the module namespace.

    Default: `d8-istio`

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **settings.configAnalysis**
  object

  Available in editions: Ultimate/EE

  Periodic Istio configuration analysis (`istioctl analyze`) that exports findings as Prometheus metrics and alerts.

  Default: `{"enabled":true}`

  - **settings.configAnalysis.enabled**
    boolean

    Enable the Istio configuration analyzer Deployment for each installed control-plane revision.

    Set to `false` to disable analysis and remove related workloads.

    Default: `true`

    Example:

    ```
    enabled: false
    ```

- **settings.controlPlane**
  object

  istiod specific settings.

  - **settings.controlPlane.extraEnvs**
    object

    Additional environment variables for the istiod (pilot) container.

    Keys reserved by the module cannot be overridden:

    - `ISTIO_MULTIROOT_MESH`
    - `ENABLE_ENHANCED_RESOURCE_SCOPING`
    - `PILOT_HTTP10`
    - `PILOT_ENABLE_AMBIENT`

    Example:

    ```
    extraEnvs:
      GODEBUG: gctrace=1
    ```

  - **settings.controlPlane.nodeSelector**
    object

    Optional `nodeSelector` for istiod. The same as the `spec.nodeSelector` pod parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.controlPlane.replicasManagement**
    object

    Replication management settings and scaling of istiod.

    Examples:

    ```
    replicasManagement:
      mode: Standard
    ```

    ```
    replicasManagement:
      mode: Static
      static:
        replicas: 3
    ```

```
replicasManagement:
  mode: HPA
  hpa:
    minReplicas: 2
    maxReplicas: 5
    metrics:
    - type: CPU
      targetAverageUtilization: 80
```

- **settings.controlPlane.replicasManagement.hpa**
  object

  Options for replicas management for the `HPA` mode.

  - **settings.controlPlane.replicasManagement.hpa.maxReplicas**
    number

    Required value

    The upper limit for the number of replicas to which the HPA can scale up. It cannot be less that `minReplicas`.

    Allowed values: `1 <= X`

  - **settings.controlPlane.replicasManagement.hpa.metrics**
    array of objects

    Required value

    The HPA will use these metrics to decide whether to increase or decrease the number of replicates.

    - **settings.controlPlane.replicasManagement.hpa.metrics.targetAverageUtilization**
      number

      Required value

      The target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

      Allowed values: `1 <= X <= 100`

    - **settings.controlPlane.replicasManagement.hpa.metrics.type**
      string

      Required value

      Metric type.

      Allowed values: `CPU`

  - **settings.controlPlane.replicasManagement.hpa.minReplicas**
    number

    Required value

    The lower limit for the number of replicas to which the HPA can scale down.

    Allowed values: `1 <= X`

- **settings.controlPlane.replicasManagement.mode**
  string

  Replicas management mode:

  - `Standard` — replicas management and scaling mode according to the global fault tolerance mode (the highAvailability parameter);
  - `Static` — the mode, where the number of replicas is specified explicitly (the static.replicas parameter);
  - `HPA` — the mode, where the number of replicas is calculated automatically using HPA based on CPU usage. You can configure this mode by modifying parameters in the hpa parameter section.

  Default: `Standard`

  Allowed values: `Standard`, `Static`, `HPA`

- **settings.controlPlane.replicasManagement.static**
  object

  Options for replicas management for the `Static` mode.

  - **settings.controlPlane.replicasManagement.static.replicas**
    number

    Required value

    Desired number of replicas.

    Allowed values: `1 <= X`

- **settings.controlPlane.resourcesManagement**
  object

  Settings for CPU and memory requests and limits by istiod pods.

  Examples:

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: InPlaceOrRecreate
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

```
resourcesManagement:
  mode: Static
  static:
    requests:
      cpu: 55m
      memory: 256Mi
    limits:
      cpu: '2'
      memory: 2Gi
```

```
resourcesManagement:
 mode: VPA
 vpa:
  mode: Auto
  cpu:
   min: 50m
   max: 2
   limitRatio: 1.5
  memory:
   min: 256Mi
   max: 2Gi
   limitRatio: 1.5
```

- **settings.controlPlane.resourcesManagement.mode**
  string

  Resource management mode:

  - `Static` — allows you to specify requests/limits. The parameters of this mode are defined in the static parameter section;
  - `VPA` — uses VPA. You can configure this mode by modifying parameters in the vpa parameter section.

  Default: `VPA`

  Allowed values: `VPA`, `Static`

- **settings.controlPlane.resourcesManagement.static**
  object

  Resource management options for the `Static` mode.

  - **settings.controlPlane.resourcesManagement.static.limits**
    object

    Configuring CPU and memory limits.

    - **settings.controlPlane.resourcesManagement.static.limits.cpu**
      string

      Configuring CPU limits.

      Pattern: `^[0-9]+m?$`

    - **settings.controlPlane.resourcesManagement.static.limits.memory**
      string or number

      Configuring memory limits.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.controlPlane.resourcesManagement.static.requests**
    object

    Resource requests settings for pods.

    - **settings.controlPlane.resourcesManagement.static.requests.cpu**
      string

      Configuring CPU requests.

      Pattern: `^[0-9]+m?$`

    - **settings.controlPlane.resourcesManagement.static.requests.memory**
      string or number

      Configuring memory requests.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.controlPlane.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.controlPlane.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.controlPlane.resourcesManagement.vpa.cpu.limitRatio**
      number

      The CPU limits/requests ratio.

      This ratio is used for calculating the initial CPU limits for a pod.

      If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

    - **settings.controlPlane.resourcesManagement.vpa.cpu.max**
      string or number

      The maximum value that the VPA can set for the CPU requests.

      Default: `2`

      Pattern: `^[0-9]+m?$`

    - **settings.controlPlane.resourcesManagement.vpa.cpu.min**
      string or number

      The minimum value that the VPA can set for the CPU requests.

      Default: `50m`

      Pattern: `^[0-9]+m?$`

  - **settings.controlPlane.resourcesManagement.vpa.memory**
    object

    Memory-related VPA settings.

    - **settings.controlPlane.resourcesManagement.vpa.memory.limitRatio**
      number

      The memory limits/requests ratio.

      This ratio is used for calculating the initial memory limits for a pod.

      If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

    - **settings.controlPlane.resourcesManagement.vpa.memory.max**
      string or number

      The maximum memory requests the VPA can set.

Default: `2Gi`

Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.controlPlane.resourcesManagement.vpa.memory.min**
  string or number

  The minimum memory requests the VPA can set.

  Default: `256Mi`

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.controlPlane.resourcesManagement.vpa.mode**
  string

  VPA operating mode.

  - `Initial` — VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
  - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.
  - `Auto` — VPA automatically recreates pods to apply updated resource values.

  > **i** Starting from Deckhouse version 1.75, this mode is considered legacy. It is recommended to use `InPlaceOrRecreate` instead.

  Default: `InPlaceOrRecreate`

  Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **settings.controlPlane.tolerations**
  array of objects

  Optional `tolerations` for istiod. The same as `spec.tolerations` for the Kubernetes pod.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.controlPlane.tolerations.effect**
    string
  - **settings.controlPlane.tolerations.key**
    string
  - **settings.controlPlane.tolerations.operator**
    string
  - **settings.controlPlane.tolerations.tolerationSeconds**
    integer
  - **settings.controlPlane.tolerations.value**
    string

- **settings.dataPlane**
  object
  - **settings.dataPlane.accessLog**
    object
    - **settings.dataPlane.accessLog.jsonLabels**
      object

      Structured access log format using key-value pairs. Template operators are described in envoy documentation.

      Default: `{"start time":"%START TIME%","method":"%REQ(:METHOD)%","path":"%REQ(X-ENVOY-ORIGINAL-PATH?:PATH)%","protocol":"%PROTOCOL%","response code":"%RESPONSE CODE%","response flags":"%RESPONSE_FLAGS%","bytes received":"%BYTES RECEIVED%","bytes sent":"%BYTES SENT%","duration":"%DURATION%","user_agent":"%REQ(USER-AGENT)%","authority":"%REQ(:AUTHORITY)%","upstream_host":"%UPSTREAM_HOST%"}`

    - **settings.dataPlane.accessLog.textFormat**
      string

      Sidecar's access log format template. Template operators are described in envoy documentation.

      Default: `[%START TIME%] "%REQ(:METHOD)% %REQ(X-ENVOY-ORIGINAL-PATH?:PATH)% %PROTOCOL%" %RESPONSE CODE% %RESPONSE_FLAGS% %RESPONSE_CODE_DETAILS% %CONNECTION_TERMINATION_DETAILS% "%UPSTREAM_TRANSPORT_FAILURE_REASON%" %BYTES RECEIVED% %BYTES SENT% %DURATION% %RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)% "%REQ(X-FORWARDED-FOR)%" "%REQ(USER-AGENT)%" "%REQ(X-REQUEST-ID)%" "%REQ(:AUTHORITY)%" "%UPSTREAM_HOST%" %UPSTREAM_LOCAL_ADDRESS% %DOWNSTREAM_LOCAL_ADDRESS% %DOWNSTREAM_REMOTE_ADDRESS% %REQUESTED_SERVER_NAME% %ROUTE_NAME%`

    - **settings.dataPlane.accessLog.type**
      string

      Default: `Text`

      Allowed values: `Text`, `JSON`

  - **settings.dataPlane.enableHTTP10**
    boolean

    Whether to handle HTTP/1.0 requests in istio-sidecars or deny them with `426 Upgrade Required` response.

    Default: `false`

    Example:

    ```
    enableHTTP10: true
    ```

  - **settings.dataPlane.extensionProviders**
    array of objects

    Additional Istio extension providers to register in the mesh configuration.

    In each provider, set exactly one of `envoyExtAuthzGrpc`, `envoyExtAuthzHttp`, `opentelemetry` or `zipkin`.

    The module does not enable the registered providers. Reference them by name in your AuthorizationPolicy (`action: CUSTOM`) or Telemetry. Mesh-wide tracing configured in `tracing` is not affected.

    The `d8-main` and `deckhouse-tracing` provider names are reserved for the module. The `envoy`, `prometheus` and `stackdriver` names are reserved for the providers built into Istio, because a provider with such a name would replace the built-in one.

    Extension provider settings.

    Default: `[]`

    Examples:

    ```
    extensionProviders:
    - name: authservice-grpc
      envoyExtAuthzGrpc:
        service: authservice.example.svc.cluster.local
        port: 10003
    ```

```
extensionProviders:
- name: oauth2-proxy
  envoyExtAuthzHttp:
    service: oauth2-proxy.example.svc.cluster.local
    port: 4180
    includeRequestHeadersInCheck:
    - authorization
    - cookie
    headersToUpstreamOnAllow:
    - authorization
    - x-auth-request-user
    headersToDownstreamOnDeny:
    - content-type
    - set-cookie
- name: otel-tracing
  opentelemetry:
    service: opentelemetry-collector.observability.svc.cluster.local
    port: 4317
- name: zipkin-tracing
  zipkin:
    service: zipkin.example.svc.cluster.local
    port: 9411
```

- **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc**
  object

  External authorization provider that implements Envoy ext_authz gRPC API.

  - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.clearRouteCache**
    boolean

    Clear route cache to let the external authorization service affect routing decisions.

  - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.failOpen**
    boolean

    Allow requests when the authorization service is unavailable or returns a 5xx error.

  - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.port**
    integer

    Required value

    Service port.

    Allowed values: `1 <= X <= 65535`

  - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.service**
    string

    Required value

    Service that implements Envoy ext_authz gRPC API. The format is `[<namespace>/]<hostname>`.

    `<hostname>` must be the full hostname of a Service, including the cluster domain (for example, `authservice.example.svc.cluster.local`), or a ServiceEntry host. Short names and IP addresses do not work. Specify `<namespace>` only if this hostname exists in several namespaces.

    If Istio cannot find the service, the requests that match AuthorizationPolicy with `action: CUSTOM` referencing this provider are denied.

    Pattern: `^([a-z0-9]([-a-z0-9]{0,61}[a-z0-9])?/)?([a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?\.)*[a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?$`

  - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.statusOnError**
    string

    HTTP status returned to the client when communication with the authorization service fails.

    Only the status codes that Envoy supports are allowed, for example `403` or `503`.

    Pattern: `^(100|20[0-8]|226|30[0-578]|4(0[0-9]|1[0-7]|2[1-4689]|31)|5(0[0-8]|1[01]))$`

    Example:

    ```
    statusOnError: '503'
    ```

  - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.timeout**
    string

    Maximum duration the proxy waits for the authorization service response.

    Pattern: `^([0-9]+(\.[0-9]+)?(ns|us|µs|ms|s|m|h))+$`

    Example:

    ```
    timeout: 5s
    ```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp**
  object

  External authorization provider that implements Envoy ext_authz HTTP API.

  - **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.clearRouteCache**
    boolean

    Clear route cache to let the external authorization service affect routing decisions.

  - **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.failOpen**
    boolean

    Allow requests when the authorization service is unavailable or returns a 5xx error.

  - **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.headersToDownstreamOnAllow**
    array of strings

    Headers from the authorization service response to add or override in the response sent back to the client when the request is allowed.

    Exact, prefix (`abc*`) and suffix (`*abc`) matches are supported.

    Example:

    ```
    headersToDownstreamOnAllow:
    - set-cookie
    ```

  - **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.headersToDownstreamOnDeny**
    array of strings

Headers from the authorization service response to send back to the client when the request is denied.

Exact, prefix (`abc*`) and suffix (`*abc`) matches are supported.

Example:

```
headersToDownstreamOnDeny:
- content-type
- set-cookie
```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.headersToUpstreamOnAllow**
  array of strings

  Headers from the authorization service response to add or override in the request sent upstream when the request is allowed.

  Exact, prefix (`abc*`) and suffix (`*abc`) matches are supported.

  Example:

  ```
  headersToUpstreamOnAllow:
  - authorization
  - x-auth-request-user
  ```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.includeAdditionalHeadersInCheck**
  object

  Additional headers with fixed values to send to the authorization service.

  A header with the same name in the original request is overridden.

  Example:

  ```
  includeAdditionalHeadersInCheck:
    x-ext-authz-source: istio
  ```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.includeRequestHeadersInCheck**
  array of strings

  Headers of the original request to send to the authorization service.

  The `Host`, `Method`, `Path` and `Content-Length` headers are always sent.

  Exact, prefix (`abc*`) and suffix (`*abc`) matches are supported.

  Example:

  ```
  includeRequestHeadersInCheck:
  - authorization
  - cookie
  ```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.pathPrefix**
  string

  Prefix added to the path of the original request before sending it to the authorization service.

  For example, with `pathPrefix: /check` a request to `/foo` is checked as `/check/foo`.

  Pattern: `^/`

  Example:

  ```
  pathPrefix: "/check"
  ```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.port**
  integer

  Required value

  Service port.

  Allowed values: `1 <= X <= 65535`

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.service**
  string

  Required value

  Service that implements Envoy ext_authz HTTP API. The format is `[<namespace>/]<hostname>`.

  `<hostname>` must be the full hostname of a Service, including the cluster domain (for example, `oauth2-proxy.example.svc.cluster.local`), or a ServiceEntry host. Short names and IP addresses do not work. Specify `<namespace>` only if this hostname exists in several namespaces.

  If Istio cannot find the service, the requests that match AuthorizationPolicy with `action: CUSTOM` referencing this provider are denied.

  Pattern: `^([a-z0-9]([-a-z0-9]{0,61}[a-z0-9])?/)?([a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?\.)*[a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?$`

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.statusOnError**
  string

  HTTP status returned to the client when communication with the authorization service fails.

  Only the status codes that Envoy supports are allowed, for example `403` or `503`.

  Pattern: `^(100|20[0-8]|226|30[0-578]|4(0[0-9]|1[0-7]|2[1-4689]|31)|5(0[0-8]|1[01]))$`

  Example:

  ```
  statusOnError: '503'
  ```

- **settings.dataPlane.extensionProviders.envoyExtAuthzHttp.timeout**
  string

  Maximum duration the proxy waits for the authorization service response.

  Pattern: `^([0-9]+(\.[0-9]+)?(ns|us|µs|ms|s|m|h))+$`

  Example:

  ```
  timeout: 5s
  ```

- **settings.dataPlane.extensionProviders.name**
  string

  Required value

  Unique extension provider name.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **settings.dataPlane.extensionProviders.opentelemetry**
  object

  Tracing provider that exports spans with OpenTelemetry Protocol (OTLP).

  Spans are exported over gRPC unless `http` is set.

  - **settings.dataPlane.extensionProviders.opentelemetry.grpc**
    object

    Settings for exporting spans with OTLP over gRPC.

    Cannot be used together with `http`.

    - **settings.dataPlane.extensionProviders.opentelemetry.grpc.initialMetadata**
      array of objects

      Additional metadata to send with each gRPC stream.

      Example:

      ```
      initialMetadata:
      - name: x-scope-orgid
        value: tenant-a
      ```

      - **settings.dataPlane.extensionProviders.opentelemetry.grpc.initialMetadata.name**
        string

        Required value

      - **settings.dataPlane.extensionProviders.opentelemetry.grpc.initialMetadata.value**
        string

        Required value

    - **settings.dataPlane.extensionProviders.opentelemetry.grpc.timeout**
      string

      Maximum duration the proxy waits for the collector response.

      Pattern: `^([0-9]+(\.[0-9]+)?(ns|us|µs|ms|s|m|h))+$`

      Example:

      ```
      timeout: 10s
      ```

  - **settings.dataPlane.extensionProviders.opentelemetry.http**
    object

    Settings for exporting spans with OTLP over HTTP.

    Cannot be used together with `grpc`.

    - **settings.dataPlane.extensionProviders.opentelemetry.http.headers**
      array of objects

      Additional headers to send with each export request.

      Example:

      ```
      headers:
      - name: x-scope-orgid
        value: tenant-a
      ```

      - **settings.dataPlane.extensionProviders.opentelemetry.http.headers.name**
        string

        Required value

      - **settings.dataPlane.extensionProviders.opentelemetry.http.headers.value**
        string

        Required value

    - **settings.dataPlane.extensionProviders.opentelemetry.http.path**
      string

      Required value

      Path of the OTLP traces endpoint.

      Example:

      ```
      path: "/v1/traces"
      ```

    - **settings.dataPlane.extensionProviders.opentelemetry.http.timeout**
      string

      Maximum duration the proxy waits for the collector response.

      Pattern: `^([0-9]+(\.[0-9]+)?(ns|us|µs|ms|s|m|h))+$`

      Example:

      ```
      timeout: 10s
      ```

  - **settings.dataPlane.extensionProviders.opentelemetry.maxTagLength**
    integer

    Maximum length of the request path to extract and include in the `http.url` span tag. If not set, the Envoy default (`256`) is used.

    Allowed values: `1 <= X`

  - **settings.dataPlane.extensionProviders.opentelemetry.port**
    integer

    Required value

    OpenTelemetry collector port.

    Allowed values: `1 <= X <= 65535`

    Example:

    ```
    port: 4317
    ```

  - **settings.dataPlane.extensionProviders.opentelemetry.resourceDetectors**
    object

OpenTelemetry resource detectors that add attributes to the exported spans.

- **settings.dataPlane.extensionProviders.opentelemetry.resourceDetectors.dynatrace**
  object

  Read resource attributes from the files written by Dynatrace OneAgent.

  Set to `{}` to enable.

- **settings.dataPlane.extensionProviders.opentelemetry.resourceDetectors.environment**
  object

  Read resource attributes from the `OTEL_RESOURCE_ATTRIBUTES` environment variable of the proxy.

  Set to `{}` to enable.

- **settings.dataPlane.extensionProviders.opentelemetry.service**
  string

  Required value

  OpenTelemetry collector service. The format is `[<namespace>/]<hostname>`.

  `<hostname>` must be the full hostname of a Service, including the cluster domain (for example, `opentelemetry-collector.observability.svc.cluster.local`), or a ServiceEntry host. Short names and IP addresses do not work. Specify `<namespace>` only if this hostname exists in several namespaces.

  If Istio cannot find the service, spans are not exported.

  Pattern: `^([a-z0-9]([-a-z0-9]{0,61}[a-z0-9])?/)?([a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?\.)*[a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?$`

  Example:

  ```
  service: opentelemetry-collector.observability.svc.cluster.local
  ```

- **settings.dataPlane.extensionProviders.zipkin**
  object

  Tracing provider that exports spans with Zipkin API.

  - **settings.dataPlane.extensionProviders.zipkin.enable64bitTraceId**
    boolean

    Use 64-bit trace IDs instead of 128-bit ones.

  - **settings.dataPlane.extensionProviders.zipkin.maxTagLength**
    integer

    Maximum length of the request path to extract and include in the `http.url` span tag. If not set, the Envoy default (`256`) is used.

    Allowed values: `1 <= X`

  - **settings.dataPlane.extensionProviders.zipkin.path**
    string

    Path of the Zipkin spans endpoint. If not set, `/api/v2/spans` is used.

    Pattern: `^/`

    Example:

    ```
    path: "/api/v2/spans"
    ```

  - **settings.dataPlane.extensionProviders.zipkin.port**
    integer

    Required value

    Zipkin collector port.

    Allowed values: `1 <= X <= 65535`

    Example:

    ```
    port: 9411
    ```

  - **settings.dataPlane.extensionProviders.zipkin.service**
    string

    Required value

    Zipkin collector service. The format is `[<namespace>/]<hostname>`.

    `<hostname>` must be the full hostname of a Service, including the cluster domain (for example, `zipkin.example.svc.cluster.local`), or a ServiceEntry host. Short names and IP addresses do not work. Specify `<namespace>` only if this hostname exists in several namespaces.

    If Istio cannot find the service, spans are not exported.

    Pattern: `^([a-z0-9]([-a-z0-9]{0,61}[a-z0-9])?/)?([a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?\.)*[a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?$`

    Example:

    ```
    service: zipkin.example.svc.cluster.local
    ```

- **settings.dataPlane.proxyConfig**
  object

  Mesh-wide defaults for ProxyConfig configurations.

  - **settings.dataPlane.proxyConfig.holdApplicationUntilProxyStarts**
    boolean

    With this feature, the sidecar-injector injects the sidecar at the first place of Pod’s container list and adds a postStart hook to be sure if the Envoy proxy is initialized before the application. So the Envoy is able to handle requests without application network errors.

    This global flag can be overriden per Pod by an annotation — `proxy.istio.io/config: '{ "holdApplicationUntilProxyStarts": true }'`.

    Has no effect on native sidecars, which Istio 1.27 and newer inject by default: they always start before the application.

    Default: `false`

    Example:

    ```
    holdApplicationUntilProxyStarts: true
    ```

  - **settings.dataPlane.proxyConfig.idleTimeout**
    string

    Timeout for connections without application activity established between the client’s istio-sidecar and the service. When the timeout expires, the connection between the sidecar and the service is closed, but the connection between the application and the sidecar is not closed. If set to `0s`,

the timeout is disabled.

This global flag can be overriden per Pod by an annotation:

```
proxy.istio.io/config: |-
  proxyMetadata:
    ISTIO_META_IDLE_TIMEOUT: "12h"
```

> **Warning!** Disabling this timeout (setting the value to `0s`) is very likely to result in leaky connections due to TCP FIN packet loss, etc.
> **Warning!** After changing this setting, a restart of the client pods is required.

Default: `1h`

Pattern: `^[0-9]+(s|m|h)$`

Example:

```
idleTimeout: 24h
```

- **settings.dataPlane.trafficRedirectionSetupMode**
  string

  Managing the redirection mode of application traffic to be forwarded under Istio control in the Pod's network namespace.

  - `CNIPlugin` — in this mode, the configuration is performed by a CNI plugin when creating a Pod on a node. This mode does not require additional permissions for Pods and is recommended. This mode has limitations when using application init-containers that perform network communication with other services. The limitations apply only to regular sidecars, which Istio 1.25 injects by default.
  - `InitContainer` — classic mode, each application Pod is automatically injected with a special init-container that configures the network environment of the Pod. In order to perform this configuration, the init-container is given additional permissions, which may not meet the security requirements of individual installations.

  Default: `InitContainer`

  Allowed values: `CNIPlugin`, `InitContainer`

  Examples:

  ```
  trafficRedirectionSetupMode: CNIPlugin
  ```

  ```
  trafficRedirectionSetupMode: InitContainer
  ```

- **settings.federation**
  object

  Available in editions: Ultimate/EE

  Parameters for federating with other clusters.

  - **settings.federation.enabled**
    boolean

    Designate this cluster as a federation member. See how to enable federation.

    Federation covers sidecar-mode workloads only. Ambient-mode workloads cannot take part in it. See ambient mesh limitations.

    Default: `false`

- **settings.globalVersion**
  string

  Specific version of Istio control-plane which handles unspecific versions of data plane (namespaces with `istio-injection=enabled` label, not `istio.io/rev=`).

  Default: `1.27`

  Allowed values: `1.25`, `1.27`, `1.29`

  Example:

  ```
  globalVersion: '1.29'
  ```

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

  Example:

  ```
  highAvailability: true
  ```

- **settings.https**
  object

  What certificate type to use with module's public web interfaces.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object
    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy.

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.https.customCertificate**

object
- **settings.https.customCertificate.secretName**
  string

  The name of the secret in the `d8-system` namespace to use with Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy.

  This secret must have the kubernetes.io/tls format.

  Default: `false`

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager` — Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy will use HTTPS and get a certificate from the clusterissuer defined in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate` — Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy will use HTTPS using the certificate from the `d8-system` namespace.
  - `OnlyInURI` — Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy will work over HTTP (thinking that there is an external HTTPS load balancer in front that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

  Caution! Unlike other modules, Istio doesn't support non-secured HTTP (`mode: Disabled`).

  Default: `CertManager`

  Allowed values: `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for Kiali, metadata-exporter and proxy-api.

  Optional. By default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.jwksResolverAdditionalRootCA**
  string

  An additional root certificate in PEM format. It is used by istiod when resolving JWKS URIs over HTTPS.

  Example: —-BEGIN CERTIFICATE—- MIIDXTCCAkWgAwIBAgIJAN… —-END CERTIFICATE—-

- **settings.multicluster**
  object

  Available in editions: Ultimate/EE

  Multicluster parameters.

  - **settings.multicluster.enabled**
    boolean

    Designate this cluster as a multicluster member. See how to enable multicluster.

    Multicluster covers sidecar-mode workloads only. Ambient-mode workloads cannot take part in it. See ambient mesh limitations.

    Default: `false`

    Example:

    ```
    enabled: true
    ```

- **settings.nodeSelector**
  object

  Optional `nodeSelector` for istio-operator, metadata-exporter and Kiali. The same as the `spec.nodeSelector` pod parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.outboundTrafficPolicyMode**
  string

  Policy for requests directed to external services that aren't registered in the mesh.

  With `RegistryOnly`, external services must be registered via a `ServiceEntry` custom resource or routed through an `egressgateway`.

  Default: `AllowAny`

  Allowed values: `AllowAny`, `RegistryOnly`

  Example:

  ```
  outboundTrafficPolicyMode: AllowAny
  ```

- **settings.sidecar**
  object

  Network settings for traffic capture by istio sidecar.

  - **settings.sidecar.excludeInboundPorts**
    array of strings

    The range of inbound ports whose traffic is guaranteed not to flow through Istio.

    You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/excludeInboundPorts` annotation.

    Default: `[]`

    Example:

    ```
    excludeInboundPorts:
    - '8080'
    - '8443'
    ```

    - **Element of the array**
      string

      Pattern: `^[0-9]{1,5}$`

  - **settings.sidecar.excludeOutboundIPRanges**
    array of strings

    Traffic to these IP ranges is guaranteed not to flow through Istio.

    You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/excludeOutboundIPRanges` annotation.

    Default: `[]`

    Example:

```
excludeOutboundIPRanges:
- 10.1.1.0/24
```

- **Element of the array**
  string

  Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **settings.sidecar.excludeOutboundPorts**
  array of strings

  The range of outbound ports whose traffic is guaranteed not to flow through Istio.

  You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/excludeOutboundPorts` annotation.

  Default: `[]`

  Example:

```
excludeOutboundPorts:
- '8080'
- '8443'
```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,5}$`

- **settings.sidecar.includeOutboundIPRanges**
  array of strings

  Traffic to these IP ranges is forcibly routed through Istio.

  You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/includeOutboundIPRanges` annotation.

  Default: `["0.0.0.0/0"]`

  Example:

```
includeOutboundIPRanges:
- 10.1.1.0/24
```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **settings.sidecar.resourcesManagement**
  object

  Manages Istio sidecar container resources.

  Caution! The setting only applies to new Pods with `istio-proxy`.

  Example:

```
resourcesManagement:
 static:
   requests:
     cpu: 100m
     memory: 128Mi
   limits:
     cpu: 2000m
     memory: 1Gi
```

  - **settings.sidecar.resourcesManagement.mode**
    string

    Resource management mode:

    - `Static` — allows you to specify requests/limits. The parameters of this mode are defined in the static parameter section;

    Default: `Static`

    Allowed values: `Static`

  - **settings.sidecar.resourcesManagement.static**
    object

    Resource management options for the `Static` mode.

    - **settings.sidecar.resourcesManagement.static.limits**
      object

      Configuring CPU and memory limits.

      - **settings.sidecar.resourcesManagement.static.limits.cpu**
        string

        Configuring CPU limits.

        Default: `2000m`

        Pattern: `^[0-9]+m?$`

      - **settings.sidecar.resourcesManagement.static.limits.memory**
        string or number

        Configuring memory limits.

        Default: `1Gi`

        Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.sidecar.resourcesManagement.static.requests**
      object

      Resource requests settings for pods.

      - **settings.sidecar.resourcesManagement.static.requests.cpu**
        string

        Configuring CPU requests.

        Default: `100m`

        Pattern: `^[0-9]+m?$`

      - **settings.sidecar.resourcesManagement.static.requests.memory**
        string or number

Configuring memory requests.

Default: `128Mi`

Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.telemetryAPI**
  object

  Telemetry API (`telemetry.istio.io`) integration.

  When `enabled` is `true`, the module drives mesh metrics via the Telemetry API and `meshConfig.defaultProviders.metrics: [prometheus]`, keeps `values.telemetry.enabled` but disables the previous `telemetry.v2` filters, and extends the always-present `Telemetry d8-main` in `d8-istio` with `spec.metrics`. When `tracing.enabled` is `true` with a configured `tracing.collector`, `spec.tracing` is added via `deckhouse-tracing` so Grafana and Kiali keep seeing `istio_*` series from sidecars.

  When `false` (default), the previous `telemetry.v2` stack stays on (including Sail's `telemetry.v2.prometheus`), without `defaultProviders.metrics`, while `Telemetry d8-main` still enables access logs (backwards compatible with releases since the access-log `Telemetry` was introduced).

  `dataPlane.accessLog` defines the Envoy log template in `meshConfig.extensionProviders`; the `Telemetry d8-main` object selects that provider for access logging.

  - **settings.telemetryAPI.enabled**
    boolean

    Telemetry API path: wires `defaultProviders.metrics`, turns off `telemetry.v2`, adds `spec.metrics` (and tracing when configured) to `Telemetry d8-main`.

    Default: `false`

    Example:

    ```
    enabled: true
    ```

- **settings.tolerations**
  array of objects

  Optional `tolerations` for istio-operator, metadata-exporter and Kiali. The same as `spec.tolerations` for the Kubernetes pod.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string
- **settings.tracing**
  object

  Tracing parameters.

  If the `ingress-nginx` module is enabled (`global.enabledModules` contains `ingress-nginx`), the module creates Istio `Telemetry` resource `ingress-nginx-disable-span-reporting` in namespace `d8-ingress-nginx`. Built-in Ingress controller pods with an Istio sidecar stop exporting spans to the tracing backend (reduces noise while keeping meshes functional).

  - **settings.tracing.collector**
    object

    Tracing collection settings. Single source for both legacy control-plane tracing and the Telemetry API path.

    - If `telemetryAPI.enabled` is `false` and `tracing.enabled` is `true`, the module fills `meshConfig.defaultConfig.tracing.zipkin` from `collector.zipkin.address` (with `tracing.sampling`). OpenTelemetry export requires the Telemetry API path.
    - If `telemetryAPI.enabled` is `true` and tracing is enabled, configure either `collector.opentelemetry` or `collector.zipkin`. When both are set, OpenTelemetry wins. In either case the extension provider is named `deckhouse-tracing` with `spec.tracing` on `Telemetry d8-main`.
    - **settings.tracing.collector.opentelemetry**
      object

      OpenTelemetry extension provider for the Telemetry API path (`meshConfig.extensionProviders` + mesh-wide `spec.tracing`).

      Requires `service` and `port` (gRPC OTLP by default; set `http.path` for HTTP export). Not used when `telemetryAPI.enabled` is `false`.

      - **settings.tracing.collector.opentelemetry.http**
        object

        Optional HTTP OTLP exporter settings (omit to use gRPC).

        - **settings.tracing.collector.opentelemetry.http.path**
          string

          OTLP traces HTTP path (defaults to `/v1/traces` in the chart when `http` is set but `path` is empty).

          Example:

          ```
          path: "/v1/traces"
          ```

        - **settings.tracing.collector.opentelemetry.http.timeout**
          string

          HTTP export timeout (Istio duration string).

          Pattern: `^([0-9]+(\.[0-9]+)?(ns|us|µs|ms|s|m|h))+$`

          Example:

          ```
          timeout: 10s
          ```

      - **settings.tracing.collector.opentelemetry.port**
        integer

        Collector port (for example `4317` for gRPC OTLP).

        Allowed values: `1 <= X <= 65535`

        Example:

        ```
        port: 4317
        ```

      - **settings.tracing.collector.opentelemetry.service**
        string

        OpenTelemetry collector service. The format is `[<namespace>/]<hostname>`.

        `<hostname>` must be the full hostname of a Service, including the cluster domain (for example, `opentelemetry-collector.observability.svc.cluster.local`), or a ServiceEntry host. Short names and IP addresses do not work. Specify `<namespace>` only if this hostname exists in several namespaces.

If Istio cannot find the service, spans are not exported.

Pattern: `^([a-z0-9]([-a-z0-9]{0,61}[a-z0-9])?/)?([a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?\.)*[a-zA-Z0-9]([-a-zA-Z0-9]{0,61}[a-zA-Z0-9])?$`

Example:

```
service: opentelemetry-collector.observability.svc.cluster.local
```

- **settings.tracing.collector.zipkin**
  object

  Zipkin protocol parameters used by Istio for sending traces. Jaeger accepts Zipkin ingestion on the standard port (`9411`).

  With tracing enabled, set `address` here for legacy mode or for Telemetry API when OpenTelemetry is not configured under `collector.opentelemetry`.

  - **settings.tracing.collector.zipkin.address**
    string

    Network address of the Zipkin collector in `<host>:<port>` format.

    If `telemetryAPI.enabled` is `true`, `<host>` must be the full hostname of a service known to Istio, including the cluster domain, for example `zipkin.myjaeger.svc.cluster.local` for a Kubernetes Service. Short names (such as `zipkin.myjaeger.svc`) and IP addresses do not work in this mode.

    Pattern: `^[0-9a-zA-Z.-]+:([1-9][0-9]{0,3}|[1-5][0-9]{4}|6[0-4][0-9]{3}|65[0-4][0-9]{2}|655[0-2][0-9]|6553[0-5])$`

    Example:

    ```
    address: zipkin.myjaeger.svc.cluster.local:9411
    ```

- **settings.tracing.enabled**
  boolean

  Turn on or off tracing collection and displaying in Kiali.

  Default: `false`

  Example:

  ```
  enabled: true
  ```

- **settings.tracing.kiali**
  object

  Span displaying settings for Kiali.

  When not configured, Kiali won’t show any tracing dashboards.

  Examples:

  ```
  kiali: {}
  ```

  ```
  kiali:
    jaegerURLForUsers: https://tracing-service:4443/jaeger
    jaegerGRPCEndpoint: http://tracing.myjaeger.svc:16685/
  ```

  - **settings.tracing.kiali.jaegerGRPCEndpoint**
    string

    Accessible from cluster address of jaeger GRPC interface for system queries by Kiali.

    When not configured, Kiali will only show external links using the `jaegerURLForUsers` config without interpretationing.

    Example:

    ```
    jaegerGRPCEndpoint: http://tracing.myjaeger.svc:16685/
    ```

  - **settings.tracing.kiali.jaegerURLForUsers**
    string

    Jaeger UI address for users. Mandatory parameter if Kiali is enabled.

    Example:

    ```
    jaegerURLForUsers: https://tracing-service:4443/jaeger
    ```

- **settings.tracing.sampling**
  number

  The sampling rate option can be used to control what percentage of requests get reported to your tracing system.

  This should be configured depending upon your traffic in the mesh and the amount of tracing data you want to collect.

  It is possible to override this option with the following Pod annotation:

  ```
  proxy.istio.io/config: |
    tracing:
      sampling: 100.0
  ```

  Default: `1.0`

  Allowed values: `0.01 <= X <= 100.0`

  Example:

  ```
  sampling: 50.05
  ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

IngressIstioController

Scope: Cluster
Version: v1alpha1

- **spec**
  object

  Required value

  - **spec.hostPort**
    object

    `HostPort` inlet settings.

    - **spec.hostPort.httpPort**
      integer

      Port for insecure HTTP connections.

      If the parameter is not set, the connection over HTTP cannot be established.

      This parameter is mandatory if `httpsPort` is not set.

      Example:

      ```
      httpPort: 80
      ```

    - **spec.hostPort.httpsPort**
      integer

      Port for secure HTTPS connections.

      If the parameter is not set, the connection over HTTPS cannot be established.

      This parameter is mandatory if `httpPort` is not set.

      Example:

      ```
      httpsPort: 443
      ```

  - **spec.ingressGatewayClass**
    string

    Required value

    Ingress gateway class is used by application Gateway resources for identifying the right Ingress gateway setup.

    The identification is organized by setting the spec.selector: `istio.deckhouse.io/ingress-gateway-class: <ingressGatewayClass value>`.

    This parameter does not change during the entire resource life.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

Maximum length: `63`

Example:

```
ingressGatewayClass: istio
```

- **spec.inlet**
  string

  Required value

  The way traffic goes to cluster from the outer network.

  - `LoadBalancer` — Ingress controller is deployed and the service of `LoadBalancer` type is provisioned.
  - `NodePort` — Ingress controller is deployed and available through nodes' ports via `nodePort`.
  - `HostPort` — Ingress controller is deployed and available through nodes' ports via `hostPort`.

    > **Caution.** There can be only one controller with this inlet type on a host.

  Allowed values: `LoadBalancer`, `HostPort`, `NodePort`

- **spec.loadBalancer**
  object

  Not required value.

  A section of parameters of the `LoadBalancer` inlet.

  - **spec.loadBalancer.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

  - **spec.loadBalancer.loadBalancerClass**
    string

    Class of the load balancer for incoming network requests (passed to the `spec.loadBalancerClass` parameter of the provisioned service with the `LoadBalancer` type).

- **spec.networkTopology**
  object

  Configures how the gateway extracts the client's original attributes (e.g. the source IP address) when it is deployed behind other proxies or load balancers.

  See Configuring Gateway Network Topology in the Istio documentation.

  - **spec.networkTopology.numTrustedProxies**
    integer

    Number of trusted proxies deployed in front of the Istio gateway proxy.

    It is used to correctly extract the client address from the `X-Forwarded-For` header and populate the `X-Envoy-External-Address` header consumed by upstream services.

    For example, if there is a cloud load balancer and a reverse proxy in front of the gateway, set this to `2`.

    It can be used with `proxyProtocol`. When both are configured and an incoming request contains an `X-Forwarded-For` header, Istio uses the trusted `X-Forwarded-For` chain in preference to the PROXY protocol attributes.

    Allowed values: `0 <= X`

    Example:

    ```
    numTrustedProxies: 2
    ```

  - **spec.networkTopology.proxyProtocol**
    boolean

    Enables the PROXY protocol on the gateway's TCP listeners, so that client attributes (such as

the source IP) forwarded by an upstream L4/TCP load balancer are preserved.

It can be used with `numTrustedProxies`. When both are configured and an incoming request contains an `X-Forwarded-For` header, Istio uses the trusted `X-Forwarded-For` chain in preference to the PROXY protocol attributes.

Example:

```
proxyProtocol: true
```

- **spec.nodePort**
  object

  `NodePort` inlet settings.

  - **spec.nodePort.httpPort**
    integer

    Port for insecure HTTP connections.

    If the parameter is not set, the connection over HTTP cannot be established.

    This parameter is mandatory if `httpsPort` is not set.

    Example:

    ```
    httpPort: 30080
    ```

  - **spec.nodePort.httpsPort**
    integer

    Port for secure HTTPS connections.

    If the parameter is not set, the connection over HTTPS cannot be established.

    This parameter is mandatory if `httpPort` is not set.

    Example:

    ```
    httpsPort: 30443
    ```

- **spec.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resourcesRequests**
  object

  Settings for CPU and memory requests and limits by ingress gateway pods.

  If omitted, the built-in VPA mode defaults are used. In `Static` mode, requests are specified directly in `static`. In `VPA` mode, the VPA adjusts requests within the configured minimum and maximum bounds.

  - **spec.resourcesRequests.mode**
    string

    Required value

    Resource management mode:

    - `Static` — allows you to specify requests directly in the `static` section;
    - `VPA` — uses VPA. You can configure this mode by modifying parameters in the `vpa` section.

    Default: `VPA`

    Allowed values: `VPA`, `Static`

  - **spec.resourcesRequests.static**
    object

    Resource management options for the `Static` mode.

    - **spec.resourcesRequests.static.cpu**

string

Configuring CPU requests.

Default: `100m`

- **spec.resourcesRequests.static.memory**
  string

  Configuring memory requests.

  Default: `128Mi`

- **spec.resourcesRequests.vpa**
  object

  Resource management options for the `VPA` mode.

  - **spec.resourcesRequests.vpa.cpu**
    object

    CPU-related VPA settings.

    - **spec.resourcesRequests.vpa.cpu.max**
      string

      The maximum value that the VPA can set for the CPU requests.

      Default: `1000m`

    - **spec.resourcesRequests.vpa.cpu.min**
      string

      The minimum value that the VPA can set for the CPU requests.

      Default: `100m`

  - **spec.resourcesRequests.vpa.memory**
    object

    Memory-related VPA settings.

    - **spec.resourcesRequests.vpa.memory.max**
      string

      The maximum memory requests the VPA can set.

      Default: `2048Mi`

    - **spec.resourcesRequests.vpa.memory.min**
      string

      The minimum memory requests the VPA can set.

      Default: `128Mi`

  - **spec.resourcesRequests.vpa.mode**
    string

    VPA operating mode.

    - `Initial` — VPA sets initial values for pod resource requests at pod creation time. Resource values are not changed automatically afterwards.
    - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod is recreated.
    - `Auto` — VPA automatically recreates pods to apply updated resource values. This mode is considered legacy starting from Deckhouse version 1.75; `InPlaceOrRecreate` is recommended.

    Default: `Initial`

    Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **spec.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Format: the standard toleration list. Instance pods inherit this field as is.

        - **spec.tolerations.effect**
          string

          Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
        - **spec.tolerations.key**
          string
        - **spec.tolerations.operator**
          string

          Default: `Equal`

          Allowed values: `Exists`, `Equal`
        - **spec.tolerations.tolerationSeconds**
          integer
        - **spec.tolerations.value**
          string

IstioFederation

Scope: Cluster
Version: v1alpha1

Custom resource for setting remote cluster as trusted one.

- **spec**
  object

  Required value

  Available in editions: Ultimate/EE

  - **spec.metadata**
    object
    - **spec.metadata.ca**
      string

      Available in editions: Ultimate/EE

      Certificate for validation HTTPS endpoint with remote cluster metadata.

      Example:

      ```
      ca: "-----BEGIN CERTIFICATE----- ..... -----END CERTIFICATE-----"
      ```
    - **spec.metadata.insecureSkipVerify**
      boolean

      Available in editions: Ultimate/EE

      Skip validation certificate on HTTPS endpoint with remote cluster metadata.

      Default: `false`

      Example:

      ```
      insecureSkipVerify: true
      ```
  - **spec.metadataEndpoint**
    string

    Required value

    Available in editions: Ultimate/EE

    HTTPS endpoint with remote cluster metadata.

    Example:

    ```
    metadataEndpoint: https://istio.k8s.example.com/metadata/
    ```
  - **spec.trustDomain**
    string

    Required value

    Available in editions: Ultimate/EE

The TrustDomain of the remote cluster.

Deckhouse uses this value so that certificates from the remote cluster are trusted only for that remote domain, not for services in the local mesh.

Pattern: `^[0-9a-zA-Z._-]+$`

Example:

```
trustDomain: cluster.local
```

- **status**
  object
  - **status.conditions**
    array of objects

    Readiness of metadata exchange with the remote cluster.

    If `spec.trustDomain` equals the domain of this cluster, the resource does not take part in the federation: once the public metadata exchange succeeds, private metadata is not requested and `PrivateMetadataExchangeReady` is `False` with reason `ClusterDomainMismatch`; the remote cluster gets `UnknownSourceCluster` from this cluster.

    - `PublicMetadataExchangeReady` — remote `public.json` is reachable and valid. Reasons:
      - `Succeeded` (`True`) — the remote public metadata is received.
      - `FetchFailed` (`False`) — the request to the metadata endpoint failed: network, DNS, timeout, TLS, a 3xx redirect (redirects are not allowed), an address resolving to a restricted IP (loopback, link-local, unspecified, multicast), a response larger than 1 MiB. The error is in `message`.
      - `EndpointNotFound` (`False`) — HTTP 404: `metadataEndpoint` most likely does not point to the remote exporter, or the remote cluster has both federation and multicluster disabled.
      - `ServerError` (`False`) — HTTP 5xx: the remote exporter or its ingress is unavailable.
      - `AccessDenied` (`False`) — HTTP 401 or 403: something on the way to the remote exporter (an ingress or a proxy with access restrictions) refused the request; the code is in `message`.
      - `UnexpectedHTTPStatus` (`False`) — another non-200 HTTP status; the code is in `message`.
      - `InvalidJSON` (`False`) — the response is not valid JSON; check that `metadataEndpoint` points to the remote exporter.
      - `InvalidPublicMetadata` (`False`) — the remote `public.json` lacks `clusterUUID`, `authnKeyPub` or `rootCA`.
      - `ClusterUUIDMismatch` (`False`) — the UUID returned by the endpoint differs from `status.metadataCache.public.clusterUUID`: the remote cluster was recreated or `metadataEndpoint` now points to another cluster. Both UUIDs are in `message`.
    - `PrivateMetadataExchangeReady` — remote private metadata is reachable and valid. Reasons:
      - `AwaitingPublic` (`Unknown`) — the public metadata exchange is failing (see `PublicMetadataExchangeReady`), so private metadata is not requested.
      - `TokenGenerationFailed` (`False`) — the request could not be signed with the authn key of this cluster; check the key Secret in this cluster.
      - `FetchFailed` (`False`) — the request to the private endpoint failed: network, DNS, timeout, TLS, a 3xx redirect, a restricted IP, a response larger than 1 MiB. The error is in `message`.
      - `UnknownSourceCluster` (`False`) — the remote cluster does not know this cluster: it has no resource for this cluster, the public metadata exchange of that resource has never succeeded (`ClusterUUIDMismatch` there means this cluster was recreated, so the remote resource has to be recreated), or that resource is an `IstioFederation` whose `spec.trustDomain` equals the domain of the remote cluster (it shows `ClusterDomainMismatch` there).
      - `TrustLost` (`False`) — the same refusal as `UnknownSourceCluster`, but this cluster has already received private metadata from the remote one: the remote resource for this cluster was deleted, recreated or became ignored, or the authn key of this cluster changed. After a recreation or a key change the condition clears within a couple of minutes once the remote cluster fetches the public metadata of this cluster.
      - `WrongAllianceKind` (`False`) — the remote cluster registered this cluster as `IstioMulticluster`, not `IstioFederation`; replace it with an `IstioFederation` on the remote side.
      - `EndpointNotFound` (`False`) — HTTP 404: the public endpoint responded, so the remote cluster most likely has federation disabled (`federation.enabled`).
      - `ServerError` (`False`) — HTTP 5xx: the remote exporter failed on the private path.
      - `ClusterDomainMismatch` (`False`) — federation requires different cluster domains: either `spec.trustDomain` equals the domain of this cluster (private metadata is not requested; set `spec.trustDomain` to the domain of the remote cluster), or the remote cluster reports the domain of this cluster in its private metadata (not checked if the remote cluster does not publish its domain). The domain is in `message`.

        - `WrongJWTAudience` (`False`) — the remote cluster rejected the token as issued for another cluster: the public and private requests were served by different clusters (DNS, a load balancer or a proxy leads to several clusters).
        - `TokenExpired` (`False`) — the token has expired because the clocks differ; check time synchronization (NTP) on both clusters.
        - `InvalidToken` (`False`) — the remote cluster did not receive or could not parse the token: a proxy or ingress on the way strips the `Authorization` header, or a platform error.
        - `WrongJWTScope` (`False`) — the token was issued for another private path: a platform error or a proxy rewriting the path.
        - `AccessDenied` (`False`) — HTTP 401 or 403 without a machine-readable reason: the remote exporter is of an older version and does not tell why (most often it does not know this cluster), or an ingress or a proxy on the way refused the request; the code is in `message`.
        - `UnexpectedHTTPStatus` (`False`) — another non-200 HTTP status; the code is in `message`.
        - `InvalidJSON` (`False`) — the remote private response is not valid JSON.
        - `InvalidPrivateMetadata` (`False`) — the remote private metadata has no `publicServices`.
        - `MissingIngressGateways` (`False`) — the remote cluster published no ingress gateway addresses (usually its LoadBalancer has no address yet, or the remote exporter failed to collect them). The private metadata fetched last, including the gateway addresses, stays in use.
        - `Succeeded` (`True`) — the remote private metadata is received.
      - `DataplaneConnectionReady` — cross-cluster dataplane health probe to the remote `alliance-healthcheck` service succeeded. Reasons:
        - `AwaitingPublic` (`Unknown`) — `status.metadataCache` has no public metadata yet.
        - `AwaitingPrivate` (`Unknown`) — `status.metadataCache` has public metadata but no private metadata yet. For a new connection the state is kept for one or two probe cycles (up to about two minutes) after the private metadata is received, so that the mesh applies it before the first probe.
        - `ProbeFailed` (`False`) — the probe through the remote ingress gateway fails; `message` has the request error or the HTTP status code. With a remote cluster on an older module version (it neither checks the resource kind nor publishes its domain), a wrong resource kind on the remote side or equal cluster domains with `spec.trustDomain` set to another domain show up only here.
        - `ConfigurationError` (`False`) — the private metadata is received, but the remote `publicServices` has no `alliance-healthcheck` service (for example, the remote istio module version is older). Details are in `message`.
        - `MetadataUnavailable` (`False`) — platform error: the remote cluster UUID cannot be read from the cached metadata.
        - `Succeeded` (`True`) — the dataplane connection to the remote cluster works.
      - **status.conditions.lastProbeTime**
        string

        Required value
      - **status.conditions.lastTransitionTime**
        string

        Required value
      - **status.conditions.message**
        string

        Required value
      - **status.conditions.reason**
        string

        Required value
      - **status.conditions.status**
        string

        Required value

        Allowed values: `True`, `False`, `Unknown`
      - **status.conditions.type**
        string

        Required value
  - **status.metadataCache**
    object
    - **status.metadataCache.private**
      object

        - **status.metadataCache.private.clusterDomain**
          string
        - **status.metadataCache.private.ingressGateways**
          array of objects
          - **status.metadataCache.private.ingressGateways.address**
            string
          - **status.metadataCache.private.ingressGateways.port**
            integer
        - **status.metadataCache.private.publicServices**
          array of objects
          - **status.metadataCache.private.publicServices.hostname**
            string
          - **status.metadataCache.private.publicServices.ports**
            array of objects
            - **status.metadataCache.private.publicServices.ports.name**
              string
            - **status.metadataCache.private.publicServices.ports.port**
              integer
            - **status.metadataCache.private.publicServices.ports.protocol**
              string
      - **status.metadataCache.public**
        object
        - **status.metadataCache.public.authnKeyPub**
          string
        - **status.metadataCache.public.clusterUUID**
          string
        - **status.metadataCache.public.rootCA**
          string

IstioMulticluster

Scope: Cluster
Version: v1alpha1

Custom resource for setting remote cluster as trusted one.

- **spec**
  object

  Required value

  Available in editions: Ultimate/EE

  - **spec.enableIngressGateway**
    boolean

    Available in editions: Ultimate/EE

    Whether to reach the pods of the remote cluster through its ingress gateway.

    If the pods of the clusters are directly reachable from each other (flat network), set it to `false` to avoid the extra hop through the ingress gateway.

    Set the same value on both sides: in the remote cluster, in the IstioMulticluster that describes this cluster. A cluster deploys its ingress gateway only if federation is enabled or at least one IstioMulticluster in it has `enableIngressGateway: true`. If `false` is set on one side only, the other side may find no ingress gateway to connect through (the `IngressGatewayNotDeployed` reason in `status.conditions`).

    Default: `true`

  - **spec.metadata**
    object
    - **spec.metadata.ca**
      string

      Available in editions: Ultimate/EE

      HTTPS certificate authority for remote cluster metadata.

    - **spec.metadata.insecureSkipVerify**
      boolean

      Available in editions: Ultimate/EE

      HTTPS check or not for remote cluster metadata.

      Default: `false`

Example:

```
insecureSkipVerify: true
```

- **spec.metadataEndpoint**
  string

  Required value

  Available in editions: Ultimate/EE

  HTTPS endpoint with remote cluster metadata.

  Example:

  ```
  metadataEndpoint: https://istio.k8s.example.com/metadata/
  ```

- **status**
  object
  - **status.conditions**
    array of objects

    Readiness of metadata exchange with the remote cluster.

    - `PublicMetadataExchangeReady` — remote `public.json` is reachable and valid. Reasons:
      - `Succeeded` (`True`) — the remote public metadata is received.
      - `FetchFailed` (`False`) — the request to the metadata endpoint failed: network, DNS, timeout, TLS, a 3xx redirect (redirects are not allowed), an address resolving to a restricted IP (loopback, link-local, unspecified, multicast), a response larger than 1 MiB. The error is in `message`.
      - `EndpointNotFound` (`False`) — HTTP 404: `metadataEndpoint` most likely does not point to the remote exporter, or the remote cluster has both federation and multicluster disabled.
      - `ServerError` (`False`) — HTTP 5xx: the remote exporter or its ingress is unavailable.
      - `AccessDenied` (`False`) — HTTP 401 or 403: something on the way to the remote exporter (an ingress or a proxy with access restrictions) refused the request; the code is in `message`.
      - `UnexpectedHTTPStatus` (`False`) — another non-200 HTTP status; the code is in `message`.
      - `InvalidJSON` (`False`) — the response is not valid JSON; check that `metadataEndpoint` points to the remote exporter.
      - `InvalidPublicMetadata` (`False`) — the remote `public.json` lacks `clusterUUID`, `authnKeyPub` or `rootCA`.
      - `ClusterUUIDMismatch` (`False`) — the UUID returned by the endpoint differs from `status.metadataCache.public.clusterUUID`: the remote cluster was recreated or `metadataEndpoint` now points to another cluster. Both UUIDs are in `message`.
    - `PrivateMetadataExchangeReady` — remote private metadata is reachable and valid. Reasons:
      - `AwaitingPublic` (`Unknown`) — the public metadata exchange is failing (see `PublicMetadataExchangeReady`), so private metadata is not requested.
      - `TokenGenerationFailed` (`False`) — the request could not be signed with the authn key of this cluster; check the key Secret in this cluster.
      - `FetchFailed` (`False`) — the request to the private endpoint failed: network, DNS, timeout, TLS, a 3xx redirect, a restricted IP, a response larger than 1 MiB. The error is in `message`.
      - `UnknownSourceCluster` (`False`) — the remote cluster does not know this cluster: it has no resource for this cluster, the public metadata exchange of that resource has never succeeded (`ClusterUUIDMismatch` there means this cluster was recreated, so the remote resource has to be recreated), or the remote cluster has an `IstioFederation` for this cluster instead of an `IstioMulticluster` (with equal domains, as multicluster requires, it is ignored there, so the wrong kind shows up here and not as `WrongAllianceKind`).
      - `TrustLost` (`False`) — the same refusal as `UnknownSourceCluster`, but this cluster has already received private metadata from the remote one: the remote resource for this cluster was deleted, recreated or became ignored, or the authn key of this cluster changed. After a recreation or a key change the condition clears within a couple of minutes once the remote cluster fetches the public metadata of this cluster.
      - `WrongAllianceKind` (`False`) — the remote cluster registered this cluster as `IstioFederation`, not `IstioMulticluster`; replace it with an `IstioMulticluster` on the remote side.
      - `EndpointNotFound` (`False`) — HTTP 404: the public endpoint responded, so the remote cluster most likely has multicluster disabled (`multicluster.enabled`).
      - `ServerError` (`False`) — HTTP 5xx: the remote exporter failed on the private path.
      - `ClusterDomainMismatch` (`False`) — the remote cluster domain differs from the domain of this cluster, while multicluster requires equal domains. Both domains are in `message`. Not checked if the remote cluster does not publish its domain.

    - `WrongJWTAudience` (`False`) — the remote cluster rejected the token as issued for another cluster: the public and private requests were served by different clusters (DNS, a load balancer or a proxy leads to several clusters).
    - `TokenExpired` (`False`) — the token has expired because the clocks differ; check time synchronization (NTP) on both clusters.
    - `InvalidToken` (`False`) — the remote cluster did not receive or could not parse the token: a proxy or ingress on the way strips the `Authorization` header, or a platform error.
    - `WrongJWTScope` (`False`) — the token was issued for another private path: a platform error or a proxy rewriting the path.
    - `AccessDenied` (`False`) — HTTP 401 or 403 without a machine-readable reason: the remote exporter is of an older version and does not tell why (most often it does not know this cluster), or an ingress or a proxy on the way refused the request; the code is in `message`.
    - `UnexpectedHTTPStatus` (`False`) — another non-200 HTTP status; the code is in `message`.
    - `InvalidJSON` (`False`) — the remote private response is not valid JSON.
    - `InvalidPrivateMetadata` (`False`) — the remote private metadata has an empty `networkName` or `apiHost`.
    - `MissingIngressGateways` (`False`) — `spec.enableIngressGateway` is `true`, but the remote cluster published no ingress gateway addresses (usually its LoadBalancer has no address yet, or the remote exporter failed to collect them). A remote cluster on an older module version that deploys no ingress gateway is also reported with this reason, not with `IngressGatewayNotDeployed`. The private metadata fetched last, including the gateway addresses, stays in use.
    - `IngressGatewayNotDeployed` (`False`) — `spec.enableIngressGateway` is `true`, but the remote cluster deploys no ingress gateway. Most often, the IstioMulticluster that describes this cluster in the remote cluster has `spec.enableIngressGateway: false`, and nothing else there needs the ingress gateway (see `spec.enableIngressGateway`); `message` lists what else to check in the remote cluster. The cached addresses are cleared, and this cluster does not connect to the remote cluster until this is fixed.
    - `Succeeded` (`True`) — the remote private metadata is received.
  - `RemoteAPIServerReady` — remote multicluster API host (`apiHost`) serves the authenticated `/api` endpoint. Reasons:
    - `AwaitingPrivate` (`Unknown`) — the private metadata exchange has not succeeded yet (see `PrivateMetadataExchangeReady`), including while the public metadata exchange fails.
    - `TokenGenerationFailed` (`False`) — the API token could not be signed with the authn key of this cluster; check the key Secret in this cluster.
    - `MissingAPIHost` (`False`) — the remote `apiHost` consists only of whitespace (an empty `apiHost` is reported as `InvalidPrivateMetadata` on `PrivateMetadataExchangeReady`).
    - `RemoteAPIUnreachable` (`False`) — the request to the remote API failed: network, DNS, timeout, TLS, a redirect, a non-HTTPS `apiHost`, a restricted IP, a response larger than 1 MiB. The error is in `message`.
    - `RemoteAPIBadResponse` (`False`) — the remote API returned a non-200 HTTP status (the code is in `message`); check the remote api-proxy and its permissions.
    - `RemoteAPIInvalidResponse` (`False`) — the remote API response is not valid JSON; check that `apiHost` points to the remote api-proxy.
    - `RemoteAPIUnexpectedResponse` (`False`) — `apiHost` does not serve the Kubernetes API (the response kind is not `APIVersions`).
    - `RemoteAPIReachable` (`True`) — the remote API server is reachable.
  - `DataplaneConnectionReady` — cross-cluster dataplane health probe to the remote `alliance-healthcheck` service succeeded. Reasons:
    - `AwaitingPublic` (`Unknown`) — `status.metadataCache` has no public metadata yet.
    - `AwaitingPrivate` (`Unknown`) — `status.metadataCache` has public metadata but no private metadata yet. For a new connection the state is kept for one or two probe cycles (up to about two minutes) after the private metadata is received, so that the mesh applies it before the first probe.
    - `ProbeFailed` (`False`) — the probe to the remote `alliance-healthcheck` service fails (through the remote ingress gateway, or directly to remote Pods when `spec.enableIngressGateway` is `false`); `message` has the request error or the HTTP status code. With a remote cluster on an older module version, a wrong resource kind or different cluster domains show up only here.
    - `MetadataUnavailable` (`False`) — platform error: the remote cluster UUID cannot be read from the cached metadata.
    - `Succeeded` (`True`) — the dataplane connection to the remote cluster works.
  - **status.conditions.lastProbeTime**
    string

    Required value

  - **status.conditions.lastTransitionTime**
    string

    Required value

        - **status.conditions.message**
          string

          Required value
        - **status.conditions.reason**
          string

          Required value
        - **status.conditions.status**
          string

          Required value

          Allowed values: `True`, `False`, `Unknown`
        - **status.conditions.type**
          string

          Required value
    - **status.metadataCache**
      object
      - **status.metadataCache.private**
        object
        - **status.metadataCache.private.ambientGateways**
          array of objects
          - **status.metadataCache.private.ambientGateways.address**
            string
          - **status.metadataCache.private.ambientGateways.port**
            integer
        - **status.metadataCache.private.apiHost**
          string
        - **status.metadataCache.private.ca**
          string
        - **status.metadataCache.private.clusterDomain**
          string
        - **status.metadataCache.private.clusterID**
          string
        - **status.metadataCache.private.ingressGateways**
          array of objects
          - **status.metadataCache.private.ingressGateways.address**
            string
          - **status.metadataCache.private.ingressGateways.port**
            integer
        - **status.metadataCache.private.networkName**
          string
      - **status.metadataCache.public**
        object
        - **status.metadataCache.public.authnKeyPub**
          string
        - **status.metadataCache.public.clusterUUID**
          string
        - **status.metadataCache.public.rootCA**
          string

WaypointInstance

Short names: wpi

Scope: Namespaced
Version: v1alpha1

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `51`
- **spec**
  object
  - **spec.allowedRoutes**
    object

    Configuration for restricting which Routes can attach to the Gateway.

- **spec.allowedRoutes.namespaces**
  object

  Configuration for restricting the namespaces of Routes that can attach to the Gateway.

  - **spec.allowedRoutes.namespaces.from**
    string

    Specifies which namespaces are allowed to attach Routes to this Gateway.

    Possible values:

    - `All`: Routes in all namespaces may be attached.
    - `Selector`: Only Routes in namespaces matching the `selector` may be attached.
    - `Same`: Only Routes in the same namespace as the Gateway may be attached.

    Default: `Same`

    Allowed values: `All`, `Selector`, `Same`

  - **spec.allowedRoutes.namespaces.selector**
    object

    Label selector for selecting namespaces.

    Required when `from` is `Selector`.

    - **spec.allowedRoutes.namespaces.selector.matchExpressions**
      array of objects

      A list of label selector requirements.

      - **spec.allowedRoutes.namespaces.selector.matchExpressions.key**
        string

        Required value

      - **spec.allowedRoutes.namespaces.selector.matchExpressions.operator**
        string

        Required value

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.allowedRoutes.namespaces.selector.matchExpressions.values**
        array of strings
    - **spec.allowedRoutes.namespaces.selector.matchLabels**
      object

      A map of {key,value} pairs.

      A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions with operator `In` and the values array containing only the value.

- **spec.nodeSelector**
  object

  Node selector for waypoint proxy pods.

- **spec.replicasManagement**
  object

  Replication management settings and scaling for the waypoint instance.

  - **spec.replicasManagement.hpa**
    object

    Options for replicas management for the `HPA` mode.

    - **spec.replicasManagement.hpa.maxReplicas**
      integer

      The upper limit for the number of replicas to which the HPA can scale up.

      Allowed values: `1 <= X`

    - **spec.replicasManagement.hpa.metrics**
      array of objects

      The HPA will use these metrics to decide whether to increase or decrease the number of replicas.

- **spec.replicasManagement.hpa.metrics.targetAverageUtilization**
  integer

  Required value

  The target value of the average resource metric across all relevant pods, represented as a percentage of the requested value.

  Allowed values: `1 <= X <= 100`

- **spec.replicasManagement.hpa.metrics.type**
  string

  Required value

  Metric type.

  Allowed values: `CPU`

- **spec.replicasManagement.hpa.minReplicas**
  integer

  The lower limit for the number of replicas to which the HPA can scale down.

  Allowed values: `1 <= X`

- **spec.replicasManagement.mode**
  string

  Replicas management mode.

  Possible values:

  - `Static`: the mode where the number of replicas is specified explicitly.
  - `HPA`: the mode where the number of replicas is calculated automatically using HPA based on CPU usage.

  Default: `Static`

  Allowed values: `Static`, `HPA`

- **spec.replicasManagement.static**
  object

  Options for replicas management for the `Static` mode.

  - **spec.replicasManagement.static.replicas**
    integer

    Desired number of replicas.

    Allowed values: `1 <= X`

- **spec.resourcesManagement**
  object

  CPU and memory request and limit settings for the waypoint Pods.

  - **spec.resourcesManagement.mode**
    string

    Resource management mode.

    Default: `VPA`

    Allowed values: `VPA`, `Static`

  - **spec.resourcesManagement.static**
    object

    Static mode settings.

    - **spec.resourcesManagement.static.limits**
      object

      Resource limits.

      - **spec.resourcesManagement.static.limits.cpu**
        string

        CPU limits.

      - **spec.resourcesManagement.static.limits.memory**

string

Memory limits.

- **spec.resourcesManagement.static.requests**
  object

  Resource requests.

  - **spec.resourcesManagement.static.requests.cpu**
    string

    CPU requests.

    Default: `100m`

  - **spec.resourcesManagement.static.requests.memory**
    string

    Memory requests.

    Default: `128Mi`

- **spec.resourcesManagement.vpa**
  object

  Resource management settings for the VPA mode.

  - **spec.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **spec.resourcesManagement.vpa.cpu.limitRatio**
      number

      The CPU limits/requests ratio.

      If set, the limits are calculated based on the requests and the specified ratio.

    - **spec.resourcesManagement.vpa.cpu.max**
      string

      Maximum value of allowed CPU requests to be submitted by the VPA.

      Default: `1000m`

    - **spec.resourcesManagement.vpa.cpu.min**
      string

      Minimum value of allowed CPU requests to be submitted by the VPA.

      Default: `100m`

  - **spec.resourcesManagement.vpa.memory**
    object

    Memory-related VPA settings.

    - **spec.resourcesManagement.vpa.memory.limitRatio**
      number

      The memory limits/requests ratio.

      If set, the limits are calculated based on the requests and the specified ratio.

    - **spec.resourcesManagement.vpa.memory.max**
      string

      Maximum value of allowed memory requests to be submitted by the VPA.

      Default: `2048Mi`

    - **spec.resourcesManagement.vpa.memory.min**
      string

      Minimum value of allowed memory requests to be submitted by the VPA.

      Default: `128Mi`

  - **spec.resourcesManagement.vpa.mode**
    string

VPA operating mode.

Default: `InPlaceOrRecreate`

Allowed values: `Initial`, `InPlaceOrRecreate`

- **spec.tolerations**
  array of objects

  Tolerations for waypoint proxy pods.

  - **spec.tolerations.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **spec.tolerations.key**
    string
  - **spec.tolerations.operator**
    string

    Default: `Equal`

    Allowed values: `Exists`, `Equal`
  - **spec.tolerations.tolerationSeconds**
    integer
  - **spec.tolerations.value**
    string
- **spec.waypointFor**
  string

  Controls the `istio.io/waypoint-for` label on all managed resources.

  Default: `All`

  Allowed values: `All`, `Service`, `Workload`

- **status**
  object
  - **status.observedGeneration**
    integer

    Allowed values: `0 <= X`
  - **status.synced**
    boolean

    True when desired and actual resources are in sync.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The module has requirements for installation

Routing

DestinationRule

Reference.

Allows you to:

- Define a strategy for balancing traffic between service endpoints:
  - The balancing algorithm to use (LEAST_CONN, ROUND_ROBIN, ...);
  - Symptoms that an endpoint is unhealthy and rules for removing it from load balancing;
  - Limits for TCP connections and endpoint requests;
  - Sticky Sessions;
  - Circuit Breaker;
- Define alternative endpoint groups for traffic processing (suitable for Canary Deployments). Also, you can configure balancing strategies for each group;
- Configuring TLS for outgoing requests.

VirtualService

Reference.

Using VirtualService is optional; regular services fit just fine if their capabilities match your requirements.

Allows you to configure request routing:

- Arguments on which routing decisions are based on:
  - Host;
  - URI;
  - Weight;
- Parameters of the resulting directions:
  - The new host;
  - The new URI;
  - If the host is defined using DestinationRule, then requests can be sent to `subsets`;
  - Timeout and retry settings.

⚠ Istio must be aware of the `destination`; if you use an external API, register it via ServiceEntry.

ServiceEntry

Reference.

It is similar to Endpoints + Service in vanilla Kubernetes. Informs Istio about the existence of an external service and lets you redefine its address.

Authentication

Answers the question “Who has made the request?” Not to be confused with authorization - the latter determines what the authenticated subject can or cannot do.

There are two authentication methods:

- mTLS;
- JWT tokens;

PeerAuthentication

Reference.

Allows you to define the mTLS strategy for an individual namespace. Defines how traffic will be tunneled (or not) to the sidecar. Each mTLS request can automatically identify the source and allows you to use it in the authorization rules.

RequestAuthentication

Reference.

Allows you to configure JWT authentication for requests.

Authorization

⚠ Authorization without the use of mTLS or JWT authentication will not work fully. In this case, you will be able to use only basic arguments, such as `source.ip` and `request.headers`, for defining policies.

AuthorizationPolicy

Reference.

Enables and defines access control to the `workload`. The `AuthorizationPolicy` custom resource supports both ALLOW and DENY rules. The following decision-making algorithm is used if at least one policy is defined for a workload:

- The request is denied if it falls under the DENY policy.
- The request is allowed if there are no ALLOW policies for the service.
- The request is allowed if it falls under the ALLOW policy.
- In all other cases, the request is denied.

The following arguments are used in the decision-making algorithm:

- source:
  - namespace
  - principal (i.e., the ID the user has received after authentication)
  - IP
- destination:
  - method (GET, POST, ...)
  - Host
  - port
  - URI
- conditions:
  - HTTP-headers
  - source arguments
  - destination arguments
  - JWT-tokens

Sidecar

Reference

This resource limits the number of services for which information is transmitted to the `istio-proxy` sidecar.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> **i** The module lifecycle stage: General Availability
>
> The module has requirements for installation

Circuit Breaker

The `outlierDetection` settings in the DestinationRule custom resource help to determine whether some endpoints do not behave as expected. Refer to the Envoy documentation for more details on the Outlier Detection algorithm.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: reviews-cb-policy
spec:
  host: reviews.prod.svc.cluster.local
  trafficPolicy:
    connectionPool:
      tcp:
        maxConnections: 100 # The maximum number of connections to the host (cumulative
for all endpoints)
      http:
        maxRequestsPerConnection: 10 # The connection will be re-established after every
10 requests
    outlierDetection:
      consecutive5xxErrors: 7 # Seven consecutive errors are allowed (including 5XX, TCP
and HTTP timeouts)
      interval: 5m          # over 5 minutes.
      baseEjectionTime: 15m   # Upon reaching the error limit, the endpoint will be
excluded from balancing for 15 minutes.
```

Additionally, the VirtualService resource is used to configure the HTTP timeouts. These timeouts are also taken into account when calculating error statistics for endpoints.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: my-productpage-rule
  namespace: myns
spec:
  hosts:
  - productpage
  http:
  - timeout: 5s
    route:
    - destination:
        host: productpage
```

gRPC balancing

⚠ Assign a name with the `grpc` prefix or value to the port in the corresponding service to make gRPC service balancing start automatically.

Locality Failover

i Read the Istio Locality Failover documentation if needed.

Istio allows you to configure a priority-based locality (geographic location) failover between endpoints. Istio uses node labels with the appropriate hierarchy to define the zone:

- `topology.istio.io/subzone`
- `topology.kubernetes.io/zone`
- `topology.kubernetes.io/region`

This comes in handy for inter-cluster failover when used together with a multicluster.

⚠ The Locality Failover can be enabled using the DestinationRule CR. Note that you also have to configure the outlierDetection.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: helloworld
spec:
  host: helloworld
  trafficPolicy:
    loadBalancer:
      localityLbSetting:
        enabled: true # Locality Failover is enabled
    outlierDetection: # outlierDetection must be enabled
      consecutive5xxErrors: 1
      interval: 1s
      baseEjectionTime: 1m
```

Retry

You can use the VirtualService resource to configure Retry for requests.

⚠ All requests (including POST ones) are retried three times by default.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: ratings-route
spec:
  hosts:
  - ratings.prod.svc.cluster.local
  http:
  - route:
    - destination:
        host: ratings.prod.svc.cluster.local
    retries:
      attempts: 3
      perTryTimeout: 2s
      retryOn: gateway-error,connect-failure,refused-stream
```

Canary

Istio is only responsible for flexible request routing that relies on special request headers (such as cookies) or simply randomness. The CI/CD system is responsible for customizing this routing and switching between canary versions.

The idea is that two Deployments with different versions of the application are deployed in the same namespace. The Pods of different versions have different labels (`version: v1` and `version: v2`).

You have to configure two custom resources:

- A DestinationRule – defines how to identify different versions of your application (subsets);
- A VirtualService – defines how to balance traffic between different versions of your application.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: productpage-canary
spec:
  host: productpage
  # subsets are only available when accessing the host via the VirtualService from a Pod
managed by Istio.
  # These subsets must be defined in the routes.
  subsets:
  - name: v1
    labels:
      version: v1
  - name: v2
    labels:
      version: v2
```

Cookie-based routing

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: productpage-canary
spec:
  hosts:
  - productpage
  http:
  - match:
    - headers:
       cookie:
         regex: "^(.*;?)?(canary=yes)(;.*)?"
    route:
    - destination:
        host: productpage
        subset: v2 # The reference to the subset from the DestinationRule.
  - route:
    - destination:
        host: productpage
        subset: v1
```

Probability-based routing

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: productpage-canary
spec:
  hosts:
  - productpage
  http:
  - route:
    - destination:
        host: productpage
        subset: v1 # The reference to the subset from the DestinationRule.
      weight: 90 # Percentage of traffic that the Pods with the version: v1 label will be
getting.
  - route:
    - destination:
        host: productpage
        subset: v2
      weight: 10
```

Ingress to publish applications

Istio Ingress Gateway

The IngressIstioController custom resource spins up a dedicated Istio Ingress Gateway proxy. Each controller instance gets its own gateway class, and you select the instance from an Istio `Gateway` resource by referencing the matching `istio.deckhouse.io/ingress-gateway-class` label. The module manages the gateway workload and its `Service`, while the `Gateway` and routing resources (`VirtualService`) remain yours to manage.

Start by creating an `IngressIstioController`. In the example below, HTTP and HTTPS are exposed on the selected frontend nodes using host ports:

```
apiVersion: deckhouse.io/v1alpha1
kind: IngressIstioController
metadata:
  name: main
spec:
  # The value selected by Gateway resources via the istio.deckhouse.io/ingress-gateway-
class label.
  ingressGatewayClass: istio-hp
  # IngressIstioController works with LoadBalancer, NodePort, and HostPort inlets.
  inlet: HostPort
  hostPort:
    httpPort: 80
    httpsPort: 443
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      operator: Equal
      value: frontend
  resourcesRequests:
    mode: VPA
```

Note that the TLS secret for an ingress gateway must be created in the `d8-ingress-istio` namespace, not in your application’s namespace — this is an easy detail to miss.

```
apiVersion: v1
kind: Secret
metadata:
  name: app-tls-secret
  namespace: d8-ingress-istio # note the namespace isn't app-ns
type: kubernetes.io/tls
data:
  tls.crt: |
    <tls.crt data>
  tls.key: |
    <tls.key data>
```

```
apiVersion: networking.istio.io/v1beta1
kind: Gateway
metadata:
  name: gateway-app
  namespace: app-ns
spec:
  selector:
    # label selector for using the Istio Ingress Gateway main-hp
    istio.deckhouse.io/ingress-gateway-class: istio-hp
  servers:
    - port:
        # standard template for using the HTTP protocol
        number: 80
        name: http
        protocol: HTTP
      hosts:
        - app.example.com
    - port:
        # standard template for using the HTTPS protocol
        number: 443
        name: https
        protocol: HTTPS
      tls:
        mode: SIMPLE
        # a secret with a certificate and a key, which must be created in the d8-ingress-
istio namespace
        # supported secret formats can be found at
https://istio.io/latest/docs/tasks/traffic-management/ingress/secure-ingress/#key-
formats
        credentialName: app-tls-secret
      hosts:
        - app.example.com
```

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: vs-app
  namespace: app-ns
spec:
  gateways:
    - gateway-app
  hosts:
    - app.example.com
  http:
    - route:
        - destination:
            host: app-svc
```

For the full list of controller settings — load-balancer annotations, network topology, scheduling, and resource management — see the IngressIstioController custom resource reference.

Preserving client attributes behind external proxies

When the gateway is deployed behind other proxies or load balancers (for example, a cloud load balancer or a reverse proxy), configure `spec.networkTopology` so that the gateway can correctly extract the client's original attributes, such as the source IP address. See Configuring Gateway Network Topology in the Istio documentation for details.

Use `numTrustedProxies` when the upstream proxies pass the client IP address in the `X-Forwarded-For` header. Set it to the number of trusted proxies deployed in front of the gateway so that Istio extracts the correct client address and populates the `X-Envoy-External-Address` header for upstream services. For example, if a cloud load balancer and a reverse proxy sit in front of the gateway, set the value to `2`:

```
apiVersion: deckhouse.io/v1alpha1
kind: IngressIstioController
metadata:
  name: main
spec:
  ingressGatewayClass: istio-hp
  inlet: LoadBalancer
  networkTopology:
    numTrustedProxies: 2
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  resourcesRequests:
    mode: VPA
```

Use `proxyProtocol` when an upstream L4/TCP load balancer forwards the client attributes via the PROXY protocol instead of HTTP headers. When this parameter is enabled, the gateway starts parsing the PROXY protocol header on incoming TCP connections:

```
apiVersion: deckhouse.io/v1alpha1
kind: IngressIstioController
metadata:
  name: main
spec:
  ingressGatewayClass: istio-hp
  inlet: LoadBalancer
  networkTopology:
    proxyProtocol: true
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  resourcesRequests:
    mode: VPA
```

i `numTrustedProxies` and `proxyProtocol` can be used together. When both are configured and an incoming request contains an `X-Forwarded-For` header, Istio uses the trusted `X-Forwarded-For` chain in preference to the PROXY protocol attributes.

Managing gateway resource requests

Use `spec.resourcesRequests` to control CPU and memory requests for the ingress gateway pods. Two modes are available:

- `Static` — requests are specified directly and stay fixed:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: IngressIstioController
  metadata:
    name: main
  spec:
    ingressGatewayClass: istio-hp
    inlet: HostPort
    hostPort:
      httpPort: 80
      httpsPort: 443
    resourcesRequests:
      mode: Static
      static:
        cpu: 100m
        memory: 128Mi
  ```

- `VPA` — a Vertical Pod Autoscaler adjusts requests within the configured `min`/`max` bounds. Starting from DP version 1.75, the recommended VPA mode is `InPlaceOrRecreate`, which updates pod resources in place when the cluster supports it and falls back to recreating the pod otherwise (the

legacy `Auto` mode always recreates the pod):

```
apiVersion: deckhouse.io/v1alpha1
kind: IngressIstioController
metadata:
  name: main
spec:
  ingressGatewayClass: istio-hp
  inlet: HostPort
  hostPort:
    httpPort: 80
    httpsPort: 443
  resourcesRequests:
    mode: VPA
    vpa:
      mode: InPlaceOrRecreate
      cpu:
        min: 100m
        max: 1000m
      memory:
        min: 128Mi
        max: 2048Mi
```

Ingress NGINX

To use Ingress, you need to:

- Configure the Ingress controller by adding Istio sidecar to it. In our case, you need to enable the `enableIstioSidecar` parameter in the ingress-nginx module's IngressNginxController custom resource.
- Set up an Ingress that refers to the Service. The following annotations are mandatory for Ingress:
  - `nginx.ingress.kubernetes.io/service-upstream: "true"` — using this annotation, the Ingress controller sends requests to a single ClusterIP (from Service CIDR) while envoy load balances them. Ingress controller's sidecar is only catching traffic directed to Service CIDR.
  - `nginx.ingress.kubernetes.io/upstream-vhost: myservice.myns.svc` — using this annotation, the sidecar container can identify the application service that serves requests.

Examples:

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: productpage
  namespace: bookinfo
  annotations:
    # Nginx proxies traffic to the ClusterIP instead of pods' own IPs.
    nginx.ingress.kubernetes.io/service-upstream: "true"
    # In Istio, all routing is carried out based on the `Host:` headers.
    # Instead of letting Istio know about the `productpage.example.com` external domain,
    # we use the internal domain of which Istio is aware.
    nginx.ingress.kubernetes.io/upstream-vhost: productpage.bookinfo.svc
spec:
  rules:
    - host: productpage.example.com
      http:
        paths:
        - path: /
          pathType: Prefix
          backend:
            service:
              name: productpage
              port:
                number: 9080
```

```
apiVersion: v1
kind: Service
metadata:
  name: productpage
  namespace: bookinfo
spec:
  ports:
  - name: http
    port: 9080
  selector:
    app: productpage
  type: ClusterIP
```

Authorization configuration examples

Decision-making algorithm

The following algorithm for deciding the fate of a request becomes active after `AuthorizationPolicy` is created for the application:

- The request is denied if it falls under the DENY policy;
- The request is allowed if there are no ALLOW policies for the application;
- The request is allowed if it falls under the ALLOW policy.
- All other requests are denied.

In other words, if you explicitly deny something, then only this restrictive rule will work. If you explicitly allow something, only explicitly authorized requests will be allowed (however, restrictions will stay in force and have precedence).

⚠ The policies based on high-level parameters like namespace or principal require enabling Istio for all involved applications. Also, there must be organized Mutual TLS between applications.

Examples:

- Let’s deny POST requests for the myapp application. Since a policy is defined, only POST requests to the application are denied (as per the algorithm above).

  ```
  apiVersion: security.istio.io/v1beta1
  kind: AuthorizationPolicy
  metadata:
    name: deny-post-requests
    namespace: foo
  spec:
    selector:
      matchLabels:
        app: myapp
    action: DENY
    rules:
    - to:
      - operation:
          methods: ["POST"]
  ```

- Below, the ALLOW policy is defined for the application. It only allows requests from the `bar` namespace (other requests are denied).

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  action: ALLOW # The default value, can be skipped.
  rules:
  - from:
    - source:
       namespaces: ["bar"]
```

- Below, the ALLOW policy is defined for the application. Note that it does not have any rules, so not a single request matches it (still, the policy exists). Thus, our decision-making algorithm suggests that if something is allowed, then everything else is denied. In this case, “everything else” includes all the requests.

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  action: ALLOW # The default value, can be skipped.
  rules: []
```

- Below, the (default) ALLOW policy is defined for the application. Note that it has an empty rule. Any request matches this rule, so it is naturally approved.

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: allow-all
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  rules:
  - {}
```

Deny all actions for the foo namespace

There are two ways you can do that:

- Explicitly. Here, the DENY policy is created. It has a single `{}` rule that covers all the requests:

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec:
  action: DENY
  rules:
  - {}
```

- Implicitly. Here, the (default) ALLOW policy is created that does not have any rules. Thus, no requests

will match it, and the policy will deny all of them.

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec: {}
```

Deny requests from the foo NS only

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: deny-from-ns-foo
 namespace: myns
spec:
 action: DENY
 rules:
 - from:
   - source:
      namespaces: ["foo"]
```

Allow requests for the foo NS only

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-intra-namespace-only
 namespace: foo
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      namespaces: ["foo"]
```

Allow requests from anywhere in the cluster

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-my-cluster
 namespace: myns
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      principals: ["mycluster.local/*"]
```

Allow any requests for foo or bar clusters

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-foo-or-bar-clusters-to-ns-baz
 namespace: baz
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      principals: ["foo.local/*", "bar.local/*"]
```

Allow any requests only from entities in the baz namespace of the foo or bar clusters

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-foo-or-bar-clusters-to-ns-baz
 namespace: baz
spec:
 action: ALLOW
 rules:
 - from:
   - source: # Logical conjunction is used for the rules below.
      namespaces: ["baz"]
      principals: ["foo.local/*", "bar.local/*"]
```

Allow from any cluster (via mTLS)

⚠ The denying rules (if they exist) have priority over any other rules. For details, refer to Decision-making algorithm.

Example:

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-any-cluster-with-mtls
 namespace: myns
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      principals: ["*"] # To force the mTLS usage.
```

Allow all requests from anywhere (including no mTLS - plain text traffic)

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-any
 namespace: myns
spec:
 action: ALLOW
 rules: [{}]
```

Setting up federation for two clusters using the IstioFederation CR

⚠ Federation covers sidecar-mode workloads only. For details, refer to Ambient mesh limitations.

Cluster A:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioFederation
metadata:
  name: cluster-b
spec:
  metadataEndpoint: https://istio.k8s-b.example.com/metadata/
  trustDomain: cluster-b.local
```

Cluster B:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioFederation
metadata:
  name: cluster-a
spec:
  metadataEndpoint: https://istio.k8s-a.example.com/metadata/
  trustDomain: cluster-a.local
```

Setting up multicluster for two clusters using the IstioMulticluster CR

⚠ Multicluster covers sidecar-mode workloads only. For details, refer to Ambient mesh limitations.

Cluster A:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioMulticluster
metadata:
  name: cluster-b
spec:
  metadataEndpoint: https://istio.k8s-b.example.com/metadata/
```

Cluster B:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioMulticluster
metadata:
  name: cluster-a
spec:
  metadataEndpoint: https://istio.k8s-a.example.com/metadata/
```

Ambient mesh

⚠ Ambient mesh support is experimental and not recommended for production use.

⚠ Ambient-mode workloads cannot take part in federation or multicluster. For details, refer to Ambient mesh limitations.

The ambient mesh components mentioned in this section are described on the module overview page.

Enabling ambient mesh

Ambient mode requires the `CNIPlugin` traffic redirection mode and Istio 1.25 or newer.

The following is a module configuration example with the ambient mode enabled:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  enabled: true
  version: 2
  settings:
    dataPlane:
      trafficRedirectionSetupMode: CNIPlugin
    ambient:
      enabled: true
```

Once enabled, the module runs the `ztunnel` DaemonSet and the waypoint controller. To enroll workloads into the ambient mesh, follow the steps below.

Enrolling workloads into the ambient (L4) mesh

Add the `istio.io/dataplane-mode=ambient` label to a namespace to capture the traffic of its pods with `ztunnel`. This provides L4 features (mutual TLS, identity, L4 authorization) without a sidecar:

```
d8 k label namespace myns istio.io/dataplane-mode=ambient
```

Adding a waypoint for L7 features

To get L7 features (HTTP routing, L7 authorization, richer telemetry), create a WaypointInstance resource in the namespace:

The following is a WaypointInstance resource example, which creates a waypoint for all workloads and services in a namespace:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: WaypointInstance
metadata:
  name: main
  namespace: myns
spec:
  waypointFor: All
  replicasManagement:
    mode: Static
    static:
      replicas: 2
  resourcesManagement:
    mode: VPA
    vpa:
      mode: InPlaceOrRecreate
      cpu:
        min: 100m
        max: 1000m
      memory:
        min: 128Mi
        max: 2048Mi
```

The controller provisions the waypoint infrastructure (Deployment, Service, Gateway, VPA, and a PDB — when the effective replica count is `>= 2`). The controller **does not** attach workloads to the waypoint. You can do that with the `istio.io/use-waypoint` label.

To attach all workloads and services in the namespace to the waypoint, run the following command:

```
d8 k label namespace myns istio.io/use-waypoint=main
```

To attach a single service or workload, run the following command:

```
d8 k -n myns label service myservice istio.io/use-waypoint=main
```

Disabling ambient mesh

> ⚠ Before disabling ambient mode, delete all WaypointInstance resources. With ambient mode disabled, the waypoint controller is not running and cannot reconcile or clean up waypoint resources. This leaves orphaned waypoints, which are reported by Deckhouse Platform (DP) in the `D8IstioActiveWaypointsWithAmbientDisabled` alert.

To disable the ambient mode, follow these steps:

1. Check if any WaypointInstance resources remain and delete them as necessary using the following commands:

   ```
   d8 k get waypointinstance -A
   d8 k -n myns delete waypointinstance main
   ```

2. Disable the ambient mode by setting `ambient.enabled` to `false` in the module configuration.

Control the data-plane behavior

Jobs with an Istio sidecar

The module doesn't inject the sidecar into Job Pods unless the Pod template asks for it explicitly:

```
spec:
  template:
    metadata:
      annotations:
        sidecar.istio.io/inject: "true"
```

This example assumes the namespace is labeled for Istio injection. In a namespace without an injection label, use the Pod template label `sidecar.istio.io/inject: "true"` instead of the annotation. For a CronJob, put these settings under `spec.jobTemplate.spec.template.metadata`.

A regular sidecar, which Istio 1.25 injects by default, keeps running after the application container exits and prevents the Job from completing. If the Pod uses a regular sidecar, for example with Istio 1.25, also add the `sidecar.istio.io/nativeSidecar: "true"` annotation to the Pod template.

Prevent istio-proxy from terminating before the main application's connections are closed

With native sidecars, which Istio 1.27 and newer inject by default, `istio-proxy` stops only after the application containers have exited: it receives SIGTERM after them, and the application keeps network access while shutting down.

With a regular sidecar, which Istio 1.25 injects by default, all containers in a Pod, including `istio-proxy`, receive SIGTERM simultaneously. Applications that need network access while shutting down lose it when `istio-proxy` stops first. For these Pods, add a preStop hook to `istio-proxy`. The hook waits until the application has no network sockets left in the Pod's network namespace:

```
annotations:
  inject.istio.io/templates: "sidecar,d8-hold-istio-proxy-termination-until-application-
stops"
```

The `d8-hold-istio-proxy-termination-until-application-stops` injection template works only with Istio 1.25. With Istio 1.27 and newer, it does nothing, even for Pods with a regular sidecar. Use a native sidecar for these Pods instead.

Telemetry API for mesh metrics and access logs

Istio Telemetry API (`telemetry.istio.io`) is the recommended way to configure the collection of data on the operation of services (metrics, access logs, tracing providers) in the mesh together with `meshConfig`.

The module can run in two modes, controlled by `telemetryAPI.enabled`:

Mode	Behaviour

Mode	Behaviour
`false` (default)	Classic path: full `telemetry.v2` in the Istio Operator / `Istio` resource (including Sail's `telemetry.v2.prometheus`). The module always deploys `Telemetry` `d8-main` in `d8-istio` for stdout access logs only; there is no `spec.metrics` / `spec.tracing` on that object and no `defaultProviders.metrics`
`true`	Telemetry API path: `meshConfig.defaultProviders.metrics` selects the built-in Prometheus provider; `telemetry.v2` integrations are toggled off; the same `Telemetry` `d8-main` gains `spec.metrics` (and optional `spec.tracing` via `deckhouse-tracing` when `tracing.collector` is configured). Access log format comes from `dataPlane.accessLog`

Enabling Telemetry API mode

Apply a `ModuleConfig` for the Istio module (or the same structure in the cluster config):

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  version: 1
  enabled: true
  settings:
    telemetryAPI:
      enabled: true
```

Wait until the `Istio` resource in `d8-istio` reconciles and workloads have picked up the new config (restart application pods if dashboards stay empty after traffic was sent).

Verifying metrics and logs

Generate traffic between meshed pods, then on a pod with `istio-proxy`:

```
# Prometheus text from the sidecar admin API (istio-proxy has pilot-agent, not curl).
istio_proxy_pod="$(
  d8 k -n my-namespace get pods -l app=my-app -o jsonpath='{.items[0].metadata.name}'
)"
d8 k exec -n my-namespace "${istio_proxy_pod}" -c istio-proxy -- \
  /usr/local/bin/pilot-agent request GET stats/prometheus | head
```

Example of successful output:

```
# TYPE istio_requests_total counter
istio_requests_total{...} 12
istio_request_duration_milliseconds_bucket{...} 12
istio_request_bytes_bucket{...} 12
istio_response_bytes_bucket{...} 12
```

If you see series such as `istio_requests_total`, metrics are wired correctly.

Prometheus scraping and Grafana

The module creates a `PodMonitor` for sidecar metrics when the `operator-prometheus` module is enabled. Monitored namespaces are derived automatically from mesh membership (istio-injected workloads); you can exclude a namespace from scraping with label `istio.deckhouse.io/discard-metrics: "true"` on the Namespace.

If workload dashboards stay empty while control plane dashboards work, confirm that:

- workloads run with the Istio sidecar and label `service.istio.io/canonical-name` is present on pods;
- the namespace is not marked with `istio.deckhouse.io/discard-metrics: "true"`.

Extra `Telemetry` policies (optional)

Prefer additional `Telemetry` objects that use a workload selector (or `targetRef`) to pin policies to matching pods. Two or more selector-less `Telemetry` resources in the same namespace are invalid—Istio reports IST0160 because the effective policy becomes ambiguous rather than cleanly “merged”. The module already ships `d8-main` in `d8-istio` as the single mesh-wide defaults object; avoid placing another selector-less `Telemetry` there unless you are intentionally replacing chart output.

Beyond that, scoped policies—for example metrics per namespace—look like:

```
apiVersion: telemetry.istio.io/v1alpha1
kind: Telemetry
metadata:
  name: team-a-prometheus-defaults
  namespace: team-a
spec:
  metrics:
  - providers:
    - name: prometheus
```

For tag removal, disabling specific metrics or modes, follow Customizing Istio metrics with Telemetry API.

Tracing with Telemetry API

`tracing.collector` is the single ModuleConfig entry for mesh-wide trace export (Zipkin or OpenTelemetry).

- `telemetryAPI.enabled: false` plus `tracing.enabled` `true`: Legacy only: `meshConfig.defaultConfig.tracing.zipkin` from `tracing.collector.zipkin.address` (`host:port`, Jaeger Zipkin port `9411`). OTLP (OpenTelemetry Protocol) export requires Telemetry API mode.
- `telemetryAPI.enabled: true` plus `tracing.enabled: true`: The module registers `deckhouse-tracing` when `tracing.collector.opentelemetry` has `service` and `port`, or when `tracing.collector.zipkin.address` is set (OpenTelemetry wins if both are configured). Legacy `defaultConfig.tracing` is omitted; mesh-wide `Telemetry` `d8-main` gets `spec.tracing` (`tracing.sampling` → `randomSamplingPercentage`, default `1.0`).

To send traces from some workloads to another OpenTelemetry or Zipkin backend, register it in `dataPlane.extensionProviders` and reference it from a Telemetry with `selector` in the application namespace. Do not create a second Telemetry without a selector in `d8-istio` (IST0160). A proxy sends spans to a single tracing provider, so these workloads send traces to that backend instead of `deckhouse-tracing`. Other exporters, such as SkyWalking, cannot be registered. See Distributed tracing with Telemetry API.

Example — Telemetry API bundle + bundled Zipkin/Jaeger collector

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  version: 1
  enabled: true
  settings:
    telemetryAPI:
      enabled: true
    tracing:
      enabled: true
      sampling: 25
      collector:
        zipkin:
          address: "jaeger-collector.observability.svc.cluster.local:9411"
```

Roll out the `Istio` manifests in `d8-istio`; confirm workloads pick up telemetry before blaming dashboards.

Kiali

To see traces inside Kiali UI, configure `tracing.kiali` (Jaeger URL + cluster-internal gRPC endpoint) whenever Kiali is enabled.

Example — mesh-wide OTLP via ModuleConfig

Deploy a Collector reachable from the mesh, then enable Telemetry API mode and point `tracing.collector.opentelemetry` at it. The module adds extension provider `deckhouse-tracing` and `spec.tracing` on `d8-main`—do not patch the generated `Istio` `meshConfig` for mesh-wide OTLP.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  version: 1
  enabled: true
  settings:
    telemetryAPI:
      enabled: true
    tracing:
      enabled: true
      sampling: 10
      collector:
        opentelemetry:
          service: opentelemetry-collector.observability.svc.cluster.local
          port: 4317
```

For HTTP OTLP, add `collector.opentelemetry.http.path` (and optional `timeout`) per `tracing.collector.opentelemetry.http`.

For per-workload overrides, create a Telemetry with `selector` in the application namespace and reference `deckhouse-tracing` or a provider registered in `dataPlane.extensionProviders`.

Example — tracing only for selected workloads

Use `selector` (or `targetRef`) so Telemetry targets only matching pods—the pattern below is IST0160-safe. Within a single namespace, `Telemetry` without selectors can still exist at most once; do not pile multiple selector-less manifests there.

Register the provider in `dataPlane.extensionProviders`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  version: 1
  enabled: true
  settings:
    dataPlane:
      extensionProviders:
      - name: jaeger-zipkin
        zipkin:
          service: jaeger-collector.observability.svc.cluster.local
          port: 9411
```

Reference it from a Telemetry with `selector`:

```
apiVersion: telemetry.istio.io/v1alpha1
kind: Telemetry
metadata:
  name: checkout-tracing
  namespace: shop
spec:
  selector:
    matchLabels:
      app: checkout
  tracing:
  - providers:
    - name: jaeger-zipkin
    randomSamplingPercentage: 100.0
```

Example — disable span export for ingress-only namespaces

In DP, when the `ingress-nginx` module is enabled, the Istio chart creates `Telemetry` `ingress-nginx-disable-span-reporting` in `d8-ingress-nginx` with `tracing.disableSpanReporting` so Ingress controller pods with `istio-proxy` stop exporting spans. For other namespaces:

```
apiVersion: telemetry.istio.io/v1alpha1
kind: Telemetry
metadata:
  name: no-tracing-example
  namespace: my-namespace
spec:
  tracing:
  - disableSpanReporting: true
```

Rolling back to the legacy telemetry stack

```
spec:
  settings:
    telemetryAPI:
      enabled: false
```

The module-managed `Telemetry` objects for this mode disappear on the next sync; Istio restores the full `telemetry.v2` configuration.

Debugging Istio with istioctl from the debug container

The DP debug container includes versioned `istioctl` binaries. Use it when you need to inspect Istio configuration, run analyzers, or retrieve Envoy proxy configuration from application Pods.

Before starting the debug container, create a dedicated ServiceAccount and grant it the permissions required by the `istioctl` commands you want to run. For example, the following manifest grants permissions that allow running the `istioctl proxy-config` commands for Pods in a single application namespace:

```
apiVersion: v1
kind: ServiceAccount
metadata:
  name: istioctl-debug
  namespace: <debug-namespace>
---
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: istioctl-debug
  namespace: <target-namespace>
rules:
  - apiGroups: [""]
    resources:
      - pods
    verbs:
      - get
      - list
  - apiGroups: [""]
    resources:
      - pods/portforward
    verbs:
      - create
---
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: istioctl-debug
  namespace: <target-namespace>
subjects:
  - kind: ServiceAccount
    name: istioctl-debug
    namespace: <debug-namespace>
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: Role
  name: istioctl-debug
```

Replace `<debug-namespace>` with the namespace where the temporary debug Pod will be created, and `<target-namespace>` with the namespace of the application Pod you want to inspect. Create the Role and RoleBinding resources for every target namespace where `istioctl` must access Pods.

This RBAC manifest is intended for commands that address a Pod directly, for example, to a resource like `<pod-name>.<target-namespace>`. If you use typed resource names such as `deployment/<name>`, grant additional read access to those resource types so `istioctl` can resolve them to Pods.

> ⚠ Creating Pods in system namespaces such as `d8-system` and using system ServiceAccounts such as `deckhouse` usually requires the `cluster-admin` level of privileges. Use a dedicated ServiceAccount with the minimum required permissions instead.

Start a temporary debug Pod with the built-in debug image:

```
IMG="$(d8 k -n d8-system get cm debug-container -o jsonpath='{.data.image}')"

d8 k -n <debug-namespace> run istioctl-debug \
  --rm -it \
  --restart=Never \
  --image="$IMG" \
  --overrides='{"spec":{"serviceAccountName":"istioctl-
debug","automountServiceAccountToken":true}}' \
  -- bash
```

Select the minor version of Istio used by the target control plane:

```
export ISTIOCTL_VERSION=1.29
```

Available values are `1.25`, `1.27`, and `1.29`. You can also run a specific binary directly: `istioctl-1.25`, `istioctl-1.27`, or `istioctl-1.29`.

Example:

```
istioctl pc all <pod-name>.<target-namespace>
```

The `istioctl pc` commands require a target Pod with an injected `istio-proxy` sidecar. If the target Pod has no sidecar, Envoy admin port `15000` will not be available.

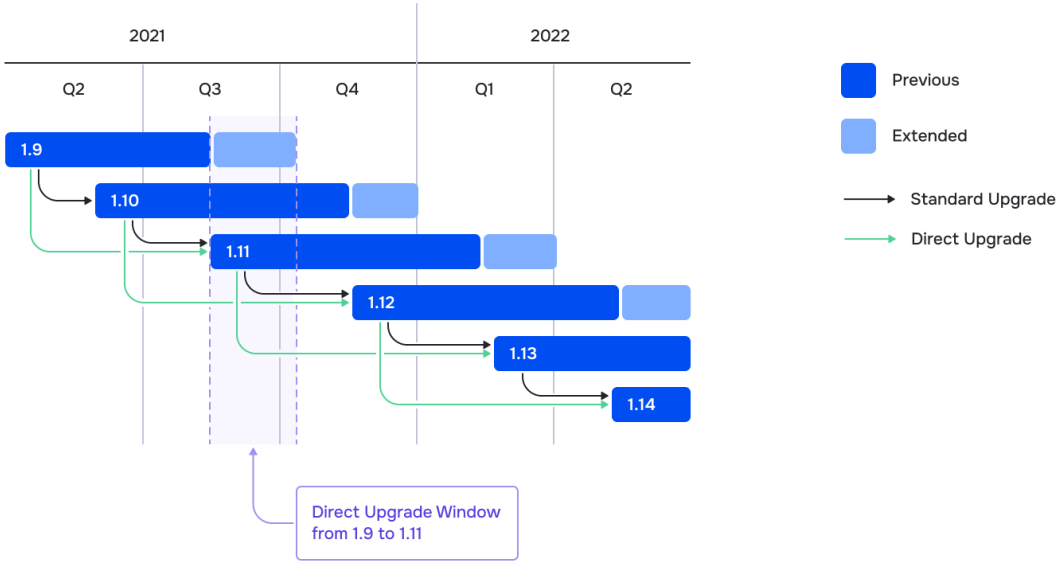
⚠ The RBAC manifest above is not enough to run `istioctl analyze` or `istioctl analyze -A`. These commands require additional read-only access to namespaces and to the Kubernetes and Istio resources covered by the analyzers. Grant such access separately according to your security policy.

CNIPlugin application traffic redirection mode restrictions

The restriction described below applies only to regular sidecars, which Istio 1.25 injects by default. A native sidecar starts before the application init containers, so their traffic goes through the mesh like the rest of the Pod's traffic.

Unlike the `InitContainer` mode, the redirection setting is done at the moment of Pod creating, not at the moment of triggering the `istio-init` init container. This means that application init containers will not be able to interact with other services because all traffic will be redirected to the `istio-proxy` sidecar container, which is not yet running. Workarounds:

- Run the application init container from the user with uid `1337`. Requests from this user are not intercepted under Istio control.
- Exclude a service IP address or port from Istio control using the `traffic.sidecar.istio.io/excludeOutboundIPRanges` or `traffic.sidecar.istio.io/excludeOutboundPorts` annotations.



⚠ Each of the workarounds removes traffic from Istio's control and disables encryption between application services.

UID `1337` is reserved by Istio for the `istio-proxy` sidecar container. Do not run application containers with this UID — their traffic bypasses Istio entirely (no routing rules, mTLS, or telemetry). Use UID `1337` only in init containers when network requests are required before the sidecar is ready.

Upgrading Istio

Upgrading Istio control-plane

- DP allows you to install different control-plane versions simultaneously:
  - A single global version to handle namespaces or Pods with indifferent version (namespace label `istio-injection: enabled`). It is configured by the globalVersion parameter.
  - Additional versions handle namespaces or Pods with explicitly configured versions (`istio.io/rev: v1x25` label for namespace or Pod). They are configured by the `additionalVersions` parameter. The `istio.io/rev` label on a Pod is taken into account only if its namespace has neither the `istio-injection` nor the `istio.io/rev` label.
- Istio declares backward compatibility between data-plane and control-plane in the range of two minor versions:

- Upgrade algorithm (for example, from `1.25` to `1.27`):
  - Configure the target version in the additionalVersions parameter (`additionalVersions: ["1.27"]`).
- Wait for the corresponding pod `istiod-v1x27-xxx-yyy` to appear in the `d8-istio` namespace.
- For every application namespace with Istio enabled:
  - Change the `istio-injection: enabled` label to `istio.io/rev: v1x27`.
  - Recreate the Pods in the namespace one at a time while monitoring application health.
- Reconfigure `globalVersion` to `1.27` and remove the `additionalVersions` configuration.
- Make sure, the old `istiod` pod has gone.
- Change application namespace labels to `istio-injection: enabled`.

To find all Pods with the old Istio revision (version 1.25 in this example), execute the command:

```
d8 k get pods -A -o json | jq --arg revision "v1x25" \
  '.items[] | select(.metadata.annotations."sidecar.istio.io/status" // "{}" | fromjson
|
    .revision == $revision) | .metadata.namespace + "/" + .metadata.name'
```

Auto upgrading istio data-plane

To automate istio-sidecar upgrading, set a label `istio.deckhouse.io/auto-upgrade="true"` on the application `Namespace` or on the individual resources — `Deployment`, `DaemonSet` or `StatefulSet`.

Automatic upgrading is triggered when the current data-plane version of a Pod with an istio-sidecar differs from the desired version. Adding a version to the `additionalVersions` parameter does not restart application Pods by itself. A mismatch usually appears in the following cases:

- The `globalVersion` parameter changed for a namespace that uses the global Istio version (`istio-injection=enabled` or `istio.io/rev=default`).
- The `istio.io/rev` label changed on a Namespace, or on a Pod in a namespace without the `istio-injection` and `istio.io/rev` labels.
- The patch version of the installed control plane was updated.

Before restarting a workload, the module checks that the corresponding control plane is installed and ready. Then the module adds or updates the `istio.deckhouse.io/full-version` annotation in `spec.template.metadata.annotations`, and Kubernetes performs a regular rollout. Within the same namespace, the module does not start upgrading the next workload until the previously upgraded workload is ready.

The `istio.deckhouse.io/auto-upgrade="true"` label must be set on the same entity that defines Istio usage for the workload:

- If injection is enabled at the namespace level with `istio-injection=enabled`, `istio.io/rev=<REVISION>`, or `istio.io/rev=default`, you can set `istio.deckhouse.io/auto-upgrade="true"` on the same Namespace.
- If sidecar injection is enabled at the workload or pod template level, for example with `sidecar.istio.io/inject="true"`, set `istio.deckhouse.io/auto-upgrade="true"` on the corresponding Deployment, DaemonSet, or StatefulSet.
- A namespace with only the `istio.deckhouse.io/auto-upgrade="true"` label does not enable automatic upgrading for a workload if injection is configured only at the workload or pod template level.

Automatic upgrading is supported only for Deployment, DaemonSet, and StatefulSet resources. Job, CronJob, standalone Pod, and custom controllers, including Kruise `AdvancedDaemonSet`, are not handled. If an ingress controller is managed by an `AdvancedDaemonSet`, the `istio.deckhouse.io/auto-upgrade="true"` label on that resource is ignored. Upgrade such ingress controllers manually following the “Istio control plane upgrade” procedure and the “Ingress NGINX integration” section.

Use the `D8IstioDataPlaneVersionMismatch` alert to detect Pods whose patch data-plane version differs from the control plane version — the scenario that automatic upgrading addresses. The `D8IstioActualDataPlaneVersionNotEqualDesired` alert indicates a revision mismatch and usually requires changing namespace or Pod labels before sidecars can be updated.

⚠ Do not delete the old Istio control plane manually during an upgrade. The old `istiod` and related resources are removed automatically after there are no sidecars connected to the old revision left in the cluster. Manual deletion can break the regular upgrade automation.

Customizing istio-proxy sidecar resource management

You can override the global istio-proxy sidecar resource limits for specific workloads by adding annotations to your application Pods.

Supported annotations

Use these Pod annotations to customize sidecar resources:

Annotation	Description	Example Value
`sidecar.istio.io/proxyCPU`	CPU request for sidecar	`200m`
`sidecar.istio.io/proxyCPULimit`	CPU limit for sidecar	`"1"`
`sidecar.istio.io/proxyMemory`	Memory request for sidecar	`128Mi`
`sidecar.istio.io/proxyMemoryLimit`	Memory limit for sidecar	`512Mi`

Configuration Examples

For Deployments:

```
apiVersion: apps/v1
kind: Deployment
metadata:
# ...
spec:
  template:
    metadata:
      annotations:
         sidecar.istio.io/proxyCPU: 200m
         sidecar.istio.io/proxyCPULimit: "1"
         sidecar.istio.io/proxyMemory: 128Mi
         sidecar.istio.io/proxyMemoryLimit: 512Mi
# ... rest of your deployment spec
```

For ReplicaSets:

```
apiVersion: apps/v1
kind: ReplicaSet
metadata:
# ...
spec:
  template:
    metadata:
      annotations:
          sidecar.istio.io/proxyCPU: 200m
          sidecar.istio.io/proxyCPULimit: "1"
          sidecar.istio.io/proxyMemory: 128Mi
          sidecar.istio.io/proxyMemoryLimit: 512Mi
# ... rest of your deployment spec
```

For Pod:

```
apiVersion: v1
kind: Pod
metadata:
  annotations:
    sidecar.istio.io/proxyCPU: 200m
    sidecar.istio.io/proxyCPULimit: "1"
    sidecar.istio.io/proxyMemory: 128Mi
    sidecar.istio.io/proxyMemoryLimit: 512Mi
# ... rest of your pod spec
```

⚠ All four parameters must be defined together - if you set any of these annotations, you must specify all four (`sidecar.istio.io/proxyCPU`, `sidecar.istio.io/proxyCPULimit`, `sidecar.istio.io/proxyMemory`, and `sidecar.istio.io/proxyMemoryLimit`).

Providing a custom CA via a Secret reference

Instead of pasting the CA certificate and key inline into the module configuration (via `ca.cert` and `ca.key`), you can reference an existing Secret with the `ca.secretRef` parameter. This lets you issue the CA with any preferred tooling, for example, cert-manager (self-signed issuer, Vault issuer, etc.).

The referenced Secret may be in one of the following formats (auto-detected):

- a cert-manager `kubernetes.io/tls` Secret with the `tls.crt`, `tls.key` and `ca.crt` keys;
- a native Istio `cacerts` Secret with the `ca-cert.pem`, `ca-key.pem`, `cert-chain.pem` and `root-cert.pem` keys.

The signing certificate must be a CA certificate (`isCA: true` / `basicConstraints = CA:TRUE`) whose key matches it.

Example: self-signed CA issued by cert-manager

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: istio-ca
  namespace: my-pki
spec:
  secretName: istio-ca
  commonName: istiod-ca
  isCA: true
  usages:
    - digital signature
    - key encipherment
    - cert sign
  issuerRef:
    kind: Issuer
    name: selfsigned-issuer
```

Example: intermediate CA issued by a Vault issuer

If you already run a HashiCorp Vault PKI, you can have cert-manager issue the Istio CA as an intermediate signed by your Vault root/intermediate. The resulting Secret has exactly the same layout and is auto-detected the same way — the only requirement is `isCA: true`.

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: vault-issuer
  namespace: my-pki
spec:
  vault:
    # Path of the intermediate PKI role that is allowed to issue CA certificates.
    path: pki_int/sign/istio-ca
    server: https://vault.example.com:8200
    # Vault must return the CA chain so that ca.crt contains the root.
    caBundle: <base64-encoded Vault CA bundle>
    auth:
      kubernetes:
        role: istio-ca-issuer
        mountPath: /v1/auth/kubernetes
        serviceAccountRef:
          name: cert-manager
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: istio-ca
  namespace: my-pki
spec:
  secretName: istio-ca
  commonName: istiod-ca
  # Mandatory: the issued certificate must itself be a CA so istiod can sign workload
certs.
  isCA: true
  duration: 87600h   # 10y, adjust to your rotation policy
  usages:
    - digital signature
    - key encipherment
    - cert sign
    - crl sign
  issuerRef:
    kind: Issuer
    name: vault-issuer
```

⚠ The Vault PKI role must permit issuing CA certificates (`isCA`), and the issuer must return the CA chain so that `ca.crt` contains the Vault root. Otherwise the module cannot determine the root and the leaf validation will fail, hard-blocking the rollout.

Then reference the resulting Secret in the module configuration (identical for both examples above):

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  version: 3
  enabled: true
  settings:
    ca:
      secretRef:
        name: istio-ca
        namespace: my-pki
```

i If `namespace` is omitted, the Secret is looked up in the `d8-istio` namespace.

⚠ If the referenced Secret is missing or malformed on the first resolution of this `secretRef`, the module will not proceed until the issue is fixed. It will not silently fall back to a self-signed CA — or to any CA that was in use before this `secretRef` was configured — to avoid unexpectedly running on an unrelated CA.

If the same `secretRef` was already resolved successfully and later becomes unavailable or invalid (for example, it is briefly deleted during rotation, or its chain expires), the module keeps using that last successfully-resolved CA instead of hard-blocking. It never switches to a different CA on its own — it only reuses the exact material istiod is already running with — so an already-working mesh is not regressed while the source is fixed. Repointing `secretRef` to a different Secret counts as a first resolution: if that new Secret cannot be resolved, the module hard-blocks rather than keeping the previous CA.

i The referenced Secret is re-resolved on a 5-minute schedule, so changes to the source Secret may propagate with a delay.

When using an intermediate CA, keep the root stable across rotations. The module publishes `root-cert.pem` (the `ca.crt` trust anchor) as the webhook `caBundle` and as the workload trust root, while the signing (intermediate) certificate may change. Rotating the intermediate under a stable root is seamless; changing the root is a mesh-wide trust change and requires the old and new roots to overlap in the trust bundle during the transition.

Reverting to a self-signed CA

Removing `ca.secretRef` (or inline `ca.cert`) from the module configuration does not switch the mesh back to an auto-generated self-signed CA on its own. The module intentionally keeps the last-published CA — stored in the `d8-istio/cacerts` Secret — so an already-working mesh is never rotated implicitly: rotating the mesh root breaks mTLS cluster-wide until every workload re-trusts the new root.

To deliberately return to a self-signed CA:

1. Remove the `ca.secretRef` (or `ca.cert`) configuration from the `istio` ModuleConfig.
2. Delete the module-owned `d8-istio/cacerts` Secret:

   ```
   d8 k -n d8-istio delete secret cacerts
   ```

3. Restart the Deckhouse pod so the module drops the last-published CA it holds in memory:

   ```
   d8 k -n d8-system rollout restart deployment deckhouse
   ```

⚠ This is a mesh-wide trust change and triggers a rollout: istiod republishes the new root as the webhook `caBundle` and workloads must re-trust it. Perform it during a maintenance window.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The keepalived module

> The module lifecycle stage: General Availability

> ⚠ This module does not work with the cilium module.

This module (managed via custom resources) is intended for configuring keepalived clusters on nodes.

Third-party components

List of third-party software used in the `keepalived` module:

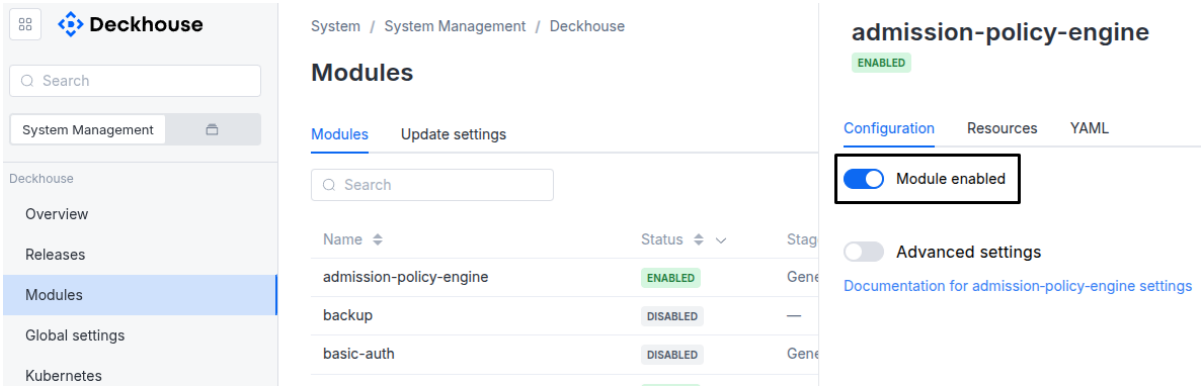
- keepalived 2.2.7

  License: GNU General Public License v2.0

  Provides simple and robust facilities for loadbalancing and high-availability to Linux system and Linux based infrastructures.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `keepalived` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

Example of enabling the module:

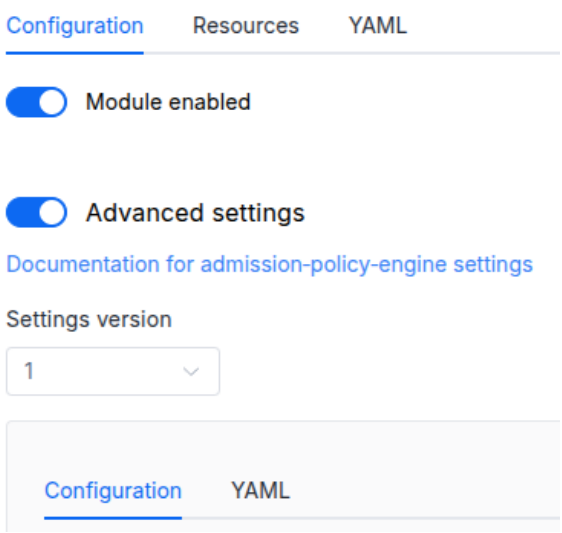
```
d8 system module enable keepalived
```

- **Using ModuleConfig `keepalived`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `keepalived` (create it if necessary);

  Example of a manifest to enable module `keepalived`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: keepalived
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `keepalived` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `keepalived` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `keepalived`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `keepalived` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc keepalived
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `keepalived` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `keepalived`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: keepalived
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Keepalived clusters are configured using the custom resource.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

KeepalivedInstance

Scope: Cluster
Version: v1alpha1

The custom resource for configuring keepalived clusters.

Each `KeepalivedInstance` custom resource defines a single keepalived cluster.

`metadata.name` — the name of the cluster (used in pod names).

- **spec**
  object

  Required value

  - **spec.nodeSelector**
    object

    Required value

    Defines the `nodeSelector` parameter for keepalived pods.

    Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

  - **spec.tolerations**
    array of objects

    Defines `tolerations` for keepalived pods.

    Format: the standard toleration list. Instance pods inherit this field as is.

    - **spec.tolerations.effect**
      string

      Defines the taint’s effect this toleration is associated with (it matches any effect if empty).

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **spec.tolerations.key**
      string

      Defines the taint’s key this toleration is associated with (it matches any key if empty).

If the key is omitted (emplty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

- **spec.tolerations.operator**
  string

  Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

  Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

  Default: `Equal`

  Allowed values: `Exists`, `Equal`

- **spec.tolerations.tolerationSeconds**
  integer

  Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

  If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

  The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the operator parameter is set to `Exists`.

- **spec.vrrpInstances**
  array of objects

  Required value

  A list of VRRP instances in the keepalived cluster. Essentially, it is a list of address groups that migrate between servers simultaneously and cannot work separately.

  Do not confuse `vrrpInstance` with `KeepalivedInstance`. `vrrpInstance` is a component of `KeepalivedInstance`.

  The `keepalived` module configures VRRP instances so that all addresses (all groups) are evenly distributed across all servers (instead of gathering together on the same node).

  - **spec.vrrpInstances.id**
    integer

    Required value

    A unique **cluster-wide** identifier of a VRRP group.

    Do not use the same ID in different `KeepalivedInstance` instances unless you have a perfect reason to do so.

    Allowed values: `1 <= X <= 255`

  - **spec.vrrpInstances.interface**
    object

    Required value

    Defines the strategy of detecting interface for the service VRRP traffic on the node.

    - **spec.vrrpInstances.interface.detectionStrategy**
      string

      You can select one of the following three interface detecting strategis:

      - `Name` — set the interface name explicitly using the `spec.vrrpInstances[].interface.name` parameter. In this case, all nodes must have the same interface that serves the correct network (e.g., eth0).
      - `NetworkAddress` — find an interface with an IP from this subnet on the node and use it.
      - `DefaultRoute` — use the interface for the default route on the node (254 “main” in the table).
    - **spec.vrrpInstances.interface.name**

string

The name of the interface for the service VRRP traffic if the `Name` `detectionStrategy` is used.

A mandatory parameter if `detectionStrategy` = `Name`.

- **spec.vrrpInstances.interface.networkAddress**
  string

  The address of the subnet to use for determining an interface if `detectionStrategy` = `NetworkAddress`.

  A mandatory parameter if `detectionStrategy` = `NetworkAddress`.

  Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

  Example:

  ```
  networkAddress: 192.168.42.0/24
  ```

- **spec.vrrpInstances.preempt**
  boolean

  Defines if the IP is passed to a node after its recovery from a failure.

  It makes sense not to pass the IP if you have just one `vrrpInstance` to preserve connections. If you have a lot of groups and a lot of traffic, it is better to pass it to prevent the concentration of all groups on one node.

  The default is — `true`, that is, the IP will passed to a node after its recovery.

- **spec.vrrpInstances.virtualIPAddresses**
  array of objects

  Required value

  A list of IP addresses that will “jump” between the servers **in tandem**

  - **spec.vrrpInstances.virtualIPAddresses.address**
    string

    Required value

    One of the group addresses.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

    Example:

    ```
    address: 192.168.42.15/32
    ```

  - **spec.vrrpInstances.virtualIPAddresses.interface**
    object

    Not required value.

    An interface for binding a virtual IP address on a node (similar to `spec.vrrpInstances[].interface`).

    If omitted, the main service interface defined in `spec.vrrpInstances[].interface` will be used.

    - **spec.vrrpInstances.virtualIPAddresses.interface.detectionStrategy**
      string

      You can select one of the following three interface detecting strategis ti bind an IP address:

      - `Name` — set the interface name explicitly using the `spec.vrrpInstances[].virtualIPAddresses[].interface.name` parameter. In this case, all nodes must have the same interface that serves the correct network (e.g., eth0).
      - `NetworkAddress` — find an interface with an IP from this subnet on the node and use it.
      - `DefaultRoute` — use the interface for the default route on the node (254 “main” in the table).
    - **spec.vrrpInstances.virtualIPAddresses.interface.name**
      string

A name of the interface to bind a virtual IP address if `virtualIPaddresses[].detectionStrategy = Name` is used.

A mandatory parameter if `virtualIPaddresses[].detectionStrategy = Name`.

- **spec.vrrpInstances.virtualIPAddresses.interface.networkAddress**
  string

  The address of the subnet to use for determining an interface if `virtualIPaddresses[].detectionStrategy = NetworkAddress`.

  A mandatory parameter if `virtualIPaddresses[].detectionStrategy = NetworkAddress`.

  Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

  Example:

```
networkAddress: 192.168.42.0/24
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

keepalived: FAQ

> The module lifecycle stage: General Availability

How to manually switch keepalived?

1. Enter the desired pod using a debug container with a shared process namespace: `d8 k debug -n d8-keepalived -it keepalived-<name> --profile=general --target keepalived`.
2. Edit the configuration file `vim /proc/1/root/etc/keepalived/keepalived.conf`, replace the value in the `priority` line with <number of keepalived pods + 1> or set a value higher than the current VRRP master (e.g., `255`).
3. Apply settings – send a signal to reload the configuration: `kill -HUP 1`.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Three public IP addresses

Suppose there are three public IP addresses on three front nodes. Each virtual IP address is placed in a separate VRRP group. Thus, each address “jumps” independently of the others, and if there are three nodes in the cluster with the `node-role.deckhouse.io/frontend: ""` labels, then each IP gets its own MASTER node.

```
apiVersion: deckhouse.io/v1alpha1
kind: KeepalivedInstance
metadata:
  name: front
spec:
  nodeSelector: # Mandatory.
    node-role.deckhouse.io/frontend: ""
  tolerations:  # Optional.
  - key: dedicated.deckhouse.io
    operator: Equal
    value: frontend
  vrrpInstances:
  - id: 1 # The unique cluster ID.
    interface:
      detectionStrategy: DefaultRoute # The card with the default route is used as a
service network one.
    virtualIPAddresses:
    - address: 42.43.44.101/32
      # The interface parameter is omitted since IP addresses are based on the cards that
service VRRP traffic.
  - id: 2
    interface:
      detectionStrategy: DefaultRoute
    virtualIPAddresses:
    - address: 42.43.44.102/32
  - id: 3
    interface:
      detectionStrategy: DefaultRoute
    virtualIPAddresses:
    - address: 42.43.44.103/32
```

Suppose there is a gateway with a pair of IP addresses for LAN and WAN. In the case of the gateway, the private and public IPs are bind together, and they will “jump” between the nodes in tandem. In the below example, the VRRP traffic is routed through the LAN interface. It can be detected using the NetworkAddress method (assuming that each node has an IP belonging to this subnet).

```
apiVersion: deckhouse.io/v1alpha1
kind: KeepalivedInstance
metadata:
  name: mygateway
spec:
  nodeSelector:
    node-role.deckhouse.io/mygateway: ""
  tolerations:
  - key: node-role.deckhouse.io/mygateway
    operator: Exists
  vrrpInstances:
  - id: 4 # Since "1", "2", "3" IDs are used in the "front" KeepalivedInstance above.
    interface:
      detectionStrategy: NetworkAddress
      networkAddress: 192.168.42.0/24
    virtualIPAddresses:
    - address: 192.168.42.1/24
      # In this case, we have already detected the local network (above); thus, the
interface parameter can be safely omitted.
    - address: 42.43.44.1/28
      interface:
        detectionStrategy: Name
        name: ens7 # we use the fact that an interface for public IPs is called "ens7" on
all nodes
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The kube-dns module

> The module lifecycle stage: General Availability

The module installs CoreDNS components for managing DNS in the Kubernetes cluster.

> **Caution.** The module deletes all the previously installed kubeadm Deployments, ConfigMaps as well as RBAC for CoreDNS. When deploying your own CoreDNS, avoid using the names `coredns` or `system:coredns` for any resources (Deployment, Service, ConfigMap, ServiceAccount, ClusterRole, ClusterRoleBinding). Use alternative names like `infra-dns` to prevent automatic removal by Deckhouse Platform.

Third-party components

List of third-party software used in the `kube-dns` module:

- CoreDNS

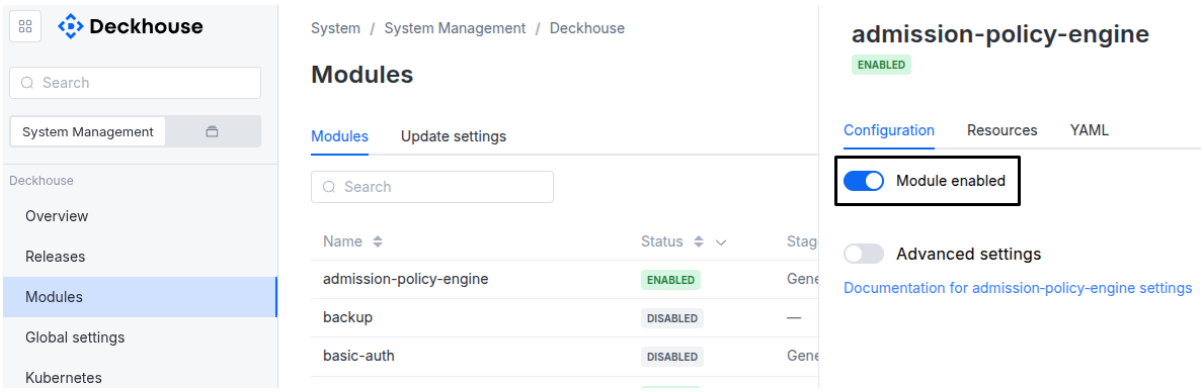
  License: Apache License 2.0

  A DNS server/forwarder that chains plugins.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability



The module has 1 alert.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `kube-dns` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

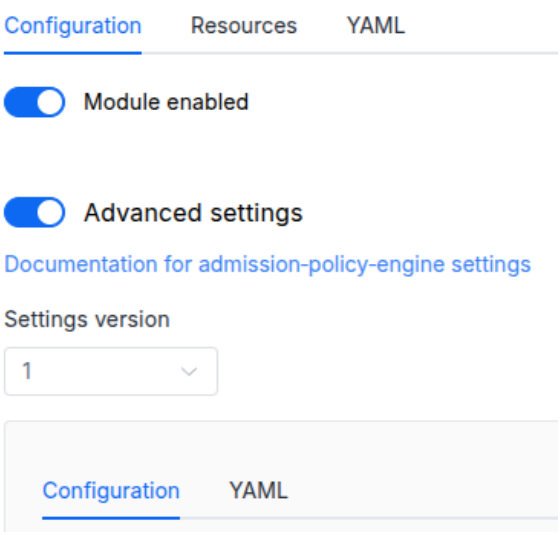
  ```
  d8 system module enable kube-dns
  ```

- **Using ModuleConfig `kube-dns`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `kube-dns` (create it if necessary);

  Example of a manifest to enable module `kube-dns`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: kube-dns
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `kube-dns` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `kube-dns` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `kube-dns`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `kube-dns` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc kube-dns
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `kube-dns` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `kube-dns`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: kube-dns
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.clusterDomainAliases**
    array of strings

    A list of cluster domain aliases; these are resolved on par with `global.discovery.clusterDomain`.

    Please note: the domain alias must not match the domain used in the DNS name template in the publicDomainTemplate parameter.

    - **Element of the array**
      string

      Pattern: `^[0-9a-zA-Z\.-]+$`

  - **settings.enableLogs**
    boolean

    Enable CoreDNS logging.

    Default: `false`

  - **settings.hosts**
    array of objects

    Not required value.

    A static list of hosts similar to that of `/etc/hosts`.

    - **settings.hosts.domain**
      string

      Pattern: `^[0-9a-zA-Z\.-]+$`

    - **settings.hosts.ip**
      string

      Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}$`

  - **settings.stubZones**
    array of objects

A list of additional zones CoreDNS should be authoritative for.

Default: `[]`

Example:

```
stubZones:
- zone: example.com
  upstreamNameservers:
  - 8.8.8.8
  cacheTTLSeconds: 3600
  transportProtocolMode: PreferUDP
```

- **settings.stubZones.cacheTTLSeconds**
  integer

  Max TTL in seconds for NOERROR responses.

  Default: `30`

  Allowed values: `1 <= X <= 3600`

- **settings.stubZones.transportProtocolMode**
  string

  The mode of the transport protocol for communicating with the upstream DNS server:

  - `PreferUDP` — UDP is used, even if the original request came over TCP. Note that if the DNS response from the upstream DNS server exceeds 512 bytes and has been truncated and marked with the TC bit (RFC 1035), then it will be resent over TCP (RFC 5966). The request will not be resent over TCP if there are other UDP issues.
  - `ForceTCP` — Always uses TCP, even if the original request is over UDP.
  - `KeepOriginal` — Uses the same protocol (TCP or UDP) as the original request.

  Default: `PreferUDP`

  Allowed values: `PreferUDP`, `ForceTCP`, `KeepOriginal`

- **settings.stubZones.upstreamNameservers**
  array of strings

  Required value

  A list of IP addresses of recursive DNS servers that CoreDNS will use to resolve domains in this zone.

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}(:[0-9]{1,})?$`

- **settings.stubZones.zone**
  string

  Required value

  The CoreDNS zone.

  Pattern: `^[0-9a-zA-Z\.\-_]+$`

  Example:

  ```
  zone: consul.local
  ```

- **settings.transportProtocolMode**
  string

  The mode of the transport protocol for communicating with the upstream DNS server:

  - `PreferUDP` — UDP is used, even if the original request came over TCP. Note that if the DNS response from the upstream DNS server exceeds 512 bytes and has been truncated and marked with the TC bit (RFC 1035), then it will be resent over TCP (RFC 5966). The request will not be resent over TCP if there are other UDP issues.
  - `ForceTCP` — Always uses TCP, even if the original request is over UDP.
  - `KeepOriginal` — Uses the same protocol (TCP or UDP) as the original request.

  Default: `PreferUDP`

  Allowed values: `PreferUDP`, `ForceTCP`, `KeepOriginal`

- **settings.upstreamNameservers**
  array of strings

  A list of IP addresses of recursive DNS servers that CoreDNS will use to resolve external domains.

  By default, the `/etc/resolv.conf` list is used.

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}(:[0-9]{1,})?$`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

FAQ

> The module lifecycle stage: General Availability

How to change cluster domain with minimal downtime?

> **Before you start.** The cluster domain must already be managed from the `control-plane-manager` ModuleConfig. If the `D8ObsoleteClusterDomainInClusterConfiguration` alert is firing, it is still kept in `ClusterConfiguration`; finish the migration first:
>
> 1. Copy the current value into `spec.settings.network.clusterDomain` of the `control-plane-manager` ModuleConfig. Keep the value exactly as it is now: admission rejects a mismatch on the initial move.
>
>    ```
>    d8 k edit mc control-plane-manager
>    ```
>
> 2. Remove `clusterDomain` from `ClusterConfiguration`:
>
>    ```
>    d8 system edit cluster-configuration
>    ```
>
> 3. Make sure the alert has cleared.

Add a new domain and retain the previous one. To do this, modify the configuration parameters:

1. In the controlPlaneManager.apiserver:
   - controlPlaneManager.apiserver.certSANs,
   - apiserver.serviceAccount.additionalAPIAudiences,
   - apiserver.serviceAccount.additionalAPIIssuers.

   Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  enabled: true
  version: 3
  settings:
    apiserver:
      certSANs:
       - kubernetes.default.svc.<old clusterDomain>
       - kubernetes.default.svc.<new clusterDomain>
      serviceAccount:
        additionalAPIAudiences:
        - https://kubernetes.default.svc.<old clusterDomain>
        - https://kubernetes.default.svc.<new clusterDomain>
        additionalAPIIssuers:
        - https://kubernetes.default.svc.<old clusterDomain>
        - https://kubernetes.default.svc.<new clusterDomain>
```

2. In the kubeDns.clusterDomainAliases:

   Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: kube-dns
spec:
  version: 1
  enabled: true
  settings:
    clusterDomainAliases:
      - <old clusterDomain>
      - <new clusterDomain>
```

3. Wait until the `kube-apiserver` has restarted.

```
d8 k -n kube-system get pods -l component=kube-apiserver
```

4. Set `spec.settings.network.clusterDomain` to the new domain:

```
d8 k edit mc control-plane-manager
```

5. Restart deckhouse pods:

```
kubectl -n d8-system rollout restart deployment deckhouse
```

⚠ **Important.** In kubernetes, controllers in the cluster use advanced ServiceAccount tokens to interact with API server. These tokens have extra fields `iss:` and `aud:` that contain `clusterDomain` (e.g. `"iss": "https://kubernetes.default.svc.cluster.local"`). After changing the clusterDomain, the API server will start issuing tokens with the new service-account-issuer, but thanks to the configuration of additionalAPIAudiences and additionalAPIIssuers, the apiserver will continue to accept the old tokens. After 48 minutes (80% of 3607 seconds), Kubernetes will begin to refresh the issued tokens, and the new service-account-issuer will be used for the updated tokens. After 90 minutes (3607 seconds plus a short buffer) following the kube-apiserver restart, you can remove the serviceAccount configuration from the control-plane-manager configuration.

⚠ **Important.** In case you need to remove old domain from `clusterDomainAliases` in kube-dns configuration, recreation of all pods in cluster is required, so new pods will have correct search domain in `/etc/resolv.conf` file. This will lead to service downtime until pods are restarted.

```
d8 k delete pods --all-namespaces --all
```

⚠ **Important!** If you use istio module, you have to restart all the application pods under istio control after changing `clusterDomain`.

How to scale-up kube-dns replicas?

Deckhouse distributes kube-dns pods based on the following principles. It searches for nodes with the labels `node-role.deckhouse.io/` and `node-role.kubernetes.io/`, then applies the following rules:

- If there are nodes with the `kube-dns` role in the cluster, the number of replicas is calculated as the sum of these nodes and the master nodes, but not more than masters count plus 2.
- If kube-dns nodes are absent, the system searches for nodes with the `system` role, and the number of replicas is then determined as the sum of system nodes and master nodes, but not more than masters count plus 2.
- If only master nodes are present in the cluster, the number of kube-dns replicas will be equal to the number of masters.

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

i The module lifecycle stage: General Availability

Configuration example

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: kube-dns
spec:
  version: 1
  enabled: true
  settings:
    upstreamNameservers:
    - 8.8.8.8
    - 8.8.4.4
    hosts:
    - domain: one.example.com
      ip: 192.168.0.1
    - domain: two.another.example.com
      ip: 10.10.0.128
    stubZones:
    - zone: consul.local
      upstreamNameservers:
      - 10.150.0.1
    enableLogs: true
    clusterDomainAliases:
    - foo.bar
    - baz.qux
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The kube-proxy module

> The module lifecycle stage: General Availability

The module deletes the entire `kubeadm` kube-proxy set (`DaemonSet`, `ConfigMap`, `RBAC`) and installs its own.

For security reasons, for NodePort services, connections are only allowed to the nodes' InternalIP by default. You can lift this restriction using the `node.deckhouse.io/nodeport-bind-internal-ip: "false"` annotation.

Here is an example of a NodeGroup annotation:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: myng
spec:
  nodeTemplate:
    annotations:
      node.deckhouse.io/nodeport-bind-internal-ip: "false"
...
```

> **Note!** Following the addition, deletion, or changing the annotation, you have to restart kube-proxy Pods manually.
>
> **Note!** The kube-proxy module is automatically disabled when the cni-cilium module is enabled.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The local-path-provisioner module

> The module lifecycle stage: General Availability

Local Path Provisioner provides a way for the Kubernetes users to utilize the local storage on each node.

How does it work?

For each custom resource LocalPathProvisioner, a corresponding `StorageClass` is created.

The allowed topology for `StorageClass` is calculated based on the list of `nodeGroup` names from the CR. The topology is used for scheduling Pods.

When a Pod orders a disk:

- a `HostPath` PV is created
- the `Provisioner` creates a local disk folder on the desired node along the path consisting of the `path` custom resource parameter, the PV name and the PVC name.

  Example of a path:

```
/opt/local-path-provisioner/pvc-d9bd3878-f710-417b-a4b3-38811aa8aac1_d8-monitoring_prometheus-main-db-prometheus-main-0
```

Limitations

- The disk size limit is not supported for the local path provisioned volumes.

Third-party components

List of third-party software used in the `local-path-provisioner` module:

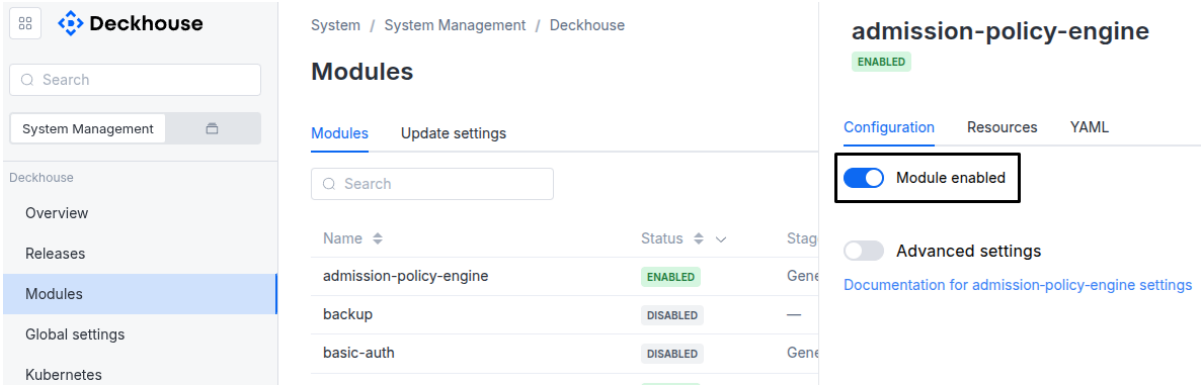
- Local-path-provisioner

  License: Apache License 2.0

  Local Path Provisioner provides a way for the Kubernetes users to utilize the local storage in each node by creating hostPath based persistent volume on the node automatically.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `local-path-provisioner` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

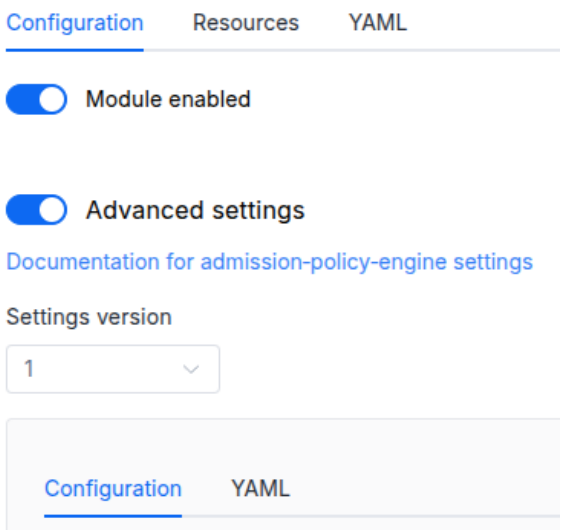
```
d8 system module enable local-path-provisioner
```

- **Using ModuleConfig `local-path-provisioner`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `local-path-provisioner` (create it if necessary);

  Example of a manifest to enable module `local-path-provisioner`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: local-path-provisioner
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `local-path-provisioner` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `local-path-provisioner` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `local-path-provisioner`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `local-path-provisioner` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc local-path-provisioner
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `local-path-provisioner` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `local-path-provisioner`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: local-path-provisioner
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

The module does not require any configuration.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

LocalPathProvisioner

Scope: Cluster
Version: v1alpha1

Parameters of the `local-path-provisioner` instance.

- **spec**
  object
  - **spec.nodeGroups**
    array of strings

    Select nodeGroups for storageClass allowedTopologies.

    Example:

    ```
    nodeGroups:
    - master
    - worker
    ```
  - **spec.path**
    string

    Required value

    Node root path for PV’s.

    An absolute path without quotes, backslashes, whitespace and control characters.

    Pattern: `^/[^"\\\s\p{Cc}]*$`

    Example:

    ```
    path: "/opt/local-path-provisioner"
    ```
  - **spec.reclaimPolicy**
    string

    Retain policy for PV’s.

    Default: `Retain`

Allowed values: `Retain`, `Delete`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

How to configure Prometheus to use local storage for storing data?

Deploy custom resource `LocalPathProvisioner`:

```
apiVersion: deckhouse.io/v1alpha1
kind: LocalPathProvisioner
metadata:
  name: localpath-system
spec:
  nodeGroups:
  - system
  path: "/opt/local-path-provisioner"
```

- `spec.nodeGroups` must match NodeGroup where prometheus Pods run.
- `spec.path` - node data path.

Add to the following parameters to the `prometheus` module configuration:

```
longtermStorageClass: localpath-system
storageClass: localpath-system
```

Wait for the restart of Prometheus Pods.

What happens to existing volumes when `spec.path` changes?

New volumes are created under the new path. Volumes created earlier stay in the old directory. With `reclaimPolicy: Delete`, a helper Pod removes the directory of a deleted volume and mounts the old path to do so. When Pod Security Standards in system namespaces reject Pods instead of only warning about them, the SecurityPolicyException `helper-<name>` of the LocalPathProvisioner allows only the current path, so the helper Pod for an old volume is rejected: the PersistentVolume stays `Released`, and its data stays on the node. With `reclaimPolicy: Retain` (the default), no helper Pod is started on deletion, and this limitation does not apply.

Before changing `spec.path`, delete the PersistentVolumeClaims of the volumes created under the old path. If such a volume stays `Released` after the change, delete its directory on the node and then the PersistentVolume.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Example of a `LocalPathProvisioner` custom resource

Reclaim policy set by default to `Retain`.

```
apiVersion: deckhouse.io/v1alpha1
kind: LocalPathProvisioner
metadata:
  name: localpath-system
spec:
  nodeGroups:
  - system
  path: "/opt/local-path-provisioner"
```

Example of a `LocalPathProvisioner` custom resource with `reclaimPolicy` set

Reclaim policy set to `Delete`.

```
apiVersion: deckhouse.io/v1alpha1
kind: LocalPathProvisioner
metadata:
  name: localpath-system
spec:
  nodeGroups:
  - system
  path: "/opt/local-path-provisioner"
  reclaimPolicy: "Delete"
```

The metallb module

> Available with limitations in: **Core, SE, SE+, Certified Core/CSE Lite (1.73)**
>
> Available without limitations in: **Ultimate/EE**

> Included with limitations in extensions: **Advanced Networking**

> The module lifecycle stage: General Availability

This module implements the `LoadBalancer` mechanism for services in bare metal clusters.

Supports the following operating modes:

- **Layer 2 Mode** – introduces an improved load-balancing mechanism for bare metal clusters (compared to the standard L2 mode in MetalLB), enabling the use of multiple “public” IP addresses for cluster services.
- **BGP Mode** – fully based on the MetalLB solution.

Layer 2 mode

In Layer 2 mode, one or more nodes take responsibility for providing the service within the “public” network. From the network’s perspective, it appears as if each of these nodes has multiple IP addresses assigned to its network interface. Technically, this is achieved by the module responding to ARP requests for IPv4 services and NDP requests for IPv6 services. The primary advantage of Layer 2 mode is its versatility: it works in any Ethernet network without requiring specialized hardware.

Advantages of the module over the classic MetalLB

MetalLB in L2 mode allows ordering Service with `LoadBalancer` type, the operation of which is based on the

fact that balancing nodes simulate ARP-responses from the “public” IP in a peering network. This mode has a significant limitation — only one balancing node handles all the incoming traffic of this service at a time. Therefore:

- The node selected as the leader for the “public” IP becomes a “bottleneck”, with no possibility of horizontal scaling.
- If the balancer node fails, all current connections will be dropped while switching to a new balancing node that will be selected as the leader.

This module helps to overcome these limitations. It introduces a new resource, MetalLoadBalancerClass, which allows associating a group of nodes with an IP address pool using a `nodeSelector`. Afterward, a standard Service resource of type `LoadBalancer` can be created, specifying the name of the corresponding MetalLoadBalancerClass. Additionally, annotations can be used to define the required number of IP addresses for L2 advertisement.

Thus:

- The application will receive not a single, but several (according to the number of balancer nodes) “public” IPs. These IPs will need to be configured as A-records for the application’s public domain. For further horizontal scaling, additional balancer nodes will need to be added, the corresponding Service will be created automatically, you just need to add them to the list of A-records for the application domain.
- If one of the balancer nodes fails, only part of the connections will fail over to the healthy node.

BGP Mode

Metallb in BGP mode provides an efficient and scalable way to expose `LoadBalancer` type Services in Kubernetes clusters running on bare metal. By utilizing the standardized BGP protocol, metallb seamlessly integrates into existing network infrastructure and ensures high availability of Services.

How metallb Works in BGP Mode

In BGP mode, metallb establishes BGP sessions with routers (or Top-of-Rack switches) and announces the IP addresses of `LoadBalancer` type services to them. This is accomplished as follows:

Configuration.

- Metallb is configured with a pool of IP addresses that it can assign to Services.
- BGP session parameters are defined: the Autonomous System (AS) number of the Kubernetes cluster, the IP addresses of the routers (peers), the AS number of the peers, and optionally, authentication passwords.
- For each IP address pool, specific announcement parameters can be set, such as community strings.

Establishing BGP Sessions.

- On each node of the Kubernetes cluster where metallb is running, the speaker component establishes BGP sessions with the specified routers.
- Routing information is exchanged between metallb and the routers.

Assigning IP Addresses to Services.

- When a Service of type `LoadBalancer` is created, metallb selects a free IP address from the configured pool and assigns it to the Service.
- The controller component tracks changes to Services and manages IP address assignments.

Announcing IP Addresses.

- After an IP address is assigned, the speaker on the node elected as the leader for that Service begins announcing the IP address over the established BGP sessions.
- The routers receive this announcement and update their routing tables, directing traffic for that IP address to the node that announced it.

Traffic Distribution.

- Routers use Equal-Cost Multi-Path (ECMP) or other load balancing algorithms to distribute traffic among nodes announcing the same Service IP address.
- Inside the Kubernetes cluster, traffic arriving at a node is forwarded to the Service’s pods using the mechanisms of the employed CNI (iptables/IPVS, eBPF programs, etc.).

Advantages of Using BGP

- **Standardized Protocol:** BGP is a widely used and well-established routing protocol.
- **Flexibility and Scalability:** BGP allows you to integrate your Kubernetes cluster into your existing network infrastructure and scale your services.
- **Load Distribution:** Using ECMP allows for efficient load distribution across cluster nodes.
- **Fault Tolerance:** If a node announcing an IP address fails, routers automatically redirect traffic to other nodes announcing the same IP.

Disadvantages of Using BGP

- **Configuration Complexity:** Configuring BGP can be more complex than configuring ARP/NDP announcements (in Layer 2 mode).
- **Network Equipment Requirements:** Routers must support BGP and ECMP.

Third-party components

List of third-party software used in the `metallb` module:

- MetalLB 0.15.2

  License: Apache License 2.0

  A load-balancer implementation for bare metal Kubernetes clusters, using standard routing protocols.

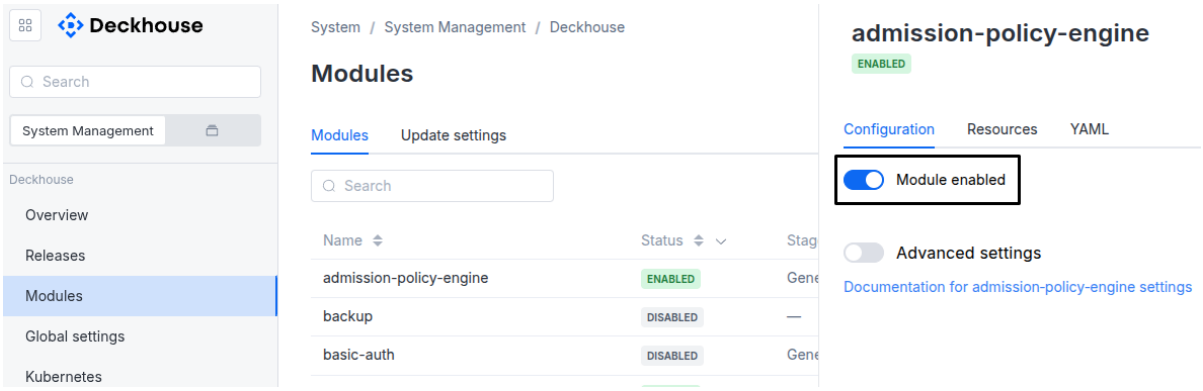
> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> Available with limitations in: **Core, SE, SE+, Certified Core/CSE Lite (1.73)**
>
> Available without limitations in: **Ultimate/EE**

> Included with limitations in extensions: **Advanced Networking**

> The module lifecycle stage: General Availability



The module has 7 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `metallb` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

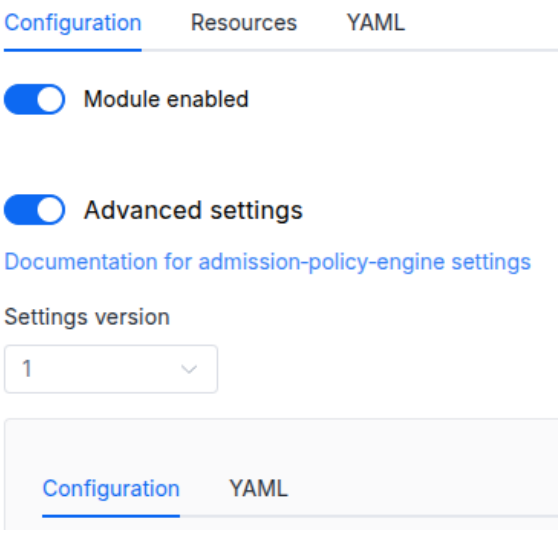
```
d8 system module enable metallb
```

- **Using ModuleConfig `metallb`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `metallb` (create it if necessary);

  Example of a manifest to enable module `metallb`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: metallb
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `metallb` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `metallb` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `metallb`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `metallb` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc metallb
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `metallb` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `metallb`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: metallb
spec:
  version: 3
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Remove all `addressPool` elements with the `layer2` protocol.

- Updates from version **2** to **3**:

  Address pools and BGP settings have been moved to separate Custom Resources. Please remove the following fields from the `metallb ModuleConfig`:

  - `.settings.addressPools`
  - `.settings.bgpPeers`
  - `.settings.bgpCommunities`

Parameters

Schema version: 3

Example:

```
nodeSelector:
  node-role.deckhouse.io/control-plane: ''
```

- **settings**
  object
  - **settings.addressPools**
    Deprecated
    array of objects

    A list of IP ranges to assign to services.

    Format — a data array similar to that of MetalLB’s.

    Default: `[]`

    - **settings.addressPools.addresses**
      array of strings

      Required value

      A list of ranges, where each range can look like a subnet/mask or a numeric address range (with “-“ as a delimiter).

    - **settings.addressPools.auto-assign**
      boolean

      Auto-assign flag used to prevent metallb from automatic allocation for a pool.

      Default: `true`

    - **settings.addressPools.avoid-buggy-ips**
      boolean

      Prevents addresses ending with `.0` and `.255` to be used by a pool.

      Default: `false`

    - **settings.addressPools.bgp-advertisements**
      array of objects

      Defines BGP advertisements.

- **settings.addressPools.bgp-advertisements.aggregation-length**
  integer

  The aggregation-length advertisement option lets you “roll up” prefix into a larger one.

  Works for IPv4 addresses.

  Default: `32`

  Allowed values: `1 <= X`

- **settings.addressPools.bgp-advertisements.communities**
  array of strings

  Keys from the bgpCommunities parameter to be associated with the announcement.

  Example:

  ```
  communities:
  - no-advertise
  ```

- **settings.addressPools.bgp-advertisements.localpref**
  integer

  The `BGP LOCAL_PREF` attribute which is used by BGP best path algorithm.

  Path with higher localpref is preferred over one with lower localpref.

- **settings.addressPools.name**
  string

  Required value

  The name of the pool. It should conform to RFC 1123: dot-separated parts in lowercase, consists of alphanumeric characters, ‘-‘. Each part must start and end with an alphanumeric character.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.addressPools.protocol**
  string

  Required value

  The protocol used by the speaker to announce services.

  Allowed values: `bgp`, `layer2`

- **settings.bgpCommunities**
  Deprecated
  object

  Available in editions: Ultimate/EE

  The BGP communities list.

  Example:

  ```
  bgpCommunities:
    no-advertise: 65535:65282
  ```

- **settings.bgpPeers**
  Deprecated
  array of objects

  Available in editions: Ultimate/EE

  A list of external BGP routers to use with the module.

  Format — a data array similar to that of MetalLB’s.

  Default: `[]`

  - **settings.bgpPeers.hold-time**
    integer or string

    The timeout after which the neighboring BGP peer is considered dead. This value is divided by three to get the keep-alive interval.

    The recommended value is `3s` (i.e., keep-alive packets are sent once per second). Note that

the BGP protocol does not support values lower than this. By default, the parameter is set to `90s` (i.e., keep-alive packets are sent every 30 seconds).

Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **settings.bgpPeers.my-asn**
  integer

  Required value

  The AS number in the cluster.

  Allowed values: `0 <= X <= 4294967295`

- **settings.bgpPeers.node-selector**
  object

  The additional pseudo-selector implemented by the speaker application. It selects nodes that are allowed to connect to external BGP routers. Do not confuse it with `speaker.nodeSelector` and `nodeSelector`.

  An optional parameter.

  The format is `matchLabels` or `matchExpressions`.

  - **settings.bgpPeers.node-selector.matchExpressions**
    array of objects
    - **settings.bgpPeers.node-selector.matchExpressions.key**
      string
    - **settings.bgpPeers.node-selector.matchExpressions.operator**
      string
    - **settings.bgpPeers.node-selector.matchExpressions.values**
      array of strings
  - **settings.bgpPeers.node-selector.matchLabels**
    object
- **settings.bgpPeers.password**
  string

  Authentication password for BGP-routers enforcing TCP MD5 authenticated sessions.

- **settings.bgpPeers.peer-address**
  string

  Required value

  The IP address of the external BGP router.

  Pattern: `^([0-9]{1,3}\.){3}[0-9]{1,3}$`

- **settings.bgpPeers.peer-asn**
  integer

  Required value

  The AS number on the external BGP router.

  Allowed values: `0 <= X <= 4294967295`

- **settings.bgpPeers.peer-port**
  integer

  Port to dial when establishing the session.

  Default: `179`

  Allowed values: `0 <= X <= 16384`

- **settings.bgpPeers.router-id**
  string

  BGP router ID to advertise to the peer.

- **settings.bgpPeers.source-address**
  string

  The source IP address for outbound connections.

  Pattern: `^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$`

- **settings.loadBalancerClass**
  string

An optional field describing the LoadBalancer class. The LoadBalancerClass field should be used in L2 LoadBalancer mode to specify the MetalLoadBalancerClass that defines the balancer parameters for the Service.

- **settings.nodeSelector**
  object

  A selector for the main controller. It is the same as the Pod's `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.speaker**
  Deprecated
  object

  Settings for the `speaker` component that implements the LoadBalancer's IPs publishing protocol for external infrastructure.

  - **settings.speaker.nodeSelector**
    Deprecated
    object

    A selector for the speaker DaemonSet. It is the same as the Pod's `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.speaker.tolerations**
    array of objects

    Tolerations for the speaker DaemonSet. They are the same as the Pod's `spec.tolerations` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

    - **settings.speaker.tolerations.effect**
      string
    - **settings.speaker.tolerations.key**
      string
    - **settings.speaker.tolerations.operator**
      string
    - **settings.speaker.tolerations.tolerationSeconds**
      integer
    - **settings.speaker.tolerations.value**
      string

- **settings.tolerations**
  array of objects

  Tolerations for the main controller. They are the same as the Pod's `spec.tolerations` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

MetalLoadBalancerBGPPeer

Short names: mlbbp

Scope: Cluster
Version: v1alpha1

Describes the settings of a BGP router (neighbor) and the parameters for establishing a session with it.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object
  - **spec.bfd**
    object

    BFD profile configuration. Note: BFD is currently not supported as it requires the FRR BGP implementation, which is not yet available in Deckhouse MetalLB. This field is a placeholder for future use.

    - **spec.bfd.detectMultiplier**
      integer

      The number of missed BFD packets to consider a session down.

    - **spec.bfd.echoInterval**
      integer

      The minimum interval (in milliseconds) between transmitted BFD echo packets.

    - **spec.bfd.echoMode**
      boolean

      Enables or disables BFD echo mode.

    - **spec.bfd.minimumTTL**
      integer

      For multi hop sessions only: configure the minimum expected TTL for an incoming BFD control packet.

      The TTL is measured in network hops.

    - **spec.bfd.passiveMode**
      boolean

      Enables passive mode for BFD (does not attempt to bring up the session first).

    - **spec.bfd.receiveInterval**
      integer

      The minimum interval (in milliseconds) between received BFD control packets.

    - **spec.bfd.transmitInterval**
      integer

      The minimum interval (in milliseconds) between transmitted BFD control packets.

  - **spec.holdTime**
    string

    The requested BGP hold time.

    Pattern: `^([0-9]+(ms|s|m|h))+$`

  - **spec.myASN**
    integer

Required value

The local Autonomous System Number (ASN) used for peering.

Allowed values: `1 <= X <= 4294967295`

- **spec.passwordSecretRef**
  object

  Reference to the Secret containing the password for BGP session authentication.

  Important: the target Secret MUST have the label `network.deckhouse.io/metallb-bgp-password: "true"`.

  - **spec.passwordSecretRef.name**
    string

    Required value

    Name of the Secret.

  - **spec.passwordSecretRef.namespace**
    string

    Required value

    Namespace of the Secret.

- **spec.peerASN**
  integer

  Required value

  The Autonomous System Number (ASN) of the BGP peer.

  Allowed values: `1 <= X <= 4294967295`

- **spec.peerAddress**
  string

  Required value

  The IP address of the BGP peer.

- **spec.peerPort**
  integer

  The port of the BGP peer.

  Allowed values: `1 <= X <= 65535`

- **spec.routerID**
  string

  BGP router ID to advertise to the peer. Must be a valid IPv4 address.

- **spec.sourceAddresses**
  array of objects

  Per-node override of the local IP address used for peering.

  - **spec.sourceAddresses.address**
    string

    Required value

    IP address to peer from this node.

  - **spec.sourceAddresses.nodeName**
    string

    Required value

    Name of the node.

- **status**
  object

MetalLoadBalancerClass

Short names: mlbc

Scope: Cluster

Version: v1alpha1

MetalLoadBalancerClass is the Schema for the metalloadbalancerclasses API

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object
  - **spec.addressPool**
    array of strings

    An array of public IP address ranges. Each range can be specified using a CIDR notation or by directly specifying the range, for example, `10.10.10.1-10.10.10.100`.

    Examples:

    ```
    addressPool: 10.42.0.0/24
    ```

    ```
    addressPool: 10.33.5.100-10.33.5.106
    ```

  - **spec.isDefault**
    boolean

    Whether MetalLoadBalancerClass is selected for all services by default.

    Example:

    ```
    isDefault: true
    ```

  - **spec.l2**
    object

    Available in editions: SE, SE+, Ultimate/EE

    - **spec.l2.interfaces**
      array of strings

      Available in editions: SE, SE+, Ultimate/EE

      A list of network interfaces from which the assigned IP addresses will be announced. If this field is not filled in or an empty array is specified, the announcement will occur from all interfaces on the node. It is highly recommended to configure this parameter to prevent the announcement of addresses from all node interfaces.

      Example:

      ```
      interfaces:
      - eth1
      - eth2
      ```

  - **spec.nodeSelector**
    object

    Allows restricting the list of nodes from which the announcement will occur. Specified as a set of labels for filtering nodes.

  - **spec.type**
    string

    Selecting the load balancer operating mode.

    Example:

    ```
    type: L2
    ```

- **status**
  object

MetalLoadBalancerConfiguration

Short names: mlbconfig

Scope: Cluster
Version: v1alpha1

Defines the routing topology: from which nodes, to which BGP peers, and which IP address pools to advertise.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object
  - **spec.advertisements**
    array of objects

    List of advertisements and their configurations.

    - **spec.advertisements.bgp**
      object

      BGP-specific advertisement configuration.

      - **spec.advertisements.bgp.aggregationLength**
        integer

        Subnet mask for route aggregation.

        Allowed values: `0 <= X <= 128`

      - **spec.advertisements.bgp.communities**
        array of strings

        BGP communities to associate with the advertisement.

        - **Element of the array**
          string

          Pattern: `^([0-9]+:[0-9]+|no-export|no-advertise|local-as|none)$`

      - **spec.advertisements.bgp.localPref**
        integer

        BGP LOCAL_PREF attribute.

        Allowed values: `0 <= X <= 4294967295`

    - **spec.advertisements.poolNames**
      array of strings

      Required value

      List of MetalLoadBalancerPool names to advertise.

  - **spec.bgp**
    object

    BGP specific configuration.

    - **spec.bgp.peerNames**
      array of strings

      List of MetalLoadBalancerBGPPeer names to associate with this configuration.

  - **spec.mode**
    string

    Required value

    The routing mode. Only BGP is supported in this configuration.

    Allowed values: `BGP`

  - **spec.nodeSelector**
    object

    Allows limiting the list of nodes from which addresses will be announced.

    Specified as a set of labels for node filtering.

- **status**

object

MetalLoadBalancerPool

Short names: mlbp

Scope: Cluster
Version: v1alpha1

Describes an IP address pool (MetalLoadBalancerPool) to be used by the load balancer in BGP mode.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object
  - **spec.addresses**
    array of strings

    Required value

    An array of public IP address ranges.

    Each range can be specified using a CIDR notation or by directly specifying the range, for example, `10.10.10.1-10.10.10.100`.

  - **spec.autoAssign**
    boolean

    AutoAssign flag used to prevent MetalLB from automatic allocation for a pool.

    Default: `true`

  - **spec.avoidBuggyIPs**
    boolean

    AvoidBuggyIPs prevents addresses ending with `.0` and `.255` from being used by a pool.

    Default: `false`

- **status**
  object

Examples

> The module lifecycle stage: General Availability

Use the `metallb` module to expose LoadBalancer Services in bare-metal clusters without a cloud load balancer. The module supports L2 and BGP modes.

Example of metallb usage in L2 LoadBalancer mode

Enable the `metallb` module.

Prepare the application to publish:

```
d8 k create deploy nginx --image=nginx
```

Create a MetalLoadBalancerClass:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerClass
metadata:
  name: ingress
spec:
  addressPool:
    - 192.168.2.100-192.168.2.150
  isDefault: false
  l2:
    # Network interfaces that announce the assigned IP addresses.
    interfaces:
      - eth1
  nodeSelector:
    # Selects nodes that run the L2 load balancer.
    node-role.kubernetes.io/loadbalancer: ""
  type: L2
```

In this example, `spec.nodeSelector` selects nodes with the `node-role.kubernetes.io/loadbalancer` label. Make sure the nodes intended to announce the Service IP addresses have this label.

> ⚠ If `spec.l2.interfaces` is omitted or empty, the assigned IP addresses are announced from all network interfaces of the selected nodes. Specify the interfaces intended for address announcements.

Create a Service with the annotation and `loadBalancerClass` set:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-deployment
  annotations:
    network.deckhouse.io/l2-load-balancer-external-ips-count: "3"
spec:
  type: LoadBalancer
  # Selects the MetalLoadBalancerClass named ingress.
  # Can be omitted if the cluster has a MetalLoadBalancerClass with isDefault: true
  # and BGP LoadBalancer mode is not used.
  loadBalancerClass: ingress
  ports:
    - port: 8000
      protocol: TCP
      targetPort: 80
  selector:
    app: nginx
```

As a result, the Service of type `LoadBalancer` receives the specified number of IP addresses:

```
d8 k get svc
```

Output example:

```
NAME                    TYPE           CLUSTER-IP      EXTERNAL-IP
PORT(S)          AGE
nginx-deployment        LoadBalancer   10.222.130.11
192.168.2.100,192.168.2.101,192.168.2.102   8000:30544/TCP   11s
```

When creating a Service, you can also specify certain IP addresses from the pool that will be assigned to it.

You can use the assigned `EXTERNAL-IP` addresses in DNS A records for the application domain. Check that the application responds at these addresses:

```
$ curl -s -o /dev/null -w "%{http_code}" 192.168.2.100:8000
200
$ curl -s -o /dev/null -w "%{http_code}" 192.168.2.101:8000
200
$ curl -s -o /dev/null -w "%{http_code}" 192.168.2.102:8000
200
```

Running speakers on nodes with custom taints

In L2 LoadBalancer mode, the speaker runs as a DaemonSet on the nodes selected by the `nodeSelector` parameter of MetalLoadBalancerClass. The speaker tolerates only the following taints known to Deckhouse Platform (DP):

- `node-role.kubernetes.io/master`
- `node-role.kubernetes.io/control-plane`
- `node.deckhouse.io/etcd-arbiter`
- `dedicated.deckhouse.io` and `dedicated` with any value
- `DeletionCandidateOfClusterAutoscaler` and `ToBeDeletedByClusterAutoscaler`

If a selected node has a taint with any other key, the speaker is not scheduled on it, and the addresses are not announced from that node.

To run the speaker on such nodes, add the taint key to the `customTolerationKeys` parameter of the `global` ModuleConfig. The key must match the taint key set on the nodes, for example, in the `spec.nodeTemplate.taints` parameter of NodeGroup. Adding a key there allows both the speaker and the other system components (CNI, CSI, monitoring) to run on such nodes:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: global
spec:
  version: 3
  settings:
    modules:
      placement:
        customTolerationKeys:
          - dedicated.example.com
```

Check that the speaker pods are running on the tainted nodes:

```
d8 k -n d8-metallb get pods -l app=l2lb-speaker -o wide
```

The speaker in BGP LoadBalancer mode has the same tolerations, so this setting applies to it as well.

Example of metallb usage in BGP LoadBalancer mode

Enable the `metallb` module and create the following objects for BGP mode:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerPool
metadata:
  name: mypool
spec:
  addresses:
    - 192.168.219.100-192.168.219.200
---
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerBGPPeer
metadata:
  name: myrouter
spec:
  peerAddress: 172.18.18.10
  peerASN: 64601
  myASN: 64600
  holdTime: 3s
---
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerConfiguration
metadata:
  name: defaults
spec:
  mode: BGP
  nodeSelector:
    node-role.deckhouse.io/metallb: ""
  bgp:
    peerNames:
      - myrouter
  advertisements:
    - poolNames:
        - mypool
```

In this example, `spec.nodeSelector` selects nodes with the `node-role.deckhouse.io/metallb` label. Make sure the nodes intended to run the speaker pods have this label.

Configure BGP peering on the network equipment.

Example of using L2 LoadBalancer and BGP LoadBalancer modes simultaneously

The module can serve services in L2 LoadBalancer mode and BGP LoadBalancer mode at the same time. The modes are served by different sets of components: `l2lb-controller` and `l2lb-speaker` in L2 LoadBalancer mode, `controller` and `speaker` in BGP LoadBalancer mode. The sets run independently, but they process the same services and see each other’s address pools, so the modes can work together only in the configuration described below.

Enable the module and configure both modes:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerClass
metadata:
  name: ingress
spec:
  addressPool:
    - 192.168.2.100-192.168.2.150
  # A default class is not allowed.
  isDefault: false
  l2:
    # Network interfaces that announce the assigned IP addresses.
    interfaces:
      - eth1
  nodeSelector:
    node-role.kubernetes.io/loadbalancer: ""
  type: L2
---
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerPool
metadata:
  name: mypool
spec:
  # The addresses do not overlap with the MetalLoadBalancerClass pool.
  addresses:
    - 192.168.219.100-192.168.219.200
---
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerBGPPeer
metadata:
  name: myrouter
spec:
  peerAddress: 172.18.18.10
  peerASN: 64601
  myASN: 64600
  holdTime: 3s
---
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerConfiguration
metadata:
  name: defaults
spec:
  mode: BGP
  nodeSelector:
    node-role.deckhouse.io/metallb: ""
  bgp:
    peerNames:
      - myrouter
  advertisements:
    - poolNames:
        - mypool
```

Create an L2 LoadBalancer service with MetalLoadBalancerClass specified explicitly:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-l2
  annotations:
    network.deckhouse.io/l2-load-balancer-external-ips-count: "2"
spec:
  type: LoadBalancer
  # MetalLoadBalancerClass name.
  loadBalancerClass: ingress
  ports:
    - port: 8000
      protocol: TCP
      targetPort: 80
  selector:
    app: nginx
```

Create a BGP LoadBalancer service without `spec.loadBalancerClass` and with the pool specified explicitly:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-bgp
  annotations:
    # MetalLoadBalancerPool name.
    network.deckhouse.io/load-balancer-pool: mypool
spec:
  type: LoadBalancer
  ports:
    - port: 8000
      protocol: TCP
      targetPort: 80
  selector:
    app: nginx
```

As a result, the `nginx-l2` service will be assigned two addresses from the MetalLoadBalancerClass pool, and the `nginx-bgp` service will be assigned one address from MetalLoadBalancerPool:

```
d8 k get svc
```

Output example:

```
NAME        TYPE           CLUSTER-IP      EXTERNAL-IP                   PORT(S)          AGE
nginx-bgp   LoadBalancer   10.222.41.120   192.168.219.100               8000:31942/TCP   12s
nginx-l2    LoadBalancer   10.222.130.11   192.168.2.100,192.168.2.101   8000:30544/TCP   15s
```

Limitations when running the modes simultaneously

When both modes run in the cluster, the following limitations apply:

- Each L2 LoadBalancer service must specify MetalLoadBalancerClass explicitly in `spec.loadBalancerClass`. The BGP LoadBalancer controller processes services without this parameter, and a service with multiple addresses stops receiving traffic until it is recreated (although the nodes keep responding to ARP requests for its addresses).
- No MetalLoadBalancerClass may have the `isDefault: true` parameter set. Otherwise, the L2 LoadBalancer controller allocates a hidden address from its pool for each BGP LoadBalancer service, and the L2 LoadBalancer pool is silently exhausted.
- A BGP LoadBalancer service must not specify `spec.loadBalancerClass` and is assigned only one IPv4 address. Services with multiple addresses are supported only in L2 LoadBalancer mode.
- Specify a pool for a BGP LoadBalancer service with the `network.deckhouse.io/load-balancer-pool` annotation or an address with the `network.deckhouse.io/load-balancer-ips` annotation. The BGP LoadBalancer controller also sees the MetalLoadBalancerClass pools, so without an annotation it may assign the service an address from the L2 LoadBalancer pool that is not announced via BGP.
- Addresses in MetalLoadBalancerPool must not overlap with addresses in the `addressPool` parameter of MetalLoadBalancerClass. If they overlap, the `speaker` components do not apply the configuration and report the `CIDR ... overlaps with already defined CIDR` error.
- A service can be moved from L2 LoadBalancer mode to BGP LoadBalancer mode only by following the

migration procedure.
- The controller logs may contain messages like `PoolStatusController ... the object has been modified`. They do not affect traffic.

Example of migration from L2 LoadBalancer mode to BGP LoadBalancer mode

During the migration, the L2 LoadBalancer components and the BGP LoadBalancer components run in the cluster simultaneously, and the limitations of simultaneous operation apply. Both controllers can process the same services:

- The BGP LoadBalancer controller processes all services of the `LoadBalancer` type that have no `spec.loadBalancerClass` parameter set.
- The L2 LoadBalancer controller processes services whose `spec.loadBalancerClass` is the name of a MetalLoadBalancerClass. If the cluster has a MetalLoadBalancerClass with the `isDefault: true` parameter, the L2 LoadBalancer controller also processes all other services of the `LoadBalancer` type.

The examples below use the `l2-default` default class. The module creates a class with this name when it converts legacy module settings. Your cluster may have a default class with a different name. Find it and use its name instead of `l2-default`:

```
d8 k get metalloadbalancerclass -o custom-columns='NAME:.metadata.name,DEFAULT:.spec.isDefault'
```

> ⚠ The procedure described below is the only supported way to migrate from L2 LoadBalancer mode to BGP LoadBalancer mode. Enabling BGP LoadBalancer mode without preparing L2 services, having an address in the pools of both modes at the same time, and manually creating MetalLB objects (IPAddressPool, BGPAdvertisement, etc.) lead to service unavailability.
>
> The migration involves a brief unavailability: less than 1 second when recreating a service in step 1 and about 11 seconds for each service moved to BGP LoadBalancer mode in step 4.

Before you begin

Make sure that the cluster and the network meet the following requirements:

- The cluster runs the Enterprise, Ultimate, or Certified Security Pro edition. BGP LoadBalancer mode is not available in other editions.
- The network equipment accepts `/32` BGP announcements from the nodes for addresses from the L2 LoadBalancer subnet. Such a route has a longer prefix, so the router prefers it over the route to the directly connected subnet.
- Clients of the moved services are outside the L2 LoadBalancer subnet, or the network sends their traffic to these addresses through the router. Clients in the same subnet resolve the service address via ARP and do not use the router. After the move, the nodes no longer respond to ARP requests for the address, and such clients lose access to the service.

Step 1. Binding L2 services to MetalLoadBalancerClass

If you enable BGP LoadBalancer mode while L2 services have no `spec.loadBalancerClass` set, the BGP LoadBalancer controller starts processing them. Services with multiple addresses (the `network.deckhouse.io/l2-load-balancer-external-ips-count` annotation is greater than `1`) stop receiving traffic: the controller cannot assign multiple IPv4 addresses to a service and clears its status, while the nodes keep responding to ARP requests for these addresses. Disabling BGP LoadBalancer mode does not restore such services, only recreating them helps.

Find services of the `LoadBalancer` type that have no `spec.loadBalancerClass` set (`<none>` in the `CLASS` column):

```
d8 k get svc -A -o custom-
columns='NAMESPACE:.metadata.namespace,NAME:.metadata.name,TYPE:.spec.type,CLASS:.spec.lo
adBalancerClass,EXTERNAL-IP:.status.loadBalancer.ingress[*].ip' | awk 'NR==1 ||
$3=="LoadBalancer"'
```

Output example:

```
NAMESPACE   NAME               TYPE           CLASS    EXTERNAL-IP
default     nginx-deployment   LoadBalancer   <none>   192.168.2.100,192.168.2.101
default     web                LoadBalancer   <none>   192.168.2.120
```

Recreate each service that should remain in L2 LoadBalancer mode with `spec.loadBalancerClass` set explicitly. This parameter cannot be changed for an existing service. To keep the current addresses of the service, list them in the `network.deckhouse.io/load-balancer-ips` annotation.

Save the service manifest to the `nginx-deployment.yaml` file:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-deployment
  namespace: default
  annotations:
    network.deckhouse.io/l2-load-balancer-external-ips-count: "2"
    network.deckhouse.io/load-balancer-ips: "192.168.2.100,192.168.2.101"
spec:
  type: LoadBalancer
  # MetalLoadBalancerClass name.
  loadBalancerClass: l2-default
  ports:
    - port: 8000
      protocol: TCP
      targetPort: 80
  selector:
    app: nginx
```

Delete the service and create it again from the saved manifest:

```
d8 k -n default delete svc nginx-deployment && d8 k apply -f nginx-deployment.yaml
```

Do not set `spec.loadBalancerClass` for services that will be moved to BGP LoadBalancer mode. It is enough to pin their current address with the `network.deckhouse.io/load-balancer-ips` annotation, no recreation is required:

```
d8 k -n default annotate svc web network.deckhouse.io/load-balancer-ips=192.168.2.120
```

In BGP LoadBalancer mode, a service is assigned only one IPv4 address, so only services with a single address can be moved to this mode. Keep services with multiple addresses in L2 LoadBalancer mode.

Step 2. Disabling the default MetalLoadBalancerClass

While MetalLoadBalancerClass has the `isDefault: true` parameter set, the L2 LoadBalancer controller also processes BGP LoadBalancer services. For each such service, it allocates an address from the MetalLoadBalancerClass pool and announces it via ARP, although this address is not shown in the service status. Such hidden addresses silently consume the L2 LoadBalancer pool and can lead to its exhaustion. Services with an address pinned by the `network.deckhouse.io/load-balancer-ips` annotation are not affected by this issue.

Set the `isDefault` parameter to `false`:

```
d8 k patch metalloadbalancerclass l2-default --type=merge -p '{"spec":{"isDefault":false}}'
```

The parameter affects only new services. Services that have already been bound to the default MetalLoadBalancerClass remain bound to it.

Addresses allocated in L2 LoadBalancer mode are represented by SDNInternalL2LBService objects named `<service name>-<MetalLoadBalancerClass name>-<index>`:

```
d8 k get sdninternall2lbservices -A
```

If BGP LoadBalancer mode has already been enabled earlier and the list contains objects for services of this mode, these services received a hidden address from the L2 LoadBalancer pool before `isDefault` was disabled. Disabling `isDefault` does not release such an address, since the service remains bound to MetalLoadBalancerClass. Specify the current address of such a service from the BGP LoadBalancer pool in its `network.deckhouse.io/load-balancer-ips` annotation. This address is not in the L2 LoadBalancer pool, so the L2 LoadBalancer controller releases the hidden address, and the service address does not change. An example for the `web-bgp` service with the `192.168.219.100` address:

```
d8 k -n default annotate svc web-bgp network.deckhouse.io/load-balancer-ips=192.168.219.100
```

Step 3. Enabling BGP LoadBalancer mode

Create a MetalLoadBalancerPool, a MetalLoadBalancerBGPPeer, and a MetalLoadBalancerConfiguration as shown in the BGP LoadBalancer example. Addresses in MetalLoadBalancerPool must not overlap with addresses in the `addressPool` parameter of MetalLoadBalancerClass.

Make sure that the components of both modes are running in the module:

```
d8 k -n d8-metallb get pods
```

Check that the addresses of L2 services have not changed:

```
d8 k get svc -A
```

While both modes are running simultaneously, the controller logs may contain messages like `PoolStatusController ... "l2-default": the object has been modified`. They do not affect traffic.

Step 4. Moving a single-address service to BGP LoadBalancer mode

Move services one at a time. With a single `d8 k apply` command, remove the service address from the `addressPool` parameter of MetalLoadBalancerClass and add it to the `addresses` parameter of MetalLoadBalancerPool. The address must not be in the pools of both modes at the same time: in this case, the `speaker` components cannot apply the configuration due to overlapping pools (`CIDR "192.168.2.120/32" in pool "l2-default" overlaps with already defined CIDR`).

Prepare a file with the MetalLoadBalancerClass and MetalLoadBalancerPool manifests. Take the current parameters of both objects from the cluster and change only the address lists:

```
d8 k get metalloadbalancerclass l2-default -o yaml
d8 k get metalloadbalancerpool mypool -o yaml
```

Put MetalLoadBalancerClass first in the file. `d8 k apply` applies the manifests in the order they appear, so the address is removed from the L2 LoadBalancer pool before it is added to MetalLoadBalancerPool.

An example of moving the `192.168.2.120` address that belongs to the `192.168.2.100-192.168.2.150` range. The `migrate-192.168.2.120.yaml` file:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerClass
metadata:
  name: l2-default
spec:
  addressPool:
    - 192.168.2.100-192.168.2.119
    - 192.168.2.121-192.168.2.150
  isDefault: false
  # Keep the current values of the parameters.
  l2:
    interfaces:
      - eth1
  nodeSelector:
    node-role.kubernetes.io/loadbalancer: ""
  type: L2
---
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerPool
metadata:
  name: mypool
spec:
  addresses:
    - 192.168.219.100-192.168.219.200
    - 192.168.2.120/32
```

Apply both manifests with a single command:

```
d8 k apply -f migrate-192.168.2.120.yaml
```

The L2 LoadBalancer controller releases the address, after which the BGP LoadBalancer controller assigns it to the service and starts announcing it via BGP. Check the service events:

```
d8 k -n default describe svc web
```

The service events should show, in order, `ClearAssignment` (the address is removed from the L2 LoadBalancer pool), `IPAllocated` (the address is assigned by the BGP LoadBalancer controller), and `nodeAssigned` with `protocol "bgp"` (the address is announced via BGP).

Make sure that the router has a `/32` route to the service address via the cluster nodes, and that the nodes no longer respond to ARP requests for this address.

Additional configuration examples for Service

After setting up a load balancer, use Service annotations to control address allocation and sharing.

Creating a Service and assigning it specific IP addresses from the pool

To assign specific addresses to a Service, list them in the `network.deckhouse.io/load-balancer-ips` annotation. To assign more than one address, also set the `network.deckhouse.io/l2-load-balancer-external-ips-count` annotation to the number of addresses to allocate from the pool. The value must not be less than the number of addresses in `network.deckhouse.io/load-balancer-ips`; otherwise, the extra addresses are not assigned.

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-deployment
  annotations:
    # The number of addresses that will be allocated from the pool declared in
MetalLoadBalancerClass.
    network.deckhouse.io/l2-load-balancer-external-ips-count: "3"
    # A list of addresses from the pool declared in MetalLoadBalancerClass that will be
allocated to the Service.
    network.deckhouse.io/load-balancer-ips: "192.168.2.102,192.168.2.103,192.168.2.104"
spec:
  type: LoadBalancer
  # Selects the MetalLoadBalancerClass named ingress.
  # Can be omitted if the cluster has a MetalLoadBalancerClass with isDefault: true
  # and BGP LoadBalancer mode is not used.
  loadBalancerClass: ingress
  ports:
    - port: 8000
      protocol: TCP
      targetPort: 80
  selector:
    app: nginx
```

As a result, the Service of type `LoadBalancer` receives the specified IP addresses:

```
d8 k get svc
```

Output example:

```
NAME                    TYPE           CLUSTER-IP      EXTERNAL-IP
PORT(S)          AGE
nginx-deployment        LoadBalancer   10.222.130.11
192.168.2.102,192.168.2.103,192.168.2.104   8000:30544/TCP   11s
```

Creating a Service with a specific IP address

To assign a specific IP address to a Service, add the `network.deckhouse.io/load-balancer-ips` annotation:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx
  annotations:
    network.deckhouse.io/load-balancer-ips: 192.168.2.105
spec:
  loadBalancerClass: ingress
  ports:
    - port: 80
      targetPort: 80
  selector:
    app: nginx
  type: LoadBalancer
```

Creating Services with shared IP addresses

To allow multiple Services to share an IP address, add the `network.deckhouse.io/load-balancer-shared-ip-key` annotation to each Service. Its value is the sharing key. Services can share an IP address under the following conditions:

- They have the same sharing key.
- Their protocol and port combinations do not conflict (for example, TCP/53 and UDP/53 can use the same IP address).
- They use `externalTrafficPolicy: Cluster`, or they both point to the exact same set of pods (that is, the pod selectors are identical).

> ⚠ Even when these conditions are met, MetalLB does not guarantee that the Services will receive the same IP address. To request a specific shared address, set `network.deckhouse.io/load-balancer-ips` on both Services.

The following example configures two Services to share an IP address:

```
apiVersion: v1
kind: Service
metadata:
  name: dns-service-tcp
  namespace: default
  annotations:
    network.deckhouse.io/load-balancer-shared-ip-key: "key-to-share-1.2.3.4"
spec:
  type: LoadBalancer
  loadBalancerClass: ingress
  ports:
    - name: dnstcp
      protocol: TCP
      port: 53
      targetPort: 53
  selector:
    app: dns
---
apiVersion: v1
kind: Service
metadata:
  name: dns-service-udp
  namespace: default
  annotations:
    network.deckhouse.io/load-balancer-shared-ip-key: "key-to-share-1.2.3.4"
spec:
  type: LoadBalancer
  loadBalancerClass: ingress
  ports:
    - name: dnsudp
      protocol: UDP
      port: 53
      targetPort: 53
  selector:
    app: dns
```

Assigning an IP address pool to a Service in BGP LoadBalancer mode

In BGP LoadBalancer mode, assign an IP address pool to a Service using the `network.deckhouse.io/load-balancer-pool` annotation. For L2 LoadBalancer mode, use the MetalLoadBalancerClass settings, as shown in the L2 LoadBalancer mode example.

```
apiVersion: v1
kind: Service
metadata:
  name: nginx
  annotations:
    network.deckhouse.io/load-balancer-pool: mypool
spec:
  ports:
    - port: 80
      targetPort: 80
  selector:
    app: nginx
  type: LoadBalancer
```

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Module multitenancy-manager

> **i** Included in extensions: **Multitenancy**

> ⚠ The module lifecycle stage: Preview

The module enables the creation of projects in a Kubernetes cluster. **Project** is an isolated environment where applications can be deployed.

Main features

- Creating projects from project templates. A template sets the pod security profile, network isolation, log collection, node placement and other policies of the project namespaces.
- Several namespaces in one project. The template settings and the access granted to the project apply to all of them.
- Access to the whole project through `.spec.administrators`, ProjectRoleBinding and ClusterProjectRoleBinding.
- A resource quota for each project.
- A project for every namespace: a namespace created directly becomes a project automatically.
- Control over which cluster-wide resources, such as StorageClass or ClusterIssuer, projects can use.

> ⚠ The secret-copier module cannot be used together with the `multitenancy-manager` module: it copies Secrets into every namespace, project namespaces included.

Project composition

A project includes:

- **The main namespace** — created automatically, its name matches the project name.
- **Additional namespaces** (optional) — created with the ProjectNamespace resource and named `<project name>-<name>`. The project settings (security policies, network policies, log collection, etc.) and the access granted to the project automatically apply to all of its namespaces.
- **Standard fields** — the list of administrators (`.spec.administrators`) and resource quotas (`.spec.quota`), managed by the Project resource itself independently of the template.
- **Resources from the template** (optional) — policies and settings described in a ProjectTemplate and created by the controller in the project namespaces, and the objects of its `manifests`, applied with the rights of a project administrator.

How the module works

This section describes how the module creates projects, adds namespaces to them, grants access and turns existing namespaces into projects.

Creating a project

To create projects, the following Custom Resources are used:

- ProjectTemplate — a resource that describes the project template: which settings and policies its namespaces get and which parameters can be passed when creating a project;
- Project — a resource that describes a specific project.

When creating a Project resource from a specific ProjectTemplate, the following happens:

1. The parameters passed are validated against the OpenAPI specification (the `parametersSchema.openAPIV3Schema` field of ProjectTemplate);
2. A namespace is created with the name of the Project;
3. The project resources are created from the template:
   - in modern templates (`deckhouse.io/v1alpha2`) the settings, such as the pod security profile, network isolation, log collection and node placement, are described by structured fields. The controller itself creates the corresponding objects in every namespace of the project. Other objects go to `manifests` and are applied with the rights of a project administrator;
   - a template with a Helm `resourcesTemplate` is rendered through Helm. This form is deprecated, and so is the `deckhouse.io/v1alpha1` version of ProjectTemplate, which has no other form (see details). No template can get a new `resourcesTemplate`, a template is created through `deckhouse.io/v1alpha2` only, and the field goes away in a future release, so move such a template to structured fields and `manifests`;
4. The standard fields of the project are applied independently of the template: `.spec.quota` is reconciled into a ProjectQuotaStatus of the project, which puts the `d8-project-quota` ResourceQuota

into every namespace of the project, and `.spec.administrators` into an auto-managed ProjectRoleBinding.

The Project API is served as `deckhouse.io/v1alpha3`. `v1alpha2` manifests keep working through a conversion webhook, and `v1alpha1` is no longer served (see Project API versions). The `projectTemplateName` field is optional: when omitted, the `simple` template is used, which only creates the project namespace.

Project names are validated on creation. Names longer than 61 characters, names with the system prefixes `d8-` and `kube-`, names of existing namespaces or of namespaces that a ProjectNamespace has claimed, and names of namespaces whose ServiceAccounts a cluster-wide binding or a binding of another project still names are not allowed. A project `foo-bar` beside a project `foo` is allowed, but it is a separate project and not an additional namespace of `foo`. The webhook warns about it, and an alert lists such pairs (see details).

⚠ A change of a project template applies to every project created from it.

Multiple namespaces in a project

A project can span several namespaces. Additional namespaces are created with the ProjectNamespace resource in the main namespace of the project and are named `<project name>-<name>` (for example, `backend-cache` for the `backend` project).

The following automatically applies to the additional namespaces:

- the project template settings — the pod security profile, network policies, log collection, and other policies are created in every namespace of the project;
- the access granted via ProjectRoleBinding and ClusterProjectRoleBinding, including the automatic access of the project administrators.

The project quota (`.spec.quota`) applies in every namespace of the project as one limit on the sum of their usage.

Deleting a project deletes all of its namespaces — both the main and the additional ones. See the usage examples for details.

Access to a project

User access to a project is managed at the level of the whole project rather than individual namespaces:

- The subjects listed in `.spec.administrators` automatically get the project administrator role (`d8:project:admin`).
- The ProjectRoleBinding resource grants a role in all namespaces of one project.
- A ClusterProjectRoleBinding grants a role in all projects of the cluster at once, except the virtual ones.

A ProjectRoleBinding or ClusterProjectRoleBinding can grant only ClusterRoles named `d8:project:*`, `d8:namespace:*`, `d8:project-capability:*`, `d8:namespace-capability:*` or `d8:custom:*`. For details on the roles, see the user-authz module documentation. See the usage examples for details on the bindings.

Automatic project creation for namespaces

Users can still create namespaces directly (`d8 k create namespace`), unless the `allowNamespacesWithoutProjects` parameter is `false`: then users create environments as Project objects, and only cluster administrators (`system:masters`, `system:sudouser`), Deckhouse, the module controller and system components create namespaces directly. Every namespace that belongs to no project becomes a project of its own, with the same name and a full-fledged template:

- the template is picked from what the namespace already carries — `secure` if it has vulnerability scanning enabled, `default` if it has a Pod Security Standard or extended monitoring, and `simple` (namespace only) otherwise;
- the project parameters are filled in from the current state of the namespace, so adopting it changes nothing inside;
- from then on the project is the source of truth and is edited like any other. The namespace cannot be deleted directly: to remove the environment, delete the Project, and its namespace is deleted with it.

System namespaces (`d8-*`, `kube-*`, `upmeter-*`, `default`, and anything labeled `heritage: deckhouse` or `heritage: upmeter`) are never adopted: they are listed on the virtual `deckhouse` project (except `default`). No label leaves a new user namespace without a project: users cannot put the `heritage: upmeter` label on a namespace, and only the module sets the `projects.deckhouse.io/project` label. A namespace whose name is longer than 61 characters (the Project name limit) is also skipped, and so is a namespace named `deckhouse`: a Project of that name is the virtual project.

Users cannot create a namespace that could not become a project (see details).

Isolating a project

A namespace alone does not isolate a project. The project adds the following:

- Access to the whole project through `.spec.administrators`, ProjectRoleBinding and ClusterProjectRoleBinding. A plain RoleBinding in one namespace is allowed for delegatable roles.
- A resource limit on the whole project through `.spec.quota`, applied as the `d8-project-quota` ResourceQuota in every namespace of the project and as a limit on the sum of their usage.
- Network isolation through the `networkPolicy.mode: Isolated` field of the template.
- The pod security profile through the `podSecurityStandard` field of the template.

Managing access to cluster-wide resources

Objects in project namespaces can reference cluster-wide resources. For example, a PersistentVolumeClaim can use a StorageClass, a Certificate can use a ClusterIssuer, and a RoleBinding can use a ClusterRole. The module allows cluster administrators to define which cluster-wide resources can be used from project namespaces and which values are used by default.

This mechanism works independently of RBAC. RBAC determines *who can create and modify* objects, while the cluster-wide resource access mechanism determines *which resources* those objects can use.

How access management works

The following resources are used to manage access to cluster-wide resources:

- GrantableClusterResourceDefinition registers a type of cluster-wide resource whose access can be managed. These resources are provided by Deckhouse Platform or by module developers.
- GrantableClusterResourceReference defines where a registered cluster-wide resource is used, for example, which resource field contains a reference to it. These resources are provided by modules.
- ClusterResourceGrantPolicy defines access rules. Using labels, a cluster administrator selects the projects to which the policy applies and defines the allowed and denied resources, as well as the resource used by default.
- In every namespace of every project, the controller keeps an AvailableClusterResource for each GrantableClusterResourceDefinition. It lists the cluster-wide resources available to the project under the policies that apply and is read-only.
- When an object is created or modified, webhooks check whether it is allowed to use the specified cluster-wide resource. When an object is created, the resource configured as the project default can also be inserted automatically.

The webhooks reject requests while the module controller is unavailable. Until it is back, objects of the registered kinds (for example, PersistentVolumeClaim, Service or RoleBinding) cannot be created or changed in project namespaces, except by the platform components and members of the `system:masters` group. To keep the controller available, enable `highAvailability`.

```
flowchart LR
    A["Module developer or Deckhouse Platform
provides GrantableClusterResourceDefinition
and GrantableClusterResourceReference"] --> C
    B["Cluster administrator
creates
ClusterResourceGrantPolicy"] --> C["Controller"]
    C --> D["Creates AvailableClusterResource
in each project namespace"]
    E["User creates an object
(for example,
PersistentVolumeClaim)"] --> F["Mutating webhook
/defaults"]
    F --> G["Validating webhook
/is-granted"]
    D -. Available names .-> G
    G --> H["Object created
or rejected"]
```

Until the administrator creates a ClusterResourceGrantPolicy, resource availability is determined by their registration: resources are available to all projects if `defaultAvailability: All` (the default value) is set in GrantableClusterResourceDefinition and the resource does not match the `excluded` or `reserved` filters.

Resource quotas are not part of this mechanism. They are managed using the standard Kubernetes ResourceQuota resource.

Access checks are performed only for objects in project namespaces. If an access policy changes, cluster-wide resources already used by existing objects remain available to those objects.

Access checks and default value assignment

The mechanism determines cluster-wide resource availability and default values based on registered resources and policies that apply to the project.

Determining cluster-wide resource availability

If multiple rules apply to a cluster-wide resource, its availability is determined in the following order:

1. The `excluded` value in GrantableClusterResourceDefinition: the resource is unavailable regardless of policy settings.
2. The `denied` and `deniedSelector` values in the corresponding ClusterResourceGrantPolicy entry.
3. The `allowed` and `allowedSelector` values in the corresponding ClusterResourceGrantPolicy entry.
4. The `reserved` value in GrantableClusterResourceDefinition: a reserved resource that the previous steps have not made available is unavailable. The next steps do not apply to it, so `availabilityDefault: All` does not make it available.
5. The `availabilityDefault` value in the ClusterResourceGrantPolicy entries that apply to the project. If an entry sets `allowed` or `allowedSelector` without `availabilityDefault`, every resource not on its lists is unavailable. If one applicable entry sets `All`, it wins over `None` in the others.
6. The `defaultAvailability` value in GrantableClusterResourceDefinition.

The first matching step decides. Steps 2, 3 and 5 combine the entries of all ClusterResourceGrantPolicy objects that apply to the project, including the service policies of its template and of the project itself.

Assigning default values

The behavior when an object is created depends on the mode configured in GrantableClusterResourceReference:

- `None`: The value is checked for availability but is not assigned automatically.
- `FillEmpty`: If no value is specified, the project default is assigned.
- `Coerce`: If no value is specified or the specified cluster-wide resource is unavailable to the project, the project default is assigned. Replacing a specified value is reported as an admission warning in the response to the request.

The project default is determined in the following order:

1. The `default` value from the corresponding ClusterResourceGrantPolicy entry.
2. The value determined using `defaultFrom` in GrantableClusterResourceDefinition.
3. If no value is found, no default is assigned.

Checking existing objects

When an access policy changes, values already used by existing objects are preserved. When an object is updated, only new values are checked. If the value of a field has not changed, it remains valid even after access to the resource has been restricted.

This allows existing objects to continue operating after access to cluster-wide resources is restricted.

System requests

Requests from platform components and from members of the `system:masters` group are not checked. The platform components are the API server, the ServiceAccounts of Deckhouse, of this module and of the `user-authz` module, all ServiceAccounts of the `d8-system`, `kube-system` and `d8-user-authz` namespaces, and kubelets. To test a policy, send the request as a project user, for example with `d8 k --as <USER_NAME>`.

Monitoring access policy violations

If an existing object uses a cluster-wide resource that becomes unavailable to the project after a policy change, the object continues to operate, but the discrepancy is detected by the monitoring system.

When such objects are detected, the `ClusterResourceGrantPolicyViolation` alert is triggered. Information about violations is available on the Grafana dashboard under “Security” → “Cluster Resource Grant Violations”.

The `d8_cluster_objects_grant_violated` metric is used for monitoring. It is exported by the module controller, which recounts the violations of a project namespace on every reconcile and at least every two minutes, using the same availability rules as the admission webhook.

Resources registered by Deckhouse Platform

Deckhouse Platform registers the following cluster-wide resources:

Definition name	Cluster-wide resource	Where it is used	Default assignment mode
`storageclasses`	StorageClass (storage.k8s.io)	PersistentVolumeClaim `.spec.storageClassName`	`Coerce`; `None` for a PersistentVolumeClaim with `.spec.dataSource` or `.spec.dataSourceRef`

Definition name	Cluster-wide resource	Where it is used	Default assignment mode
`loadbalancerclasses`	`loadbalancerclass` value	Service `.spec.loadBalancerClass` (for services of the `LoadBalancer` type)	`FillEmpty`
`clusterissuers`	ClusterIssuer (cert-manager.io)	Certificate `.spec.issuerRef.name`; Ingress: `cert-manager.io/cluster-issuer` annotation	`FillEmpty` or `None`
`clusterroles`	ClusterRole (rbac.authorization.k8s.io)	RoleBinding `.roleRef.name`	`None`
`applicationpackages`	ApplicationPackage (deckhouse.io)	Application `.spec.packageName`	`None`

The `clusterroles` registration excludes every ClusterRole without the `rbac.deckhouse.io/delegatable: "true"` label. By default, a RoleBinding in a project can reference the `d8:namespace:*` and `d8:project:*` roles, the deprecated `d8:use:role:*` aliases, and the `user-authz:user`, `user-authz:privileged-user`, `user-authz:editor` and `user-authz:admin` roles of the basic model.

The `clusterissuers` definition is shipped by the `cert-manager` module, so it is registered only when that module is enabled.

The `storageclasses` definition and the `storageclasses-pvc` GrantableClusterResourceReference are registered by this module unless the `storage-foundation` module of version 1.0.3 or later is enabled. While such a version of `storage-foundation` is enabled, that module registers them under the same names and can extend them. When `storage-foundation` is enabled, disabled or updated to such a version, the objects pass from one module to the other, so ClusterResourceGrantPolicy objects keep restricting StorageClass.

Access management resources

Resource	Scope	Created by	Manual creation	Purpose
GrantableClusterResourceDefinition	Cluster	Module developer or Deckhouse Platform	Allowed for custom resources	Registers a type of cluster-wide resource whose access can be managed
GrantableClusterResourceReference	Cluster	Module developer	Allowed for fields of custom resources	Defines where a registered cluster-wide resource is used
ClusterResourceGrantPolicy	Cluster	Cluster administrator	Required	Defines allowed and denied resources, as well as the resource used by the project by default
AvailableClusterResource	Namespace	Controller (automatically)	Prohibited (protected by a webhook)	Read-only catalog of resources available to the project

For detailed access configuration scenarios, viewing resources available to projects, access checks and default assignment rules, and recommendations for module developers, refer to “Usage examples”.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

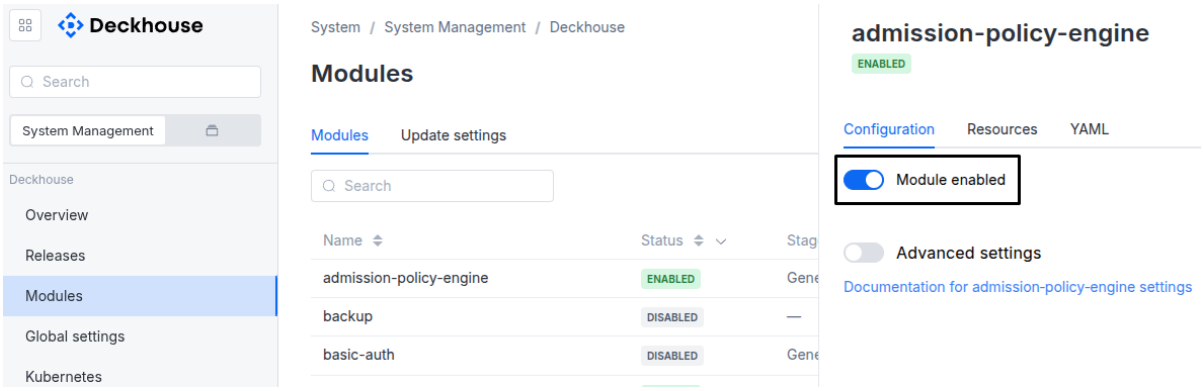
The multitenancy-manager module: configuration

> **i** Included in extensions: **Multitenancy**

> ⚠ The module lifecycle stage: Preview

The module has 22 alerts.

The module does not have any mandatory parameters.



The module has 22 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `multitenancy-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

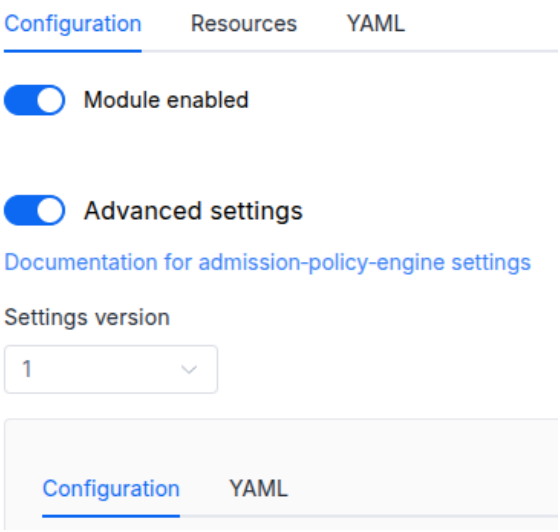
```
d8 system module enable multitenancy-manager
```

- **Using ModuleConfig `multitenancy-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `multitenancy-manager` (create it if necessary);

  Example of a manifest to enable module `multitenancy-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: multitenancy-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `multitenancy-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `multitenancy-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `multitenancy-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `multitenancy-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc multitenancy-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `multitenancy-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `multitenancy-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: multitenancy-manager
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.allowNamespacesWithoutProjects**
    boolean

    Whether namespaces can be created directly, outside a Project.

    The parameter decides only who creates namespaces directly. Whatever its value, the controller turns every namespace that is not a system one into a project of its own.

    If `true`, anyone allowed to create namespaces can create one directly (`d8 k create namespace`), and the controller turns such a namespace into a project of its own (see Automatic project creation for namespaces).

    If `false`, users create environments as Project objects, and additional namespaces of a project as

ProjectNamespace objects. Only cluster administrators (the `system:masters` group and `system:sudouser`), Deckhouse, the module controller and system components create namespaces directly; the full list is in Who bypasses admission. Anyone can create the `default` namespace. The check is a ValidatingAdmissionPolicy that the API server evaluates itself, so it does not depend on the module controller being available.

Default: `true`

- **settings.highAvailability**
  boolean

  Whether the module runs in the high availability mode.

  If not set, the mode is chosen automatically, as described for the global `highAvailability` parameter.

  Examples:

```
highAvailability: true
```

```
highAvailability: false
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The multitenancy-manager module: custom resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> ⚠ The module lifecycle stage: Preview

ClusterProjectRoleBinding

Short names: cprb

Scope: Cluster
Version: v1alpha3

ClusterProjectRoleBinding grants a role to subjects across all namespaces of all projects in the cluster, except the virtual projects `deckhouse` and `default`.

- **spec**
  object

  Required value

  - **spec.roleRef**
    object

    Required value

    Reference to the granted ClusterRole. Allowed prefixes: `d8:project:*`, `d8:namespace:*`, `d8:project-capability:*`, `d8:namespace-capability:*`, `d8:custom:*`.

    - **spec.roleRef.kind**
      string

      Required value

      Kind of the granted role.

      Allowed values: `ClusterRole`

    - **spec.roleRef.name**
      string

Required value

Name of the granted ClusterRole.

- **spec.subjects**
  array of objects

  Required value

  Subjects (users, groups or service accounts) the role is granted to.

  - **spec.subjects.apiGroup**
    string

    API group of the subject: `rbac.authorization.k8s.io` for `User` and `Group`, empty for `ServiceAccount`.

  - **spec.subjects.kind**
    string

    Required value

    Kind of the subject.

    Allowed values: `User`, `Group`, `ServiceAccount`

  - **spec.subjects.name**
    string

    Required value

    Name of the subject: the user name (`User.spec.email`) for `User`, `Group.spec.name` for `Group`, the ServiceAccount name for `ServiceAccount`.

  - **spec.subjects.namespace**
    string

    Namespace of the ServiceAccount.

    If omitted, the binding names the ServiceAccount with this name in each namespace of every project.

- **status**
  object
  - **status.boundProjects**
    integer

    Number of projects the binding is currently applied to.

  - **status.conditions**
    array of objects

    Current state of the object.

    - **status.conditions.lastProbeTime**
      string

      Time of the last check of the condition.

    - **status.conditions.lastTransitionTime**
      string

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Message with details of the condition state.

    - **status.conditions.status**
      string

      Condition state: `True`, `False` or `Unknown`.

    - **status.conditions.type**
      string

      Condition type.

  - **status.observedGeneration**
    integer

    Last generation of the object processed by the controller.

AvailableClusterResource

Short names: available

Scope: Namespaced
Version: v1alpha1

Contains information about cluster-wide resources available to the project and the value used by default.

The resource is automatically created and updated by the `multitenancy-manager` controller in the project namespace for each registered GrantableClusterResourceDefinition. It is deleted from the project namespaces when the corresponding GrantableClusterResourceDefinition is deleted. The AvailableClusterResource name matches the name of the corresponding GrantableClusterResourceDefinition.

Information about available cluster-wide resources and the default value is stored in the `status` field.

For more information about viewing available cluster-wide resources, refer to Usage examples.

> **i** **Warning.** The resource is read-only. Manual creation of AvailableClusterResource is prohibited.

- **status**
  object

  Cluster-wide resource availability status for the project.

  - **status.available**
    array of objects

    List of cluster-wide resources available to the project, indicating the resource used by default. Each resource is listed once.

    Information about a cluster-wide resource available to the project.

    - **status.available.default**
      boolean

      Indicates that the cluster-wide resource is used by default in the project.

    - **status.available.fields**
      object

      Values of the cluster-wide resource fields listed in `spec.catalogFields` of the corresponding GrantableClusterResourceDefinition, keyed by field name.

      A value keeps its JSON type: string, number, boolean, object or array. A field whose value is missing in the resource or is longer than 512 bytes is not shown. If `status.available` with the fields of all resources would take more than 512 KiB in JSON serialization, `fields` is absent in every entry; the names and the default are still listed.

    - **status.available.name**
      string

      Required value

      Name of the cluster-wide resource available to the project.

  - **status.availableCount**
    integer

    Number of cluster-wide resources available to the project.

    Used when displaying the resource list. Names of available cluster-wide resources are listed in `status.available`.

  - **status.default**
    string

    Name of the cluster-wide resource used by default in the project.

    The value can be automatically assigned to the corresponding field of a resource being created if the field is empty or the specified value is unavailable to the project. The field remains empty if no default value is configured or the default value is unavailable to the project.

  - **status.grantedResourceKind**
    string

    Kind of the cluster-wide resource.

  - **status.observedGeneration**

integer

Resource generation based on which the controller generated the current `status`.

ClusterResourceGrantPolicy

Short names: crgp

Scope: Cluster

- v1alpha2
- v1alpha1

Defines a policy for project access to cluster-wide resources and the values used by default.

The resource applies to the project namespaces selected by `spec.projectSelector` (by the labels of the Project) and `spec.namespaceSelector` (by the labels of the namespace). For each type of cluster-wide resource, the policy allows you to configure allowed and denied resources, as well as their availability rules and default values.

The cluster-wide resource type is specified using `spec.resources[].resourceName`, which references the corresponding GrantableClusterResourceDefinition.

The policy is created by a cluster administrator.

For configuration examples, refer to Usage examples.

- **spec**
  object

  Required value

  ClusterResourceGrantPolicy parameters.

  - **spec.namespaceSelector**
    object

    Label selector for project namespaces to which the policy applies.

    The selector is matched against the labels of the namespace. When `spec.projectSelector` is also specified, both must match. If the selector is not specified, all namespaces of the selected projects are covered. An empty selector matches all namespaces. The namespaces of the virtual projects `deckhouse` and `default` are never covered.

    The value of the `projects.deckhouse.io/project-namespace` label is the name that a project user gives to a ProjectNamespace. Without `spec.projectSelector`, a selector on this label also covers the namespace of a ProjectNamespace with the same name in any other project.

    An additional namespace of a project is created by a project user. It carries the labels set by the module and the labels of the project template, which it inherits from the main namespace; a label set by hand on the main namespace is not inherited. A policy that restricts resources by such a label does not cover a new additional namespace.

    - **spec.namespaceSelector.matchExpressions**
      array of objects

      List of label selector expressions.

      All expressions must match.

      Label selector expression.

      - **spec.namespaceSelector.matchExpressions.key**
        string

        Required value

        Label key to which the expression applies.

      - **spec.namespaceSelector.matchExpressions.operator**
        string

        Required value

        Operator that defines the relationship between the key and the set of values.

      - **spec.namespaceSelector.matchExpressions.values**
        array of strings

        List of label values.

        For the `In` and `NotIn` operators, the list must contain at least one value. For the

`Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.namespaceSelector.matchLabels**
  object

  Set of namespace labels to which the policy applies.

  All specified labels must match.

- **spec.projectSelector**
  object

  Label selector for projects to which the policy applies.

  The selector is matched against the labels of the Project object. The policy applies to every namespace of a selected project, including an additional namespace created later, unless `spec.namespaceSelector` narrows the choice. If the selector is not specified, projects are not chosen by their labels. An empty selector matches all projects, except the virtual projects `deckhouse` and `default`, whose namespaces are never covered.

  If neither `spec.projectSelector` nor `spec.namespaceSelector` is specified, the policy does not apply to any projects on its own. Such a policy is a library policy that a ProjectTemplate applies through `spec.grantPolicies`.

  - **spec.projectSelector.matchExpressions**
    array of objects

    List of label selector expressions.

    All expressions must match.

    Label selector expression.

    - **spec.projectSelector.matchExpressions.key**
      string

      Required value

      Label key to which the expression applies.

    - **spec.projectSelector.matchExpressions.operator**
      string

      Required value

      Operator that defines the relationship between the key and the set of values.

    - **spec.projectSelector.matchExpressions.values**
      array of strings

      List of label values.

      For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

  - **spec.projectSelector.matchLabels**
    object

    Set of labels for projects to which the policy applies.

    All specified labels must match.

- **spec.resources**
  array of objects

  Required value

  Access settings for cluster-wide resources for the selected projects.

  Access settings for one type of cluster-wide resource.

  - **spec.resources.allowed**
    array of strings

    List of names of cluster-wide resources available to the projects.

    Combined with resources selected using `allowedSelector`. An empty list is not accepted: omit the field instead, or set `availabilityDefault: None` to make nothing available.

  - **spec.resources.allowedSelector**
    object

    Label selector for cluster-wide resources available to the projects.

Combined with resources specified in `allowed`. Applies only to cluster-wide resources represented by Kubernetes objects. An empty selector is not accepted: omit the field instead, or set `availabilityDefault` to open or lock the resource without a list.

- **spec.resources.allowedSelector.matchExpressions**
  array of objects

  List of label selector expressions.

  All expressions must match.

  Label selector expression.

  - **spec.resources.allowedSelector.matchExpressions.key**
    string

    Required value

    Label key to which the expression applies.

  - **spec.resources.allowedSelector.matchExpressions.operator**
    string

    Required value

    Operator that defines the relationship between the key and the set of values.

  - **spec.resources.allowedSelector.matchExpressions.values**
    array of strings

    List of label values.

    For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.resources.allowedSelector.matchLabels**
  object

  Set of labels for cluster-wide resources.

  All specified labels must match.

- **spec.resources.availabilityDefault**
  string

  Determines the availability of cluster-wide resources that are not explicitly specified using `allowed`, `allowedSelector`, `denied`, or `deniedSelector`.

  Overrides `defaultAvailability` of the corresponding GrantableClusterResourceDefinition for the projects selected by the policy.

  `All` makes all such cluster-wide resources available, while `None` makes them unavailable.

  Usually, you do not need to specify this parameter. If `allowed` or `allowedSelector` is set and `availabilityDefault` is not specified, access to all other cluster-wide resources of this type is automatically denied. Set this parameter explicitly only to change availability without specifying a list of allowed resources: `All` to make all resources of the type available, or `None` to make them unavailable.

  Allowed values: `All`, `None`

- **spec.resources.default**
  string

  Name of the cluster-wide resource used by default in the selected projects.

  Overrides the value determined using `defaultFrom` in the corresponding GrantableClusterResourceDefinition.

- **spec.resources.denied**
  array of strings

  List of names of cluster-wide resources unavailable to the projects.

  Deny rules take precedence over `allowed` and `allowedSelector`.

- **spec.resources.deniedSelector**
  object

  Label selector for cluster-wide resources unavailable to the projects.

  Deny rules take precedence over `allowed` and `allowedSelector`. Applies only to cluster-

wide resources represented by Kubernetes objects. An empty selector is not accepted.

- **spec.resources.deniedSelector.matchExpressions**
  array of objects

  List of label selector expressions.

  All expressions must match.

  Label selector expression.

  - **spec.resources.deniedSelector.matchExpressions.key**
    string

    Required value

    Label key to which the expression applies.

  - **spec.resources.deniedSelector.matchExpressions.operator**
    string

    Required value

    Operator that defines the relationship between the key and the set of values.

  - **spec.resources.deniedSelector.matchExpressions.values**
    array of strings

    List of label values.

    For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.resources.deniedSelector.matchLabels**
  object

  Set of labels for cluster-wide resources.

  All specified labels must match.

- **spec.resources.resourceName**
  string

  Required value

  Name of the GrantableClusterResourceDefinition for which the access settings are configured.

- **status**
  object

  ClusterResourceGrantPolicy status.

  - **status.conditions**
    array of objects

    Current state of the ClusterResourceGrantPolicy.

    Information about one aspect of the current resource state.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Required value

      Message with additional information about the condition state.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      Resource generation on which the condition state is based.

      Allowed values: `0 <= X`

        - **status.conditions.reason**
          string

          Required value

          Reason for the last change in the condition state.

          Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

          Length: `1..1024`

        - **status.conditions.status**
          string

          Required value

          Condition state.

          Allowed values: `True`, `False`, `Unknown`

        - **status.conditions.type**
          string

          Required value

          Condition type.

          Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

          Maximum length: `316`

    - **status.observedGeneration**
      integer

      Latest resource generation processed by the controller.

Deprecated resource. Support for the resource might be removed in a later release.

Defines a policy for project access to cluster-wide resources and the values used by default.

The resource applies to the project namespaces whose labels match `spec.projectSelector`. A policy written through `multitenancy.deckhouse.io/v1alpha2` may also select projects by the labels of the Project; this version shows that selector as JSON in the `multitenancy.deckhouse.io/v1alpha2-project-selector` annotation. For each type of cluster-wide resource, the policy allows you to configure allowed and denied resources, as well as their availability rules and default values.

The cluster-wide resource type is specified using `spec.resources[].resourceName`, which references the corresponding GrantableClusterResourceDefinition.

The policy is created by a cluster administrator.

For configuration examples, refer to Usage examples.

- **spec**
  object

  Required value

  ClusterResourceGrantPolicy parameters.

    - **spec.projectSelector**
      object

      Label selector for project namespaces to which the policy applies.

      The selector is matched against the labels of the namespace, the same as `spec.namespaceSelector` of `multitenancy.deckhouse.io/v1alpha2`, which is the version to use.

      If the selector is not specified and the `multitenancy.deckhouse.io/v1alpha2-project-selector` annotation is absent, the policy does not apply to any projects. An empty selector matches all project namespaces, except the namespaces of the virtual projects `deckhouse` and `default`.

      The annotation holds `spec.projectSelector` of `v1alpha2`, which is matched against the labels of the Project. Keep the annotation when you update the policy through this version.

        - **spec.projectSelector.matchExpressions**
          array of objects

          List of label selector expressions.

All expressions must match.

Label selector expression.

- **spec.projectSelector.matchExpressions.key**
  string

  Required value

  Label key to which the expression applies.

- **spec.projectSelector.matchExpressions.operator**
  string

  Required value

  Operator that defines the relationship between the key and the set of values.

- **spec.projectSelector.matchExpressions.values**
  array of strings

  List of label values.

  For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.projectSelector.matchLabels**
  object

  Set of namespace labels to which the policy applies.

  All specified labels must match.

- **spec.resources**
  array of objects

  Required value

  Access settings for cluster-wide resources for the selected projects.

  Access settings for one type of cluster-wide resource.

  - **spec.resources.allowed**
    array of strings

    List of names of cluster-wide resources available to the projects.

    Combined with resources selected using `allowedSelector`. An empty list is not accepted: omit the field instead, or set `availabilityDefault: None` to make nothing available.

  - **spec.resources.allowedSelector**
    object

    Label selector for cluster-wide resources available to the projects.

    Combined with resources specified in `allowed`. Applies only to cluster-wide resources represented by Kubernetes objects. An empty selector is not accepted: omit the field instead, or set `availabilityDefault` to open or lock the resource without a list.

    - **spec.resources.allowedSelector.matchExpressions**
      array of objects

      List of label selector expressions.

      All expressions must match.

      Label selector expression.

      - **spec.resources.allowedSelector.matchExpressions.key**
        string

        Required value

        Label key to which the expression applies.

      - **spec.resources.allowedSelector.matchExpressions.operator**
        string

        Required value

        Operator that defines the relationship between the key and the set of values.

      - **spec.resources.allowedSelector.matchExpressions.values**

array of strings

List of label values.

For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.resources.allowedSelector.matchLabels**
  object

  Set of labels for cluster-wide resources.

  All specified labels must match.

- **spec.resources.availabilityDefault**
  string

  Determines the availability of cluster-wide resources that are not explicitly specified using `allowed`, `allowedSelector`, `denied`, or `deniedSelector`.

  Overrides `defaultAvailability` of the corresponding GrantableClusterResourceDefinition for the projects selected by the policy.

  `All` makes all such cluster-wide resources available, while `None` makes them unavailable.

  Usually, you do not need to specify this parameter. If `allowed` or `allowedSelector` is set and `availabilityDefault` is not specified, access to all other cluster-wide resources of this type is automatically denied. Set this parameter explicitly only to change availability without specifying a list of allowed resources: `All` to make all resources of the type available, or `None` to make them unavailable.

  Allowed values: `All`, `None`

- **spec.resources.default**
  string

  Name of the cluster-wide resource used by default in the selected projects.

  Overrides the value determined using `defaultFrom` in the corresponding GrantableClusterResourceDefinition.

- **spec.resources.denied**
  array of strings

  List of names of cluster-wide resources unavailable to the projects.

  Deny rules take precedence over `allowed` and `allowedSelector`.

- **spec.resources.deniedSelector**
  object

  Label selector for cluster-wide resources unavailable to the projects.

  Deny rules take precedence over `allowed` and `allowedSelector`. Applies only to cluster-wide resources represented by Kubernetes objects. An empty selector is not accepted.

  - **spec.resources.deniedSelector.matchExpressions**
    array of objects

    List of label selector expressions.

    All expressions must match.

    Label selector expression.

    - **spec.resources.deniedSelector.matchExpressions.key**
      string

      Required value

      Label key to which the expression applies.

    - **spec.resources.deniedSelector.matchExpressions.operator**
      string

      Required value

      Operator that defines the relationship between the key and the set of values.

    - **spec.resources.deniedSelector.matchExpressions.values**
      array of strings

      List of label values.

For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.resources.deniedSelector.matchLabels**
  object

  Set of labels for cluster-wide resources.

  All specified labels must match.

- **spec.resources.resourceName**
  string

  Required value

  Name of the GrantableClusterResourceDefinition for which the access settings are configured.

- **status**
  object

  ClusterResourceGrantPolicy status.

  - **status.conditions**
    array of objects

    Current state of the ClusterResourceGrantPolicy.

    Information about one aspect of the current resource state.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Required value

      Message with additional information about the condition state.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      Resource generation on which the condition state is based.

      Allowed values: `0 <= X`

    - **status.conditions.reason**
      string

      Required value

      Reason for the last change in the condition state.

      Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

      Length: `1..1024`

    - **status.conditions.status**
      string

      Required value

      Condition state.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Condition type.

      Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

Maximum length: `316`

- **status.observedGeneration**
  integer

  Latest resource generation processed by the controller.

GrantableClusterResourceDefinition

Short names: gcrd

Scope: Cluster
Version: v1alpha1

Registers a type of cluster-wide resource for managing project access to it.

GrantableClusterResourceDefinition defines a cluster-wide resource for which access can be configured using ClusterResourceGrantPolicy, as well as the baseline rules for its availability and use of a default value.

The resource can register both Kubernetes objects, such as StorageClass or ClusterRole, and values that are not represented by separate Kubernetes objects.

Places where the cluster-wide resource is used in other Kubernetes resources are registered separately using GrantableClusterResourceReference.

GrantableClusterResourceDefinition is created by DP or a module developer. Custom definitions can be created to manage access to additional types of cluster-wide resources.

For more information, refer to “Usage examples”.

- **spec**
  object

  Required value

  GrantableClusterResourceDefinition parameters.

  - **spec.catalogFields**
    array of objects

    Fields of the cluster-wide resources shown to projects in AvailableClusterResource.

    For each available resource, the controller reads the value of every listed field from the resource and puts it into `status.available[].fields` of AvailableClusterResource under the specified name.

    Rules:

    - Applies only to definitions with `grantedResource`, which must be cluster-scoped. For values that are not represented by Kubernetes objects, the parameter is not allowed.
    - At most 10 fields can be listed.
    - A field whose value is missing in the resource is not shown.
    - A value longer than 512 bytes in JSON serialization is not shown.
    - If `status.available` of one AvailableClusterResource with the fields of all resources would take more than 512 KiB in JSON serialization, no fields are shown in it.

    The paths are checked when the object is created or updated, and an invalid entry is refused. The result for the stored object is shown in the `CatalogFieldsValid` condition. Values left out for their size are reported by `CatalogFieldsSkipped` warning events on the GrantableClusterResourceDefinition.

    > **Warning.** The values are visible to all users of every project the resource is available to. List only non-secret data.

    Field of the cluster-wide resource shown to projects.

    - **spec.catalogFields.name**
      string

      Required value

      Name of the field in `status.available[].fields` of AvailableClusterResource, in lowerCamelCase (for example, `reclaimPolicy`).

      Pattern: `^[a-z][a-zA-Z0-9]*$`

      Maximum length: `63`

    - **spec.catalogFields.path**

string

Required value

Path to the value in the cluster-wide resource, for example `$.provisioner`.

Must be an RFC 9535 JSONPath singular query of at most 256 characters that selects exactly one value: member names and array indexes only, without wildcards (`*`), descendant segments (`..`), slices or filters.

Paths that read `metadata.managedFields` or the `kubectl.kubernetes.io/last-applied-configuration` annotation, or a parent that contains them (for example, `$.metadata`), are not allowed: these fields hold a copy of the whole resource.

Length: `1..256`

- **spec.defaultAvailability**
  string

  Baseline availability of cluster-wide resources to projects.

  Allowed values:

  - `All`: Resources are available by default.
  - `None`: Resources are unavailable by default.

  The value applies if availability is not determined by ClusterResourceGrantPolicy.

  Default: `All`

  Allowed values: `All`, `None`

- **spec.defaultFrom**
  object

  Settings for determining the cluster-wide resource used by default.

  The resource is identified by the specified annotation carrying the value `true` (compared case-insensitively; `false` marks a resource that is not the default, as the Kubernetes convention for `storageclass.kubernetes.io/is-default-class` does) and is used as the default value if one is not specified using ClusterResourceGrantPolicy. When more than one resource carries `true`, there is no default.

  - **spec.defaultFrom.annotationKey**
    string

    Key of the annotation that marks the cluster-wide resource used by default; only the value `true` counts.

- **spec.enforcement**
  string

  Method for checking cluster-wide resource availability.

  Allowed values:

  - `Managed`: The check is performed by `multitenancy-manager` webhooks.
  - `External`: The check is performed by an external mechanism, such as a module webhook.

  Default: `Managed`

  Allowed values: `Managed`, `External`

- **spec.excluded**
  array of objects

  Filters for excluded cluster-wide resources that are always unavailable to projects regardless of ClusterResourceGrantPolicy settings.

  A resource is considered excluded if it matches at least one of the specified filters.

  Filter for cluster-wide resources by name and labels.

  - **spec.excluded.matchExpressions**
    array of objects

    List of label selector expressions for cluster-wide resources.

    All expressions must match.

    Label selector expression.

    - **spec.excluded.matchExpressions.key**

string

Required value

Label key to which the expression applies.

- **spec.excluded.matchExpressions.operator**
  string

  Required value

  Operator that defines the relationship between the key and the set of values.

- **spec.excluded.matchExpressions.values**
  array of strings

  List of label values.

  For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.excluded.matchLabels**
  object

  Set of labels for cluster-wide resources.

  All specified labels must match.

- **spec.excluded.names**
  array of strings

  List of cluster-wide resource names.

- **spec.grantedResource**
  object

  Kubernetes cluster-wide resource for which access is configured.

  Must be a cluster-scoped resource: a namespaced one (for example, Secret) is refused when the object is created or updated, and a definition stored with one is not processed, which the `GrantedResourceValid` condition shows. A resource that is not served yet (its CRD is not installed) is accepted and checked once it is served.

  If the parameter is not specified, access management applies to values that are not represented by separate Kubernetes objects.

  - **spec.grantedResource.apiGroup**
    string

    API group of the cluster-wide resource.

    For the core API group, specify an empty string (`""`).

  - **spec.grantedResource.kind**
    string

    Kind of the cluster-wide resource (for example, StorageClass).

- **spec.reserved**
  array of objects

  Filters for reserved cluster-wide resources that are unavailable to projects by default.

  A reserved resource becomes available to a project only if a ClusterResourceGrantPolicy that applies to the project lists it in `allowed` or matches it with `allowedSelector`. `availabilityDefault: All` in a policy and `defaultAvailability` do not make it available. The `excluded` filters and the `denied` and `deniedSelector` values of a policy take precedence over `allowed` and `allowedSelector`.

  A resource is considered reserved if it matches at least one of the specified filters.

  Filter for cluster-wide resources by name and labels.

  - **spec.reserved.matchExpressions**
    array of objects

    List of label selector expressions for cluster-wide resources.

    All expressions must match.

    Label selector expression.

    - **spec.reserved.matchExpressions.key**

string

Required value

Label key to which the expression applies.

- **spec.reserved.matchExpressions.operator**
  string

  Required value

  Operator that defines the relationship between the key and the set of values.

- **spec.reserved.matchExpressions.values**
  array of strings

  List of label values.

  For the `In` and `NotIn` operators, the list must contain at least one value. For the `Exists` and `DoesNotExist` operators, the list must be empty.

- **spec.reserved.matchLabels**
  object

  Set of labels for cluster-wide resources.

  All specified labels must match.

- **spec.reserved.names**
  array of strings

  List of cluster-wide resource names.

- **status**
  object

  GrantableClusterResourceDefinition status.

  - **status.conditions**
    array of objects

    Current state of the GrantableClusterResourceDefinition.

    - `GrantedResourceValid`: whether `spec.grantedResource` can be processed. `True` with the reason `ClusterScoped` for a cluster-scoped resource or `ValueBacked` for a definition without `grantedResource`. `False` with the reason `Namespaced` for a namespaced resource: the definition is not processed, no project gets its AvailableClusterResource, and the grant webhooks skip the references to it: their values are not checked. `Unknown` with the reason `KindNotServed` while the resource is not served (for example, its CRD is not installed yet), or `MappingFailed` if its scope could not be determined.
    - `CatalogFieldsValid`: whether `spec.catalogFields` pass the checks applied when the object is created or updated: the paths are valid singular queries that do not read `metadata.managedFields` or the `kubectl.kubernetes.io/last-applied-configuration` annotation, and the definition has `grantedResource` (reasons `Valid`, `InvalidCatalogFields`; the message lists all problems). A definition without `catalogFields` has the condition `True`. `False` means the object was stored bypassing these checks; the invalid entries are not shown in AvailableClusterResource.

    Information about one aspect of the current resource state.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Required value

      Message with additional information about the condition state.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      Resource generation on which the condition state is based.

      Allowed values: `0 <= X`

        - **status.conditions.reason**
          string

          Required value

          Reason for the last change in the condition state.

          Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

          Length: `1..1024`

        - **status.conditions.status**
          string

          Required value

          Condition state.

          Allowed values: `True`, `False`, `Unknown`

        - **status.conditions.type**
          string

          Required value

          Condition type.

          Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

          Maximum length: `316`

    - **status.observedGeneration**
      integer

      Latest resource generation processed by the controller.

    - **status.referenceCount**
      integer

      Number of GrantableClusterResourceReference resources associated with this definition.

    - **status.references**
      array of objects

      List of GrantableClusterResourceReference resources associated with this definition.

      Information about a GrantableClusterResourceReference associated with this definition.

        - **status.references.name**
          string

          Required value

          Name of the GrantableClusterResourceReference.

        - **status.references.resources**
          array of strings

          Types of Kubernetes resources that contain registered references to the cluster-wide resource.

GrantableClusterResourceReference

Short names: gcrr

Scope: Cluster
Version: v1alpha1

Registers where a cluster-wide resource is used in other Kubernetes resources.

GrantableClusterResourceReference defines Kubernetes resources and fields that contain references to a cluster-wide resource registered using GrantableClusterResourceDefinition. For such fields, you can configure availability checks for the specified cluster-wide resource and automatic default value assignment.

One GrantableClusterResourceDefinition can be associated with multiple GrantableClusterResourceReference resources if the cluster-wide resource is used in different resources or fields.

GrantableClusterResourceReference is created by a module developer when adding a reference to a registered cluster-wide resource.

For more information about registering references to cluster-wide resources, refer to “Usage examples”.

- **spec**
  object

  Required value

  GrantableClusterResourceReference parameters.

  - **spec.fieldPaths**
    array of objects

    Required value

    List of Kubernetes resource fields that contain references to the cluster-wide resource.

    For each field, you can limit applicability to specific resources, API groups and versions, define a matching condition, and configure default value assignment.

    At least one item is required. The `resources`, `apiGroups` and `apiVersions` of an item must be a subset of the corresponding lists in `spec.rule` (`*` in `spec.rule` accepts any value). Every combination of API group, version and resource that `spec.rule` matches must be covered by at least one item, otherwise requests for it would not be checked at all. Either give items scoped to every such combination, or add an item without `resources`, `apiGroups` and `apiVersions` as the fallback for all other cases. An object that violates either rule is rejected.

    Settings for a field that contains a reference to the cluster-wide resource.

    If a request matches multiple items, the most specific one applies: `resources` takes precedence over `apiGroups`, and `apiGroups` takes precedence over `apiVersions`. `*` in `resources`, `apiGroups`, or `apiVersions` does not restrict the item and does not make it more specific. Items whose `match` condition does not hold for the object are skipped. Of equally restricted items, an item with `match` takes precedence over an item without it. If several items are equally specific, the first one in the list applies. An item without restrictions and without `match` is used in all other cases.

    Several items with the same `path` can therefore handle different objects of one resource. For example, an item with `match` on `$.spec['dataSource','dataSourceRef'].kind` and `defaulting: None` handles the PersistentVolumeClaims that restore or clone a volume, and an item without `match` and with `defaulting: Coerce` handles all other PersistentVolumeClaims.

    - **spec.fieldPaths.apiGroups**
      array of strings

      API groups to which the field settings apply.

      If the parameter is not specified, the settings apply to all API groups that match `spec.rule`.

    - **spec.fieldPaths.apiVersions**
      array of strings

      API versions to which the field settings apply.

      If the parameter is not specified, the settings apply to all API versions that match `spec.rule`.

    - **spec.fieldPaths.defaulting**
      string

      Default value assignment mode.

      Allowed values:

      - `None`: No value is assigned; only the availability of the specified cluster-wide resource is checked.
      - `FillEmpty`: The default value is assigned when an object is created if the field is empty.
      - `Coerce`: The default value is assigned when an object is created if the field is empty or the specified cluster-wide resource is unavailable to the project.

      `FillEmpty` and `Coerce` require `path` to point to a single field, so only a simple member path is accepted, for example `$.spec.storageClassName` or `$.metadata.annotations['cert-manager.io/cluster-issuer']`. A path with a wildcard, an array index or a filter is rejected with these modes and can only be used with `None`.

      Default: `None`

      Allowed values: `None`, `FillEmpty`, `Coerce`

    - **spec.fieldPaths.match**
      object

Condition for applying the field settings.

If the condition does not match, the item is skipped: the next most specific item applies, and if there is none, availability checks and default value assignment are not performed for this field.

Without `equals` and `in`, the condition matches when `fieldPath` points to a string value.

- **spec.fieldPaths.match.equals**
  string

  Value that the field specified in `fieldPath` must match.

- **spec.fieldPaths.match.fieldPath**
  string

  Required value

  JSONPath to the field whose value is checked by the condition.

  Must be a valid RFC 9535 JSONPath of at most 256 characters; an object with a path that does not parse is rejected.

  Maximum length: `256`

- **spec.fieldPaths.match.in**
  array of strings

  List of allowed values for the field specified in `fieldPath`.

- **spec.fieldPaths.message**
  string

  Text appended to the rejection of an object whose field references a cluster-wide resource that is unavailable to the project.

  Use it to tell the user what to do, for example why the value cannot be replaced with the project default.

  Maximum length: `512`

- **spec.fieldPaths.path**
  string

  Required value

  JSONPath to the string field containing the name of the cluster-wide resource.

  The path can also point to an annotation, for example, `$.metadata.annotations['cert-manager.io/cluster-issuer']`.

  Must be a valid RFC 9535 JSONPath of at most 256 characters; an object with a path that does not parse is rejected, whatever `defaulting` is set to. A field name that is not a plain identifier (contains `-`, `.` or `/`, or starts with a digit) must be written in brackets, for example `$.spec['foo-bar']`.

  An availability check evaluates the full JSONPath, including wildcards, array indexes and filters. Default value assignment does not: with `defaulting: FillEmpty` or `defaulting: Coerce`, only a simple member path is accepted.

  Maximum length: `256`

- **spec.fieldPaths.resources**
  array of strings

  Kubernetes resource names in plural, for example, `pods` or `cronjobs`, to which the field settings apply.

  If the parameter is not specified, the settings apply to all resources that match `spec.rule`. `*` has the same effect as omitting the parameter: it does not restrict the item and does not make it more specific.

  - **Element of the array**
    string

- **spec.grantableClusterResourceName**
  string

  Required value

  Name of the GrantableClusterResourceDefinition that registers the cluster-wide resource referenced by the fields.

- **spec.rule**
  object

  Required value

  Rule for selecting Kubernetes resources to which GrantableClusterResourceReference applies.

  - **spec.rule.apiGroups**
    array of strings

    Required value

    API groups of Kubernetes resources. The core group is the empty string.

    `*` is not accepted: the admission webhook is registered for the listed groups only, so a wildcard would silently intercept nothing.

  - **spec.rule.apiVersions**
    array of strings

    Required value

    API versions of Kubernetes resources.

    Use `*` to select all API versions.

  - **spec.rule.resources**
    array of strings

    Required value

    Kubernetes resource names in plural form (for example, `ingresses`).

- **status**
  object

  GrantableClusterResourceReference status.

  - **status.bound**
    boolean

    Indicates that the GrantableClusterResourceDefinition specified in `spec.grantableClusterResourceName` exists.

  - **status.conditions**
    array of objects

    Current state of GrantableClusterResourceReference.

    - `Bound`: whether the GrantableClusterResourceDefinition specified in `spec.grantableClusterResourceName` exists (reasons `Resolved`, `UnknownResource`).
    - `FieldPathsValid`: whether `spec.fieldPaths` pass the checks applied when the object is created or updated: the paths are valid, defaulting paths are simple member paths, item scopes are within `spec.rule`, and every combination `spec.rule` matches is covered (reasons `Valid`, `InvalidFieldPaths`; the message lists all problems). `False` means the object was stored bypassing these checks; the invalid paths are skipped during availability checks.

    Information about one aspect of the current resource state.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Required value

      Message with additional information about the condition state.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      Resource generation on which the condition state is based.

      Allowed values: `0 <= X`

        - **status.conditions.reason**
          string

          Required value

          Reason for the last change in the condition state.

          Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

          Length: `1..1024`

        - **status.conditions.status**
          string

          Required value

          Condition state.

          Allowed values: `True`, `False`, `Unknown`

        - **status.conditions.type**
          string

          Required value

          Condition type.

          Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

          Maximum length: `316`

    - **status.observedGeneration**
      integer

      Latest resource generation processed by the controller.

ProjectNamespace

Short names: pns

Scope: Namespaced
Version: v1alpha3

Describes an additional namespace of a project.

Available in the commercial editions of Deckhouse Platform. In Deckhouse Platform Open, a ProjectNamespace cannot be created, and the controller neither creates nor manages its namespace.

It must be created in the project's main namespace (the namespace whose name equals the project name). The controller creates a namespace named `<project>-<spec.name>`, labels it with the project ownership labels, and adds it to the parent `Project.status.namespaces` with kind `Additional`. Deleting the ProjectNamespace removes that namespace.

- **spec**
  object

  Required value

  - **spec.name**
    string

    Required value

    Suffix of the resulting namespace. The created namespace is `<project>-<name>`, where `<project>` is the main namespace this object lives in.

    The resulting name `<project>-<name>` must be no longer than 63 characters.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Length: `1..61`

- **status**
  object
  - **status.conditions**
    array of objects

    Current state of the object.

    - **status.conditions.lastProbeTime**
      string

Time of the last check of the condition.

- **status.conditions.lastTransitionTime**
  string

  Time when the condition last changed.

- **status.conditions.message**
  string

  Message with details of the condition state.

- **status.conditions.status**
  string

  Condition state: `True`, `False` or `Unknown`.

- **status.conditions.type**
  string

  Condition type.

- **status.namespace**
  string

  The namespace the controller created for this ProjectNamespace.

- **status.observedGeneration**
  integer

  Last generation of the object processed by the controller.

ProjectQuotaStatus

Short names: pqs

Scope: Cluster
Version: v1alpha1

Limits and usage of the quota of a project, summed over all namespaces of the project.

The object is read-only. The controller creates it from `Project.spec.quota`, keeps it up to date and deletes it when the field is cleared or the project is deleted; set the quota of a project in `Project.spec.quota`. The name of the object is the name of the project.

The controller puts the `d8-project-quota` ResourceQuota with the limits of `spec.hard` into every namespace of the project, the ones created later included, so that the usage of each namespace is counted by its own ResourceQuota and no namespace alone uses more than the whole project may. The status shows the usage summed over the namespaces.

- **spec**
  object

  Required value

  - **spec.hard**
    object

    Limits of the project, copied by the controller from `Project.spec.quota`, in the format of `ResourceQuota.spec.hard`, for example `requests.cpu: "100"`.

    Accepted keys are the ones a ResourceQuota counts in a namespace: `cpu`, `memory`, `requests.*`, `limits.*`, `pods`, `services`, `services.loadbalancers`, `services.nodeports`, `persistentvolumeclaims`, `configmaps`, `secrets`, `replicationcontrollers`, `ephemeral-storage`, the storage class and device class keys, the requests of extended resources and `count/<RESOURCE>[.<GROUP>]` for a namespaced resource the API server serves. `projectNamespaces` is an alias of `count/projectnamespaces.deckhouse.io`, the number of ProjectNamespace objects of the project.

    Where the `virtualization` module is enabled, the virtual machines of the project are limited by their specification with `virtualmachines.virtualization.deckhouse.io/cores`, `virtualmachines.virtualization.deckhouse.io/cpu`, `virtualmachines.virtualization.deckhouse.io/memory`, `virtualmachines.virtualization.deckhouse.io/gpus` and `<GPU_CLASS>.gpuclass.virtualization.deckhouse.io/gpus`; no ResourceQuota counts these keys, so they do not go into `d8-project-quota`. The Services of type LoadBalancer are limited by class, pool and address with `<CLASS>.loadbalancerclass.network.deckhouse.io/services`, `<CLASS>.loadbalancerclass.network.deckhouse.io/addresses`, `<POOL>.loadbalancerpool.network.deckhouse.io/addresses` and `loadbalancers.network.deckhouse.io/addresses`, which do not go into it either.

`resourcequotas`, `count/resourcequotas`, the count of a cluster-scoped resource and a misspelled resource are refused. A `count/` key of a group the API server does not serve yet is accepted with a warning and counts nothing until the module that provides the group is enabled.

- **status**
  object
  - **status.conditions**
    array of objects

    State of the quota:

    - If `Enforced` is `True`, the quota applies in every namespace of the project. If `Enforced` is `False`, `reason` says why: `ControlPlaneNotManaged` (Deckhouse Platform does not manage the control plane, so the sum is not enforced), `Suspended` (the `quota-ledger-suspend` ConfigMap suspends the check of the sum), `WebhookMissing` (the webhook of the quota ledger is missing or its `caBundle` is not the CA of the ledger certificate), `WebhookMisconfigured` (that webhook is changed so that writes of `d8-project-quota` do not reach the ledger), `WebhookNotCalled` (some API server admits objects without calling that webhook), `KeyNotServed` (nothing counts a key: the API server does not serve the resource of a `count/` key yet, or the module that serves the resources of a key is disabled) or `KeyRollout` (the `d8-project-quota` ResourceQuota of some namespace is not there or not calculated with every limit yet).
    - If `Exceeded` is `True`, the usage of the project is above the quota on some key. The `reason` says how the usage got above the quota: `HardLowered` (the limit was set below the usage, by a change or when the quota was created) or `Overshoot` (the usage grew past the limit).
    - **status.conditions.lastTransitionTime**
      string

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Message with details of the condition state.

    - **status.conditions.observedGeneration**
      integer

      Generation of the object the condition was set for.

    - **status.conditions.reason**
      string

      Reason of the condition state.

    - **status.conditions.status**
      string

      Required value

      Condition state: `True`, `False` or `Unknown`.

    - **status.conditions.type**
      string

      Required value

      Condition type.

  - **status.hard**
    object

    Limits the controller applies, `spec.hard` with the alias expanded.

  - **status.namespaceCount**
    integer

    Number of namespaces of the project.

  - **status.observedGeneration**
    integer

    Last generation of the object the controller processed.

  - **status.topNamespaces**
    array of objects

    Namespaces closest to a limit, at most 50 of them. The usage of every namespace is in its `d8-project-quota` ResourceQuota.

    - **status.topNamespaces.name**

string

Required value

Name of the namespace.

- **status.topNamespaces.used**
  object

  Usage of the namespace.

- **status.used**
  object

  Usage of the project, summed over all of its namespaces.

ProjectRoleBinding

Short names: prb

Scope: Namespaced
Version: v1alpha3

ProjectRoleBinding grants a role to subjects across all namespaces of a single project.

It must be created in the project's main namespace (the namespace whose name equals the project name).

- **spec**
  object

  Required value

  - **spec.roleRef**
    object

    Required value

    Reference to the granted ClusterRole. Allowed prefixes: `d8:project:*`, `d8:namespace:*`, `d8:project-capability:*`, `d8:namespace-capability:*`, `d8:custom:*`.

    - **spec.roleRef.kind**
      string

      Required value

      Kind of the granted role.

      Allowed values: `ClusterRole`

    - **spec.roleRef.name**
      string

      Required value

      Name of the granted ClusterRole.

  - **spec.subjects**
    array of objects

    Required value

    Subjects (users, groups or service accounts) the role is granted to.

    - **spec.subjects.apiGroup**
      string

      API group of the subject: `rbac.authorization.k8s.io` for `User` and `Group`, empty for `ServiceAccount`.

    - **spec.subjects.kind**
      string

      Required value

      Kind of the subject.

      Allowed values: `User`, `Group`, `ServiceAccount`

    - **spec.subjects.name**
      string

      Required value

Name of the subject: the user name (`User.spec.email`) for `User` , `Group.spec.name` for `Group` , the ServiceAccount name for `ServiceAccount` .

- **spec.subjects.namespace**
  string

  Namespace of the ServiceAccount.

  If omitted, the binding names the ServiceAccount with this name in each namespace of the project.

- **status**
  object
  - **status.conditions**
    array of objects

    Current state of the object.

    - **status.conditions.lastProbeTime**
      string

      Time of the last check of the condition.

    - **status.conditions.lastTransitionTime**
      string

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Message with details of the condition state.

    - **status.conditions.status**
      string

      Condition state: `True` , `False` or `Unknown` .

    - **status.conditions.type**
      string

      Condition type.

  - **status.observedGeneration**
    integer

    Last generation of the object processed by the controller.

Project

Scope: Cluster

- v1alpha3
- v1alpha2
- v1alpha1

Describes a project: an isolated environment for applications.

A project consists of the main namespace named after the project, the additional namespaces (ProjectNamespace), if any, and the settings, policies and objects that its ProjectTemplate describes. See Creating a project.

- **spec**
  object
  - **spec.administrators**
    array of objects

    Users and groups that get administrative access to the project.

    The controller grants them the `d8:project:admin` role through the `d8-administrators` ProjectRoleBinding. For `User` , the name is the user name (`User.spec.email`); for `Group` , it is `Group.spec.name` .

    Cannot be set together with `parameters.administrators` .

    - **spec.administrators.kind**
      string

      Required value

      Kind of the subject.

Allowed values: `User`, `Group`

- **spec.administrators.name**
  string

  Required value

  Subject name. For `User`, the user name (`User.spec.email`). For `Group`, `Group.spec.name` (the name in the token), not `metadata.name`. The name cannot contain control characters or line breaks and cannot start with `system:multitenancy-manager:`, the prefix of the users that the controller acts as. An update that keeps such a name as it was is accepted with a warning.

  Pattern: `^[^\x00-\x1f\x7f]+$`

- **spec.description**
  string

  Arbitrary description of the project's purpose. Specify an empty string if no description is required.

- **spec.grants**
  object

  Cluster-wide resources available to the namespaces of the project, added to the ones its template grants.

  The controller turns them into managed ClusterResourceGrantPolicy objects named `project-<PROJECT_NAME>-*`, owned by the project. Changing the field needs the right to create ClusterResourceGrantPolicy objects. `deckhouse.io/v1alpha2` cannot describe the field, so a write of a project with grants through that version, a write of its status included, is refused.

  - **spec.grants.grantPolicies**
    array of strings

    References to library ClusterResourceGrantPolicy objects (created without `projectSelector` and `namespaceSelector`).

    The controller creates and maintains one managed policy per reference, `project-<PROJECT_NAME>-<POLICY_NAME>`, copying its resources and binding them to every namespace of the project.

  - **spec.grants.resources**
    array of objects

    Rules of access to cluster-wide resources for the namespaces of the project, in the format of `resources` of a ProjectTemplate.

    The controller turns them into the `project-<PROJECT_NAME>-inline` ClusterResourceGrantPolicy, which applies to every namespace of the project.

    Access settings for one type of cluster-wide resource.

    - **spec.grants.resources.allowed**
      array of strings

      List of names of cluster-wide resources available to the project.

      Combined with the resources selected with `allowedSelector`.

    - **spec.grants.resources.allowedSelector**
      object

      Label selector of cluster-wide resources available to the project.

      Combined with the resources listed in `allowed`. Applies only to cluster-wide resources represented by Kubernetes objects.

      - **spec.grants.resources.allowedSelector.matchExpressions**
        array of objects

        List of label selector expressions.

        All expressions must match.

        - **spec.grants.resources.allowedSelector.matchExpressions.key**
          string

          Required value

          Label key to which the expression applies.

        - **spec.grants.resources.allowedSelector.matchExpressions.operator**

string

Required value

Operator that defines the relationship between the key and the set of values.

- **spec.grants.resources.allowedSelector.matchExpressions.values**
  array of strings

  List of label values.

- **spec.grants.resources.allowedSelector.matchLabels**
  object

  Set of labels of cluster-wide resources.

  All specified labels must match.

- **spec.grants.resources.availabilityDefault**
  string

  Availability of the cluster-wide resources of this type that `allowed`, `allowedSelector`, `denied` and `deniedSelector` do not name.

  Overrides `defaultAvailability` of the GrantableClusterResourceDefinition. If `allowed` or `allowedSelector` is set and this field is not, all other resources of this type are unavailable to the project.

  Allowed values: `All`, `None`

- **spec.grants.resources.default**
  string

  Name of the cluster-wide resource used by default in the project.

  Overrides the value determined with `defaultFrom` in the GrantableClusterResourceDefinition.

- **spec.grants.resources.denied**
  array of strings

  List of names of cluster-wide resources unavailable to the project.

  Deny rules take precedence over `allowed` and `allowedSelector`.

- **spec.grants.resources.deniedSelector**
  object

  Label selector of cluster-wide resources unavailable to the project.

  Deny rules take precedence over `allowed` and `allowedSelector`.

  - **spec.grants.resources.deniedSelector.matchExpressions**
    array of objects

    List of label selector expressions.

    All expressions must match.

    - **spec.grants.resources.deniedSelector.matchExpressions.key**
      string

      Required value

      Label key to which the expression applies.

    - **spec.grants.resources.deniedSelector.matchExpressions.operator**
      string

      Required value

      Operator that defines the relationship between the key and the set of values.

    - **spec.grants.resources.deniedSelector.matchExpressions.values**
      array of strings

      List of label values.

  - **spec.grants.resources.deniedSelector.matchLabels**
    object

    Set of labels of cluster-wide resources.

All specified labels must match.

- **spec.grants.resources.resourceName**
  string

  Required value

  Name of the GrantableClusterResourceDefinition that registers the type of cluster-wide resource.

- **spec.parameters**
  object

  Values of the parameters that the template declares in `parametersSchema`.

  The structured fields of the template take them through `{fromParam: <NAME>}`. `manifests` and `resourcesTemplate` get them in `{{ .parameters }}`, completed with the defaults of `parametersSchema`. The values are validated against `parametersSchema.openAPIV3Schema` of the template when the project is created or changed.

- **spec.projectTemplateName**
  string

  Name of the ProjectTemplate the project is created from.

  The `simple` template creates only the project namespace.

  Default: `simple`

- **spec.quota**
  object

  Resource quota of the whole project.

  The controller puts the `d8-project-quota` ResourceQuota into every namespace of the project, sums the usage over them and shows the limits and the usage in the read-only ProjectQuotaStatus object of the project. Clearing the field deletes that ProjectQuotaStatus.

  Changing the field needs the `update` verb on `projects/quota` in the `deckhouse.io` group for the project, which the `manage_quotas` capability of the `multitenancy-manager` module grants.

  Keys and values follow the `ResourceQuota.spec.hard` format, for example `requests.cpu: "100"`. Memory and storage quantities must include an explicit unit suffix (for example `requests.memory: 2Gi`); bare numbers are interpreted as bytes, so the admission webhook rejects a bare number other than 0. An update that leaves such a value as it was is accepted with a warning, and so is a create through `deckhouse.io/v1alpha2`, where such a value comes from `parameters.resourceQuota`.

  Cannot be set together with `parameters.resourceQuota`.

- **status**
  object
  - **status.conditions**
    array of objects

    Current state of the project.

    The condition types are described in Project status and diagnostics.

    - **status.conditions.lastProbeTime**
      string

      Time of the last check of the condition.

    - **status.conditions.lastTransitionTime**
      string

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Message with details of the condition state.

    - **status.conditions.status**
      string

      Condition state: `True`, `False` or `Unknown`.

    - **status.conditions.type**
      string

Condition type.

- **status.handingOver**
  array of objects

  Objects of `manifests` that an upgrade of the project release is taking over.

  Each entry names the object and the release revision the upgrade is expected to deploy. The object stays in the cluster, and `manifestObjects` does not list it while the entry exists. The entry is removed once the upgrade deploys the object. If the upgrade does not deploy it, the object goes back to `manifests`. It gets the `projects.deckhouse.io/project` and `projects.deckhouse.io/source: manifests` labels back and loses the `heritage`, `app.kubernetes.io/managed-by` and `projects.deckhouse.io/project-template` labels, and `manifestObjects` lists it again.

  No object is handed over while the upgrade would also take an object that is not an object of `manifests` and exists without the `app.kubernetes.io/managed-by: Helm` label and the `meta.helm.sh/release-name` annotation of the release. The upgrade does not run then, and the `ResourcesUpgraded` condition names that object.

  - **status.handingOver.apiVersion**
    string

    API version of the object.

  - **status.handingOver.kind**
    string

    Kind of the object.

  - **status.handingOver.name**
    string

    Name of the object.

  - **status.handingOver.namespace**
    string

    Namespace of the object.

  - **status.handingOver.revision**
    integer

    Release revision the upgrade is expected to deploy.

- **status.keptObjects**
  array of objects

  Objects that the project release stopped holding and that were left in place instead of being deleted.

  These are the objects of a Helm text in `resourcesTemplate` after the project switched to structured fields, a quota kept for a handover after `.spec.quota` stopped covering it, and the objects of the release of the structured fields that `manifests` render. The release no longer manages them. They carry the `projects.deckhouse.io/kept-from-helm-template: "true"` label, and while it is there, only a requester who may make the same change across the cluster may change or delete them.

  An object leaves the list once it is deleted, the label is removed from it, the release renders it again, or `manifests` take it over. When the project is deleted, the cluster-scoped ones that still carry the label are deleted with it.

  - **status.keptObjects.apiVersion**
    string

    API version of the object.

  - **status.keptObjects.kind**
    string

    Kind of the object.

  - **status.keptObjects.name**
    string

    Name of the object.

  - **status.keptObjects.namespace**
    string

    Namespace of the object, empty for a cluster-scoped one.

- **status.manifestObjects**
  array of objects

  Objects that the controller applied from `manifests` of the project template, as the `system:multitenancy-manager:project:<PROJECT_NAME>` user. They carry the `projects.deckhouse.io/project` label with the project name and the `projects.deckhouse.io/source: manifests` label. An object that the template does not render any more is deleted and leaves the list. One that lost one of these labels by then, or whose namespace left the project, leaves the list and stays in place.

  - **status.manifestObjects.apiVersion**
    string

    API version of the object.

  - **status.manifestObjects.kind**
    string

    Kind of the object.

  - **status.manifestObjects.name**
    string

    Name of the object.

  - **status.manifestObjects.namespace**
    string

    Namespace of the object.

- **status.namespaces**
  array of objects

  Namespaces that belong to the project.

  - **status.namespaces.kind**
    string

    Kind of the namespace (Main or Additional).

  - **status.namespaces.name**
    string

    Name of the namespace.

- **status.observedGeneration**
  integer

  Last generation of the project processed by the controller.

- **status.resources**
  object

  Rendered and skipped resources.

- **status.state**
  string

  State of the project: `Deployed` or `Error`. The conditions and their messages give the details.

- **status.templateGeneration**
  integer

  Generation of the template the project was last rendered from.

- **status.usage**
  object

  Current utilization of the project quota.

Describes a project: an isolated environment for applications.

A project consists of the main namespace named after the project, the additional namespaces (ProjectNamespace), if any, and the settings, policies and objects that its ProjectTemplate describes. See Creating a project.

- **spec**
  object
  - **spec.description**
    string

    Arbitrary description of the project’s purpose. Specify an empty string if no description is required.

- **spec.parameters**
  object

  Values of the parameters that the template declares in `parametersSchema`.

  The structured fields of the template take them through `{fromParam: <NAME>}`. `manifests` and `resourcesTemplate` get them in `{{ .parameters }}`, completed with the defaults of `parametersSchema`. The values are validated against `parametersSchema.openAPIV3Schema` of the template when the project is created or changed.

- **spec.projectTemplateName**
  string

  Name of the ProjectTemplate the project is created from.

  The `simple` template creates only the project namespace.

  Default: `simple`

- **status**
  object
  - **status.conditions**
    array of objects

    Current state of the project.

    The condition types are described in Project status and diagnostics.

    - **status.conditions.lastProbeTime**
      string

      Time of the last check of the condition.

    - **status.conditions.lastTransitionTime**
      string

      Time when the condition last changed.

    - **status.conditions.message**
      string

      Message with details of the condition state.

    - **status.conditions.status**
      string

      Condition state: `True`, `False` or `Unknown`.

    - **status.conditions.type**
      string

      Condition type.

  - **status.handingOver**
    array of objects

    Objects of `manifests` that an upgrade of the project release is taking over.

    Each entry names the object and the release revision the upgrade is expected to deploy. The object stays in the cluster, and `manifestObjects` does not list it while the entry exists. The entry is removed once the upgrade deploys the object. If the upgrade does not deploy it, the object goes back to `manifests`. It gets the `projects.deckhouse.io/project` and `projects.deckhouse.io/source: manifests` labels back and loses the `heritage`, `app.kubernetes.io/managed-by` and `projects.deckhouse.io/project-template` labels, and `manifestObjects` lists it again.

    No object is handed over while the upgrade would also take an object that is not an object of `manifests` and exists without the `app.kubernetes.io/managed-by: Helm` label and the `meta.helm.sh/release-name` annotation of the release. The upgrade does not run then, and the `ResourcesUpgraded` condition names that object.

    - **status.handingOver.apiVersion**
      string

      API version of the object.

    - **status.handingOver.kind**
      string

      Kind of the object.

    - **status.handingOver.name**

string

Name of the object.

- **status.handingOver.namespace**
  string

  Namespace of the object.

- **status.handingOver.revision**
  integer

  Release revision the upgrade is expected to deploy.

- **status.keptObjects**
  array of objects

  Objects that the project release stopped holding and that were left in place instead of being deleted.

  These are the objects of a Helm text in `resourcesTemplate` after the project switched to structured fields, a quota kept for a handover after `.spec.quota` stopped covering it, and the objects of the release of the structured fields that `manifests` render. The release no longer manages them. They carry the `projects.deckhouse.io/kept-from-helm-template: "true"` label, and while it is there, only a requester who may make the same change across the cluster may change or delete them.

  An object leaves the list once it is deleted, the label is removed from it, the release renders it again, or `manifests` take it over. When the project is deleted, the cluster-scoped ones that still carry the label are deleted with it.

  - **status.keptObjects.apiVersion**
    string

    API version of the object.

  - **status.keptObjects.kind**
    string

    Kind of the object.

  - **status.keptObjects.name**
    string

    Name of the object.

  - **status.keptObjects.namespace**
    string

    Namespace of the object, empty for a cluster-scoped one.

- **status.manifestObjects**
  array of objects

  Objects that the controller applied from `manifests` of the project template, as the `system:multitenancy-manager:project:<PROJECT_NAME>` user. They carry the `projects.deckhouse.io/project` label with the project name and the `projects.deckhouse.io/source: manifests` label. An object that the template does not render any more is deleted and leaves the list. One that lost one of these labels by then, or whose namespace left the project, leaves the list and stays in place.

  - **status.manifestObjects.apiVersion**
    string

    API version of the object.

  - **status.manifestObjects.kind**
    string

    Kind of the object.

  - **status.manifestObjects.name**
    string

    Name of the object.

  - **status.manifestObjects.namespace**
    string

    Namespace of the object.

- **status.namespaces**

array of strings

Used namespaces.

- **status.observedGeneration**
  integer

  Last generation of the project processed by the controller.

- **status.resources**
  object

  Rendered and skipped resources.

- **status.state**
  string

  State of the project: `Deployed` or `Error`. The conditions and their messages give the details.

- **status.templateGeneration**
  integer

  Generation of the template the project was last rendered from.

Deprecated resource. Support for the resource might be removed in a later release.

ProjectTemplate

Scope: Cluster

- v1alpha2
- v1alpha1

Describes the project template as a set of structured, declarative fields.

This resource is referenced by the Project custom resource. The `resources` and `grantPolicies` fields become ClusterResourceGrantPolicy objects that apply to the projects of this template. The other fields become objects in the namespaces of the projects.

Objects that no structured field describes are rendered from `manifests`. Instead of the fields that render objects, a template created through `deckhouse.io/v1alpha1` can carry a Helm template in `resourcesTemplate`. This form is deprecated, and no template can get a new `resourcesTemplate`.

The `virtual` name is reserved for the template of the virtual projects `default` and `deckhouse`: a ProjectTemplate with this name cannot be created.

- **spec**
  object
  - **spec.allowedGIDs**

    Range of group IDs allowed in the project containers. A literal `{min, max}` object or a parameter reference `{fromParam: "<name>"}`.

  - **spec.allowedUIDs**

    Range of user IDs allowed in the project containers. A literal `{min, max}` object or a parameter reference `{fromParam: "<name>"}`.

  - **spec.description**
    string

    Arbitrary description of the template’s purpose. Specify an empty string if no description is required.

  - **spec.features**
    object

    Optional project capabilities.

    - **spec.features.monitoring**

      Enable extended monitoring for the project. A literal boolean or a parameter reference `{fromParam: "<name>"}`.

    - **spec.features.vulnerabilityScanning**

      Enable periodic vulnerability scans (Trivy) for the project. A literal boolean or a parameter reference `{fromParam: "<name>"}`.

  - **spec.grantPolicies**
    array of strings

References to library ClusterResourceGrantPolicy objects (created without `projectSelector` and `namespaceSelector`).

The controller creates and maintains one managed policy per reference, copying its resources and binding them to the namespaces rendered from this template.

- **spec.logShipping**
  object

  Forwarding of the project logs to a cluster log destination.

  - **spec.logShipping.clusterDestinationRef**

    Name of the ClusterLogDestination to ship logs to. A literal string or a parameter reference `{fromParam: "<name>"}`.

- **spec.manifests**
  string

  A template in the `go template` format with the `helm` functions that renders objects into the namespaces of a project, next to the objects that the structured fields render.

  The template gets the project name in `{{ .projectName }}`, the template name in `{{ .projectTemplateName }}` and the project parameters completed with the defaults of `parametersSchema` in `{{ .parameters }}`, the same values as `resourcesTemplate`. A project whose parameters turn into objects or keys of the rendered manifests instead of values is refused, so quote every substitution.

  The controller applies the objects with server-side apply as the `system:multitenancy-manager:project:<PROJECT NAME>` user, and the `d8-manifests` ProjectRoleBinding of the project grants this user the `d8:project:admin` role. So an object gets only what this role allows in the namespaces of the project, not the rights of the controller. An AuthorizationRule of the `Admin` access level is refused when the manifests create it or raise an existing one to this level, although the role allows it. The administrators of a project are set in `.spec.administrators` of the Project. The objects are applied once the binding is Ready, and the `ManifestsApplied` condition of the project says whether they are applied and names the objects that the API server refused with the code of each refusal, such as 403.

  An object without `metadata.namespace` is created in the main namespace of the project, and a namespace that an object names has to be a namespace of the project or one that a ProjectNamespace of the same `manifests` makes. The objects of such a namespace are applied once it exists, and until then the `ManifestsApplied` condition names the namespaces they wait for. See Additional namespaces in manifests. A cluster-scoped object, an object in a namespace outside the project and an object with the `heritage: multitenancy-manager` or `heritage: deckhouse` label are refused. The objects get the `projects.deckhouse.io/project` label with the project name and the `projects.deckhouse.io/source: manifests` label, and `.status.manifestObjects` of the project lists them. An object that the template does not render any more is deleted.

  An object that a switch of the project from a Helm text left in place and listed in `.status.keptObjects` is taken over when `manifests` renders an object of the same kind, namespace and name. The object then has what `manifests` renders, and a field that the Helm text set and `manifests` leaves out is removed, the annotations of Helm included. The same list moves an object from the release of the structured fields to `manifests`. When the structured fields stop rendering an object that `manifests` render under the same kind, namespace and name, the controller leaves it in place with the `projects.deckhouse.io/kept-from-helm-template: "true"` label and lists it in `.status.keptObjects`, and `manifests` take it over in the same change. If `manifests` cannot apply it, the object stays on the list. See Moving an object of the release to manifests. Any other object that exists already and that `manifests` did not create is changed only when it has the two labels, and otherwise the `ManifestsApplied` condition names it. An object that `manifests` created and that the template renders otherwise after a change, for example a NetworkPolicy named `isolated` once `networkPolicy.mode` is `Isolated`, goes to the objects the project renders from the template in the same change. It gets what the template renders, and a field that only `manifests` set is removed.

  Like the objects that the structured fields render, these objects are changed through the template only. The `d8-multitenancy-manager-manifests-objects` admission policy refuses to create, change or delete an object with the `projects.deckhouse.io/source: manifests` label to everyone, project and cluster administrators included. Only the user the `manifests` of the project are applied as, the controller, the service accounts of the `d8-*` namespaces and the cluster components can do it. Anyone who may update a workload may restart its rollout, when the `kubectl.kubernetes.io/restartedAt` annotation of its pod template is the only change. `metadata.resourceVersion`, `metadata.generation` and `metadata.managedFields` are not compared, because the API server sets them on the write. The controller applies the objects again after a while, which puts back the fields that the template sets if something else changed them. A project template can be read by users who have no access to its projects, the ones with the `User` access level included, so do not put secret values into `manifests`.

The field cannot be set together with `resourcesTemplate`. `deckhouse.io/v1alpha1` has no place for it, so a write of a template that has it through `deckhouse.io/v1alpha1` is refused. See Describing other objects in manifests.

- **spec.namespaceMetadata**
  object

  Extra labels and annotations for the project namespaces.

  - **spec.namespaceMetadata.annotations**

    A literal annotation map or a parameter reference `{fromParam: "<name>"}`.

    The annotations are set on the main namespace of the project only.

  - **spec.namespaceMetadata.labels**

    A literal label map or a parameter reference `{fromParam: "<name>"}`.

    The labels are set on every namespace of the project, including the additional ones, and are listed in the `projects.deckhouse.io/template-labels` annotation of each.

    Labels that the module manages (`heritage`, `app.kubernetes.io/managed-by`, `projects.deckhouse.io/*`, `multitenancy.deckhouse.io/*`, and the pod security, monitoring and scanning labels) and the `kubernetes.io/metadata.name` label cannot be set in this field. A template that sets one here is refused, and so is a Project whose parameters put one here. A template or Project that already has such a label can still be changed while it keeps the label as it is. The label is not applied, and the response warns about it.

    GitOps tracking labels (`app.kubernetes.io/instance`, `argocd.argoproj.io/*`, `kustomize.toolkit.fluxcd.io/*`, `helm.toolkit.fluxcd.io/*`, `kapp.k14s.io/*`) are set on the main namespace only. A custom tracking key is inherited like any other label.

    When a namespace becomes a project automatically, its own labels are not copied into the Project and do not reach this field. A label declared in `spec.parameters.namespace.labels` of the Project reaches it through the built-in templates and is inherited.

- **spec.networkPolicy**
  object

  Network isolation of the project namespaces.

  - **spec.networkPolicy.mode**

    Network isolation mode of the project namespaces.

    - `Isolated`: Every namespace of the project gets the `isolated` NetworkPolicy. It allows incoming traffic only from the project namespaces, Prometheus, the ingress-nginx controller and the service-with-healthchecks agent, and outgoing traffic only to the project namespaces and to DNS in `kube-system`.
    - `NotRestricted`: No NetworkPolicy is created.

    If the field is not set, no NetworkPolicy is created either.

    A literal string (`Isolated`/`NotRestricted`) or a parameter reference `{fromParam: "<name>"}`. The webhook refuses a literal outside the two values.

- **spec.nodeSelector**

  Node selector of the pods in the main namespace of the project. A literal label map or a parameter reference `{fromParam: "<name>"}`.

  It is set as the `scheduler.alpha.kubernetes.io/node-selector` annotation of the main namespace and is merged into the node selector of every pod there. A pod whose selector conflicts with it is rejected. The additional namespaces of the project do not get it.

- **spec.parametersSchema**
  object

  OpenAPI v3 schema of the parameters of a project.

  A boolean `requiredRequests` parameter declared here is read by name: when it is `true` for a project, the pods in every namespace of the project must have CPU and memory requests (an OperationPolicy in the `Deny` mode).

  - **spec.parametersSchema.openAPIV3Schema**
    object

    Required value

    OpenAPI specification that the parameters of a project are validated against when the project

is created or changed.

- **spec.podSecurityStandard**

  Pod Security Standard profile applied to the project namespaces.

  - `Privileged`: Unrestricted policy.
  - `Baseline`: Minimally restrictive policy that prevents known privilege escalations.
  - `Restricted`: Heavily restricted policy that follows current pod hardening best practices.

  A literal string (`Privileged`/`Baseline`/`Restricted`) or a parameter reference `{fromParam: "<name>"}` pointing at a `parametersSchema` property. The webhook refuses a literal outside the three values and a reference to an undeclared or mistyped parameter.

- **spec.resources**
  array of objects

  Rules of access to cluster-wide resources for the projects of the template.

  The controller turns them into the `template-<TEMPLATE_NAME>-inline` ClusterResourceGrantPolicy, which applies to the namespaces of the projects of this template.

  Access settings for one type of cluster-wide resource.

  - **spec.resources.allowed**
    array of strings

    List of names of cluster-wide resources available to the projects.

    Combined with the resources selected with `allowedSelector`.

  - **spec.resources.allowedSelector**
    object

    Label selector of cluster-wide resources available to the projects.

    Combined with the resources listed in `allowed`. Applies only to cluster-wide resources represented by Kubernetes objects.

    - **spec.resources.allowedSelector.matchExpressions**
      array of objects

      List of label selector expressions.

      All expressions must match.

      - **spec.resources.allowedSelector.matchExpressions.key**
        string

        Required value

        Label key to which the expression applies.

      - **spec.resources.allowedSelector.matchExpressions.operator**
        string

        Required value

        Operator that defines the relationship between the key and the set of values.

      - **spec.resources.allowedSelector.matchExpressions.values**
        array of strings

        List of label values.

    - **spec.resources.allowedSelector.matchLabels**
      object

      Set of labels of cluster-wide resources.

      All specified labels must match.

  - **spec.resources.availabilityDefault**
    string

    Availability of the cluster-wide resources of this type that `allowed`, `allowedSelector`, `denied` and `deniedSelector` do not name.

    Overrides `defaultAvailability` of the GrantableClusterResourceDefinition. If `allowed` or `allowedSelector` is set and this field is not, all other resources of this type are unavailable to the projects.

    Allowed values: `All`, `None`

- **spec.resources.default**
  string

  Name of the cluster-wide resource used by default in the projects.

  Overrides the value determined with `defaultFrom` in the GrantableClusterResourceDefinition.

- **spec.resources.denied**
  array of strings

  List of names of cluster-wide resources unavailable to the projects.

  Deny rules take precedence over `allowed` and `allowedSelector`.

- **spec.resources.deniedSelector**
  object

  Label selector of cluster-wide resources unavailable to the projects.

  Deny rules take precedence over `allowed` and `allowedSelector`.

  - **spec.resources.deniedSelector.matchExpressions**
    array of objects

    List of label selector expressions.

    All expressions must match.

    - **spec.resources.deniedSelector.matchExpressions.key**
      string

      Required value

      Label key to which the expression applies.

    - **spec.resources.deniedSelector.matchExpressions.operator**
      string

      Required value

      Operator that defines the relationship between the key and the set of values.

    - **spec.resources.deniedSelector.matchExpressions.values**
      array of strings

      List of label values.

  - **spec.resources.deniedSelector.matchLabels**
    object

    Set of labels of cluster-wide resources.

    All specified labels must match.

- **spec.resources.resourceName**
  string

  Required value

  Name of the GrantableClusterResourceDefinition that registers the type of cluster-wide resource.

- **spec.resourcesTemplate**
  string

  A template in the `go template` format with the `helm` functions that renders the objects of a project.

  The field is deprecated and is kept for the templates created through `deckhouse.io/v1alpha1`. Describe new templates with the structured fields and `manifests`. No template can get a new `resourcesTemplate` through either version: a create with a non-empty one and an update that sets one on a template that has none are refused, and a create through `deckhouse.io/v1alpha1` is refused as a whole. A template that has one keeps it, and it can be changed through either version while `deckhouse.io/v1alpha1` can describe the whole template. So a template with a Helm text cannot be created again, for example from a backup or from Git; move it to the structured fields and `manifests` first. The field leaves `deckhouse.io/v1alpha2` together with `deckhouse.io/v1alpha1` in a future release. See Moving a template from a Helm text.

  When the field is not empty, the template is rendered from it. It cannot be set together with the fields that render objects into the project namespaces (`podSecurityStandard`, `networkPolicy`, `namespaceMetadata`, `manifests` and the others), while `resources` and `grantPolicies` apply in

either case. A template that projects use keeps a non-empty `resourcesTemplate` until a change sets such fields or `manifests` in its place.

After such a change, as after a move of a project to a structured template, the AuthorizationRule and ResourceQuota objects of the Helm text that `.spec.administrators` and `.spec.quota` of the project replace are deleted once these fields work, and an AuthorizationRule that names nobody from `.spec.administrators` any more is deleted at once. Every other object of the Helm text that the new fields do not render under the same kind and name is left in place and listed in `.status.keptObjects` of the project, until `manifests` renders an object of the same kind, namespace and name and takes it over. `.status.keptObjects` also lists an object of the release of the structured fields that `manifests` render when the release drops it, until `manifests` take it over. See Switching a project from a Helm text and Moving an object of the release to manifests.

The template gets the project name in `{{ .projectName }}`, the template name in `{{ .projectTemplateName }}` and the project parameters completed with the defaults of `parametersSchema` in `{{ .parameters }}`. When `parametersSchema` declares the `administrators` and `resourceQuota` parameters, they hold the administrators and the quota of the project, laid out as in a `deckhouse.io/v1alpha2` Project. A project whose parameters turn into objects or keys of the rendered manifests instead of values is refused, so quote every substitution.

An object without `metadata.namespace` or in a namespace outside the project is created in the main namespace of the project. The labels the template puts on the main namespace, except the ones the module manages and the GitOps tracking labels, are listed in its `projects.deckhouse.io/template-labels` annotation and are set on the additional namespaces too.

- **spec.runtimeAudit**
  object

  Runtime audit rules; effective only when allowedUIDs/allowedGIDs are set.

  - **spec.runtimeAudit.enabled**

    A literal boolean or a parameter reference `{fromParam: "<name>"}`.

- **spec.title**
  string

  Short human-readable name of the template.

- **spec.tolerations**

  Default tolerations of the pods in the main namespace of the project. A literal list of tolerations or a parameter reference `{fromParam: "<name>"}`.

  They are set as the `scheduler.alpha.kubernetes.io/defaultTolerations` annotation of the main namespace. The additional namespaces of the project do not get them.

- **status**
  object
  - **status.message**
    string

    Message indicating the cause of the current status.

  - **status.ready**
    boolean

    Whether the template is ready to use. Indicates that the template has been successfully validated.

Deprecated resource. Support for the resource might be removed in a later release.

Describes the project template.

This resource is referenced by the Project custom resource.

The version is deprecated. A template is created through `deckhouse.io/v1alpha2`, and a create through `deckhouse.io/v1alpha1` is refused. The templates created through `deckhouse.io/v1alpha1` earlier are read, changed and deleted through it as before.

- **spec**
  object
  - **spec.description**
    string

    Arbitrary description of the template’s purpose. Specify an empty string if no description is required.

  - **spec.parametersSchema**
    object

Required value

Schema of the project parameters.

Only `openAPIV3Schema` is supported.

- **spec.parametersSchema.openAPIV3Schema**
  object

  Required value

  OpenAPI specification for parameters.

  This is used to check the validity of the parameters that are passed when creating a new project.

- **spec.resourcesTemplate**
  string

  Required value

  A template that defines resources in the `go template` format to be created when setting up a new project.

  Templates are fully compatible with all `helm` functions.

  See Moving a template from a Helm text.

  The following parameters are available in templates:

  - `{{ .projectName }}` — the name of the `Project` for which the template is being rendered.
  - `{{ .projectTemplateName }}` — the name of the `ProjectTemplate`.
  - `{{ .parameters }}` — a dictionary of custom values, described in the .spec.parametersSchema and defined in the .spec.parameters.

  `.metadata.namespace` of an object is optional: an object without it is created in the main namespace of the project.

- **status**
  object
  - **status.message**
    string

    Message indicating the cause of the current status.

  - **status.ready**
    boolean

    Whether the template is ready to use. Indicates that the template has been successfully validated.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The multitenancy-manager module: usage examples

> ⚠ The module lifecycle stage: Preview

Default project templates

Deckhouse Platform includes the following project templates. They are cumulative: each one includes the capabilities of the previous one and adds its own. Parameter values are set in the `.spec.parameters` field of a Project:

- `simple`: Minimal template that creates only the project namespace. Use it when you only need an isolated namespace managed as a project and configure access and limits through the standard fields and project role bindings.

  Parameters:

  - `namespace.labels` and `namespace.annotations`: Extra labels and annotations for the project namespace.
  - `requiredRequests` (default `false`): When `true`, the pods in the project must specify CPU and memory requests (an OperationPolicy in the `Deny` mode).

- `default`: Template that covers basic project use cases. On top of the namespace, it sets up network isolation, a pod security profile, extended monitoring and log shipping.

  Parameters (besides the ones listed for `simple`):

  - `networkPolicy`: `Isolated` (default) allows incoming traffic only from the project namespaces, Prometheus, the ingress-nginx controller and the service-with-healthchecks agent, and outgoing traffic only to the project namespaces and to DNS in `kube-system`. `NotRestricted` allows all traffic.
  - `podSecurityProfile`: The Pod Security Standards profile for the project namespaces: `Baseline` (default) prevents known privilege escalations, `Restricted` applies the strictest hardening practices, `Privileged` restricts nothing. An empty string sets no profile. The project puts no `security.deckhouse.io/pod-policy` label on its namespaces, and the default policy of the `admission-policy-engine` module applies to them.
  - `extendedMonitoringEnabled` (default `true`): Alerts on controller outages and restarts, 5xx errors in ingress-nginx and low free space on the project's persistent volumes.
  - `clusterLogDestinationName`: The name of the ClusterLogDestination to ship the project logs to. Left unset, the project logs are not shipped anywhere.
  - `requiredRequests` (default `true` in this template): When `true`, the pods in the project must specify CPU and memory requests (an OperationPolicy in the `Deny` mode). When an existing namespace becomes a project, the parameter is set to `false`, so running workloads are not blocked.

- `secure`: Includes all the capabilities of the `default` template, and additionally restricts the users and groups inside containers, audits their calls to the kernel and scans images for vulnerabilities.

  Parameters (besides the ones listed for `default`):

  - `allowedUIDs` and `allowedGIDs`: The ranges (`min`, `max`) of IDs permitted for users and groups inside the project containers. See Security Context.
  - `runtimeAuditEnabled` (default `false`): Audit rules that catch calls to the kernel and find malicious activity. They work only if the UID/GID ranges are set.
  - `securityScanningEnabled` (default `true`): Periodic scanning of the launched images for known vulnerabilities (CVE) with Trivy, every 24 hours.

- `secure-with-dedicated-nodes`: Includes all the capabilities of the `secure` template, and additionally places the pods of the main namespace of the project on dedicated nodes.

  Parameters (besides the ones listed for `secure`). If `dedicatedNodes` is set, at least one of its two fields must be set. Without `dedicatedNodes`, the pods are not placed on dedicated nodes:

- `dedicatedNodes.nodeSelector`: The node selector of the main namespace. It is merged into the node selector of every pod there, and a pod whose selector conflicts with it is rejected.
- `dedicatedNodes.defaultTolerations`: Tolerations in the format of the pod's `spec.tolerations`. They are **added** to the pods created in the main namespace.

The `default`, `secure`, and `secure-with-dedicated-nodes` templates are described in the structured form (`deckhouse.io/v1alpha2`). The `simple` template is a minimal structured template that creates the namespace, sets its labels and annotations from the project parameters and, with `requiredRequests: true`, creates the OperationPolicy.

The exact set of parameters is in the template installed in the cluster. To view the parameter schema of a template, use the command:

```
d8 k get projecttemplates <PROJECT_TEMPLATE_NAME> -o
jsonpath='{.spec.parametersSchema.openAPIV3Schema}' | jq
```

To view the whole template, use the command:

```
d8 k get projecttemplates <PROJECT_TEMPLATE_NAME> -o yaml
```

Creating a project

To create a project, follow these steps:

1. Create a Project, specifying the name of the project template in .spec.projectTemplateName field.
2. Set the standard fields .spec.administrators and .spec.quota. They work with any template.
3. In the .spec.parameters field of the Project resource, specify the parameter values suitable for the ProjectTemplate .spec.parametersSchema.openAPIV3Schema.

   Example of a Project created from the `default` ProjectTemplate:

   ```
   apiVersion: deckhouse.io/v1alpha3
   kind: Project
   metadata:
     name: my-project
   spec:
     description: This is an example from the Deckhouse documentation.
     projectTemplateName: default
     # Standard fields, managed by the Project resource itself.
     administrators:
       - kind: Group
         name: k8s-admins
     quota:
       requests.cpu: "5"
       requests.memory: 5Gi
       requests.storage: 1Gi
       limits.cpu: "5"
       limits.memory: 5Gi
     # Template-specific parameters.
     parameters:
       networkPolicy: Isolated
       podSecurityProfile: Restricted
       extendedMonitoringEnabled: true
   ```

   The Project API versions are described in Project API versions.
4. To check the status of the project, execute the command:

   ```
   d8 k get projects my-project
   ```

   A successfully created project should be in the `Deployed` state. If the state equals `Error`, add the `-o yaml` argument to the command (e.g., `d8 k get projects my-project -o yaml`) to get more detailed information about the error.

Project API versions

The Project API is served as `deckhouse.io/v1alpha3`. `v1alpha2` manifests keep working: a conversion webhook lifts `parameters.administrators` and `parameters.resourceQuota` into the `.spec.administrators` and `.spec.quota` standard fields automatically. If one administrator does not fit `.spec.administrators` (for example, it has `accessLevel`), the whole list stays in `parameters` and `.spec.administrators` is not filled. The same holds for a quota with anything other than quantities (for example, `scopes`), for a quota with the number `0` anywhere in it, and for an empty list or quota. A template that checks a value with `with` skips the number `0` and sets no limit, while in `.spec.quota` it would be a hard limit of zero. The string `"0"` is lifted into `.spec.quota` as such a limit. A `v1alpha2` client reads a `0` from `.spec.quota` as the string `"0"`. A project cannot set `.spec.administrators` together with `parameters.administrators`, or `.spec.quota` together with `parameters.resourceQuota`. The `spec.grants` field exists only in `deckhouse.io/v1alpha3`: a change of a project that has it through `deckhouse.io/v1alpha2` is refused, see Granting cluster-wide resources to one project.

The `deckhouse.io/v1alpha1` version is no longer served, and the API server refuses a manifest with `apiVersion: deckhouse.io/v1alpha1`. Before applying such a manifest, change `apiVersion` to `deckhouse.io/v1alpha3`, rename `spec.projectTypeName` to `spec.projectTemplateName` (a ProjectTemplate with that name must exist) and `spec.template` to `spec.parameters`, and move `administrators` and `resourceQuota` from the parameters to `.spec.administrators` and `.spec.quota`.

Creating a project without specifying a template

The `projectTemplateName` field is optional: when omitted, the `simple` template is used. Such a project consists only of the namespace and the standard fields (administrators, quota) — no template policies are created in it. Use it when the namespace needs no template settings or they are managed by other means:

```
apiVersion: deckhouse.io/v1alpha3
kind: Project
metadata:
  name: my-plain-project
spec:
  administrators:
    - kind: Group
      name: k8s-admins
  quota:
    requests.cpu: "2"
```

A template can be assigned later by setting it in `.spec.projectTemplateName`.

Project naming rules

The project name is also the name of its main namespace, so the following rules are checked when a project is created:

- The name cannot start with `d8-` or `kube-`: these prefixes are reserved for system namespaces.
- The name cannot be `default` or `deckhouse`: these names belong to the virtual projects.
- The name cannot be longer than 61 characters.
- The name cannot be the name of an existing namespace, or of a namespace that a ProjectNamespace has claimed. The resulting name `<project>-<spec.name>` is taken from the moment the ProjectNamespace is created, before the controller creates the namespace. A namespace that belongs to no project becomes a project automatically.
- The name cannot be the name of a namespace whose ServiceAccounts are still named among the subjects of a ClusterProjectRoleBinding, or of a ProjectRoleBinding of a project that the name extends with a dash and a suffix (`foo` for `foo-extra`). Such subjects are often left from a deleted additional namespace, and without this rule the ServiceAccounts of the new project would get the rights of that binding. Remove these subjects from the binding first. The refusal does not name the binding.

A project can be named after another project with a dash and a suffix (`foo-bar` beside `foo`). It is a separate project with a namespace of its own, not an additional namespace of `foo`, and the template, administrators, quota and bindings of `foo` do not apply to it. The webhook allows such a project with a warning, and the controller sends the `NamedLikeAdditionalNamespace` Warning event on the new project. The `MultitenancyManagerProjectNamedLikeAdditionalNamespace` alert lists every such pair of projects, including the ones made from namespaces that existed before. To add a namespace to a project, create a ProjectNamespace.

Project status and diagnostics

The `.status.state` field of a project is either `Deployed` (all project resources are in sync, or the objects of `manifests` wait for their binding) or `Error`. The cause of an error is described in the conditions (`.status.conditions`):

```
d8 k get project my-project -o jsonpath='{range .status.conditions[*]}{.type}={.status}:
{.message}{"\n"}{end}'
```

Condition	False means
`ProjectTemplateFound`	The template referenced in `.spec.projectTemplateName` was not found.
`Validated`	The project parameters failed validation against the template schema (`parametersSchema`).
`ResourcesUpgraded`	The project resources could not be created or updated from the template (details in `message`).
`StandardFieldsApplied`	The standard fields (quota or administrators) could not be applied.
`TemplateRolesAllowed`	The template creates a binding to a role forbidden for granting in projects — the project switches to `Error`, the role is named in `message`.
`ManifestsApplied`	The objects of the template's `manifests` are not applied. The `message` says what they wait for, why none of them is applied, which existing objects they leave alone, or which objects the API server refused, with the code of each refusal (for example, `403 Forbidden`).
`HelmOwnership`	The namespace of the project belongs to another Helm release. The `message` names the release (see Creating a project automatically for a namespace).
`NamespaceDeleted`	The project is being deleted, and its namespace is still terminating. The `message` says since when and what remains in it.
`QuotaWithinLimits`	The usage of the project is above its quota; the `message` names the limits. A project without a quota does not have the condition.

The `HandoverPending` condition is read the other way round. It is `True` while AuthorizationRule and ResourceQuota objects kept from a Helm text wait for the standard fields that replace them, and it is removed once they are deleted (see Switching a project from a Helm text).

Other useful status fields:

- `.status.namespaces`: All namespaces of the project with their kind (`Main` or `Additional`).
- `.status.usage`: The usage of the project summed over all of its namespaces, taken from its ProjectQuotaStatus.
- `.status.resources`: State of the individual objects created from the template.
- `.status.keptObjects`: Objects of a Helm text and of the release of the structured fields that the release left in place instead of deleting them, until `manifests` take them over.
- `.status.manifestObjects`: Objects applied from `manifests` of the template.

Service objects of a project

The controller creates service objects in the project namespaces. They are managed automatically — editing them manually is not possible (the attempt is rejected):

Object	Where	Comes from
`ProjectQuotaStatus/<PROJECT_NAME>`	Cluster-scoped	The `.spec.quota` field of the project (see Project quota).

Object	Where	Comes from
`ResourceQuota/d8-project-quota`	Every namespace of the project	The `.spec.quota` field of the project.
`ProjectRoleBinding/d8-administrators`	The main namespace	The `.spec.administrators` field of the project.
`ProjectRoleBinding/d8-manifests`	The main namespace	The `manifests` field of the project template. It grants the `d8:project:admin` role to the user that applies these objects.
`RoleBinding/d8:prb:<name>`	Every namespace of the project	The fan-out of the ProjectRoleBinding named `<name>`.
`RoleBinding/d8:cprb:<name>`	Every namespace of every project	The fan-out of the ClusterProjectRoleBinding named `<name>`.

When the source object (a binding, the quota field, etc.) is removed, the corresponding service objects are removed automatically.

Virtual projects

Besides the user-created projects, the `d8 k get projects` list always contains two **virtual** projects (labeled `projects.deckhouse.io/virtual-project: "true"`):

- `deckhouse` — groups system namespaces (`d8-*`, `kube-*`, `upmeter-*`, `heritage: deckhouse` / `heritage: upmeter`);
- `default` — groups remaining namespaces that do not belong to any project (the `default` namespace itself).

Virtual-project status is rebuilt from the live namespace list: a deleted namespace disappears from that list. Virtual projects do not recreate namespaces.

Virtual projects exist for completeness: with them, every namespace of the cluster belongs to some project. They cannot be managed: they are not editable, ProjectNamespace and ProjectRoleBinding resources cannot be created in them, and ClusterProjectRoleBinding does not extend to them. Their project template, `virtual`, is reserved for them: a user project with `projectTemplateName: virtual` is refused by the webhook, since such a project would get no namespace of its own. The `projects.deckhouse.io/virtual-project: "true"` label is reserved too: the webhook refuses a project that is created with it or gets it added. A project is virtual by its template, not by the label, so a user project that already carries the label is an ordinary project; it keeps the label with a warning until the label is removed. No ClusterResourceGrantPolicy applies to their namespaces either, even one whose selectors match a virtual Project, because the cluster resource availability rules apply only in namespaces with the `projects.deckhouse.io/project` label, and the namespaces of virtual projects do not carry it.

No ProjectTemplate object named `virtual` exists, and the webhook refuses to create one. A template with this name that is already in the cluster is not used by any project and can be deleted.

Additional project namespaces

In Deckhouse Platform Open (CE), a project has only its main namespace.

If an application needs several namespaces (for example, a separate one for a cache or queues), add them to the project with the ProjectNamespace resource. A ProjectNamespace is created **in the main namespace of the project**; the resulting namespace is named `<project name>-<spec.name>`:

```
apiVersion: deckhouse.io/v1alpha3
kind: ProjectNamespace
metadata:
  name: cache
  namespace: my-project
spec:
  name: cache   # The my-project-cache namespace will be created.
```

You can check the project composition in its status:

```
d8 k get project my-project -o jsonpath='{.status.namespaces}'
```

The rules for working with ProjectNamespace:

- The `spec.name` field is immutable: to rename a namespace, delete the ProjectNamespace and create a new one.
- The resulting name `<project name>-<spec.name>` cannot be longer than 63 characters (the Kubernetes limit on namespace names).
- A ProjectNamespace can only be created in the main namespace of a project. It cannot be "nested" into an additional namespace or a foreign project.
- The resulting name must be free. The request is rejected when a namespace with that name exists and is not a namespace of this project, when a project has that name, or when another ProjectNamespace already claims it (the ProjectNamespace `a-backend` of project `team` and the ProjectNamespace `backend` of project `team-a` both claim `team-a-backend`).
- The request is also rejected when the ServiceAccounts of a namespace with the resulting name are still named among the subjects of a ClusterProjectRoleBinding, or of a ProjectRoleBinding of another project that the resulting name extends with a dash and a suffix (`team` for `team-a-backend` of project `team-a`). Remove these subjects from the binding first. A ProjectRoleBinding of the same project is no obstacle, and the ServiceAccounts it names get the rights back once the namespace is created again.
- Deleting a ProjectNamespace deletes its namespace. Deleting the project deletes all of its namespaces.
- A namespace with the resulting name that is not a namespace of this project is never taken into it, even when it appears after the ProjectNamespace was created. The ProjectNamespace then does not become ready, and deleting it leaves the namespace as it is.
- A project can be deleted only by a user allowed to delete each of its namespaces (the `delete` verb on `namespaces`): the main namespace and every namespace labeled `projects.deckhouse.io/project: <project name>`. Otherwise the request is refused, and the refusal names the namespace the user may not delete. A namespace that does not exist is not checked. The identities the Project webhook skips (see Who bypasses admission) delete projects without this check.

What applies to the additional namespaces

The following automatically applies in **all** namespaces of the project (the main and the additional ones alike):

- **Access**: the ProjectRoleBinding and ClusterProjectRoleBinding bindings, including the automatic access of the project administrators. When a new namespace is added, all existing bindings fan out into it without any user action.
- **Namespaced template objects**: the network policy (`networkPolicy.mode: Isolated`) and the log collection setup (`logShipping`) are created in every namespace of the project. The network isolation allows traffic between the namespaces of one project. A Helm `resourcesTemplate` creates its objects in the main namespace unless an object names another namespace of the project. So does `manifests`, whose objects are not applied while one of them names a namespace outside the project.
- **Cluster-scoped template policies** (`OperationPolicy`, the `SecurityPolicy` from `allowedUIDs`/`allowedGIDs`): they select namespaces by the `projects.deckhouse.io/project` label, that is, they cover the whole project.
- **The project quota**: the `d8-project-quota` ResourceQuota with the limits of the project quota is created in every namespace of the project.
- **Inherited labels**: the pod security profile (`security.deckhouse.io/pod-policy`), extended monitoring (`extended-monitoring.deckhouse.io/enabled`), vulnerability scanning (`security-scanning.deckhouse.io/enabled`), the template label (`projects.deckhouse.io/project-template`) and the labels the template sets through `namespaceMetadata.labels` are synced from the main namespace to the additional ones. For a template with `resourcesTemplate`, these are the labels its Helm text puts on the main namespace. The sync is complete: if a feature is turned off or a label is removed in the template, the label is removed from the additional namespaces as well. The labels of the template are listed in the `projects.deckhouse.io/template-labels` annotation of each project namespace; they are changed through the Project or its ProjectTemplate, and a direct edit of one on an additional namespace is reverted. Thanks to the template label, the cluster resource availability rules also apply in all namespaces of the project.

The following stays in the **main** namespace only:

- The annotations from the template's `namespaceMetadata`
- The labels and annotations set on the main namespace directly or by a GitOps tool, including the ones the namespace had before it became a project, other than the pod security, monitoring and scanning labels above
- The GitOps tracking labels (`app.kubernetes.io/instance`, `argocd.argoproj.io/*`,

`kustomize.toolkit.fluxcd.io/*`, `helm.toolkit.fluxcd.io/*`, `kapp.k14s.io/*`), even when the template sets them
- The node placement annotations (from the template's `nodeSelector` and `tolerations` fields)

GitOps tracking labels are not inherited because a GitOps tool would treat an additional namespace that carries them as its own and could delete it. The module recognizes only the keys listed above. A custom tracking key that the template sets, for example the one configured with `application.instanceLabelKey` in Argo CD, is inherited.

When a namespace becomes a project automatically, its own labels and annotations stay on it and are not copied into the Project, so the additional namespaces of the project do not inherit them. The pod security, monitoring and scanning labels are the exception. Adoption turns them into parameters of the project, and they are inherited as on any project. To put another label of such a namespace on the additional namespaces too, declare it in `spec.parameters.namespace.labels` of the Project, or set it on each additional namespace directly.

The built-in templates of adopted projects are rewritten by the controller, so a label added to their `namespaceMetadata.labels` does not stay there. A grant policy whose `namespaceSelector` matches such a label does not cover the new additional namespaces until the label is declared in the Project. To cover the whole project, select it with `projectSelector`.

Labels of the project namespaces

Label	Main	Additional	Purpose
`projects.deckhouse.io/project: <PROJECT_NAME>`	✓	✓	Project ownership — the common label of all namespaces of the project
`projects.deckhouse.io/project-namespace: <spec.name>`	—	✓	Marks an additional namespace (the name of the ProjectNamespace resource)
`projects.deckhouse.io/project-template: <PROJECT_TEMPLATE_NAME>`	✓	✓	The project template; the cluster resource availability rules match by it
`heritage: multitenancy-manager`	✓	✓	The namespace is managed by the project controller: its `spec`, finalizers and the labels listed in this table are changed through the Project; other labels and annotations may be changed directly
`projects.deckhouse.io/quota: pending`, `projects.deckhouse.io/quota: enforced`	✓	✓	The namespace belongs to a project with a quota; only the controller sets the label
`quota.projects.deckhouse.io/vm: enforced`, `quota.projects.deckhouse.io/lb: enforced`	✓	✓	The quota of the project has keys of virtual machines or of load balancers
`security.deckhouse.io/pod-policy`, `extended-monitoring.deckhouse.io/enabled`, `security-scanning.deckhouse.io/enabled`	✓	✓ (inherited)	Policies and features from the project template

Label	Main	Additional	Purpose
Labels from the template's `namespaceMetadata.labels`	✓	✓ (inherited)	Labels of the project template. They are listed in the `projects.deckhouse.io/template-labels` annotation of the namespace and changed through the Project or its ProjectTemplate
Any other label set on a namespace directly or by a GitOps tool, including the labels a namespace had before it became a project	—	—	Not set by the module. The project release neither reverts nor restores it, and the additional namespaces do not inherit it

The common `projects.deckhouse.io/project` label makes it possible to select the project namespaces with a plain `get ns`. To get all namespaces of the project (main and additional), use the command:

```
d8 k get ns -l projects.deckhouse.io/project=my-project
```

To get additional namespaces only:

```
d8 k get ns -l 'projects.deckhouse.io/project=my-
project,projects.deckhouse.io/project-namespace'
```

To get the main namespace only:

```
d8 k get ns -l 'projects.deckhouse.io/project=my-
project,!projects.deckhouse.io/project-namespace'
```

Creating a project automatically for a namespace

A namespace created directly (for example, `d8 k create ns my-app`) becomes a project with the same name:

- the template is picked from what the namespace already carries: `secure` if it has the `security-scanning.deckhouse.io/enabled` label, `default` if it has `security.deckhouse.io/pod-policy` or `extended-monitoring.deckhouse.io/enabled`, and `simple` otherwise;
- the project parameters are filled in from the current state of the namespace, so nothing inside it changes: the network policy stays unrestricted and the Pod Security Standard keeps the value the namespace already had;
- from then on the project is the source of truth and is edited like any other project. The namespace of the project cannot be deleted directly: the request is refused with the `Manual modification is forbidden` message. To remove the environment, delete the Project: `d8 k delete project <NAME>` deletes the namespace with it and returns once the namespace is gone. Only a user allowed to delete the namespace can delete its Project (see Additional project namespaces).

Users can create a namespace directly only while the `allowNamespacesWithoutProjects` parameter is `true` (the default). With `false`, only cluster administrators (`system:masters`, `system:sudouser`), Deckhouse, the module controller and system components create namespaces directly (see Who bypasses admission). Other users create a Project or a ProjectNamespace instead.

Every such namespace becomes a project of its own, whatever its name. Of the namespaces `app` and `app-staging`, `app-staging` becomes a separate project and not an additional namespace of `app`. The controller creates the project, so no admission warning reaches the author of the namespace. Instead, the controller sends the `NamedLikeAdditionalNamespace` Warning event on the new project and on the namespace. The events of cluster-scoped objects are kept in the `default` namespace, so reading them needs access to the events there: `d8 k -n default get events --field-selector reason=NamedLikeAdditionalNamespace`. The `MultitenancyManagerProjectNamedLikeAdditionalNamespace` alert lists such pairs, see Project naming rules.

System namespaces (`d8-*`, `kube-*`, `upmeter-*`, `default`, and anything labeled `heritage:`

`deckhouse` or `heritage: upmeter`) are never adopted: they are listed on the virtual `deckhouse` project (except `default`, which stays on the virtual `default` project). No label leaves a new user namespace without a project: users cannot put the `heritage: upmeter` label on a namespace, and only the module sets the `projects.deckhouse.io/project` label. A namespace whose name is longer than 61 characters (the Project name limit) is also skipped, and so is a namespace named `deckhouse`: a Project of that name is the virtual project.

So that no namespace stays outside a project, the `d8-multitenancy-manager-namespace-adoption` ValidatingAdmissionPolicy refuses to create a namespace whose name is longer than 61 characters, starts with `upmeter-` or is `deckhouse`, and to put the `heritage: upmeter` label on a namespace. The policy works whatever `allowNamespacesWithoutProjects` says and lets through the users and groups listed for the `d8-multitenancy-manager-namespace-creation` policy in Who bypasses admission. A namespace that stays without a project for 10 minutes, for example while no replica of the module controller leads, raises the `D8NamespaceNotAdopted` alert. The controller pods export the metric of the alert, so the alert is not raised while none of the pods is `Ready`.

The policy does not change the namespaces that exist already, so a namespace that was created before it, with one of these names or with the `heritage: upmeter` label, stays outside every project. To list the namespaces that belong to no project and are not system ones, run:

```
d8 k get namespaces -l '!projects.deckhouse.io/project,heritage!=deckhouse' -o name | grep -Ev '^namespace/(d8-|kube-|default$|upmeter-probe-namespace-)'
```

The list holds the namespaces that get no project: the names longer than 61 characters, `deckhouse`, the other `upmeter-*` names and the namespaces with the `heritage: upmeter` label. The namespaces of the upmeter agent can be among them, and they must not be changed. To bring a namespace under a project, remove the `heritage: upmeter` label from it (if its name does not start with `upmeter-`), and the controller creates the project. Otherwise, move the workloads of the namespace to a namespace under another name. A namespace with an empty `projects.deckhouse.io/project` label is not in the list, `d8 k get namespaces -l 'projects.deckhouse.io/project='` lists such namespaces.

On adoption, a namespace that gets the `default` or `secure` template because of its monitoring or scanning label, and has no `security.deckhouse.io/pod-policy` label, gets `podSecurityProfile: ""`. The project puts no such label on it, and the default policy of the `admission-policy-engine` module keeps applying to it. A namespace whose label has a value other than `baseline`, `restricted` or `privileged` gets `podSecurityProfile: ""` too, and the label stays on it as it is. A namespace with none of these labels gets the `simple` template, which sets no profile and has no `podSecurityProfile` parameter.

To change the profile later, set `podSecurityProfile` in the project. For a project on `simple`, first move it to `default` with `networkPolicy: NotRestricted`, `requiredRequests: false` and `extendedMonitoringEnabled: false`, so that nothing else changes.

A namespace that already belongs to another Helm release (its `meta.helm.sh/release-name` annotation names a release other than the project's) is not taken over: the project gets the `HelmOwnership` condition with the name of the foreign release and retries, and the namespace is left as it is. Remove the foreign release or its ownership annotations to let the project proceed.

Existing RoleBinding and AuthorizationRule objects inside the namespace keep working after adoption. The namespace Admin is **not** copied into `.spec.administrators` and does **not** become `d8:project:admin`: that role additionally manages ProjectRoleBinding resources, which is a wider contract than in-namespace Admin. To make the team lead a project administrator, a platform operator adds them to `.spec.administrators` or creates a ProjectRoleBinding. The namespace Admin role allows only `get`, `list` and `watch` on the Namespace object.

The labels and annotations the module sets — `heritage`, `projects.deckhouse.io/*`, `quota.projects.deckhouse.io/vm`, `quota.projects.deckhouse.io/lb`, `security.deckhouse.io/pod-policy`, `extended-monitoring.deckhouse.io/enabled`, `security-scanning.deckhouse.io/enabled`, `app.kubernetes.io/managed-by`, `meta.helm.sh/*`, the node-selector and tolerations annotations — are changed through the Project and its template; any other label or annotation (`istio-injection`, a Pod Security label, a GitOps tracking annotation) can still be set directly on the Namespace by anyone whose RBAC allows it, and the controller does not touch it. The `spec` and finalizers of the Namespace, and its deletion, stay with the controller.

This includes the labels and annotations the namespace had before it became a project. Adoption does not copy them into the project, so the project release does not own them, and the controller neither reverts a change to one of them nor brings one back once it is removed. They stay on the main namespace, and the additional namespaces of the project do not inherit them. Where such a label is needed on an additional namespace too, declare it in `spec.parameters.namespace.labels` of the Project or set it on that namespace directly.

The node-selector and tolerations annotations are the exception. They belong to the module, so

adoption copies them into the `namespace.annotations` parameter of the project, where they are changed or removed. The pod security, monitoring and scanning labels are turned into parameters of the project, and the additional namespaces inherit them. The `extended-monitoring.deckhouse.io/enabled` and `security-scanning.deckhouse.io/enabled` labels keep the value `"true"` if the namespace had it. Any other value, `"false"` included, is replaced with an empty one, because adoption turns the feature on whenever the namespace carries the label, whatever its value.

The `projects.deckhouse.io/project` label itself is set only by the controller: a namespace created by hand with that label is refused, an empty value included, so a namespace cannot be made to look owned by a project it does not belong to. A namespace belongs to the project its label names and to no other: one without the label, or with an empty value, is not counted towards the project of the same name. A namespace that already carries the empty value is not adopted either: the empty value used to keep a namespace out of adoption, and it still does until the label is removed.

For example:

1. Create a new namespace:

   ```
   d8 k create ns test
   ```

2. Make sure that the project was created:

   ```
   d8 k get projects
   ```

   A new project corresponding to the namespace will appear in the project list:

   ```
   NAME        STATE      PROJECT TEMPLATE   DESCRIPTION
   AGE
   deckhouse   Deployed   virtual            This is a virtual project
   181d
   default     Deployed   virtual            This is a virtual project
   181d
   test        Deployed   simple
   1m
   ```

To change the template of such a project, set another template in `.spec.projectTemplateName`.

⚠ If the namespace already has an object of the same kind and name as one that the new template creates, for example the `isolated` NetworkPolicy, the project switches to `Error`, and the `ResourcesUpgraded` condition names the object. Delete or rename the object first.

Standard project fields

Project administrators and the resource quota are set in fields of the Project and work with any template (including `simple`):

- `.spec.administrators` — a list of subjects (`kind: User` or `kind: Group` and `name`) that receive administrative access to the project. The controller manages this access as an auto-generated ProjectRoleBinding in the project namespace. A name cannot contain control characters or line breaks and cannot start with `system:multitenancy-manager:`, the prefix of the users that the controller acts as. An update that keeps such a name as it was is accepted with a warning.
- `.spec.quota` — a map of ResourceQuota hard limits (for example, `requests.cpu`, `limits.memory`) for the whole project. The controller turns it into the ProjectQuotaStatus of the project and reports the usage summed over the namespaces of the project in `.status.usage`; clearing the field deletes that ProjectQuotaStatus. Changing the field needs the right to set the quota of the project, and its keys follow the rules of the project quota. For `memory` and `storage`, a unit suffix is required (for example `2Gi`). Numbers without a unit mean bytes, and all of them except 0 are rejected. An update that leaves such a value as it was is accepted with a warning, so a project whose quota came from bare numbers in `parameters.resourceQuota` stays editable and can still be applied unchanged. A create through `deckhouse.io/v1alpha2` with such numbers in `parameters.resourceQuota` is accepted with a warning as well, so such a manifest can create the project again, for example from a backup.

```
apiVersion: deckhouse.io/v1alpha3
kind: Project
metadata:
  name: my-project
spec:
  projectTemplateName: simple
  administrators:
    - kind: Group
      name: k8s-admins
  quota:
    requests.cpu: "5"
    requests.memory: 5Gi
    limits.cpu: "10"
    limits.memory: 10Gi
```

⚠ A Helm `resourcesTemplate` that renders a ResourceQuota or an AuthorizationRule keeps rendering it, next to the ResourceQuota and the ProjectRoleBinding that the standard fields create. A pod in such a project has to fit every ResourceQuota of its namespace, and the access such AuthorizationRules grant adds to the access of the standard fields.

Project quota

The project quota is one limit on the sum of resource usage over all namespaces of a project, the additional namespaces included. It is set in the `.spec.quota` field of the project:

```
apiVersion: deckhouse.io/v1alpha3
kind: Project
metadata:
  name: my-project
spec:
  projectTemplateName: default
  quota:
    requests.cpu: "20"
    requests.memory: 40Gi
    projectNamespaces: "3"
```

From the field the controller makes the ProjectQuotaStatus object named after the project and keeps it up to date. The object shows the limits and the usage of the project and is read-only: only the controller creates, changes and deletes it. Clearing the field deletes it.

How the quota applies:

- The controller creates the `d8-project-quota` ResourceQuota with the limits of `spec.hard` in every namespace of the project, the ones added later included. This ResourceQuota counts the usage of its namespace, so no namespace alone uses more than the whole project may.
- A namespace that the quota applies in carries the `projects.deckhouse.io/quota: enforced` label once its `d8-project-quota` is calculated by kube-controller-manager. A namespace created for a ProjectNamespace carries `projects.deckhouse.io/quota: pending` from the start until then, and the main namespace of a project that has not been deployed yet gets it when the quota of the project is applied, so the manifests of the template wait for the quota too, however long the first attempts to deploy the project fail. The main namespace of a project that has been deployed (in the `Deployed` state), as on an upgrade of the module or when a quota is set on a running project, is not held. The label is set by the controller only.
- In a namespace labelled `projects.deckhouse.io/quota: pending`, the `d8-multitenancy-manager-quota-pending` admission policy refuses the objects of users until `d8-project-quota` is calculated, and the ProjectNamespace reports `Ready=False`. That takes seconds after a namespace is created. In a namespace labelled `projects.deckhouse.io/quota: enforced`, the `d8-multitenancy-manager-quota-guard` admission policy refuses the objects the quota counts while `d8-project-quota` has no limits calculated at all or has scopes. A limit added to a quota that is calculated already does not hold anything back: it applies once kube-controller-manager has calculated it, and `Enforced` is `False` with the `KeyRollout` reason until then.
- A ProjectQuotaStatus is deleted in two steps: its `projects.deckhouse.io/project-quota` finalizer holds it until the controller has taken the label off the namespaces, and only then the `d8-project-quota` ResourceQuota objects go with it. A namespace that is being deleted loses the

label at once, so that the objects waiting for a finalizer there, such as the volume claims protected from deletion, can be updated. If the module is disabled before the finalizer is removed, remove it by hand.

- The status of the ProjectQuotaStatus shows the usage summed over the namespaces (`status.used`), the number of namespaces and the 50 namespaces closest to a limit. The usage of every namespace is in its `d8-project-quota` ResourceQuota:

  ```
  d8 k get resourcequota -A -l projects.deckhouse.io/project=my-project
  ```

- In a namespace labelled `projects.deckhouse.io/quota: enforced`, creating an object that takes the usage of the whole project over a limit is denied with HTTP 403:

  ```
  admission webhook "quota-ledger.multitenancy-manager.deckhouse.io" denied the request: exceeded
  quota: d8-project-quota, project my-project: requested: requests.cpu=500m, used:
  requests.cpu=19800m, limited: requests.cpu=20 (3 namespaces)
  ```

  The webhook, called the quota ledger, keeps the sum of every project in the memory of its leader in the `quota-ledger` container of the module pod. While no replica answers (for a few seconds when the leader changes), a counted create in a namespace of a quota project fails with `project quota ledger unavailable (<CAUSE>), retry`; deletions, running objects and namespaces without the quota are not affected. A Deployment or a Job retries such a create by itself. The same answer comes at once, with the `too many approvals of the project are not confirmed yet` cause, for a write that would wait for the earlier approvals of its project to be confirmed while two writes from the same API server already wait: the third waiting write of a project from one API server gets a 503, and its controller retries it.

- The sum is not checked for a request with `--dry-run=server`: the API server does not write the usage of a dry run. The quota of the namespace is still checked.
- The `Enforced` condition says whether the quota applies in every namespace, and the `Exceeded` condition whether the usage is above a limit. A limit may be lowered below the current usage: the change is accepted with a warning, nothing running is evicted, and `Exceeded` is `True` with the `HardLowered` reason. The `D8ProjectQuotaExceeded` alert fires then.

Keys of a project quota

`.spec.quota` accepts the following keys:

- `cpu`, `memory`, `ephemeral-storage`, `pods`, `requests.*` and `limits.*` of CPU, memory and ephemeral storage, `requests.storage`, `requests.hugepages-<SIZE>`, the requests of extended resources (for example, `requests.nvidia.com/gpu`);
- `services`, `services.loadbalancers`, `services.nodeports`, `persistentvolumeclaims`, `configmaps`, `secrets`, `replicationcontrollers`;
- `<CLASS>.storageclass.storage.k8s.io/requests.storage` and `<CLASS>.storageclass.storage.k8s.io/persistentvolumeclaims`, `<CLASS>.deviceclass.resource.k8s.io/devices`;
- `count/<RESOURCE>[.<GROUP>]` for a namespaced resource the API server serves, for example `count/ingresses.networking.k8s.io`;
- `projectNamespaces`, an alias of `count/projectnamespaces.deckhouse.io`: the number of ProjectNamespace objects of the project, that is, of its additional namespaces. The alias is expanded in the ResourceQuota objects, and the object keeps it as written.
- the keys of virtual machines and of load balancers, which no ResourceQuota counts.

Refused are `resourcequotas` and `count/resourcequotas` (`d8-project-quota` takes one in every namespace by itself), the count of a cluster-scoped resource such as `count/namespaces`, a resource misspelled in a served group, a `count/` key of a resource that lacks one of the verbs create, list, watch and delete, and the keys with the reserved `projectquota.deckhouse.io/` prefix. A `count/` key of a group the API server does not serve yet is accepted with a warning: nothing counts it until the module that provides the group is enabled, and `Enforced` is `False` with the `KeyNotServed` reason until then. A change that keeps a key the object already has is accepted with a warning even when the key would be refused now.

A new key in a live quota starts to apply once `d8-project-quota` of every namespace has it calculated; until then `Enforced` is `False` with the `KeyRollout` reason.

Pods and volume claims with `resource-quota-overrides.deckhouse.io/*` labels set by platform controllers are counted as a ResourceQuota counts them.

Virtual machines in a project quota

Where the `virtualization` module is enabled, a project quota limits the virtual machines of the

project by their specification. No ResourceQuota counts these keys, so they do not go into `d8-project-quota`: the quota ledger checks every create of a VirtualMachine and every change of its `spec` in the namespaces of a project whose quota has them, and counts the virtual machines itself in these keys:

- `virtualmachines.virtualization.deckhouse.io/cores`: Sum of `spec.cpu.cores`.
- `virtualmachines.virtualization.deckhouse.io/cpu`: Guaranteed CPU, the sum of cores × `spec.cpu.coreFraction`. An empty `spec.cpu.coreFraction` or `Auto` counts as whole cores.
- `virtualmachines.virtualization.deckhouse.io/memory`: Sum of `spec.memory.size`.
- `virtualmachines.virtualization.deckhouse.io/gpus`: Number of GPUs in `spec.gpus`.
- `<GPU CLASS>.gpuclass.virtualization.deckhouse.io/gpus`: Number of GPUs of the `<GPU_CLASS>` GPUClass.

The number of virtual machines is limited by the ordinary `count/virtualmachines.virtualization.deckhouse.io` key.

Every virtual machine counts in the keys above, a stopped one too: a machine stopped by hand may be started at any moment. Only a machine with `runPolicy: AlwaysOff`, which is kept switched off on purpose, is not counted in them; the `count/virtualmachines.virtualization.deckhouse.io` key counts such machines too. A change that does not raise a key, such as making a machine smaller or stopping it, is never refused over the quota and passes even while the quota ledger does not answer; every other create and change of `spec` needs the ledger to answer. A change that touches only the metadata of a machine does not call the ledger. A smaller spec frees the quota only once the machine runs with it: until a restart applies it, the machine counts with the cores and memory it runs with (`status.resources`) and with the GPUs that the changes in `status.restartAwaitingChanges` show. Until the `virtualization` module has processed a change of the spec, the machine keeps what it counted before. The namespaces of such a project carry the `quota.projects.deckhouse.io/vm: enforced` label, which the controller sets. While the `virtualization` module is disabled, the keys count nothing, and `Enforced` is `False` with the `KeyNotServed` reason. The quota is accepted with a warning when the API server does not serve VirtualMachine.

The pod of a virtual machine counts in `requests.*` and `limits.*` as well, twice while the machine migrates. A quota that has both the keys of virtual machines and the keys of pods (`cpu`, `memory`, `requests.*`, `limits.*`) is accepted with a warning. Limit virtual machines with their keys and containers with `requests.*` and `limits.*`.

Load balancers in a project quota

A project quota limits the Services of type LoadBalancer of the project by their class, by their pool and by the external addresses they take. No ResourceQuota counts these keys, so they do not go into `d8-project-quota`: the quota ledger checks every create of a Service that is or was of type LoadBalancer, and every change of its `spec` or of the `network.deckhouse.io/metal-load-balancer-class`, `network.deckhouse.io/l2-load-balancer-external-ips-count`, `network.deckhouse.io/load-balancer-ips` and `network.deckhouse.io/load-balancer-pool` annotations, in the namespaces of a project whose quota has them, and counts the Services itself in these keys:

- `<CLASS>.loadbalancerclass.network.deckhouse.io/services`: Number of load balancers of the `<CLASS>` class.
- `<CLASS>.loadbalancerclass.network.deckhouse.io/addresses`: External addresses of the `<CLASS>` class.
- `<POOL>.loadbalancerpool.network.deckhouse.io/addresses`: Addresses taken from the `<POOL>` pool of the BGP mode.
- `loadbalancers.network.deckhouse.io/addresses`: All external addresses of the project.

The number of load balancers of any class is limited by the ordinary `services.loadbalancers` key.

The class of a Service is the one the `metallb` module serves it with. It comes from the first source that applies:

- The class the `metallb` module has bound the Service to in its status, even if no such MetalLoadBalancerClass exists
- `spec.loadBalancerClass`, when such a MetalLoadBalancerClass exists
- The `network.deckhouse.io/metal-load-balancer-class` annotation, when such a MetalLoadBalancerClass exists
- The MetalLoadBalancerClass with `isDefault: true`
- `spec.loadBalancerClass` without a check, the class of another load balancer controller
- `default`, the load balancers of a cloud provider

Where the API server does not serve MetalLoadBalancerClass, no class is checked: the class is `spec.loadBalancerClass`, else `default`, and the annotation, which only the `metallb` module reads, does not count. The quota ledger notices within 30 seconds that the `metallb` module has been enabled or disabled, and counts the load balancers again without a restart.

A Service with the `network.deckhouse.io/load-balancer-pool` annotation takes one address of that pool. Any other Service takes the number of addresses from its `network.deckhouse.io/l2-load-`

`balancer-external-ips-count` annotation when the value is a number above one, and one address when the annotation has any other value. The `network.deckhouse.io/load-balancer-ips` annotation only picks which addresses the Service takes, as the `metallb` module assigns them.

Every Service of type LoadBalancer counts its own addresses, also when it shares an address with other Services under the `network.deckhouse.io/load-balancer-shared-ip-key` annotation: two Services that share one address take two addresses of the quota. The namespaces of such a project carry the `quota.projects.deckhouse.io/lb: enforced` label, which the controller sets.

Clusters where Deckhouse Platform does not manage the control plane

The sum over the namespaces of a project is enforced only where Deckhouse Platform manages the control plane of the cluster (the `control-plane-manager` module is enabled). Elsewhere the `d8-multitenancy-manager-quota-pending` and `d8-multitenancy-manager-quota-guard` admission policies are not rendered, every ProjectQuotaStatus reports `Enforced=False` with the `ControlPlaneNotManaged` reason, and the `D8ProjectQuotaNotSupported` alert says so. Each namespace still keeps its `d8-project-quota` ResourceQuota, so no namespace alone uses more than the quota of the whole project.

Dividing a project quota between namespaces

A project administrator may create ResourceQuota objects of their own in the namespaces of the project. Such a quota only narrows the project quota: an object has to fit every ResourceQuota of its namespace. A quota of a project administrator cannot be named `d8-project-quota` and cannot limit `resourcequotas` or `count/resourcequotas`. A `d8-project-quota` that the controller did not create, or one with scopes, is deleted and created again by the controller.

For example, to keep the `my-project-db` namespace within a quarter of the CPU of the project:

```
apiVersion: v1
kind: ResourceQuota
metadata:
  name: db-share
  namespace: my-project-db
spec:
  hard:
    requests.cpu: "5"
```

Who manages the quotas

Changing `.spec.quota` of a Project needs the `update` verb on `projects/quota` in the `deckhouse.io` group for that project, which the `d8:system-capability:multitenancy-manager:manage_quotas` capability grants; the IAM `manager` role and the roles above it include the capability. The Project webhook checks the right, so whoever may create and change projects does not choose their quota. A ProjectQuotaStatus is written by the controller only; everyone else, cluster administrators included, can only read it. The usage in the status of `d8-project-quota` is written by Kubernetes; it is protected from other writers where Deckhouse Platform manages the control plane.

When the project quota refuses

What the response says:

Response	What it means
`403 ... exceeded quota: d8-project-quota, project <PROJECT NAME>: requested: ..., used: ..., limited: ... (<N> namespaces)`	The sum of project `<PROJECT_NAME>` would go over the limits of its quota. Raise the limits in `.spec.quota` of the project or delete what the project does not need; `status.topNamespaces` of its ProjectQuotaStatus shows where the usage is.
`403 ... exceeded quota: d8-project-quota, requested: ...` (no `project`)	The usage of this namespace alone, with the object, would go over a limit of the project, which every `d8-project-quota` ResourceQuota contains. The quota plugin of the API server refuses it before the sum of the project is checked.

Response	What it means
`503 ... project quota ledger unavailable (<CAUSE>), retry`	The ledger does not answer for a moment, for example while its leader changes. Retry; if it lasts longer than a minute, see the `D8ProjectQuotaLedgerDown` alert.
`500 ... failed calling webhook "quota-ledger.multitenancy-manager.deckhouse.io": ...`, or the same with `quota-vm.multitenancy-manager.deckhouse.io` or `quota-lb.multitenancy-manager.deckhouse.io`	The API server does not reach the ledger: no replica runs, the network, or the certificate. While the Service points at a frozen leader, the quota plugin of the API server retries the call, so each such create waits up to about 8 seconds until the address of the leader is taken out of the Service: in about 3.5 seconds by the other replica, in up to about 15 seconds by Deckhouse when no replica answers.
`403 ... ValidatingAdmissionPolicy 'd8-multitenancy-manager-quota-pending' ...`	The `d8-project-quota` of a new namespace is not calculated yet. Retry in a few seconds; if it lasts, see the `Enforced` condition of the ProjectQuotaStatus of the project and check the controller and kube-controller-manager.
`403 ... ValidatingAdmissionPolicy 'd8-multitenancy-manager-quota-guard' ...`	The `d8-project-quota` of the namespace is missing, has scopes or is not calculated at all yet. Retry in a few seconds; otherwise check the controller and kube-controller-manager.
`500 ... resource quota evaluation timed out`	The quota admission of the API server is overloaded; see the `D8ResourceQuotaAdmissionDegraded` alert.

A new additional namespace refuses the objects of users for the few seconds until its `d8-project-quota` is calculated. A namespace where the quota applies and whose `d8-project-quota` is gone does the same until the controller makes it anew, and refuses the objects of `system:sudouser` too. Of the users, only `system:sudouser` can delete `d8-project-quota`.

If the ledger keeps the objects of projects from being created and the cause cannot be removed quickly, take these steps in order until the creates work again:

1. If the creates fail with `503 ... project quota ledger unavailable`, a replica answers, and suspending the ledger helps. Within a second every running replica lets the writes through uncounted, and every ProjectQuotaStatus reports `Enforced=False` with the `Suspended` reason. Deleting the ConfigMap resumes the check; the `D8ProjectQuotaSuspended` alert reminds of it after 15 minutes.

   ```
   d8 k -n d8-multitenancy-manager create configmap quota-ledger-suspend --from-literal=reason="<REASON>"
   d8 k -n d8-multitenancy-manager delete configmap quota-ledger-suspend
   ```

   Replace `<REASON>` with why the check is suspended.

2. If the creates fail with `500 ... failed calling webhook "quota-ledger.multitenancy-manager.deckhouse.io"`, the API servers do not reach a replica that answers, as while the `D8ProjectQuotaLedgerDown` alert fires, and the suspension does not help: delete the webhook of the ledger as `system:sudouser`. The check stops within a second, and every ProjectQuotaStatus reports `Enforced=False` with the `WebhookMissing` reason. Deckhouse Platform finds the webhook of the module missing and puts it back by itself within about 4 minutes, so this buys time to fix the cause rather than switching the check off.

   ```
   d8 k --as=system:sudouser delete validatingwebhookconfiguration d8-multitenancy-manager-quota-ledger
   ```

   Check that the webhook is back: `d8 k get validatingwebhookconfiguration d8-multitenancy-manager-quota-ledger`.

3. Disable the `multitenancy-manager` module. The check goes away together with everything else the module does for projects.

Before draining the worker nodes of a cluster with project quotas (evicting the pods from the nodes with `d8 k drain` or on a node update), check that the ledger has a leader (`d8_multitenancy_quota_ledger_leader`) and that the `D8ProjectQuotaLedgerCanaryFailing` alert

is not firing: while the ledger does not answer, the pods that replace the evicted ones are not created in the namespaces of projects with a quota.

Granting access within a project

To grant access to project namespaces for users beyond the project administrators, use role bindings that reference cluster-wide roles and fan out into the appropriate project namespaces automatically:

- ProjectRoleBinding (namespaced, short name `prb`) — grants a role within a **single** project. It must be created in the project's main namespace (the namespace whose name equals the project name). The controller creates a RoleBinding in every namespace of that project.
- ClusterProjectRoleBinding (cluster-scoped, short name `cprb`) — grants a role across **all** non-virtual projects. The controller creates a RoleBinding in every namespace of every project and reports the number of bound projects in `.status.boundProjects`.

`roleRef` must reference a ClusterRole whose name starts with one of the allowed prefixes (`d8:project:`, `d8:namespace:`, `d8:project-capability:`, `d8:namespace-capability:`, `d8:custom:`). The roles are described in the `user-authz` module documentation.

The following checks apply when bindings are created:

- **Privilege escalation protection**: a binding can only be created by a user who has the right to bind (`bind`) the referenced role, checked by name. A project administrator (`d8:project:admin`) holds `bind` on exactly eight roles: `d8:project:viewer`, `d8:project:user`, `d8:project:manager`, `d8:project:admin`, `d8:namespace:viewer`, `d8:namespace:user`, `d8:namespace:manager` and `d8:namespace:admin`. A binding to any other role — a custom `d8:custom:*` role, a capability, `d8:project:superadmin` — is refused for the project administrator even when the role is narrower than their own permissions, because nothing grants them `bind` on that name. Such bindings are created by a cluster administrator, or the cluster administrator grants `bind` on the custom role to the project administrators with a ClusterRole of their own.
- The role must exist: a binding to a non-existent role is rejected.
- A ServiceAccount used as a subject of a ProjectRoleBinding must belong to a namespace of that same project. Its main namespace, its additional namespaces and a namespace a ProjectNamespace of the project has claimed qualify. A namespace that is only named like an additional namespace (`<project>-*`) but belongs to a separate project does not. When the binding is updated, a ServiceAccount the stored binding already has is not refused again. If its namespace is no longer a namespace of the project, the response carries a warning that this ServiceAccount gets no rights from the binding.
- System and subsystem roles (`d8:system:*`, `d8:subsystem:*`), as well as arbitrary roles outside the listed prefixes, cannot be granted via project bindings.
- Roles with the `rbac.deckhouse.io/disabled-for-direct-use-in-projects: "true"` annotation are forbidden for granting in projects. A cluster administrator can put this annotation on a role to phase it out: existing bindings keep working, but new ones cannot be created. If such a role is used by a project template, the project switches to the `Error` state with an explanation in the `TemplateRolesAllowed` condition.

The controller checks the ServiceAccounts by the same rule every time it updates the RoleBindings of a ProjectRoleBinding, and also when a namespace appears, is deleted or moves to another project. A subject that names ServiceAccounts goes into the RoleBindings only while their namespace is the main namespace of the project, or exists, is not being deleted and carries the `projects.deckhouse.io/project` label with the project name. Besides subjects of the `ServiceAccount` kind, this applies to the `User` subject named `system:serviceaccount:<namespace>:<name>` and the `Group` subject named `system:serviceaccounts:<namespace>`, which RBAC matches to the same ServiceAccounts. Other users and groups are not affected. So a ServiceAccount of a deleted additional namespace gets no rights when a separate project takes the name later.

The left-out subjects stay in `.spec.subjects`. The `SubjectsBound` condition of the binding is `False` and lists them, and the `SubjectsLeftOut` Warning event is sent when the list changes. The `Ready` condition stays `True`, as the binding keeps working for the other subjects. Once the namespace is a namespace of the project again, for example after the deleted ProjectNamespace is created again, the subjects get the rights back without a change to the binding. You can check the condition in the status of the binding:

```
d8 k -n my-project get projectrolebinding ci -o jsonpath='{.status.conditions[?
(@.type=="SubjectsBound")]}'
```

The `d8-administrators` binding created by the controller from the `.spec.administrators` field is managed by the controller only — it cannot be edited manually. To change the set of administrators, change the `.spec.administrators` field of the project.

The ServiceAccount rule above does not apply to this binding. An administrator given as the `User system:serviceaccount:<namespace>:<name>` or the `Group system:serviceaccounts:<namespace>` gets the rights in every namespace of the project, whichever project that namespace belongs to, because only those allowed to change the Project set its administrators. Remove such an administrator from the project before its namespace is deleted, as the ServiceAccounts of a namespace created later under the same name would get these rights.

The following bindings give the `viewer@example.com` user the `d8:project:viewer` role in every namespace of `my-project`, and the `platform` group the same role in every project except the virtual ones:

```
---
apiVersion: deckhouse.io/v1alpha3
kind: ProjectRoleBinding
metadata:
  name: viewers
  namespace: my-project
spec:
  subjects:
    - kind: User
      name: viewer@example.com
  roleRef:
    kind: ClusterRole
    name: d8:project:viewer
---
apiVersion: deckhouse.io/v1alpha3
kind: ClusterProjectRoleBinding
metadata:
  name: platform-viewers
spec:
  subjects:
    - kind: Group
      name: platform
  roleRef:
    kind: ClusterRole
    name: d8:project:viewer
```

Roles available in a RoleBinding inside a project

Besides the project bindings, a plain RoleBinding can also be used inside a project namespace — the role then applies in that single namespace only. However, in projects the set of roles available to a plain RoleBinding is restricted: only cluster roles carrying the `rbac.deckhouse.io/delegatable: "true"` label are allowed. Among the built-in ones these are the `d8:namespace:*` and `d8:project:*` roles, as well as the access-level roles of the basic role model (`user-authz:user`, `user-authz:privileged-user`, `user-authz:editor`, `user-authz:admin`).

A RoleBinding to any other cluster role (for example, `cluster-admin`, system roles, or capabilities) is rejected in a project with the message `references "<role>" which is not available to project`. This protects the project isolation from being bypassed by binding to an overly broad role.

To use a custom role in projects, add the `rbac.deckhouse.io/delegatable: "true"` label to it:

```
d8 k label clusterrole d8:custom:namespace:developer rbac.deckhouse.io/delegatable=true
```

The restriction applies in the namespaces of every project, including the ones adopted from a standalone namespace.

Structured templates

A `deckhouse.io/v1alpha2` project template is described by **structured fields**. You declaratively specify which settings the project namespaces get. The controller itself creates the corresponding objects (network policies, security policies, log collection settings, etc.) from these fields in every namespace of the project and keeps them up to date. Other objects of the project namespaces are described in `manifests`.

Available fields (all optional; the complete reference is in the ProjectTemplate resource description):

Field	What it configures
`podSecurityStandard`	Pod security profile: `Privileged`, `Baseline`, or `Restricted`. A parameter with an empty value sets no profile
`networkPolicy.mode`	Network isolation: `Isolated` (traffic is only allowed within the project and from the platform system components) or `NotRestricted`
`features.monitoring`	Extended monitoring of the project namespaces
`features.vulnerabilityScanning`	Scanning of container images for vulnerabilities
`logShipping.clusterDestinationRef`	Collecting the logs of the project pods into the given destination (`ClusterLogDestination`)
`nodeSelector`, `tolerations`	Placing the pods of the main namespace on dedicated nodes
`allowedUIDs`, `allowedGIDs`	The allowed UID/GID ranges of the project containers
`runtimeAudit.enabled`	Auditing the project processes' access to the Linux kernel
`namespaceMetadata.labels`, `namespaceMetadata.annotations`	Extra labels and annotations of the project namespaces. The labels the module manages cannot be set here. A template or a Project that sets one is refused. One that already has such a label can still be changed while it keeps the label as it is. The label is not applied, and the response warns about it
`resources`, `grantPolicies`	Granting cluster-wide resources through a project template
`manifests`	Other objects in the project namespaces, applied with the rights of a project administrator. For details, see Describing other objects in manifests
`parametersSchema.openAPIV3Schema`	The schema of parameters set when creating a project

An example of a structured template:

```
apiVersion: deckhouse.io/v1alpha2
kind: ProjectTemplate
metadata:
  name: my-template
spec:
  title: "Team template"
  description: "Isolated project with monitoring"
  podSecurityStandard: Baseline
  networkPolicy:
    mode: Isolated
  features:
    monitoring: true
    vulnerabilityScanning: true
```

Template parametrization

The following fields of the template can take a parameter: `podSecurityStandard`, `networkPolicy.mode`, `features.monitoring`, `features.vulnerabilityScanning`, `logShipping.clusterDestinationRef`, `nodeSelector`, `tolerations`, `allowedUIDs`, `allowedGIDs`, `runtimeAudit.enabled`, `namespaceMetadata.labels` and `namespaceMetadata.annotations`. Instead of a concrete value, specify `{fromParam: <parameter name>}` and declare the parameter in `parametersSchema`. The value does not have to be a scalar: a map (`nodeSelector`, `namespaceMetadata.labels`), a list (`tolerations`) or an object (`allowedUIDs`) works just as well. The other fields — `title`, `description`, `resources`, `grantPolicies` and `parametersSchema` itself — take literal values only. Each project then sets its own value in `.spec.parameters`; if the value is

not set, the `default` from the schema is used.

```
apiVersion: deckhouse.io/v1alpha2
kind: ProjectTemplate
metadata:
  name: my-parametrized-template
spec:
  podSecurityStandard:
    fromParam: securityProfile
  networkPolicy:
    mode:
      fromParam: networkMode
  parametersSchema:
    openAPIV3Schema:
      type: object
      properties:
        securityProfile:
          type: string
          enum: [Baseline, Restricted]
          default: Baseline
        networkMode:
          type: string
          enum: [Isolated, NotRestricted]
          default: Isolated
```

A project using such a template:

```
apiVersion: deckhouse.io/v1alpha3
kind: Project
metadata:
  name: my-project
spec:
  projectTemplateName: my-parametrized-template
  parameters:
    securityProfile: Restricted
```

A template whose `parametersSchema` still declares the `administrators` and `resourceQuota` parameters keeps accepting projects. A schema declares them by name, or through an `additionalProperties` that takes every parameter it does not name, as long as it takes these two in the form a `v1alpha2` Project holds them. The project parameters are validated against such a schema together with `.spec.administrators` and `.spec.quota`, laid out again as `parameters.administrators` and `parameters.resourceQuota` the way the conversion webhook lays them out for `v1alpha2`. A quota value is checked in the first form the schema takes among its canonical spelling (for example `1Gi` for `1024Mi`), a number (for example `1000` for `1k`) and a spelling with another unit (for example `2000m` for `2` when the schema has `pattern: ^[0-9]+m$`), in that order. A required field that the project leaves empty is checked in its empty form (`[]` for the administrators, `{}` for the quota). A Helm `resourcesTemplate` and `manifests` receive the parameters laid out the same way in `.parameters`, so a text written for `v1alpha2` projects keeps rendering its objects from them. A quota value reaches the text in the form it is checked in, so for a schema that takes strings a zero is the string `"0"`, which `with` and `if` take as set. The structured fields do not receive these values as parameters.

A schema that neither names the `administrators` and `resourceQuota` parameters nor takes unnamed parameters through `additionalProperties` does not declare them, and the schemas of the built-in templates do not declare them either. On a template with such a schema, these parameters grant no access and set no quota. A project that holds them, for example an empty list or a quota with the number `0` that the conversion webhook leaves in `parameters`, keeps working and can be edited. An update that keeps such a value as it was, including on a move to another template that does not declare them either, is accepted with a warning, and so are an empty list and a quota with no value other than the number `0`. Any other new or changed value is rejected. Set the administrators in `.spec.administrators` and the quota in `.spec.quota` instead. In a `v1alpha2` manifest, write them in a form that the conversion webhook lifts into these fields. Any other parameter that the schema does not declare is still rejected.

The `fromParam` references are checked when a template is created or changed: a reference to an undeclared parameter or to a parameter of an incompatible type (for example, a string parameter for a

boolean field) is rejected.

A declared parameter is type-checked even where the schema allows undeclared keys with `additionalProperties` or `x-kubernetes-preserve-unknown-fields`. A reference to an undeclared key is accepted only in such places, and the type of such a key is not checked.

The `requiredRequests` parameter is read by name, without `fromParam`. When the template declares it in `parametersSchema` with `type: boolean` and its value for the project is `true`, the controller renders an OperationPolicy in the `Deny` mode that requires CPU and memory requests from the pods in every namespace of the project. A template that does not declare the parameter renders no such policy, even if its schema allows `additionalProperties` and the project sets `requiredRequests` as an undeclared key. To keep the policy on unless a project turns it off, declare the parameter with `default: true`, as the `default`, `secure` and `secure-with-dedicated-nodes` templates do:

```
spec:
  parametersSchema:
    openAPIV3Schema:
      type: object
      properties:
        requiredRequests:
          type: boolean
          default: true
```

Template checks

The following rules apply to template operations:

- A template cannot be deleted while at least one project uses it or a project namespace is still rendered from it. After a project switches to another template, the old template stays until the new one has rendered.
- A change to a template is automatically applied to all projects created from it.
- Instead of structured fields, a template can describe its objects with a Helm text in `resourcesTemplate`. Such a template is rendered through Helm with the project name (`.projectName`), the template name (`.projectTemplateName`) and the project parameters (`.parameters`), and `resourcesTemplate` cannot be set together with the fields that render namespace objects or with `manifests`. A template that projects use keeps a non-empty `resourcesTemplate` until a change sets such fields or `manifests` in its place. What such a change, or a move of a project to another template, does with the objects the Helm text rendered is described in Switching a project from a Helm text. A project whose parameters turn into objects or keys of the rendered manifests instead of values is refused, so quote every substitution. This form is deprecated, and `resourcesTemplate` goes away from `deckhouse.io/v1alpha2` together with `deckhouse.io/v1alpha1` in a future release. The `MultitenancyManagerHelmProjectTemplate` alert names every template that still renders from a Helm text, except the built-in ones. Describe new templates with structured fields and `manifests`, and move the existing ones as Moving a template from a Helm text describes.
- A template cannot get a new `resourcesTemplate` through either version. A create with a non-empty `resourcesTemplate` and an update that sets it on a template whose `resourcesTemplate` is empty are refused. A template that has a Helm text keeps it, and the text can be changed through either version while `deckhouse.io/v1alpha1` can describe the whole template. So a template with a Helm text cannot be created again, for example from a manifest exported from another cluster, from a backup, or from Git after the template was deleted. Move such a template to structured fields and `manifests` first.
- The `deckhouse.io/v1alpha1` version of ProjectTemplate is served and deprecated, and the API server returns a warning on every request through it. A template is created through `deckhouse.io/v1alpha2` only, and a create through `deckhouse.io/v1alpha1` is refused. The templates created through `deckhouse.io/v1alpha1` earlier are read, changed and deleted through it as before. This version has the `description`, `parametersSchema` and `resourcesTemplate` fields, and `deckhouse.io/v1alpha2` keeps all three, so a template written as `v1alpha1` reads back unchanged. A change through `v1alpha1` to a template that has fields `v1alpha1` cannot describe, such as `title`, `grantPolicies`, `podSecurityStandard` or `manifests`, is refused, because it would erase them. Change such a template through `deckhouse.io/v1alpha2`.

Describing other objects in manifests

The structured fields cover the settings that most projects need. Other objects of the project namespaces, such as workloads, ConfigMap, RoleBinding or LimitRange objects, are described in `manifests`. It is a text in the `go template` format with the `helm` functions, like `resourcesTemplate`, and a template can set it together with the structured fields.

`manifests` and `resourcesTemplate` differ in whose rights create the objects. The controller installs a Helm text from `resourcesTemplate` as a Helm release with its own rights, which cover the whole cluster. So such a text can create any cluster-scoped object other than a namespace, and any object in the namespaces of the project. The controller applies the objects of `manifests` as a user of the project that holds the `d8:project:admin` role in the namespaces of the project. A template thus gets the rights of an administrator of the project, not the rights of the controller.

The text gets the project name in `.projectName`, the template name in `.projectTemplateName` and the project parameters completed with the defaults of `parametersSchema` in `.parameters`, the same values that `resourcesTemplate` gets. A project whose parameters turn into objects or keys of the rendered manifests instead of values is refused, so quote every substitution. The text is rendered without access to the cluster, so the `lookup` function finds nothing. A project template can be read by users who have no access to its projects, the ones with the `User` access level included, so do not put secret values into `manifests`.

The objects are applied as follows:

- The controller creates the `d8-manifests` ProjectRoleBinding in the main namespace of the project. It grants the `d8:project:admin` role to the `system:multitenancy-manager:project:<PROJECT_NAME>` user in every namespace of the project.
- The objects are applied once this binding is `Ready` for its current generation and the `d8:project:admin` ClusterRole has its aggregated rules. Until then the `ManifestsApplied` condition of the project says what the objects wait for, and the project stays `Deployed`.
- Each object is applied with server-side apply as this user, with the `multitenancy-manager/manifests` field manager. An object without `metadata.namespace` goes to the main namespace of the project. An object can also go to an additional namespace of the project, including one that a ProjectNamespace of the same `manifests` makes, as Additional namespaces in manifests describes.
- Each object gets the `projects.deckhouse.io/project: <PROJECT NAME>` and `projects.deckhouse.io/source: manifests` labels, and `.status.manifestObjects` of the project lists the objects.
- An object that exists already is applied only when it belongs to the project, that is, when `.status.manifestObjects` lists it, when a switch from a Helm text left it in `.status.keptObjects`, or when it has both labels. Any other object is left alone, as Limitations of manifests describes.
- The objects do not get the `heritage: multitenancy-manager` label. They get the `projects.deckhouse.io/source: manifests` label instead, and like the objects of the structured fields and of a Helm text, they are changed through the template only. The `d8-multitenancy-manager-manifests-objects` admission policy refuses to create, change or delete such an object to everyone, project and cluster administrators included. Only the user the `manifests` of the project are applied as, the controller, the service accounts of the `d8-*` namespaces and the cluster components can do it. Anyone who may update a workload may restart its rollout, when the `kubectl.kubernetes.io/restartedAt` annotation of its pod template is the only change. `metadata.resourceVersion`, `metadata.generation` and `metadata.managedFields` are not compared, because the API server sets them on the write. Within 10 minutes the controller applies the objects again, which puts back the fields that the template sets if something else changed them.
- An object that the template no longer renders is deleted as the same user after the other objects are applied, and only when none of them was refused or left alone. It is deleted through the version that the API server serves its kind at, also when it was applied through another one. An object that loses one of the two labels, and an object whose namespace left the project, leave the list and stay in place. Only the service accounts of the `d8-*` namespaces, the controller among them, and the cluster components can take a label off. The user the `manifests` are applied as can take off only the `projects.deckhouse.io/source` label.
- When one change makes the project release render an object that `manifests` applied, under the same kind, namespace and name, the release takes the object over, and the object stays in the cluster. Until the upgrade finishes, `.status.handingOver` lists the object and `.status.manifestObjects` does not. If the upgrade does not deploy the object, it goes back to `manifests`, and `.status.manifestObjects` lists it again.
- When the same change makes the release render another object that exists without the ownership marks of the release and is not an object of `manifests`, Helm cannot take that object over. The ownership marks are the `app.kubernetes.io/managed-by: Helm` label and the `meta.helm.sh/release-name` annotation with the name of the project release. The controller does not run the upgrade then and leaves the objects of `manifests` unchanged, and the `ResourcesUpgraded` condition of the project names the object that blocks the upgrade. The handover goes on once that object is deleted or gets the ownership marks.
- When the template drops `manifests` or the project moves to a template without it, the objects are deleted, and then the `d8-manifests` binding is deleted. When the project is deleted, the binding is deleted first, and the objects go with the namespaces.

Only the controller binds the users whose names start with `system:multitenancy-manager:`. A RoleBinding, ClusterRoleBinding, ProjectRoleBinding, ClusterProjectRoleBinding, AuthorizationRule or ClusterAuthorizationRule that names such a user or group is refused for everyone else, except the

garbage collector and `system:sudouser` (see Who bypasses admission). A Helm text in `resourcesTemplate` can also bind such a user, because the controller installs it with its own rights. Apart from that, the objects of a template get the rights of the `d8-manifests` binding and the rights that the cluster grants to every authenticated user (the `system:authenticated` group). For the same reason a project cannot name such a user or group among its administrators, in `.spec.administrators` or in the `administrators` parameter. A name that the project already has is accepted with a warning, so the project stays editable and the name can be removed.

The following template sets the pod security profile and the network isolation with structured fields and creates two objects in `manifests`, a LimitRange with the default limits from the project parameters and a ConfigMap with the names of the project and of its template:

```
apiVersion: deckhouse.io/v1alpha2
kind: ProjectTemplate
metadata:
  name: team-with-limits
spec:
  podSecurityStandard: Baseline
  networkPolicy:
    mode: Isolated
  parametersSchema:
    openAPIV3Schema:
      type: object
      properties:
        defaultCPU:
          type: string
          default: 500m
        defaultMemory:
          type: string
          default: 512Mi
  manifests: |
    apiVersion: v1
    kind: LimitRange
    metadata:
      name: container-defaults
    spec:
      limits:
        - type: Container
          default:
            cpu: {{ .parameters.defaultCPU | quote }}
            memory: {{ .parameters.defaultMemory | quote }}
    ---
    apiVersion: v1
    kind: ConfigMap
    metadata:
      name: project-info
    data:
      project: {{ .projectName | quote }}
      template: {{ .projectTemplateName | quote }}
```

Once the `ManifestsApplied` condition is `True`, the main namespace of every project of the template has the `container-defaults` LimitRange and the `project-info` ConfigMap. To check the condition and to list the applied objects, use the commands:

```
d8 k get project <PROJECT_NAME> -o jsonpath='{.status.conditions[?
(@.type=="ManifestsApplied")]}'
d8 k get project <PROJECT_NAME> -o jsonpath='{range .status.manifestObjects[*]}{.kind}
{.namespace}/{.name}{"\n"}{end}'
```

Additional namespaces in manifests

`manifests` can make additional namespaces of the project with ProjectNamespace objects and put

objects into them in the same text. A ProjectNamespace without `metadata.namespace` goes to the main namespace of the project, and its namespace is named `<PROJECT NAME>-<spec.name>`, so an object in it names the namespace as `{{ .projectName }}-<spec.name>`.

The namespace does not exist on the first render, so the objects are applied in two steps:

- The ProjectNamespace objects and the objects of the namespaces that exist are applied at once.
- The objects of a namespace that a ProjectNamespace of the same `manifests` makes wait until the namespace exists and the `d8-manifests` binding has reached it. Until then the `ManifestsApplied` condition is `False` and names what the objects wait for, and the project stays `Deployed`. A namespace that is being deleted is reported as terminating, and one that is not there yet as still to be created. When the ProjectNamespace is not `Ready`, the condition includes its `Ready=False` message. Objects that wait are kept. Objects that `manifests` no longer renders are deleted. The project is reconciled when the namespace is created and when the binding reaches it, so the objects are applied without any action.
- When `manifests` drops a ProjectNamespace, the ProjectNamespace is deleted, and its namespace goes with everything in it. The objects of `manifests` in that namespace leave `.status.manifestObjects` without a delete of their own.

An object in a namespace that is neither a namespace of the project nor made by a ProjectNamespace of the same `manifests` is refused, as Limitations of manifests describes. A create or a change of a project whose `manifests` render such an object is admitted with a warning that names the namespace.

The following `manifests` make the `backend` namespace and put a ConfigMap into it:

```
manifests: |
  apiVersion: deckhouse.io/v1alpha3
  kind: ProjectNamespace
  metadata:
    name: backend
  spec:
    name: backend
  ---
  apiVersion: v1
  kind: ConfigMap
  metadata:
    name: backend-settings
    namespace: "{{ .projectName }}-backend"
  data:
    team: {{ .parameters.team | quote }}
```

Limitations of manifests

`manifests` covers only what an administrator of the project can do in its namespaces. The following limitations apply:

- A text that does not render for a project, for example because of a syntax error or a `required` value that the project does not set, is accepted when the template is written, because the template is not rendered at that point. Such a project switches to `Error`, `ManifestsApplied` names the error, and a create or a change of the project is refused until the text renders. A change of `manifests` reaches every project of the template at once, so try it first on a copy of the template with one project.
- A cluster-scoped object, an object in a namespace that is neither a namespace of the project nor made by a ProjectNamespace of the same `manifests`, an object with the `heritage: multitenancy-manager` or `heritage: deckhouse` label, an object without `metadata.name` and an object that the text renders twice are refused. While the render holds such an object, none of its objects is applied, the project switches to `Error`, and the `ManifestsApplied` condition names the object.
- An object that exists already and does not belong to the project, for example one that a project administrator created by hand, is not changed, listed or deleted later. The other objects are applied, but nothing is deleted, the project switches to `Error`, `ManifestsApplied` names the object, and the controller looks again every minute. To hand the object over to `manifests`, give it the `projects.deckhouse.io/project: <PROJECT_NAME>` and `projects.deckhouse.io/source: manifests` labels, or delete it so that `manifests` creates it. Only a user who may update objects of its kind in every namespace, such as a cluster administrator, may give it the labels. Do not delete an AuthorizationRule of the `Admin` access level this way, because `manifests` does not create one. Give it the labels instead.

- An object that the `d8:project:admin` role does not allow is refused by the API server with `403 Forbidden`. Examples are a RoleBinding to a role that a project administrator cannot bind and an object of a kind that the role does not cover. The other objects are applied, the project switches to `Error`, `ManifestsApplied` names the refused object, and the controller tries again with a growing interval.
- An AuthorizationRule of the `Admin` access level is refused when `manifests` creates it, raises an existing one to this level or adds subjects to an existing one of this level, although the `d8:project:admin` role allows it. The administrators of a project are set in `.spec.administrators` of the Project. An AuthorizationRule of the `User`, `PrivilegedUser` or `Editor` level is applied as other objects are. The project switches to `Error` as for an object that the role does not allow, and a create or a change of a project whose `manifests` render a refused AuthorizationRule is admitted with a warning that names it. A create of a template whose `manifests` describe an AuthorizationRule, and a change of such `manifests`, are admitted with a warning about this refusal. An AuthorizationRule that exists already, for example one that a switch from a Helm text left in place, is taken over and updated as other objects are, unless `manifests` raises it to the `Admin` level or adds subjects to it at this level.
- An object of a kind that the API server does not serve keeps all the objects from being applied. The project switches to `Error`, and the controller tries again every minute, for example while the module that brings the kind is being enabled.
- `manifests` cannot be set together with `resourcesTemplate`.
- `deckhouse.io/v1alpha1` has no place for `manifests`, so a write through `deckhouse.io/v1alpha1` to a template that has it is refused.
- The `projects.deckhouse.io/skip-heritage-label` and `projects.deckhouse.io/unmanaged` labels of a Helm text have no effect on the objects of `manifests`.

`manifests` does not create cluster-scoped objects. To give the projects of a template access to cluster-wide resources, use `resources` and `grantPolicies`. A cluster administrator creates other cluster-scoped objects outside the template.

Moving a template from a Helm text

A template with a Helm text in `resourcesTemplate` keeps working, but this form is deprecated. `resourcesTemplate` goes away from `deckhouse.io/v1alpha2` together with `deckhouse.io/v1alpha1` in a future release, and no template can get a new one (see Template checks). The `MultitenancyManagerHelmProjectTemplate` alert names every such template, except the built-in ones. Nothing in the cluster rewrites such a template, so move it to structured fields and `manifests` where it is applied from, for example in Git or in CI.

The built-in templates `default`, `secure` and `secure-with-dedicated-nodes` are structured and accept the same parameters as their Helm texts did, except `administrators` and `resourceQuota`, so they show how a text maps to the fields. A field takes the value of a parameter with `{fromParam: <PARAMETER_NAME>}`, so the projects keep their parameters. The following table shows where the objects of such a text go:

Object of the Helm text	Replacement
The `security.deckhouse.io/pod-policy` label of the namespace from the `podSecurityProfile` parameter	`podSecurityStandard: {fromParam: podSecurityProfile}`
The NetworkPolicy objects of the `networkPolicy` parameter	`networkPolicy.mode: {fromParam: networkPolicy}`
The `extended-monitoring.deckhouse.io/enabled` label of the `extendedMonitoringEnabled` parameter	`features.monitoring: {fromParam: extendedMonitoringEnabled}`
The `security-scanning.deckhouse.io/enabled` label of the `securityScanningEnabled` parameter	`features.vulnerabilityScanning: {fromParam: securityScanningEnabled}`
The PodLoggingConfig of the `clusterLogDestinationName` parameter	`logShipping.clusterDestinationRef: {fromParam: clusterLogDestinationName}`
The SecurityPolicy of the `allowedUIDs` and `allowedGIDs` parameters	`allowedUIDs: {fromParam: allowedUIDs}` and `allowedGIDs: {fromParam: allowedGIDs}`
The FalcoAuditRules of the `runtimeAuditEnabled` parameter	`runtimeAudit.enabled: {fromParam: runtimeAuditEnabled}`
Other labels and annotations of the namespace	`namespaceMetadata.labels` and `namespaceMetadata.annotations`, in the built-in templates from the `namespace.labels` and `namespace.annotations` parameters

Object of the Helm text	Replacement
The placement on dedicated nodes	`nodeSelector` and `tolerations`, in the built-in templates from the `dedicatedNodes.nodeSelector` and `dedicatedNodes.defaultTolerations` parameters
The AuthorizationRule objects of the `administrators` parameter	`.spec.administrators` of each Project
Other AuthorizationRule objects of the `Admin` access level	`.spec.administrators` of each Project, because `manifests` does not create an AuthorizationRule of this level
The `all-pods` ResourceQuota of the `resourceQuota` parameter	`.spec.quota` of each Project
The `required-requests-*` OperationPolicy, which refuses pods without CPU and memory requests	The `requiredRequests` parameter, declared with `type: boolean` and `default: true` to keep the policy or with `default: false` to leave it off
Any other object in the namespaces of the project, such as a workload, a ConfigMap, a RoleBinding, a LimitRange or an AuthorizationRule of another access level	`manifests`
A cluster-scoped object	No replacement in a template. Access to cluster-wide resources is set with `resources` and `grantPolicies`

For example, an existing template `team` has the following Helm text, which sets the pod security profile from a parameter and creates a LimitRange in the main namespace of each project. Such a template cannot be created again, so the manifest only shows the starting point:

```
apiVersion: deckhouse.io/v1alpha1
kind: ProjectTemplate
metadata:
  name: team
spec:
  parametersSchema:
    openAPIV3Schema:
      type: object
      properties:
        podSecurityProfile:
          type: string
          enum: [Baseline, Restricted]
          default: Baseline
  resourcesTemplate: |
    apiVersion: v1
    kind: Namespace
    metadata:
      name: {{ .projectName | quote }}
      labels:
        security.deckhouse.io/pod-policy: {{ .parameters.podSecurityProfile | lower |
quote }}
    ---
    apiVersion: v1
    kind: LimitRange
    metadata:
      name: container-defaults
      namespace: {{ .projectName | quote }}
    spec:
      limits:
        - type: Container
          default:
            cpu: 500m
            memory: 512Mi
```

In the structured form, the profile goes to `podSecurityStandard` and the LimitRange goes to `manifests`. The text did not render the `required-requests-*` OperationPolicy, so the template declares the `requiredRequests` parameter with `default: false`:

```
apiVersion: deckhouse.io/v1alpha2
kind: ProjectTemplate
metadata:
  name: team
spec:
  podSecurityStandard:
    fromParam: podSecurityProfile
  parametersSchema:
    openAPIV3Schema:
      type: object
      properties:
        podSecurityProfile:
          type: string
          enum: [Baseline, Restricted]
          default: Baseline
        requiredRequests:
          type: boolean
          default: false
  manifests: |
    apiVersion: v1
    kind: LimitRange
    metadata:
      name: container-defaults
    spec:
      limits:
        - type: Container
          default:
            cpu: 500m
            memory: 512Mi
```

After the switch, the namespace of each project keeps its label, the LimitRange stays in place, and `manifests` takes it over and removes the annotations of Helm from it.

A template that no project uses can be deleted, and the alert goes with it. If the template is an unchanged copy of a built-in template, move its projects to that template in `.spec.projectTemplateName` instead, and then delete the copy. To move a template that projects use, follow these steps:

1. Find the projects of the template that still set `administrators` or `resourceQuota` in `.spec.parameters`:

   ```
   d8 k get projects -l projects.deckhouse.io/project-template=<PROJECT_TEMPLATE_NAME> -o json | jq -r '.items[] | select((.spec.parameters // {}) | has("administrators") or has("resourceQuota")) | .metadata.name'
   ```

   These values get no standard fields and are not handed over. Move them to `.spec.administrators` and `.spec.quota` first, and only as far as they mean the same there. `.spec.administrators` gives users and groups the `d8:project:admin` role, so an administrator with another access level or another kind of subject needs a ProjectRoleBinding of its own. `.spec.quota` enforces every limit it holds, `0` included, so leave out a limit that the text did not render, such as a `0` that it skipped.

2. Make every tool that writes the template, such as a GitOps tool or a generator, write it as `deckhouse.io/v1alpha2`. Once the template has a field that `deckhouse.io/v1alpha1` cannot describe, such as `manifests`, a write of the template through `deckhouse.io/v1alpha1` is refused, because it would erase that field.

3. Write the template as `deckhouse.io/v1alpha2` with the fields from the table and with `manifests`, without `resourcesTemplate`, in one change. Keep in `parametersSchema` the parameters that the projects set. Declare the `requiredRequests` parameter with `type: boolean`, with `default: true` if the text rendered the `required-requests-*` OperationPolicy and with `default: false` if it did not, so the projects keep refusing or admitting pods without CPU and memory requests as before. A template that projects use cannot lose `resourcesTemplate` without structured fields or `manifests` in its place.

4. Check each project after the switch. Its `HandoverPending` condition is removed once the replaced

objects are deleted, its `ManifestsApplied` condition says whether the objects of `manifests` are applied, and `.status.keptObjects` lists the objects left in place:

```
d8 k get project <PROJECT_NAME> -o jsonpath='{range .status.conditions[*]}{.type}=
{.status}: {.message}{"\n"}{end}{range .status.keptObjects[*]}{.kind}
{.namespace}/{.name}{"\n"}{end}'
```

5. Decide on each object that stays in `.status.keptObjects`, as Switching a project from a Helm text describes. An object that `manifests` renders under the same kind, namespace and name leaves the list once `manifests` takes it over, and from then on it has what `manifests` renders.

Switching a project from a Helm text

A project release rendered from a Helm text in `resourcesTemplate` holds whatever the text rendered. The project switches to structured fields when its template gets structured fields or `manifests` in place of `resourcesTemplate`, when the project moves to a structured template, and when a built-in template that was a Helm text is rewritten with structured fields. The release then holds only what the structured fields render. An object of the Helm text that the structured fields render under the same kind and name stays in the release and is updated in place. The other objects of the Helm text are handled as follows, and of them only an AuthorizationRule that names nobody from `.spec.administrators` any more is deleted at once.

The AuthorizationRule and ResourceQuota objects that the standard fields replace go through a handover, so the administrators never lose access and the namespace never loses its quota. These are the AuthorizationRule objects the release created that grant the `Admin` access level and nothing else to users and groups who are all administrators of the project, and the ResourceQuota objects of the main namespace without scopes whose every limit `.spec.quota` sets to the same value or a lower one. The handover goes in the following order:

1. The Project gets the `HandoverPending` condition set to `True`. Then the objects get the `helm.sh/resource-policy: keep` annotation and the `projects.deckhouse.io/kept-by-handover: "true"` annotation, so the release upgrade does not delete them.
2. The `d8-administrators` ProjectRoleBinding and the `d8-project-quota` ResourceQuota are created before the release is upgraded.
3. The kept objects are deleted once `d8-administrators` names the administrators from `.spec.administrators` and is `Ready` for its current `metadata.generation`, the `d8:project:admin` ClusterRole has its aggregated rules, and `d8-project-quota` has the limits from `.spec.quota` and is calculated, and not earlier than 2 minutes after `d8-administrators` became `Ready` and after the handover began. Until then the administrators hold both roles, and the tighter of the quotas applies. The `HandoverPending` condition says what the handover waits for, and it is removed once the kept objects are deleted.

A kept AuthorizationRule that names nobody from `.spec.administrators` any more grants only what was revoked, and it is deleted at once. A subject removed from `.spec.administrators` is removed at once from a kept AuthorizationRule that names other administrators too. A kept quota that `.spec.quota` no longer covers when the handover finishes, because a limit in `.spec.quota` was raised above it or removed, is left in place like the objects below. The `HandoverPending` condition is kept in the status of the Project, so a replace of the Project (for example, `kubectl replace` or Argo CD with the `Replace=true` option) does not lose it. If the kept objects are still there after 30 minutes, the `MultitenancyManagerProjectHandoverStuck` alert names the project and says what to check.

Every other object of the Helm text that the structured fields do not render is left in place instead of being deleted. Examples are AuthorizationRule objects of other subjects or of another access level, such as the ones a text renders for roles from its own parameters, a quota that `.spec.quota` does not cover, RoleBinding objects, network policies, and workloads with their volumes.

- Such an object keeps working as before. A rule or a binding keeps granting access, a quota keeps applying, a workload keeps running.
- The project no longer manages it. The object gets the `helm.sh/resource-policy: keep` annotation and the `projects.deckhouse.io/kept-from-helm-template: "true"` label, and it loses the `heritage: multitenancy-manager` label. While it carries the label, only a requester who may make the same change to objects of its kind across the cluster may change or delete it, for example a cluster administrator. The users of the project may not, so a network policy or a quota of the text keeps holding them. The protection does not cover the `scale` and `status` subresources: whoever may scale objects of the kind or change their status in the namespace may still do so for a kept object, which matters only for a kept workload.
- The Project lists it in `.status.keptObjects`, and the `MultitenancyManagerProjectKeepsHelmTemplateObjects` alert names the project. An object leaves the list once it is deleted or the label is removed from it. When the template renders an object of the same kind and name again, the project release takes the object over. The controller then removes the label, puts the `heritage: multitenancy-manager` label back and removes the

`helm.sh/resource-policy: keep` annotation, unless the template sets it itself.
- When `manifests` of the template renders an object of the same kind, namespace and name, the controller applies it as the user of the project and takes the object over. The object then has what `manifests` renders. A field that the Helm text set and `manifests` does not set is removed, the annotations of Helm included, such as `helm.sh/resource-policy: keep` and `meta.helm.sh/*`, and so is the `projects.deckhouse.io/kept-from-helm-template` label. A field that somebody else set on the object stays. The object leaves `.status.keptObjects`.
- When the project is deleted, the object goes with it. An object in a namespace of the project goes with the namespace, and the controller deletes a cluster-scoped object that still carries the label.

Describe what is still needed in the template or in the project, for example with a ProjectRoleBinding or with a limit in `.spec.quota`, and delete the left object, or remove the label to hand the object over to the project, after which the users of the project may change and delete it as well. An object in a namespace of the project can instead be described in `manifests` of the template, which takes it over. A cluster-scoped object without the label also stays when the project is deleted. An access that a left object grants ends only when the object is deleted. To list the left objects of a project, use the command:

```
d8 k get project <PROJECT_NAME> -o jsonpath='{range .status.keptObjects[*]}{.kind}
{.namespace}/{.name}{"\n"}{end}'
```

An edit of a Helm text, and a move of a project to another template with a Helm text, delete the objects the new text does not render, except the AuthorizationRule and ResourceQuota objects that the standard fields replace. These go through the same handover.

Administrators and a quota that are still set in `.spec.parameters`, because they could not be moved to `.spec.administrators` and `.spec.quota`, get no standard fields. Their AuthorizationRule objects and their quota are not handed over, and a switch leaves them in place. Move such values to the standard fields before the switch.

After the handover the administrators have the `d8:project:admin` role in place of the `Admin` access level. The two roles do not grant the same permissions. In particular, the access that custom ClusterRoles with the `user-authz.deckhouse.io/access-level` annotation added to the `Admin` access level is not part of `d8:project:admin`. To grant such access, create a custom role and bind it with a ProjectRoleBinding.

Moving an object of the release to manifests

A structured template renders its objects into the project release. When one change makes `manifests` render an object the release contained, under the same kind, namespace and name, the upgrade would delete the object and `manifests` would create it again. The project would be without the object in between. An example is the NetworkPolicy named `isolated` once `networkPolicy.mode` is removed and `manifests` render that NetworkPolicy.

The controller leaves the object in place instead. Before the upgrade it sets the `helm.sh/resource-policy: keep` annotation and the `projects.deckhouse.io/kept-from-helm-template: "true"` label, and lists the object in `.status.keptObjects`, the same way a switch from a Helm text leaves an object. In the same reconcile `manifests` apply the object as the user of the project, remove the label and take the object off the list. The object then has what `manifests` render. A field that the release set and `manifests` do not set is removed. A field that somebody else set stays.

If `manifests` cannot apply the object, for example because the API server refuses the kind or returns `403 Forbidden`, the object stays in `.status.keptObjects`. The `MultitenancyManagerProjectKeepsHelmTemplateObjects` alert names the project. The object keeps working, and only a requester who may make the same change to objects of its kind across the cluster may change or delete it, until `manifests` take it over or the label is removed.

An object the release drops and that `manifests` do not render is deleted by the upgrade.

Creating your own project template

To create your own template:

1. Take one of the default templates as a basis, for example, `default`.
2. Copy it to a separate file, for example, `my-project-template.yaml` using the command:

   ```
   d8 k get projecttemplates default -o yaml > my-project-template.yaml
   ```
3. Edit the `my-project-template.yaml` file and adjust the structured fields, the objects in `manifests` and the input parameters schema to your needs.

4. Change the template name in the `.metadata.name` field.
5. Remove the `heritage` label, the `metadata.resourceVersion`, `metadata.uid`, `metadata.creationTimestamp`, `metadata.generation` and `metadata.managedFields` fields and the `status` section from the file.
6. Apply your new template with the command:

   ```
   d8 k apply -f my-project-template.yaml
   ```

7. Check the availability of the new template with the command:

   ```
   d8 k get projecttemplates <NEW_TEMPLATE_NAME>
   ```

Labels for the objects of a Helm text

The following labels change how the module handles the objects of a Helm text in `resourcesTemplate`. Only existing templates have such a text, because no template can get a new `resourcesTemplate`. The objects of `manifests` never get the `heritage: multitenancy-manager` label, and the module does not read these labels on them.

Skipping the heritage label

By default, every object of the Helm text gets the `heritage: multitenancy-manager` label. With this label, only the identities listed in Who bypasses admission can change the object. To allow changes to the object (for example, for compatibility with other systems, or to control the created objects yourself), add the `projects.deckhouse.io/skip-heritage-label` label to it.

Example:

```
---
apiVersion: v1
kind: ConfigMap
metadata:
  name: my-config
  namespace: {{ .projectName }}
  labels:
    projects.deckhouse.io/skip-heritage-label: "true"
    app: my-app
data:
  key: value
```

In this case, the object gets the `projects.deckhouse.io/project` and `projects.deckhouse.io/project-template` labels, but not the `heritage: multitenancy-manager` label.

Excluding objects from management

To exclude an object from management by the module (for example, when it is managed manually or by another controller), add the `projects.deckhouse.io/unmanaged` label to it.

Example:

```
---
apiVersion: v1
kind: Secret
metadata:
  name: external-secret
  namespace: {{ .projectName }}
  labels:
    projects.deckhouse.io/unmanaged: "true"
type: Opaque
data:
  token: <base64-encoded-value>
```

Objects with the `projects.deckhouse.io/unmanaged` label:

- are created **only once**, when the project release is first installed, so an object added to the template later is not created in existing projects;
- **are not updated** when the template changes;
- are not tracked in the project status;
- get the `projects.deckhouse.io/project` and `projects.deckhouse.io/project-template` labels, but **not** the `heritage: multitenancy-manager` label;
- get the `helm.sh/resource-policy: keep` annotation, so the project release does not delete them.

> ⚠ After it is created, an `unmanaged` object does not depend on the template and must be managed manually.

Implementing validation of object changes with a custom label

The `multitenancy-manager` module uses a ValidatingAdmissionPolicy to protect objects labeled `heritage: multitenancy-manager` from manual changes. You can implement similar validation for objects with any label.

How validation works in multitenancy-manager

Validation occurs for objects labeled `heritage: multitenancy-manager`. The following components are used for this:

1. ValidatingAdmissionPolicy: Defines validation rules:
   - Operations: `CREATE`, `UPDATE` and `DELETE`. `system:masters` is not exempt.
   - Check: only the module's controller and the identities this policy lets through (for details, see Who bypasses admission) may change such an object. For a project namespace, an update that changes only labels and annotations outside the keys the module owns is allowed as well (see Creating a project automatically for a namespace).
   - Applies to all resources and API groups.
2. ValidatingAdmissionPolicyBinding: Defines which objects the validation applies to:
   - Uses `namespaceSelector` and `objectSelector` to select resources by the label `heritage: multitenancy-manager`.

Who bypasses admission

The webhooks and policies of the module have different exclusion lists:

- The **Project and ProjectTemplate webhooks** skip requests from platform components — the API server (`system:apiserver`), the service accounts of Deckhouse (`d8-system:deckhouse`), of this module (`d8-multitenancy-manager:multitenancy-manager`) and of `user-authz` (`d8-user-authz:controller`), every service account of the `d8-system`, `kube-system` and `d8-user-authz` namespaces, kubelets (`system:nodes`) — and from the `system:sudouser` identity. Everyone else is validated, `system:masters` included.
- The **ProjectRoleBinding, ProjectNamespace and ClusterProjectRoleBinding webhooks** skip nobody and validate every request. Inside them only the controller and Deckhouse service accounts are privileged; `system:sudouser` and `system:masters` are ordinary users there.
- The **ValidatingAdmissionPolicy** above lets through this module's controller; the users `system:apiserver`, `system:kube-controller-manager`, `system:kube-scheduler`, `system:volume-scheduler`, `dhctl`, `observability` and `system:sudouser`; the groups `system:nodes`, `system:serviceaccounts:kube-system` and `system:serviceaccounts:d8-system` (not `d8-user-authz`); and a rollout restart of a project workload that changes only the `kubectl.kubernetes.io/restartedAt` annotation of the pod template. Everyone else is refused, `system:masters` included.
- The **`d8-multitenancy-manager-manifests-objects` ValidatingAdmissionPolicy** guards objects labelled `projects.deckhouse.io/source: manifests`. It lets through this module's controller; the users `system:apiserver`, `system:kube-controller-manager`, `system:kube-scheduler`, `system:volume-scheduler`, `dhctl`, `observability` and `system:sudouser`; and the groups `system:nodes`, `system:serviceaccounts:kube-system` and `system:serviceaccounts:d8-system`. Every service account whose name starts with `system:serviceaccount:d8-` may create, change and delete such objects. The user `system:multitenancy-manager:project:<PROJECT_NAME>` may create, change and delete the objects of that project. A rollout restart that changes only the `kubectl.kubernetes.io/restartedAt` annotation of the pod template is allowed. An update that puts the `projects.deckhouse.io/source: manifests` label, together with the `projects.deckhouse.io/project` label, on an object that does not have the `projects.deckhouse.io/source: manifests` label yet is allowed to a requester who may

update that resource across the cluster. Everyone else is refused, `system:masters` included.
- The **ValidatingAdmissionPolicy that reserves the users the controller acts as** (the names that start with `system:multitenancy-manager:`, see Describing other objects in manifests) lets through this module's controller, the garbage collector, which runs as `system:serviceaccount:kube-system:generic-garbage-collector` or as `system:kube-controller-manager`, and `system:sudouser`. Everyone else who names such a user or group in a binding is refused, the other service accounts of `kube-system` and `system:masters` included.
- The **`d8-multitenancy-manager-namespace-creation` ValidatingAdmissionPolicy** checks namespace creation and is in force only while `allowNamespacesWithoutProjects` is `false`. It lets through the API server (`system:apiserver`), the service accounts of Deckhouse (`d8-system:deckhouse`), of this module (`d8-multitenancy-manager:multitenancy-manager`) and of the `upmeter` agent (`d8-upmeter:upmeter-agent`), every service account of the `d8-system` and `kube-system` namespaces, the groups `system:masters` and `system:nodes`, and `system:sudouser`. Unlike the lists above, it includes `system:masters`, so cluster administrators still create namespaces directly. Everyone else can create only the `default` namespace.
- The **`d8-multitenancy-manager-namespace-adoption` ValidatingAdmissionPolicy** refuses to create a namespace whose name is longer than 61 characters, starts with `upmeter-` or is `deckhouse`, and to put the `heritage: upmeter` label on a namespace, whatever `allowNamespacesWithoutProjects` says. It lets through the same users and groups as the `d8-multitenancy-manager-namespace-creation` policy.
- The **`d8-multitenancy-manager-manifests` ValidatingAdmissionPolicy** checks only the users that the controller applies `manifests` as, whose names start with `system:multitenancy-manager:project:`, and refuses them to create an AuthorizationRule of the `Admin` access level, to raise one to this level or to add subjects to one of this level. Nobody else is checked by it.
- The **`d8-multitenancy-manager-v1alpha1-template-create` ValidatingAdmissionPolicy** refuses every create of a ProjectTemplate through `deckhouse.io/v1alpha1` and lets nobody through, `system:sudouser`, `system:masters` and the platform components included. The refusal of a new `resourcesTemplate` through `deckhouse.io/v1alpha2` belongs to the ProjectTemplate webhook, so the requesters that the webhook skips, `system:sudouser` among them, can still create a template with a Helm text that way.
- The **`d8-multitenancy-manager-namespace-ownership` ValidatingAdmissionPolicy** keeps the `projects.deckhouse.io/project` label and the labels and annotations that the module sets on a project namespace. It lets through only this module's controller and `d8-system:deckhouse`. Everyone else is refused, `system:sudouser` and `system:masters` included.
- The **`d8-multitenancy-manager-project-grants` ValidatingAdmissionPolicy** keeps the ClusterResourceGrantPolicy objects that the controller makes from `spec.grants` of a Project. It refuses to create an object whose name starts with `project-`, and to create, change or delete an object that has the `multitenancy.deckhouse.io/managed-by-project` label. It lets through this module's controller, `d8-system:deckhouse`, `system:sudouser` and the service accounts of the `kube-system` namespace, the garbage collector among them. Everyone else is refused, `system:masters` included.
- The **`d8-multitenancy-manager-kept-objects` ValidatingAdmissionPolicy** guards the objects listed in `.status.keptObjects` of a project. It lets through this module's controller, the users whose names start with `system:multitenancy-manager:`, `system:sudouser` and the system users and groups of the policy that guards the `heritage: multitenancy-manager` objects. Anyone else may change such an object only with the right to make the same change across the cluster.

The `/is-granted` and `/defaults` webhooks, which check writes of objects that reference cluster-wide resources in project namespaces (see Managing access to cluster-wide resources), skip `system:masters` together with the platform components. The `/protect` webhook keeps AvailableClusterResource read-only. It lets through the controller, the platform components and `system:masters`.

An administrator who needs to bypass the Project or ProjectTemplate webhook, the policy that guards the `heritage: multitenancy-manager` objects, the `d8-multitenancy-manager-manifests-objects` policy, or the policy that reserves the users the controller acts as, does it deliberately as `system:sudouser`, for example with `d8 k --as system:sudouser …`, and the bypass is then visible in the audit log. There is no similar option for ProjectRoleBinding, ProjectNamespace and ClusterProjectRoleBinding, for a create of a ProjectTemplate through `deckhouse.io/v1alpha1`, or for the namespace labels and annotations that the `d8-multitenancy-manager-namespace-ownership` policy keeps.

Creating your own validation

To implement validation for resources with a different label (for example, `heritage: my-custom-label`):

1. Create a file with the ValidatingAdmissionPolicy and ValidatingAdmissionPolicyBinding resource manifests:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
  name: my-custom-label-validation
spec:
  failurePolicy: Fail
  matchConstraints:
    resourceRules:
      - apiGroups:   ["*"]
        apiVersions: ["*"]
        operations:  ["CREATE", "UPDATE", "DELETE"]
        resources:   ["*"]
        scope: "*"
  matchConditions:
    # Let the cluster components through, as the policy of the module does.
    - name: exclude-system-groups
      expression: '!(["system:nodes", "system:serviceaccounts:kube-system",
"system:serviceaccounts:d8-system"].exists(e, (e in request.userInfo.groups)))'
    - name: exclude-system-users
      expression: '!(["system:apiserver", "system:kube-controller-manager",
"system:kube-scheduler"].exists(e, (e == request.userInfo.username)))'
  variables:
    # A DELETE request carries no object, only oldObject.
    - name: subject
      expression: 'object == null ? oldObject : object'
  validations:
    - expression: 'request.userInfo.username == "system:serviceaccount:my-
namespace:my-service-account"' # Replace with your ServiceAccount.
      reason: Forbidden
      messageExpression: 'variables.subject.kind == ''Namespace'' ? ''This
resource is managed by '' + variables.subject.metadata.name + '' system. Manual
modification is forbidden.''
       : ''This resource is managed by '' + variables.subject.metadata.namespace
+ '' system. Manual modification is forbidden.'''
---
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicyBinding
metadata:
  name: my-custom-label-validation
spec:
  policyName: my-custom-label-validation
  validationActions: [Deny, Audit]
  matchResources:
    objectSelector:
      matchLabels:
        heritage: my-custom-label
```

2. Configure the validation parameters:
   - `policyName`: Unique policy name (must match in Policy and Binding).
   - `request.userInfo.username`: The name of the ServiceAccount allowed to change objects (replace with your ServiceAccount).
   - `heritage: my-custom-label`: The value of the `heritage` label for your resources (replace with your value). The use of the values `multitenancy-manager`, `deckhouse` is prohibited.
   - `failurePolicy`: What happens when the policy cannot be evaluated, for example when an expression fails: `Fail` rejects the request, `Ignore` admits it. A validation that returns `false` rejects the request with the `Deny` action in any case.
   - `matchConditions`: Requests that the policy does not check. Keep the cluster components in this list, otherwise the policy blocks the deletion of namespaces and the garbage collection of the labeled objects.
   - `validationActions`: Validation actions:
     - `Deny`: Deny unauthorized operations.
     - `Audit`: Record operations in the audit log.

3. Apply the policy:

3. Apply the policy:

```
d8 k apply -f my-validation-policy.yaml
```

4. Ensure your resources have the corresponding `heritage` label:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: my-resource
  labels:
    heritage: my-custom-label
```

Managing access to cluster-wide resources

The module allows you to manage project access to cluster-wide resources such as StorageClass, ClusterIssuer, ClusterRole, and others.

For a description of the mechanism, the resources it uses, and the cluster-wide resources registered by the platform, refer to the module description.

The following sections provide common scenarios for configuring and using the mechanism.

How a policy selects namespaces

A ClusterResourceGrantPolicy (`multitenancy.deckhouse.io/v1alpha2`) has two selectors, `projectSelector` and `namespaceSelector`. The policy applies to a namespace of a project when every selector it sets matches:

- `projectSelector` is matched against the labels of the Project object. It selects every namespace of a project at once, including an additional namespace created later, so use it to select a project as a whole. The module puts the `projects.deckhouse.io/project: <PROJECT_NAME>` and `projects.deckhouse.io/project-template: <PROJECT_TEMPLATE_NAME>` labels on every Project, so a project can also be selected by its name or template. The virtual projects carry only the first of these labels. The two labels cannot be set to another project or template. A manifest that replaces a whole Project may leave them out. The request is admitted with a warning, and the module puts the labels back. The template label of a Project changes as soon as `spec.projectTemplateName` changes. The same label on the namespaces shows the template they were rendered from, and the service policies of a template select namespaces by it.
- `namespaceSelector` is matched against the labels of the Namespace. It narrows the choice to some namespaces of the selected projects, or of all projects when `projectSelector` is not set. For example, it can select only the main namespace (the `projects.deckhouse.io/project-namespace` label does not exist) or only the namespaces labeled by a template.
- A policy with **neither** selector matches no project on its own. Such a policy is a library policy, applied to a project through `grantPolicies` of its ProjectTemplate or of the Project itself (`spec.grants.grantPolicies`). An explicit empty selector (`{}`) matches everything.

The namespaces of the virtual projects `deckhouse` and `default` are never covered, even by `{}`.

An additional namespace is created by a project user and carries only the labels the module sets and the labels of the project template. A policy that restricts a resource through `namespaceSelector` may therefore not cover a new additional namespace. This happens when the selector relies on a label set on a namespace by hand, on a template label whose value was changed by hand on the main namespace, or on `projects.deckhouse.io/project-namespace`, whose value is the name the user chooses. If the GrantableClusterResourceDefinition of the resource has `defaultAvailability: All` (the default), such a namespace gets access to every resource of that type.

The policy reports this in its `NewNamespacesCovered` condition. The condition checks `namespaceSelector` against the labels that a new additional namespace of each covered project would get. Denied names count as a restriction for any `defaultAvailability` value. An allow-list or `availabilityDefault: None` counts only when `defaultAvailability` is `All`.

Do not select namespaces by the `projects.deckhouse.io/project-namespace` label without a `projectSelector`. A user of any project can create a ProjectNamespace with the name that such a `namespaceSelector` expects. The policy then applies in that project and makes the resources it allows available there.

The `multitenancy.deckhouse.io/v1alpha1` version is still served. Its `projectSelector` is matched against the labels of the namespace and corresponds to `namespaceSelector` of `v1alpha2`. `v1alpha1` has no field for the `v1alpha2` `projectSelector`, so a `v1alpha1` client sees it as JSON in the

`multitenancy.deckhouse.io/v1alpha2-project-selector` annotation. A policy with this annotation selects projects by it, even though its `v1alpha1` `projectSelector` is empty.

To move a policy manifest from `v1alpha1` to `v1alpha2`, rename its `projectSelector` to `namespaceSelector`. Do not change only `apiVersion`. The same `projectSelector` is then matched against the labels of the Project, so a selector by a label that only the namespace has, such as `kubernetes.io/metadata.name` or a label from `namespaceMetadata`, matches nothing, and the policy silently stops applying to those namespaces.

When you change such a policy through `v1alpha1`, keep the annotation. `d8 k apply` and `d8 k edit` keep it, while `d8 k replace` with a manifest that lacks the annotation removes the `projectSelector`. To return to an old `v1alpha1` manifest after you set the `v1alpha2` `projectSelector`, remove the annotation explicitly, because `d8 k apply` of the old manifest leaves it in place.

For cluster administrators

The following examples show how to configure project access to cluster-wide resources using ClusterResourceGrantPolicy. They select projects with `projectSelector` by a label on the Project, which covers every namespace of the project.

Because the labels of a Project and of its namespaces take part in the match, the right to change these labels decides which policies apply. The labels of a Project are changed with the `d8:system-capability:multitenancy-manager:edit` capability, which the `iam` subsystem manager has and which also allows creating and changing the policies. The labels of a namespace are changed with the `d8:subsystem-capability:cluster:manage` `resources` capability, which the `cluster` subsystem manager has. The project roles `d8:project:*` and `d8:namespace:*` only read namespaces.

Restricting StorageClass for a project

To allow projects to use only the `fast-ssd` and `standard` StorageClasses and use `fast-ssd` by default, create the following ClusterResourceGrantPolicy:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: production-storage
spec:
  projectSelector:
    matchLabels:
      environment: production
  resources:
    - resourceName: storageclasses
      default: fast-ssd
      allowed:
        - fast-ssd
        - standard
```

When a PersistentVolumeClaim is created without a value in `spec.storageClassName`, `fast-ssd` is automatically assigned to this field. If a StorageClass that is not in the allowed list is specified, it is replaced with `fast-ssd`, because StorageClass uses the `Coerce` default assignment mode. This also covers a class that the built-in Kubernetes admission controller has filled in. The replacement is reported as an admission warning in the response to the request, so the `d8 k` output shows both the original value and the substituted one. If the project has no default StorageClass, such a PersistentVolumeClaim is rejected.

A PersistentVolumeClaim that restores a volume from a snapshot or clones another volume (`spec.dataSource` or `spec.dataSourceRef` is set) keeps its StorageClass: the class must be served by the CSI driver of the source, so it is not replaced with the project default. If such a StorageClass is not available to the project, the PersistentVolumeClaim is rejected with an explanation; specify a StorageClass that is available to the project.

To check which StorageClasses are available to the project, run the following command:

```
d8 k get available storageclasses -n <PROJECT_NAME> -o yaml
```

> **i** While the `storage-foundation` module of version 1.0.3 or later is enabled, the `storageclasses` definition and the `storageclasses-pvc` GrantableClusterResourceReference are registered by that module and can differ from the ones described here, see the documentation of that module.

Restricting ClusterIssuer for a project

To allow projects to use only the `letsencrypt-prod` and `vault-issuer` ClusterIssuers and use `letsencrypt-prod` by default, create the following ClusterResourceGrantPolicy:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: production-issuers
spec:
  projectSelector:
    matchLabels:
      environment: production
  resources:
    - resourceName: clusterissuers
      default: letsencrypt-prod
      allowed:
        - letsencrypt-prod
        - vault-issuer
```

The policy applies to a ClusterIssuer specified in either of the following ways:

- In the `.spec.issuerRef.name` field of a Certificate if `.spec.issuerRef.kind` is set to ClusterIssuer.
- In the `cert-manager.io/cluster-issuer` annotation of an Ingress.

When a Certificate with a ClusterIssuer is created without a value in `.spec.issuerRef.name`, `letsencrypt-prod` is automatically assigned to this field. If a ClusterIssuer that is not in the allowed list is specified, the Certificate is rejected.

No default value is assigned to the `cert-manager.io/cluster-issuer` annotation. If the annotation is specified, its value is checked against the same list of allowed ClusterIssuers.

> **i** Access management for ClusterIssuer is available only when the `cert-manager` module is enabled: the `clusterissuers` definition is shipped by that module.

Restricting ClusterRoles for a project

By default, a RoleBinding in a project namespace can reference every ClusterRole with the `rbac.deckhouse.io/delegatable: "true"` label, and no other ClusterRole. A policy cannot make a ClusterRole without this label available. To use such a ClusterRole in projects, add the label to it (see Roles available in a RoleBinding inside a project).

To allow the projects of the `payments` team to use only the `my-custom-role` ClusterRole and the ClusterRoles with the `shared: "true"` label, create the following ClusterResourceGrantPolicy:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: extra-roles
spec:
  projectSelector:
    matchLabels:
      team: payments
  resources:
    - resourceName: clusterroles
      allowed:
        - my-custom-role
      allowedSelector:
        matchLabels:
          shared: "true"
```

In RoleBindings of these projects, only these ClusterRoles can be used, and only the ones with the `rbac.deckhouse.io/delegatable: "true"` label. The other delegatable ClusterRoles, such as `d8:project:*` and `d8:namespace:*`, become unavailable in them, including the RoleBindings that the `manifests` of the template create. So list in the policy every role that these projects bind. ProjectRoleBinding and ClusterProjectRoleBinding are not affected, because the controller creates their RoleBindings.

The `rbac.deckhouse.io/delegatable: "true"` label is required on every ClusterRole the policy names: the `clusterroles` registration excludes roles without it from all projects, and an exclusion takes precedence over `allowed` and `allowedSelector`. A policy entry that names a role without the label grants nothing. The controller reports this in the `AllowedEffective` condition of the ClusterResourceGrantPolicy status, with the role name in the message:

```
d8 k get clusterresourcegrantpolicy extra-roles -o jsonpath='{.status.conditions[?
(@.type=="AllowedEffective")]}'
```

When a RoleBinding is created or modified, the ClusterRole specified in it is checked for availability to the project. No ClusterRole value is assigned automatically.

Restricting LoadBalancerClass for a Service

To allow projects to use only the `internal-lb` and `edge-lb` LoadBalancerClass values and use `internal-lb` by default, create the following ClusterResourceGrantPolicy:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: lb-classes
spec:
  projectSelector:
    matchLabels:
      environment: staging
  resources:
    - resourceName: loadbalancerclasses
      default: internal-lb
      allowed:
        - internal-lb
        - edge-lb
```

Unlike StorageClass, ClusterIssuer, and ClusterRole, LoadBalancerClass is not a separate Kubernetes resource. The policy defines the allowed values of the `.spec.loadBalancerClass` field for Services of the `LoadBalancer` type.

When a Service of the `LoadBalancer` type is created without a value in `.spec.loadBalancerClass`, `internal-lb` is automatically assigned to this field. If a value that is not in the allowed list is specified, the Service is rejected.

The policy does not apply to Services of other types.

Granting access to all resources of a specific type

To allow specific projects to use all resources of a selected type without listing them explicitly, set `availabilityDefault: All`.

The following policy allows all projects with the `environment: sandbox` label to use any StorageClass:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: open-storage-for-sandbox
spec:
  projectSelector:
    matchLabels:
      environment: sandbox
  resources:
    - resourceName: storageclasses
      availabilityDefault: All
```

The registered resources are available to all projects by default, so `availabilityDefault: All` changes something only where another policy restricts the resource. There it overrides the `allowed` and `allowedSelector` lists of every policy that applies to the project, the policies of its template included. `denied`, `deniedSelector` and the `excluded` filters of the registration still apply. The resources that match the `reserved` filters of the registration stay unavailable, see “Granting a reserved resource”.

Usually, explicitly specifying allowed resources using `allowed` or `allowedSelector` is sufficient for access management. Use `availabilityDefault: All` when the selected projects need access to all resources of the specified type.

Granting a reserved resource

A GrantableClusterResourceDefinition can mark some resources as reserved with `reserved`. A reserved resource is unavailable to projects by default, even when the other resources of its type are available. It becomes available to a project only if a policy that applies to the project lists it in `allowed` or matches it with `allowedSelector`. `availabilityDefault: All` and `defaultAvailability` do not make it available. `denied`, `deniedSelector` and the `excluded` filters take precedence over `allowed` and `allowedSelector` here as well.

An `allowedSelector` opens every reserved resource it matches. A broad or negative selector (`Exists`, `NotIn`, `DoesNotExist`) written for ordinary resources therefore also grants the reserved resources that happen to match it. To grant a reserved resource, name it in `allowed` or use a selector that targets it explicitly.

In the following examples, the `myclusterresources` registration reserves the `premium` and `internal` resources.

To grant a reserved resource without narrowing the other resources of the type, list it in `allowed` and set `availabilityDefault: All`:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: grant-premium
spec:
  projectSelector:
    matchLabels:
      tier: critical
  resources:
    - resourceName: myclusterresources
      allowed:
        - premium
      availabilityDefault: All
```

The selected projects get every resource of the type that is not reserved, and `premium`. The `internal` resource stays unavailable, because `availabilityDefault: All` does not open reserved resources. `availabilityDefault: All` also overrides the `allowed` and `allowedSelector` lists of the other policies that apply to the project (see “Granting access to all resources of a specific type”).

`allowed` without `availabilityDefault` makes every resource not on its list unavailable, as in any other policy. If a project must stay restricted to a list, for example by the policy of its template, grant the reserved resource with `allowed` alone: the `allowed` lists of all policies that apply to the project add up. Alternatively, list in one policy every resource the project needs, the reserved one included.

To make a reserved resource the project default, specify it in both `allowed` and `default` of the same entry. A default that the project may not use is ignored. This also applies to a reserved resource marked as the default by `defaultFrom`: it becomes the project default only where a policy allows it.

The table shows what a project gets for typical combinations of policies. The registration reserves `premium` and `internal`, excludes `system` with `excluded`, and has `defaultAvailability: All`. The `premium` resource carries the `tier: critical` label. “Policies of the project” lists the entries of all policies that apply to the project.

Policies of the project	standard	premium (reserved)	internal (reserved)	system (excluded)
None	available	—	—	—
`availabilityDefault: All`	available	—	—	—
`allowed: [premium]`	—	available	—	—
`allowed: [premium]` and `availabilityDefault: All`	available	available	—	—
`allowedSelector` matching `tier: critical`	—	available	—	—
`allowed: [standard]` in the template policy and `allowed: [premium]` in another policy	available	available	—	—
`allowed: [premium]` and, in another policy, `denied: [premium]`	—	—	—	—
`allowed: [system]`	—	—	—	—

Policies of the project	standard	premium (reserved)	internal (reserved)	system (excluded)
`allowed: [system]` and `availabilityDefault: All`	available	—	—	—

Denying individual resources

To prevent projects from using individual resources while keeping the others available, use `denied` or `deniedSelector`.

The following policy prevents projects with the `environment: dev` label from using the `expensive-nvme` and `archived-hdd` StorageClasses:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: deny-expensive-storage
spec:
  projectSelector:
    matchLabels:
      environment: dev
  resources:
    - resourceName: storageclasses
      denied:
        - expensive-nvme
        - archived-hdd
```

Deny rules take precedence over allow rules. If a resource matches both `denied` or `deniedSelector` and `allowed` or `allowedSelector`, it is considered unavailable.

Managing access using label selectors

To manage access to resources without listing their names, use `allowedSelector` and `deniedSelector`. Selectors allow or deny resources based on their labels.

The following policy allows projects with the `tier: shared` label to use StorageClasses with the `shared: "true"` label, except for StorageClasses with the `deprecated: "true"` label:

```
apiVersion: multitenancy.deckhouse.io/v1alpha2
kind: ClusterResourceGrantPolicy
metadata:
  name: shared-storage-only
spec:
  projectSelector:
    matchLabels:
      tier: shared
  resources:
    - resourceName: storageclasses
      allowedSelector:
        matchLabels:
          shared: "true"
      deniedSelector:
        matchLabels:
          deprecated: "true"
```

Granting cluster-wide resources through a project template

The availability rules for cluster-wide resources can be set directly in a structured template — they then automatically apply to all projects created from that template:

- `spec.resources`: Rules inside the template, in the same format as `resources` in a ClusterResourceGrantPolicy (resource name, `allowed`/`allowedSelector`, `default`).
- `spec.grantPolicies`: List of names of **library** ClusterResourceGrantPolicy objects. A library policy describes a reusable set of rules and sets neither `projectSelector` nor `namespaceSelector`, because the referencing template determines which projects it applies to. This way, for example, a “corporate StorageClasses” policy can be maintained by one administrator and used by several templates.

The following template restricts StorageClass for its projects and connects a library policy:

```
apiVersion: deckhouse.io/v1alpha2
kind: ProjectTemplate
metadata:
  name: my-template
spec:
  resources:
    - resourceName: storageclasses
      allowed: ["standard"]
      default: standard
  grantPolicies:
    # A library ClusterResourceGrantPolicy without selectors.
    - corporate-issuers
```

For each source, the controller creates a service policy named `template-<template>-<source>` (for `spec.resources` — `template-<template>-inline`). A template that references a policy named `inline` is rejected, and so is a template whose service policy names would match those of another template. A reference to a non-existent policy or to a policy with either selector is rejected when the template is created or updated. A service policy selects the namespaces of the template’s projects with `namespaceSelector` by their `projects.deckhouse.io/project-template` label. The label is set when the template renders, so after a project switches to another template, the rules of the old template apply until the new one has rendered.

Granting cluster-wide resources to one project

A project can be given cluster-wide resources of its own, on top of the ones its template grants, in `spec.grants` of the Project. The field has the format of the template fields: `resources` with the rules themselves and `grantPolicies` with the names of library ClusterResourceGrantPolicy objects.

```
apiVersion: deckhouse.io/v1alpha3
kind: Project
metadata:
  name: my-project
spec:
  projectTemplateName: my-template
  grants:
    resources:
      - resourceName: storageclasses
        allowed: ["fast"]
    grantPolicies:
      - corporate-issuers
```

For each source, the controller creates a service policy named `project-<PROJECT_NAME>-<SOURCE>` (for `resources`, `project-<PROJECT NAME>-inline`), owned by the project and selecting it with `projectSelector` by its `projects.deckhouse.io/project` label, so the policy applies to every namespace of the project, the ones created later included. Deleting the project deletes its service policies. The rules of the project and of its template combine as the rules of any two policies do: the allowed resources add up, and a resource that one of them denies stays unavailable.

The field has these rules:

- Changing `spec.grants` needs the right to create ClusterResourceGrantPolicy objects, the same right as creating such a policy directly. A user who may only change a project cannot grant it cluster-wide resources.

- The references and the names are checked like those of a template. A reference to a policy named `inline`, to a missing policy or to a policy with a selector is rejected. An empty or invalid `allowedSelector` or `deniedSelector` in `resources` is rejected. A `spec.grants` whose service policy names would match a policy that is not the project's, or the service policies of another project, is rejected, and so is a `spec.grants` whose service policy name is not a valid object name, which a very long name of a referenced policy causes.
- If a service policy cannot be applied, or a referenced policy is deleted later, the controller records a Warning event on the Project. The other sources stay applied, and a source removed from `spec.grants` is revoked all the same. A policy that is created again is picked up without waiting.
- The names that start with `project-` are reserved for the service policies, and a service policy is changed only through `spec.grants` of its project.
- `deckhouse.io/v1alpha2` has no place for the field, so a change of a project that has `spec.grants` through that version, a write of its status included, is rejected: it would erase the field. Change such a project through `deckhouse.io/v1alpha3`.

For project users

Project users can view the cluster-wide resources available to them and check the values used by default.

Viewing available cluster-wide resources

An AvailableClusterResource is automatically created in each project namespace for every registered resource. These resources show which cluster-wide resources are available to the project and which resource is used by default.

To view all cluster-wide resources available to a project, run the following command:

```
d8 k get available -n <PROJECT_NAME>
```

Example output:

```
NAME               KIND          DEFAULT      AVAILABLE   AGE
storageclasses     StorageClass  fast-ssd     2           5m
clusterissuers     ClusterIssuer letsencrypt  2           5m
```

To view detailed information about resources of a specific type, such as StorageClass, run the following command:

```
d8 k get available storageclasses -n <PROJECT_NAME> -o yaml
```

Example output (abridged):

```
status:
  grantedResourceKind: StorageClass
  default: fast-ssd
  availableCount: 2
  available:
    - name: fast-ssd
      default: true
      fields:
        provisioner: rbd.csi.ceph.com
        reclaimPolicy: Delete
        volumeBindingMode: WaitForFirstConsumer
        allowVolumeExpansion: true
    - name: hdd
      fields:
        provisioner: local.csi.storage.deckhouse.io
        reclaimPolicy: Retain
        volumeBindingMode: WaitForFirstConsumer
```

The `status.available[].fields` field contains the values of some fields of each available resource, so that you can choose a resource without access to the resource itself. The fields to show are selected by the module that registers the resource, in the `spec.catalogFields` parameter of its GrantableClusterResourceDefinition. For StorageClass, these are `provisioner`, `reclaimPolicy`, `volumeBindingMode` and `allowVolumeExpansion`. A value keeps its JSON type (for example, `allowVolumeExpansion` is a boolean). A field whose value is missing in the resource is not shown: in the example above, `hdd` has no `allowVolumeExpansion`. A change in a cluster-wide resource usually appears in AvailableClusterResource within 30 seconds.

An AvailableClusterResource exists as long as the corresponding GrantableClusterResourceDefinition: when the GrantableClusterResourceDefinition is deleted, its AvailableClusterResource is deleted from the namespaces of all projects.

Rejection due to an unavailable cluster-wide resource

If the cluster-wide resource is not available to the project when an object is created, or when an update sets a new value, the request is rejected with the following message:

```
[multitenancy] <KIND> "<OBJECT_NAME>" references "<RESOURCE_NAME>" which is not available to project "
<PROJECT_NAME>". Ask the cluster administrator to grant it.
```

In this case, check the available resources using AvailableClusterResource. Use a resource from the list of available resources or ask the cluster administrator to grant access to the required resource.

Assigning default values automatically

For some cluster-wide resources, the administrator can configure a default value. If the corresponding value is not specified when an object is created, it is assigned automatically.

For example, if `fast-ssd` is configured as the default StorageClass, the `fast-ssd` value can be automatically assigned to `.spec.storageClassName` when a PersistentVolumeClaim is created without this field.

You can specify a value explicitly by selecting any resource available to the project from the corresponding AvailableClusterResource.

Projects without a default value

AvailableClusterResource reports the project default in `status.default` and marks it among the names in `status.available` with `default: true`. Both are absent in the following cases:

- the grant policy sets no `default`, and the registration has no `defaultFrom`;
- the resource is granted as a list of values rather than as objects of the cluster, and `defaultFrom` does not apply to it;
- `defaultFrom` is set, but not exactly one object has the annotation set to `true`;
- a default is set, but the project may not use it, for example the default StorageClass of the cluster is not among the names granted to the project, or the default is a reserved resource that no policy allows for the project.

Then the field stays empty, and the object is created or rejected by the usual rules.

For module developers

Configuring validation of a cluster-wide resource reference

If a module resource contains a field that references a cluster-wide resource already registered using GrantableClusterResourceDefinition, create a GrantableClusterResourceReference. It defines which resources and fields use the cluster-wide resource and allows you to configure availability checks and automatic default value assignment.

For example, to configure validation of the StorageClass specified in the `.spec.storageClassName` field of a PostgresDatabase resource, add the following object to the module’s Helm chart:

```
apiVersion: multitenancy.deckhouse.io/v1alpha1
kind: GrantableClusterResourceReference
metadata:
  name: postgresdatabases-storageclasses
  labels:
    heritage: deckhouse
    module: postgres
spec:
  grantableClusterResourceName: storageclasses
  rule:
    apiGroups: ["postgres.example.com"]
    apiVersions: ["*"]
    resources: ["postgresdatabases"]
  fieldPaths:
    - path: $.spec.storageClassName
      defaulting: Coerce
```

In this example, `storageclasses` is the name of an existing GrantableClusterResourceDefinition, while `Coerce` allows the default StorageClass available to the project to be assigned when a PostgresDatabase is created if the value is missing or unavailable to the project.

If the resources listed in `rule` store the reference at different paths, limit `fieldPaths` items to specific resources using the `resources` parameter. For example, a Job and a CronJob store the PriorityClass name at different paths. In this case, when PriorityClass is registered as `priorityclasses`, use the following example:

```
apiVersion: multitenancy.deckhouse.io/v1alpha1
kind: GrantableClusterResourceReference
metadata:
  name: jobs-priorityclasses
  labels:
    heritage: deckhouse
    module: my-module
spec:
  grantableClusterResourceName: priorityclasses
  rule:
    apiGroups: ["batch"]
    apiVersions: ["v1"]
    resources: ["jobs", "cronjobs"]
  fieldPaths:
    - resources: ["jobs"]
      path: $.spec.template.spec.priorityClassName
    - resources: ["cronjobs"]
      path: $.spec.jobTemplate.spec.template.spec.priorityClassName
```

For each object, the most specific of the matching `fieldPaths` items is used: an item limited by `resources` takes precedence over items limited only by `apiGroups` or `apiVersions` and over an item without limits, which applies to all other resources from `rule`. `*` in `resources` does not limit the item: it has the same effect as omitting the parameter.

An item whose `match` condition does not hold for the object is skipped, and of equally limited items, an item with `match` takes precedence over an item without it. So several items with the same `path` can handle different objects of one resource, each with its own default assignment mode: the `storageclasses-pvc` reference checks the StorageClass of a PersistentVolumeClaim with `spec.dataSource` or `spec.dataSourceRef` in the `None` mode and of any other PersistentVolumeClaim in the `Coerce` mode. The text of the `message` parameter is appended to the rejection of an object for that item.

For descriptions of GrantableClusterResourceReference parameters, default assignment modes, `match` conditions, and configuration for resources with multiple API versions, refer to the resource description.

Registering a new cluster-wide resource

To add access management for a new cluster-wide resource:

1. Create a GrantableClusterResourceDefinition to register the cluster-wide resource with the access management mechanism.
2. Create one or more GrantableClusterResourceReference objects to define the fields that reference it.

   For example, to register the MyClusterResource resource, add the following object to the module's Helm chart:

   ```
   apiVersion: multitenancy.deckhouse.io/v1alpha1
   kind: GrantableClusterResourceDefinition
   metadata:
     name: myclusterresources
     labels:
       heritage: deckhouse
       module: my-module
   spec:
     grantedResource:
       apiGroup: my.example.com
       kind: MyClusterResource
     enforcement: Managed
     defaultAvailability: All
     excluded:
       - matchExpressions:
           - key: my.example.com/internal
             operator: Exists
   ```

   In this example, the registered resources are available to projects by default. Resources with the `my.example.com/internal` label are excluded from the available resources.

   To keep some resources unavailable by default but let an administrator grant them to individual projects, list them in `reserved` instead of `excluded`. An administrator grants such a resource as described in "Granting a reserved resource".

   Only a cluster-scoped resource can be specified in `grantedResource`. A definition of a namespaced resource (for example, Secret) is refused when it is created or updated. If such a definition is stored anyway, it is not processed: no project gets its AvailableClusterResource, and the `GrantedResourceValid` condition is `False` (read more in section "Checking resource registration status"). A resource whose CRD is not installed yet is accepted: its scope is checked once the resource is served.

   For descriptions of GrantableClusterResourceDefinition parameters and available access management modes, refer to the resource description.
3. After registering the cluster-wide resource, configure references to it using GrantableClusterResourceReference as described in "Configuring validation of a cluster-wide resource reference".

Showing resource fields to projects

Project users see the available cluster-wide resources in AvailableClusterResource (read more in section "Viewing available cluster-wide resources"), but usually cannot read the resources themselves. To help them choose, list the fields to show in `spec.catalogFields` of the GrantableClusterResourceDefinition. The controller copies the values of these fields from every available resource into `status.available[].fields` of AvailableClusterResource.

For example:

```
apiVersion: multitenancy.deckhouse.io/v1alpha1
kind: GrantableClusterResourceDefinition
metadata:
  name: myclusterresources
spec:
  grantedResource:
    apiGroup: my.example.com
    kind: MyClusterResource
  catalogFields:
    - name: tier
      path: $.spec.tier
    - name: region
      path: $.metadata.labels['my.example.com/region']
```

Rules:

- `name` is the key in `fields`, in lowerCamelCase; `path` is an RFC 9535 JSONPath singular query that selects one value: member names and array indexes only, without wildcards (`*`), descendant segments (`..`), slices or filters.
- Paths that read `metadata.managedFields` or the `kubectl.kubernetes.io/last-applied-configuration` annotation, or a parent that contains them (for example, `$.metadata`), are not allowed: these fields hold a copy of the whole resource.
- At most 10 fields can be listed.
- A value longer than 512 bytes in JSON serialization is not shown; a field whose value is missing in the resource is not shown either.
- If the `status.available` list of an AvailableClusterResource with the fields of all resources would take more than 512 KiB in JSON serialization, no fields are shown in it; the names and the default stay.
- `catalogFields` works only for definitions with `grantedResource`, which must be cluster-scoped.
- The values are visible to all users of every project the resource is available to. List only non-secret data.

Invalid paths and `catalogFields` without `grantedResource` are refused when the GrantableClusterResourceDefinition is created or updated, and are reported in its `CatalogFieldsValid` condition. Values left out for their size depend on the resources and the project, so they are reported by `CatalogFieldsSkipped` warning events on the GrantableClusterResourceDefinition:

```
d8 k describe grantableclusterresourcedefinition myclusterresources
```

Using x-deckhouse-grantable-resource in Deckhouse Platform application settings

To manage access to cluster-wide resources in Deckhouse Platform application settings, use the `x-deckhouse-grantable-resource` OpenAPI extension. In this case, deckhouse-controller automatically checks the availability of the specified resource and assigns the default value when necessary. You do not need to create GrantableClusterResourceReference manually.

For a description of the extension and usage examples, refer to “Application settings”.

Checking resource registration status

You can check the status of GrantableClusterResourceDefinition and its associated GrantableClusterResourceReference resources in the `status` field:

- `GrantableClusterResourceDefinition.status.references`: Contains a list of associated GrantableClusterResourceReference resources and information about the resources to which they apply.
- `GrantableClusterResourceReference.status.bound`: Indicates whether the corresponding GrantableClusterResourceDefinition was found.
- `GrantableClusterResourceReference.status.conditions[Bound]`: `True` with the reason `Resolved` if the definition was found, `False` with the reason `UnknownResource` if it is missing. `UnknownResource` can indicate an incorrect GrantableClusterResourceDefinition name or a missing registration.
- `GrantableClusterResourceReference.status.conditions[FieldPathsValid]`: Whether `spec.fieldPaths` pass the checks applied when the object is created or updated (reasons

`Valid`, `InvalidFieldPaths`; the message lists all problems). `False` means the object was stored bypassing these checks; the invalid paths are skipped during availability checks.
- `GrantableClusterResourceDefinition.status.conditions[GrantedResourceValid]`: Whether `spec.grantedResource` can be processed. `True` with the reason `ClusterScoped` for a cluster-scoped resource or `ValueBacked` for a definition without `grantedResource`; `False` with the reason `Namespaced` for a namespaced resource, which is not processed; `Unknown` with the reason `KindNotServed` while the resource is not served (for example, its CRD is not installed yet) or `MappingFailed` if its scope could not be determined.
- `GrantableClusterResourceDefinition.status.conditions[CatalogFieldsValid]`: Whether `spec.catalogFields` pass the checks applied when the object is created or updated (reasons `Valid`, `InvalidCatalogFields`; the message lists all problems). A definition without `catalogFields` has the condition `True`. Values left out for their size are reported by `CatalogFieldsSkipped` events (read more in section “Showing resource fields to projects”).

For example:

```
d8 k get grantableclusterresourcedefinition myclusterresources -o jsonpath='{range
.status.conditions[*]}{.type}={.status} ({.reason}): {.message}{"\n"}{end}'
```

The multitenancy-manager module: FAQ

> ⚠ The module lifecycle stage: Preview

Managing access to cluster-wide resources

What should I do if a PersistentVolumeClaim is rejected with an “is not available to project” error?

The StorageClass specified in `spec.storageClassName` is unavailable to the project. The webhook rejects such a request with a message similar to the following:

```
[multitenancy] PersistentVolumeClaim "<OBJECT_NAME>" references "<RESOURCE_NAME>" which is not available
to project "<PROJECT_NAME>". Ask the cluster administrator to grant it.
```

To view the available StorageClasses, run the following command:

```
d8 k get available storageclasses -n <PROJECT_NAME> -o yaml
```

If the required StorageClass is not in the list, use an available one or ask the cluster administrator to add it to the ClusterResourceGrantPolicy.

You can check the availability of other cluster-wide resources, such as ClusterIssuer, ClusterRole, and LoadBalancerClass, in the same way using the corresponding AvailableClusterResource.

How can I view access policies applied to a project?

A ClusterResourceGrantPolicy applies to a namespace of a project when every selector it sets matches: `spec.projectSelector` is matched against the labels of the Project, `spec.namespaceSelector` against the labels of the namespace. A policy with neither selector is a library policy and applies only through `spec.grantPolicies` of a ProjectTemplate. For details, refer to “How a policy selects namespaces”.

To view all policies and their selectors, run the following command:

```
d8 k get clusterresourcegrantpolicies -o yaml
```

You can view the resulting list of cluster-wide resources available to a specific project using AvailableClusterResource:

```
d8 k get available -n <PROJECT_NAME>
```

What happens to existing objects when access is restricted?

Existing objects continue to use their previously configured values. When an object is updated, only new values are checked, so changing an access policy does not disrupt existing objects. The same holds when access management is enabled on an existing cluster: existing objects do not need to be changed before access policies are created.

If an existing object needs to use a different cluster-wide resource, explicitly change the corresponding field to a value available to the project.

If an existing object uses a cluster-wide resource that is no longer available to the project, the `ClusterResourceGrantPolicyViolation` alert is triggered.

What does the ClusterResourceGrantPolicyViolation alert mean?

The alert indicates that one or more existing objects in a project use a cluster-wide resource that is no longer available to the project under the current policies.

Such objects continue to operate. To resolve the discrepancy, grant the project access to the cluster-wide resource in use or modify the object to use an available resource.

Detailed information about violations is available on the Grafana dashboard under “Security” → “Cluster Resource Grant Violations”. The `d8_cluster_objects_grant_violated` metric is used for monitoring; the module controller exports it, applying the same availability rules as the admission webhook.

How can I allow all StorageClasses except specific ones?

To deny specific StorageClasses while keeping the others available, use `denied` or `deniedSelector`. Deny rules take precedence over allow rules.

For a configuration example, refer to “Denying individual resources”.

What happens if there is no ClusterResourceGrantPolicy?

If no ClusterResourceGrantPolicy is configured for a resource, its availability is determined by its registration. The resource is available to all projects if `defaultAvailability: All` (the default value) is set in GrantableClusterResourceDefinition and the resource does not match the `excluded` or `reserved` filters.

For example, the `clusterroles` definition provided by Deckhouse Platform excludes every ClusterRole without the `rbac.deckhouse.io/delegatable: "true"` label. Therefore, such roles are unavailable in RoleBinding even when no policies are configured.

To restrict access, create a ClusterResourceGrantPolicy and specify the projects and the cluster-wide resources available to them.

I created a ClusterResourceGrantPolicy, but nothing changed — why?

Check the following:

1. **Selector match**. Make sure the policy’s `spec.projectSelector` matches the labels of the Project, and its `spec.namespaceSelector` the labels of the namespace:

   Get the project and its labels:

   ```
   d8 k get project <PROJECT_NAME> --show-labels
   ```

   Filter the namespaces by the `projects.deckhouse.io/project=<PROJECT_NAME>` label and show their labels:

   ```
   d8 k get ns -l projects.deckhouse.io/project=<PROJECT_NAME> --show-labels
   ```

   In a `v1alpha1` manifest, `spec.projectSelector` is what `v1alpha2` calls

`spec.namespaceSelector`. Also check the conditions in the policy status. The `SelectorsValid` condition is `False` when a selector is invalid. The `NewNamespacesCovered` condition is `False` when a restriction does not cover a new additional namespace of the project. The `AllowedEffective` condition is `False` when the GrantableClusterResourceDefinition excludes a name listed in `allowed`, for example a ClusterRole without the `rbac.deckhouse.io/delegatable: "true"` label. The message names it (see Restricting ClusterRoles for a project).

2. **Resources available to the project**. Check whether AvailableClusterResource reflects the expected policy settings:

   ```
   d8 k get available <RESOURCE_NAME> -n <PROJECT_NAME> -o yaml
   ```

3. **Cluster-wide resource registration**. Make sure a corresponding GrantableClusterResourceDefinition exists for the `resourceName` value.

4. **Reference registration**. If a specific field is expected to be checked, make sure it is registered using GrantableClusterResourceReference and that the reference is successfully associated with the corresponding GrantableClusterResourceDefinition.

For information about registration status, refer to “Checking resource registration status”.

How does cluster-wide resource access management interact with RBAC?

These mechanisms operate independently. RBAC determines *who can perform* operations on an object, while cluster-wide resource access management determines *which cluster-wide resources* that object can use.

For example, to create a PersistentVolumeClaim, a user must have the appropriate RBAC permissions, and the StorageClass specified in `.spec.storageClassName` must be available to the project.

What happens if the multitenancy-manager module is disabled?

After the module is disabled, cluster-wide resource availability checks and automatic default value assignment are no longer performed. Existing objects remain unchanged.

Fields that use the `x-deckhouse-grantable-resource` extension in Deckhouse Platform application settings are no longer checked either.

The `d8:dict` role of the `user-authz` module continues to work.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The namespace-configurator module

> **i** The module lifecycle stage: General Availability

The `namespace-configurator` module allows to assign annotations and labels to namespaces automatically.

It facilitates to enable new namespaces to monitoring system by adding `extended-monitoring.deckhouse.io/enabled=true` label.

How does it work?

This module monitors the namespaces and configuration:

- It assigns labels and annotations from the configuration to all namespaces that match the `includeNames` pattern and do not match the `excludeNames` pattern.
- Namespaces labeled `heritage` with one of the values `upmeter`, `deckhouse` or `multitenancy-manager` are ignored;
- When changing the module configuration, namespace labels and annotations will be reassigned

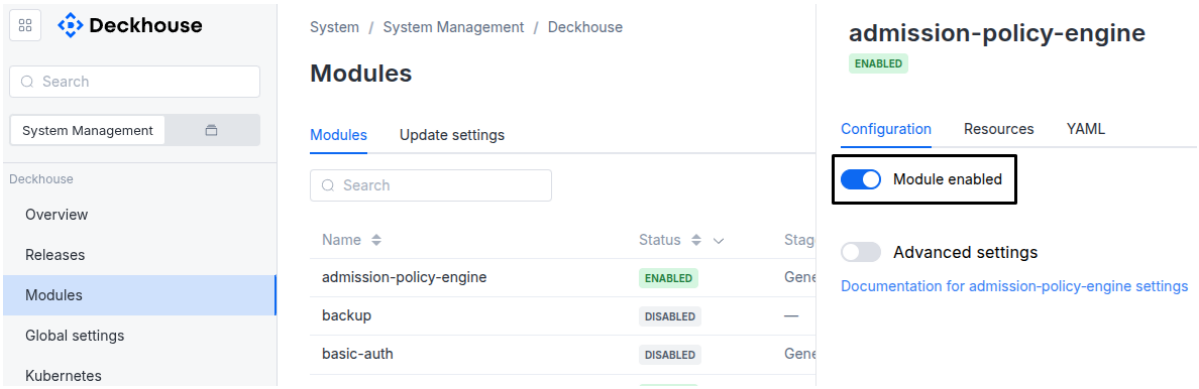
according to the configuration.

What do I need to configure?

All you need to do is to specify list of desired labels and annotations and matching patterns for namespaces in the module configuration.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `namespace-configurator` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

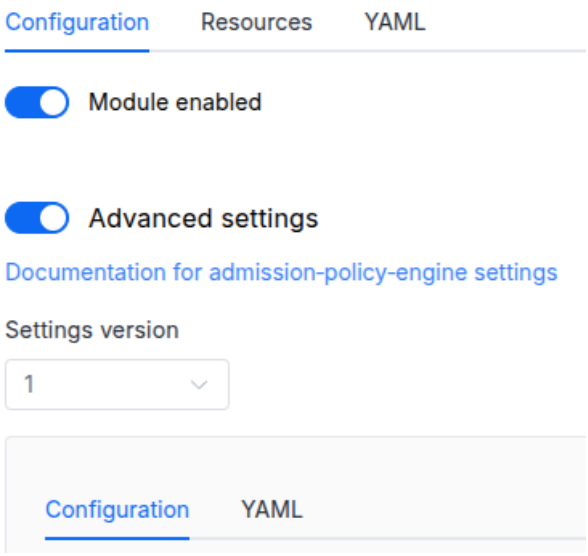
```
d8 system module enable namespace-configurator
```

- **Using ModuleConfig `namespace-configurator`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `namespace-configurator` (create it if necessary);

  Example of a manifest to enable module `namespace-configurator`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: namespace-configurator
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `namespace-configurator` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `namespace-configurator` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `namespace-configurator`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `namespace-configurator` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc namespace-configurator
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `namespace-configurator` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `namespace-configurator`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: namespace-configurator
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.configurations**
    array of objects
    - **settings.configurations.annotations**
      object

      A list of annotations in the `key: "value"` format.

      Example:

      ```
      annotations:
        example: 'true'
      ```

    - **settings.configurations.excludeNames**
      array of strings

      A list of namespace patterns to exclude.

      Default: `[]`

      Example:

      ```
      excludeNames:
      - infra-test
      ```

    - **settings.configurations.includeNames**
      array of strings

      Required value

      A list of namespace patterns to include.

      Default: `[]`

      Example:

      ```
      includeNames:
      - prod-.*
      - infra-.*
      ```

    - **settings.configurations.labels**
      object

      A list of labels in the `key: "value"` format.

      Example:

      ```
      labels:
        istio-injection: 'true'
      ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Example

Add the label `extended-monitoring.deckhouse.io/enabled=true` and the annotation `foo=bar` to every namespace starting with `prod-` and `infra-`, except `infra-test`.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: namespace-configurator
spec:
  version: 1
  enabled: true
  settings:
    configurations:
    - annotations:
        foo: bar
      labels:
        extended-monitoring.deckhouse.io/enabled: "true"
      includeNames:
      - "^prod"
      - "^infra"
      excludeNames:
      - "infra-test"
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

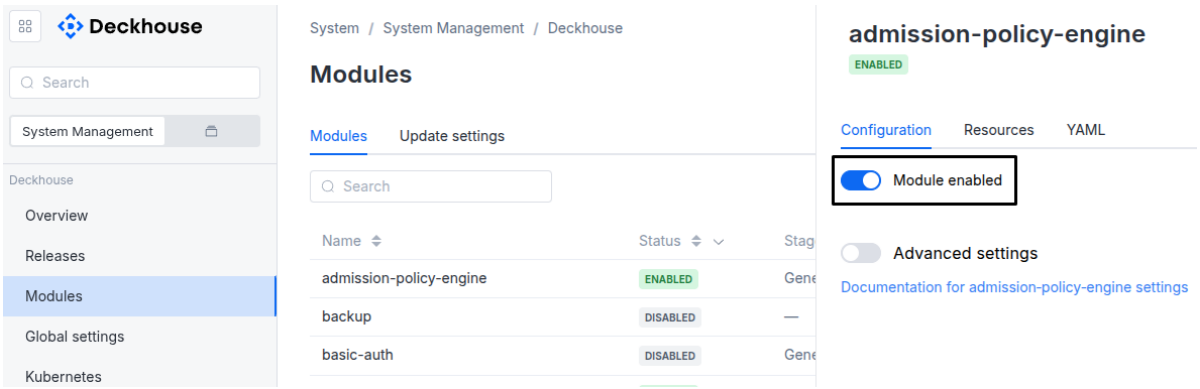
The network-gateway module

> The module lifecycle stage: General Availability

This module creates a network gateway using Kubernetes nodes. It contains a DHCP server and a SNAT manager.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-gateway` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

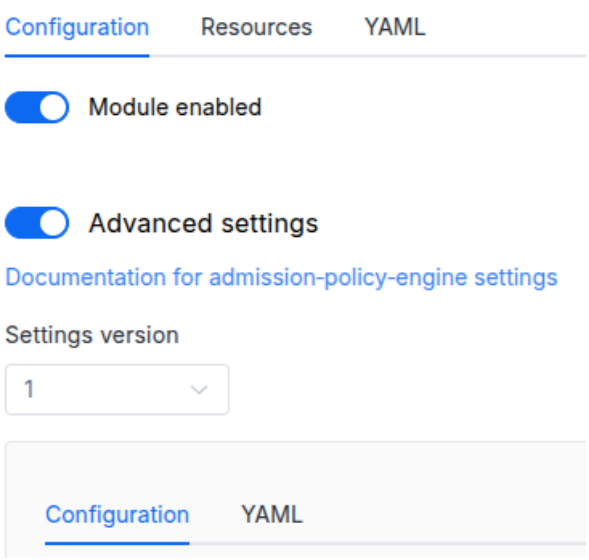
  ```
  d8 system module enable network-gateway
  ```

- **Using ModuleConfig `network-gateway`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `network-gateway` (create it if necessary);

  Example of a manifest to enable module `network-gateway`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: network-gateway
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-gateway` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `network-gateway` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the

module `network-gateway`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `network-gateway` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc network-gateway
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `network-gateway` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `network-gateway`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: network-gateway
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.disableDHCP**
    boolean

    Disables the DHCP server.

    Default: `false`
  - **settings.dns**
    object

    Settings to pass to clients via DHCP.

    - **settings.dns.search**
      array of strings

      List of search domains.

      Example:

      ```
      search:
      - office.example.com
      - srv.example.com
      ```
    - **settings.dns.servers**
      array of strings

      List of DNS servers.

      Example:

```
servers:
- 4.2.2.2
- 8.8.8.8
```

- **settings.nodeSelector**
  object

  Required value

  Selects nodes that will be used to configure iptables rules and to run the DHCP server.

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes. Instance Pods inherit this field as is.

  Example:

  ```
  nodeSelector:
    type: network-gateway
  ```

- **settings.publicAddress**
  string

  Required value

  Replaces the src of the packets outgoing from the LAN.

  Pattern: `^([0-9]{1,3}\.){3}[0-9]{1,3}$`

  Example:

  ```
  publicAddress: 10.220.203.240
  ```

- **settings.storageClass**
  string

  The name of the StorageClass to use for storing the DHCP lease.

  If omitted, the StorageClass of the existing PVC is used. If there is no PVC yet, the StorageClass will be used according to the global storageClass parameter setting.

  The global `storageClass` parameter is only considered when the module is enabled. Changing the global `storageClass` parameter while the module is enabled will not trigger disk re-provisioning.

  *Warning.** Specifying a value different from the one currently used (in the existing PVC) will result in disk re-provisioning and all data will be deleted.

  If `false` is specified, emptyDir will be forced to be used.

  Dnsmasq (underlies our DHCP server) has its own mechanisms for protecting against the duplication of IP addresses if the lease database is lost (but it is better not to lose it).

- **settings.subnet**
  string

  Required value

  The address of a local subnet that gateway serves.

  The DHCP options to pass to clients are generated based on this address:

  - Address pool — numbers starting with 50 and up to the last one.
  - Router — the subnet's first address.

  Pattern: `^([0-9]{1,3}\.){3}[0-9]{1,3}(\/([0-9]|[1-2][0-9]|3[0-2]))$`

  Example:

  ```
  subnet: 192.168.42.0/24
  ```

- **settings.tolerations**
  array of objects

  Tolerations for DHCP Pods and iptables managers.

The same as in the Pods' `spec.tolerations` parameter in Kubernetes. The instance's Pods inherit this field as is.

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The network-policy-engine module

> The module lifecycle stage: General Availability

> ⚠ Do not use the module if the cilium module is enabled because it already has network policy management.

This module manages network policies.

Deckhouse implements a conservative approach to organizing the network based on elementary network backends, such as "pure" CNI or flannel in the `host-gw` mode. This approach is simple and reliable, and has proven itself to be the best.

The NetworkPolicy implementation in Deckhouse is also simple and reliable. It is based on `kube-router` in the Network Policy Controller mode (`--run-firewall`). In this case, `kube-router` transforms NetworkPolicy policies into `iptables` rules that work in any installation regardless of the cloud or the CNI used.

The `network-policy-engine` module deploys a `d8-system` DaemonSet in the namespace with kube-router in the Network Policy Controller mode. As a result, the Kubernetes cluster fully supports Network Policies.

The following policy description formats are supported:

- `networking.k8s.io/NetworkPolicy API`;
- network policy V1/GA semantics;
- network policy beta semantics.

For the NetworkPolicy model and ready-to-use recipes, see the Network policies section of the documentation. Additional example recipes are available in an external repository.

Third-party components

List of third-party software used in the `network-policy-engine` module:

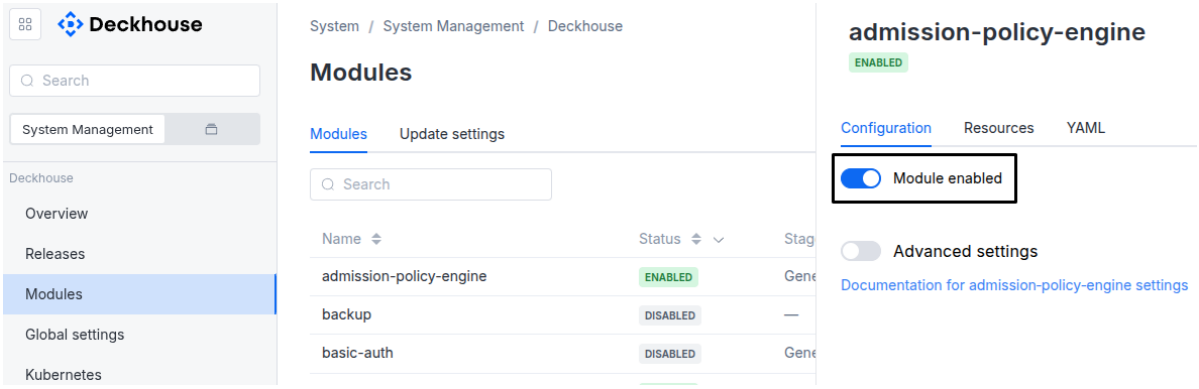
- Kube-router 2.0.1

  License: Apache License 2.0

  A turnkey solution for Kubernetes networking with aim to provide operational simplicity and high performance.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration



> The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-policy-engine` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

```
d8 system module enable network-policy-engine
```

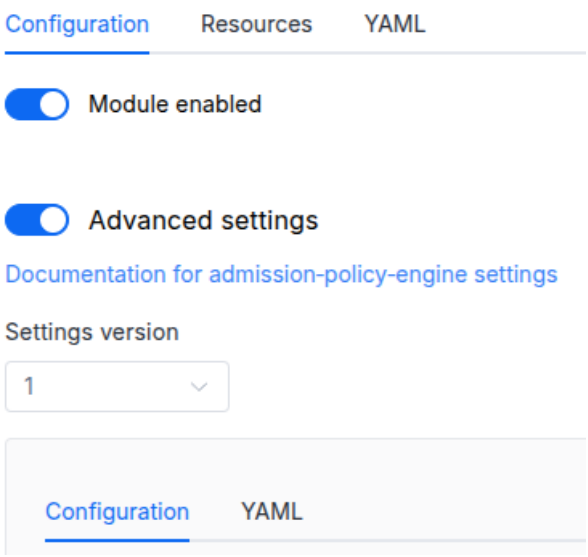
- **Using ModuleConfig `network-policy-engine`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `network-policy-engine` (create it if necessary);

  Example of a manifest to enable module `network-policy-engine`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: network-policy-engine
spec:
  enabled: true
```

How to configure the module...



You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-policy-engine` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab,

excluding the settings section. Save the changes.

Example:

You can also edit the ModuleConfig object `network-policy-engine` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `network-policy-engine`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `network-policy-engine` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc network-policy-engine
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `network-policy-engine` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `network-policy-engine`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: network-policy-engine
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Examples of network policies

Deny external traffic to Pods in the namespace, but allow traffic to external resources from within the namespace

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: delete
spec:
  podSelector: {}
  egress:
  - {}
  ingress:
  - from:
    - podSelector: {}
  policyTypes:
  - Ingress
  - Egress
```

More examples are available in this repository.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The node-local-dns module

> The module lifecycle stage: General Availability
>
> The module has requirements for installation

Module Description

This module deploys a caching DNS server on each cluster node and exports data to `Prometheus` for easy analysis of the cluster's DNS performance using the Grafana board.

The module runs the standard `CoreDNS` server (as part of a DaemonSet) on all nodes supplemented by the algorithm for configuring network and iptables rules.

Purpose

The regular DNS usage in Kubernetes poses some problems that may lead to unnecessary degradation of the service's performance:

- No request caching (in Linux, there is no caching right out-of-the-box; thus, Pods also lack it out-of-the-box).
- All the container-originated DNS requests result in a network request to the cluster DNS. Thus, even requests to resources within the same node result in network requests.
- The Pod request is first resolved in the cluster DNS zones and only then channeled to external DNS servers. For example, the request to `ya.ru` is first resolved in cluster zones such as `cluster.local`, `svc.cluster.local`, `<namespace>.svc.cluster.local`, receives negative responses, and gets appropriately resolved only on the "second" attempt.

Thus, even slight network delays may result in significant service performance degradation due to above problems.

One solution is to deploy a DNS server on each node (which is what this module does).

Outside requests (non-cached ones) are also first resolved in internal zones. Under high load (when a large number of requests are made to the same records simultaneously, as is often the case), such behavior can significantly improve the performance of DNS resolving.

Grafana dashboard

The `Kubernetes / DNS (node local)` dashboard displays:

- General graphs that allow you to evaluate the overall DNS performance.
- Graphs grouped by the node that let you analyze node data in more details if the general charts suggest that this node is unhealthy.
- Upstream-related graphs that allow you to evaluate the performance of the cluster DNS as well as the node servers specified in `/etc/resolv.conf`.

How does it work?

The module performs the following settings on each node:

- Configures an interface with the ClusterIP IP address of the `kube-dns` service.
- Starts a caching CoreDNS server that listens on this address.
- Adds a sophisticated iptables rule that uses a socket if it is open and ordinary Kubernetes magic for clusterIP if it is not.

And here is the rule itself that allows for an easy fallback:

```
-A PREROUTING -d <kube-dns IP address> -m socket --nowildcard -j NOTRACK
```

Aspects of CoreDNS configuration

Main features of the CoreDNS config:

- caching of all requests;
- forwarding all DNS requests to ClusterIP of the cluster DNS.

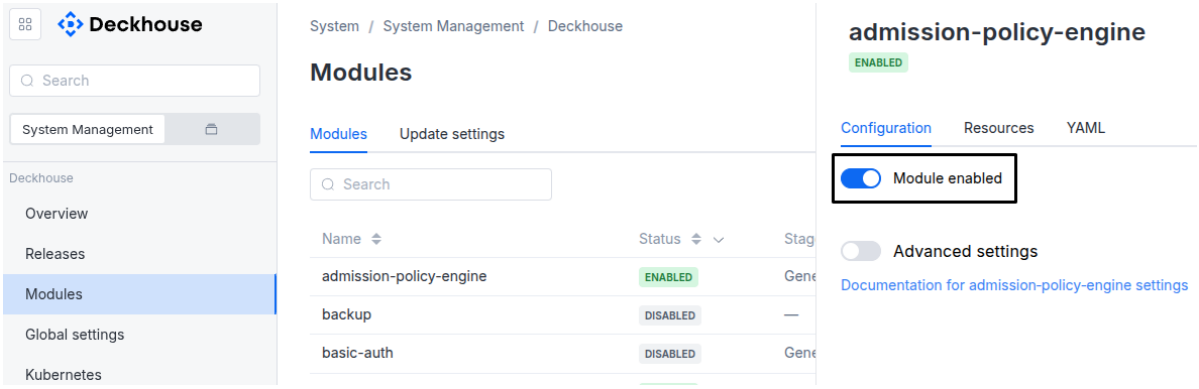
> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> **i** The module lifecycle stage: General Availability
>
> The module has requirements for installation

> **⚠**
> - The module works with all `CNIs`, but in order to work correctly with `cni-cilium`, a number of conditions must be met.
> - By default, when used together with the `cni-simple-bridge` or `cni-flannel` modules, the `node-local-dns` module **does not work** for requests from `hostNetwork`. In this case, all requests go to the `kube-dns` module. You can specify the address `169.254.20.10` in the pod configuration, but if `node-local-dns` module crashes, there will be no *fallback* to the `kube-dns` module.

The module has 5 alerts.



The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-local-dns` module and enable (or disable) the “Module enabled” toggle.

Save changes.

Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

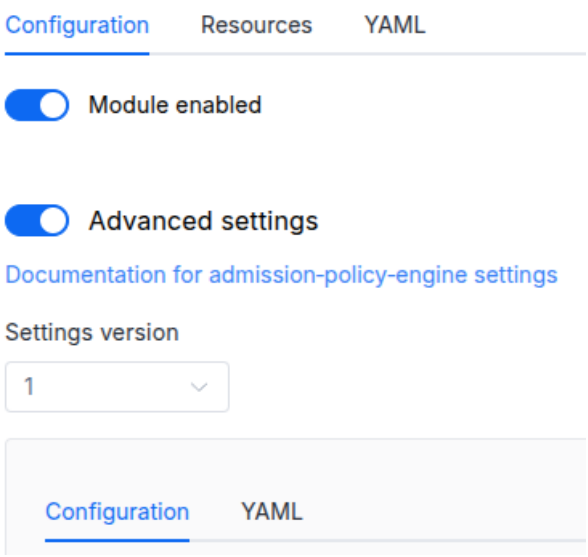
  ```
  d8 system module enable node-local-dns
  ```

- **Using ModuleConfig `node-local-dns`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `node-local-dns` (create it if necessary);

  Example of a manifest to enable module `node-local-dns`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: node-local-dns
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-local-dns` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `node-local-dns` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `node-local-dns`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `node-local-dns` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc node-local-dns
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `node-local-dns` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `node-local-dns`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: node-local-dns
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `kube-dns`: any version.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.disableIPv6**
    boolean

Disables DNS resolution over IPv6 by returning empty responses for `AAAA` queries and `NXDOMAIN` for reverse IPv6 lookup requests in the `ip6.arpa` zone.

Default: `false`

- **settings.enableLogs**
  boolean

  Enables query logging for node-local-dns instances.

  Default: `false`

- **settings.highAvailability**
  boolean

  Manual failover mode management. Within this module, the option affects the DNS records caching mechanism on nodes:

  - `true`: upon the expiration of the TTL for an individual DNS record, node-local-dns will continue to return the “stale” value immediately while simultaneously requesting a fresh value from the upstream kube-dns. Thus, in the event of issues with the nodes where kube-dns is running, applications will continue to receive responses to DNS queries with expired TTL, but without delay.
  - `false`: upon the expiration of the TTL for an individual DNS record, node-local-dns will continue to return the “stale” value, but only after querying the upstream kube-dns. Thus, in the event of issues with the nodes where kube-dns is running, applications will continue to receive DNS responses with expired TTL, but with potentially significant delay. This approach is suitable in highly dynamic environments where Services and Namespaces are frequently recreated.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

  Example:

  ```
  highAvailability: true
  ```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

The module lifecycle stage: General Availability

The module has requirements for installation

An example of configuring a custom DNS for a Pod

```
apiVersion: v1
kind: Pod
metadata:
  name: dns-example
spec:
  dnsPolicy: "None"
  dnsConfig:
    nameservers:
      - 169.254.20.10
  containers:
    - name: test
      image: nginx
```

Here you can learn more about DNS configuring.

Configuration example

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: node-local-dns
spec:
  version: 1
  enabled: true
  settings:
    enableLogs: true
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

Managing nodes

> The module lifecycle stage: General Availability

Primary functions

The `node-manager` module is responsible for managing nodes and has the following primary functions:

1. Managing multiple nodes as a related group (**NodeGroup**):
   - The ability to define metadata that are inherited by all nodes in the group.
   - Monitoring of a group as a single entity (grouping nodes on graphs by groups, grouping alerts about node unavailability, alerts about the unavailability of N or N% of nodes in a group).
2. **Chaos monkey** — the systemic termination of nodes. This feature tests the resilience of cluster elements and running applications.
3. Delaying the reboot or shutdown of a node while critical pods are running on it.
4. Installing, updating, and configuring the node software (containerd, kubelet, etc.), connecting the node to the cluster:
   - Installing operating system (see the list of supported OS) regardless of the infrastructure used (any cloud/any hardware).
   - The operating system’s basic setup (disabling auto-update, installing the necessary packages, configuring logging parameters, etc.).
   - Configuring kubernetes-api-proxy (and the system for automatically updating the list of upstreams) to balance node (kubelet) requests over API servers.
   - Installing and configuring CRI containerd and Kubernetes, adding the node to the cluster.
   - Managing node updates and their downtime (disruptions):
     - Automatic determination of a valid minor Kubernetes version for a node group based on its settings (the kubernetesVersion parameter specified for a group), the default version for the whole cluster, and the current control-plane version (no nodes can be updated ahead of the control-plane update).
     - Only one node of a group can be updated at a time, and only if all the nodes in the group are available.
     - There are two types of node updates:
       - regular updates – always performed automatically;
       - disruption-involving updates (such as updating the kernel, switching docker versions, major change of the kubelet versions, etc.) – you can choose manual or automatic mode. If automatic disruptive updates are enabled, the node is drained before the update (this functionality can be disabled).
   - Monitoring the status and progress of the update.
5. Cluster scaling.

   - Autoscaling.

     Available with supported cloud providers (learn more); not available for static nodes. Cloud providers support automatic creation or deletion of virtual machines, joining them to or

disjoining them from the cluster.

- Maintaining the desired number of nodes in a group.

  Available for both cloud providers and static nodes (when using Cluster API Provider Static).

6. Managing Linux users on nodes.
7. Managing GPU resources on nodes:
   - Automatic detection and enablement of NVIDIA GPU.
   - Configurable GPU sharing modes per NodeGroup: Exclusive, TimeSlicing, MIG.
   - Monitoring integration — ready-made Grafana dashboards are available to visualize key GPU metrics.

Nodes are managed through the NodeGroup resource, and each node group performs specific tasks. Below are examples of node groups pooled by their tasks performed:

- a group of master nodes;
- a group of nodes for routing HTTP(s) traffic (front nodes);
- a group of monitoring-related nodes;
- a group of application nodes (the so-called worker nodes), etc.

The nodes belonging to the group have common parameters and are configured automatically according to the group's parameters. Deckhouse scales groups by adding, excluding, and updating their nodes. Both Static nodes deployed in the cloud and static (bare-metal or virtual machine) nodes can be combined into a single group. It paves the way for the hybrid clusters, in which you can scale nodes on physical servers via cloud nodes.

Operations on the cloud infrastructure are performed by means provided by supported cloud providers. If there is no support for the desired cloud platform, you can use its resources as static nodes.

The static nodes (e.g., bare metal servers) are handled by the Cluster API Provider Static (CAPS).

The following Managed Kubernetes services are supported (note that some service functionality may be unavailable):

- Google Kubernetes Engine (GKE);
- Elastic Kubernetes Service (EKS).

Node types

The following node types that can be worked with within a node group (resource NodeGroup) are supported:

- `CloudEphemeral` — the nodes are automatically ordered, created, and deleted in the configured cloud provider or on physical servers using the `infra-provider-baremetal` module.
- `CloudPermanent` — the nodes differ in that their configuration is not taken from the custom resource nodeGroup, but from a special resource `<PROVIDER>ClusterConfiguration` (for example, AWSClusterConfiguration for AWS). Also, an important difference is that to apply node configuration, you need to run `dhctl converge` (by running Deckhouse installer). An example of a CloudPermanent node of a cloud cluster is a cluster master node.
- `CloudStatic` — a static node (created manually) hosted in the cloud integrated with one of the cloud providers. This node has the CSI running, and it is managed by the cloud-controller-manager. The `Node` object automatically gets the information about the cloud zone and region. Also, if a node gets deleted from the cloud, its corresponding Node object will be deleted in a cluster.
- `Static` — a static node hosted on a bare metal or virtual machine. In the case of a cloud environment, the `cloud-controller-manager` does not manage the node even if one of the cloud providers is enabled. Learn more about working with static nodes...

> **i** For Deckhouse Virtualization Platform (DVP), the DVPClusterConfiguration resource is not used. The CloudPermanent node parameters are set in the NodeGroup, DVPInstanceClass, and `cloud-provider-dvp` ModuleConfig resources.

Node grouping and group management

Grouping and managing nodes as a related group mean that all nodes in the group will have the same metadata derived from the `NodeGroup` custom resource.

The following monitoring patterns are available for node groups:

- with grouping of node parameters on the graphs for the group;
- with grouping of alerts about node unavailability;

- with alerts about unavailability of N nodes or N% of nodes in the group, etc.

Delaying node reboot or shutdown while critical pods are running

The `d8-shutdown-inhibitor` service in `node-manager` delays node shutdown or reboot if stateful applications or virtual machines (VMs) are running on the node. The delay is triggered if pods with the label `pod.deckhouse.io/inhibit-node-shutdown` are running on the node. DP delays the shutdown or reboot of the node so that the user can migrate critical pods or terminate them in a controlled manner. This is useful, for example, for stateful workloads and other scenarios where data loss must be avoided.

How it works and key features

The `d8-shutdown-inhibitor` service prevents a node from shutting down as long as there are pods on it with the `Running` status that are labeled `pod.deckhouse.io/inhibit-node-shutdown`. The `GracefulShutdownPostpone` condition is used for this blocking. Additionally, the node is cordoned off during the blocking period to prevent the scheduler from scheduling new pods on it. The kubelet reads the node's `GracefulShutdownPostpone` condition and does not begin evicting pods marked with this label as long as the condition's `status` is `True` and `reason` is `PodsWithLabelAreRunningOnNode`. If there are pods on the node with the label `pod.deckhouse.io/inhibit-node-shutdown`, a corresponding message is displayed in the node console (wall).

Delaying mechanism features in DP

The delay in restarting or shutting down a node while critical pods are running on it has the following features in DP:

- A label must be explicitly set on each pod that is to block shutdown. If pods are created via a Deployment, the label is specified in the pod template.
- This mechanism works only with a modified kubelet version included in DP. The regular Kubernetes does not support this behavior.
- The maximum block duration (`InhibitDelayMaxSec`) is `3` days. After this period expires, the shutdown may proceed regardless of whether there are pods on the node with the label `pod.deckhouse.io/inhibit-node-shutdown`.
- This mechanism does not cancel the scheduling of disruptive updates in `node-manager`. It only delays the actual reboot of the node at the time of shutdown.

> ⚠ To decide whether to block a node shutdown, DP additionally queries the NodeGroup. If the current node belongs to the `master` group and it is the only master node in the cluster, the shutdown block will not be applied to it.

For information on enabling the delay mechanism, refer to the section "How to delay a node reboot while critical pods are running on it".

Automatic deploying, configuring and updating Kubernetes nodes

Automatic deployment (partially supported for *static/hybrid* nodes/clusters), configuration, and continuing software updates are supported for all cluster types (cloud or bare metal based).

Deploying Kubernetes nodes

Deckhouse automatically deploys cluster nodes by performing the following **idempotent** operations:

- Configuring the OS and optimizing it for containerd and Kubernetes:
  - Installing the needed packages from the distribution's repository.
  - Configuring kernel parameters, logging, log rotation, and other system parameters.
- Installing the appropriate versions of containerd and kubelet; adding the node to the Kubernetes cluster.
- Configuring kubernetes-api-proxy and updating the list of upstream resources for balancing node requests to the Kubernetes API.

Keeping nodes up-to-date

Two types of updates can be applied to keep cluster nodes up to date:

- **Regular**. These updates are always applied automatically and do not cause the node to stop or reboot.
- **Disruptive**. An example of such updates is a kernel or containerd version update, a major kubelet

version change, etc. For this type of updates you can choose manual or automatic mode (disruptions parameter section). In automatic mode, the node is gracefully drained before the update.

Only one node of the group is updated at a time, and only if all the nodes in the group are available.

The `node-manager` module has a set of built-in metrics for monitoring the update process, alerting about issues with the update, or when a decision to proceed needs to be made by an administrator.

Working with nodes on supported cloud platforms

Each supported cloud provider can provision nodes in an automated manner. For this, you have to specify the required parameters for each node or a group of nodes.

Depending on the provider, these parameters can include:

- type of a node, the number of processor cores, the amount of RAM;
- disk size;
- security settings;
- connected networks;
- other parameters.

Creating, starting, and connecting virtual machines to the cluster are performed automatically.

Scaling nodes in the cloud

Two methods of scaling nodes in a group are supported:

- **Automatic scaling**

  If there is a resource shortage or pods in the `Pending` state are present, nodes will be added to the group. If there is no load on one or more nodes, they will be removed from the cluster. Autoscaling takes into account the group priority (the group with the highest priority will be scaled first).

  To enable automatic node scaling, specify *different* non-zero values for the minimum and maximum number of nodes in the group.

- **Fixed number of nodes**

  In this case, Deckhouse will maintain the specified number of nodes (e.g., by provisioning new nodes when nodes fail).

  To set a fixed number of nodes in a group and disable automatic scaling, specify the *same* values for minPerZone and maxPerZone.

Working with static nodes

When working with static nodes, some features of the `node-manager` module are limited:

- **No node provisioning.** Resources (bare metal servers, virtual machines, linked resources) are provisioned manually. Subsequent configuration of resources (connecting a node to the cluster, setting up monitoring, etc.) is performed either fully (similar to nodes in the cloud) or partly automatically.
- **No node autoscaling.** Maintaining the specified number of nodes in a group is supported when using Cluster API Provider Static (parameter staticInstances.count). That is, Deckhouse will attempt to maintain the specified number of nodes in the group, cleaning up unnecessary nodes and setting up new ones as needed (by picking them from StaticInstance resources that are in *Pending* state).

Configuring/clearing up a node, joining it to a cluster, and disjoining it can be done in the following ways:

- **Manually** using the pre-made scripts.

  To configure the server (VM) and join a node to the cluster, a special bootstrap script must be downloaded and run. This script is generated for each group of static nodes (each `NodeGroup` resource). It is located in the `d8-cloud-instance-manager/manual-bootstrap-for-<NAME-NODEGROUP>` secret. See an example of how to add a static node to a cluster.

  To disjoin a cluster node and clean up the server (virtual machine), you need to run the `/var/lib/bashible/cleanup_static_node.sh` script (it is present on each static node). An example of decommissioning a cluster node and cleaning up the server can be found in FAQ.

- **Automatically** using Cluster API Provider Static.

Cluster API Provider Static (CAPS) connects to the server (VM) using StaticInstance and SSHCredentials resources, configures, and joins the node into the cluster.

If necessary (for example, if the StaticInstance resource associated with the server is deleted or the number of group nodes is reduced), the Cluster API Provider Static connects to the cluster node, clears it, and disconnects it from the cluster.

- **Manually with subsequent transfer of the Node under automatic control** of Cluster API Provider Static.

  > **i** This feature is available starting with Deckhouse 1.63.

  To transfer an existing cluster node under CAPS management, it is necessary to prepare the StaticInstance and SSHCredentials resources for this node, as with automatic management in the point above, however the StaticInstance resource must additionally be annotated as `static.node.deckhouse.io/skip-bootstrap-phase: ""`.

Cluster API Provider Static

Cluster API Provider Static (CAPS) is an implementation of a declarative management provider for static nodes (bare metal servers or virtual machines) for the Kubernetes Cluster API. Essentially, CAPS is an additional layer of abstraction to the existing Deckhouse functionality that provides automatic static node configuration and cleanup using scripts generated for each node group (see Working with Static Nodes).

CAPS features are as follows:

- configuring a bare metal server (or virtual machine) to join a Kubernetes cluster;
- joining a node to the Kubernetes cluster;
- disjoining the node from the Kubernetes cluster;
- cleaning the bare metal server (or virtual machine) after disjoining the node from the Kubernetes cluster.

CAPS uses the following CustomResource when operating:

- **StaticInstance.** Each `StaticInstance` resource details a specific host (server, VM) that is managed using CAPS.
- **SSHCredentials**. Contains the SSH credentials required to connect to the host (`SSHCredentials` data is specified in the credentialsRef parameter of the `StaticInstance` resource).
- **NodeGroup**. The staticInstances parameter section defines the required number of nodes in the group and the filter for the `StaticInstance` resources that can be used in the group.

CAPS is enabled automatically if the NodeGroup has the staticInstances parameter section filled in. If the `staticInstances` parameter section in the `NodeGroup` is empty, then setting up and cleaning up nodes for that group is done *manually* rather than using CAPS (see adding a static node to a cluster and cleaning up a node).

The workflow for dealing with static nodes when using Cluster API Provider Static (CAPS) (see the adding a node example) is as follows:

1. **Preparing resources.**

   Before bringing a bare metal server or virtual machine under CAPS control, some preliminary steps may be necessary:

   - Preparing the storage system, adding mount points, and so on.
   - Installing the OS-specific packages.
   - Configuring the network. For example, configuring the network between the server and the cluster nodes.
   - Configuring SSH access to the server, creating a user that is a member of sudoers group. A good practice is to create a separate user and unique keys for each server.

2. **Creating a SSHCredentials resource.**

   The `SSHCredentials` resource contains the parameters required by CAPS to connect to a server via SSH. A single `SSHCredentials` resource can be used to connect to multiple servers, but it is a good practice to create unique users and access keys to connect to each server. In this case, the `SSHCredentials` resource will also be unique for each server.

3. **Creating a StaticInstance resource.**

   For every server (VM) in the cluster, an individual `StaticInstance` resource is created. It contains the IP address for connecting and a link to the `SSHCredentials` resource with the data to be used

for connecting.

The following is a list of possible `StaticInstance` states and its associated servers (VMs) and cluster nodes:

- `Pending`. The server is not configured and there is no associated node in the cluster.
- `Bootstrapping`. The procedure for configuring the server (VM) and connecting the node to the cluster is in progress.
- `Running`. The server is configured and the associated node is added to the cluster.
- `Cleaning`. The procedure of cleaning up the server and disconnecting the node from the cluster is in progress.

> **i** You can transfer the existing manually-bootstrapped cluster node under CAPS management by annotating its StaticInstance with `static.node.deckhouse.io/skip-bootstrap-phase: ""`.

4. **Creating a NodeGroup resource.**

   When using CAPS, you have to focus on the nodeType parameter (must be `Static`) of the `NodeGroup` resource as well as the staticInstances parameter section.

   The staticInstances.labelSelector parameter section defines a filter that CAPS applies to select the `StaticInstance` resources to be used for a group. The filter allows only certain `StaticInstance` to be used for specific node groups, and also allows a single `StaticInstance` to be used in different node groups. You can choose not to define a filter to use any available `StaticInstance` for a node group.

   The staticInstances.count parameter specifies the desired number of nodes in the group. When the parameter changes, CAPS starts adding or removing the desired number of nodes (this process runs in parallel).

Using the data in the staticInstances parameter section, CAPS attempts to maintain the specified number of nodes in the group (count parameter). If a node needs to be added to the group, CAPS selects the resource StaticInstance that matches the filter and is in the `Pending` state, configures the server (VM), and joins the node to the cluster. If a node needs to be removed from the group, CAPS selects the StaticInstance that is in the `Running` state, cleans up the server (VM) and disconnects the node from the cluster (the corresponding `StaticInstance` then goes to the `Pending` state and can be reused).

Custom node settings

The NodeGroupConfiguration resource allows you to automate actions on group nodes. It supports running bash scripts on nodes (you can use the bashbooster command set) as well as the Go Template templating engine, and is a great way to automate operations such as:

- Installing and configuring additional OS packages.

  Examples:

  - installing the plugin for kubectl;
  - installing containerd with Nvidia GPU support.

- Updating the OS kernel to a specific version.

  Examples:

  - Debian kernel update;
  - CentOS kernel update.

- Modifying OS parameters.

  Examples:

  - customizing the sysctl parameter;
  - adding a root certificate.

- Collecting information on a node and carrying out other similar tasks.

The `NodeGroupConfiguration` resource allows you to assign priority to scripts being run or limit them to running on specific node groups and OS types.

The script code is stored in the content of the resource. When a script is created on a node, the contents of the `content` parameter are fed into the Go Template templating engine. The latter embeds an extra layer of logic when generating a script. When parsed by the templating engine, a context with

a set of dynamic variables becomes available.

The following variables are supported by the templating engine:

- `.cloudProvider` (for node groups of nodeType `CloudEphemeral` or `CloudPermanent`) — cloud provider dataset.

  Example of data...

  ```
  cloudProvider:
    instanceClassKind: OpenStackInstanceClass
    machineClassKind: OpenStackMachineClass
    openstack:
      connection:
        authURL: https://cloud.provider.com/v3/
        domainName: Default
        password: p@ssw0rd
        region: region2
        tenantName: mytenantname
        username: mytenantusername
      externalNetworkNames:
      - public
      instances:
        imageName: ubuntu-24-04-cloud-amd64
        mainNetwork: kube
        securityGroups:
        - kube
        sshKeyPairName: kube
      internalNetworkNames:
      - kube
      podNetworkMode: DirectRoutingWithPortSecurityEnabled
    region: region2
    type: openstack
    zones:
    - nova
  ```

- `.cri` — the CRI in use (starting with Deckhouse 1.49, only `Containerd` is supported).
- `.kubernetesVersion` — the Kubernetes version in use.
- `.nodeUsers` — the dataset with information about node users added via the NodeUser.

  Example of data...

  ```
  nodeUsers:
  - name: user1
    spec:
      isSudoer: true
      nodeGroups:
      - '*'
      passwordHash: PASSWORD_HASH
      sshPublicKey: SSH_PUBLIC_KEY
      uid: 1050
  ```

- `.nodeGroup` — node group dataset.

  Example of data...

```
nodeGroup:
  cloudProviderType: openstack
  cri:
    type: Containerd
  disruptions:
    approvalMode: Automatic
  kubelet:
    containerLogMaxFiles: 4
    containerLogMaxSize: 50Mi
    resourceReservation:
      mode: "Off"
  kubernetesVersion: "1.31"
  manualRolloutID: ""
  name: master
  nodeTemplate:
    labels:
      node-role.kubernetes.io/control-plane: ""
      node-role.kubernetes.io/master: ""
    taints:
    - effect: NoSchedule
      key: node-role.kubernetes.io/master
  nodeType: CloudPermanent
  updateEpoch: "1699879470"
```

An example of using variables in a template:

```
{{- range .nodeUsers }}
echo 'Tuning environment for user {{ .name }}'
# Some code for tuning user environment
{{- end }}
```

An example of using bashbooster commands:

```
bb-event-on 'bb-package-installed' 'post-install'
post-install() {
  bb-log-info "Setting reboot flag due to kernel was updated"
  bb-flag-set reboot
}
```

The progress of script execution can be seen on the node in the bashible service log using the command:

```
journalctl -u bashible.service
```

The scripts themselves are located on the node in the directory `/var/lib/bashible/bundle_steps/`.

The service decides to re-run the scripts by comparing the single checksum of all files located at `/var/lib/bashible/configuration_checksum` with the checksum located in the `kubernetes` cluster in the `configuration-checksums` secret namespace `d8-cloud-instance-manager`.

You can see the checksum using the following command:

```
d8 k -n d8-cloud-instance-manager get secret configuration-checksums -o yaml
```

The service compares checksums every minute.

The checksum in the cluster changes every 4 hours, thereby re-running the scripts on all nodes. Forcing the execution of bashible on a node can be done by deleting the file with the script checksum using the following command:

```
rm /var/lib/bashible/configuration_checksum
```

Features of writing scripts

When writing your own scripts, it is important to consider the following features of their use in Deckhouse:

1. Scripts in deckhouse are executed once every 4 hours or more often based on external triggers. Therefore, it is important to write scripts in such a way that they check the need for their changes in the system before performing actions, thereby not making changes every time they are launched.
2. There are built-in scripts that perform various actions, including installing and configuring services. This is important to consider when choosing the priority of custom scripts. For example, if a script is planned to restart a service, then this script should be called after the service installation script, since otherwise it will not be able to execute when deploying a new node.

Useful features of some scripts:

- `032_configure_containerd.sh`: Merges the containerd configuration files and **restarts** the service. The location of the configuration files depends on the CRI used on the cluster nodes:
  - `/etc/containerd/conf.d/*.toml`: For containerd v1.
  - `/etc/containerd/conf2.d/*.toml`: For containerd v2.

  Note that directories containing configuration files are not created automatically. Files must be added to these directories in scripts with a priority of less than `32`.

Chaos Monkey

The instrument (you can enable it for each `NodeGroup` individually) for unexpected and random termination of nodes in a systemic manner. Chaos Monkey tests the resilience of cluster elements, applications, and infrastructure components.

Monitoring

DP exports the group availability Prometheus metrics for each `NodeGroup`.

What information does Prometheus collect and in what form?

Metrics have the `d8_node_group_` prefix.

All the collected metrics have a label that allow you to identify the node group: `node_group_name`.

The following metrics are collected for each node group:

- `d8_node_group_ready` — the number of Kubernetes nodes in the group that are `Ready`.
- `d8_node_group_nodes` — the number of Kubernetes nodes (in any state) in the group.
- `d8_node_group_instances` — the number of instances (in any state) in the group.
- `d8_node_group_desired` — the number of desired `Machines` in the group.
- `d8_node_group_min` — the minimum number of instances in the group.
- `d8_node_group_max` — the maximum number of instances in the group.
- `d8_node_group_up_to_date` — the number of up-to-date nodes in the group.
- `d8_node_group_standby` — the number of over provisioned instances (see the `standby` parameter) in the group.
- `d8_node_group_has_errors` — equals to 1 if there are errors in the group.

Third-party components

List of third-party software used in the `node-manager` module:

- Gardener Machine Controller Manager v0.36.0

  License: Apache License 2.0

  An operator that manages VMs as a kubernetes custom resource.

- Cluster API 1.12.11

  License: Apache License 2.0

  Kubernetes Cluster API for declarative cluster lifecycle management.

- Cluster Autoscaler v1.33.1, v1.34.4, v1.35.2, v1.36.1, v1.36.1

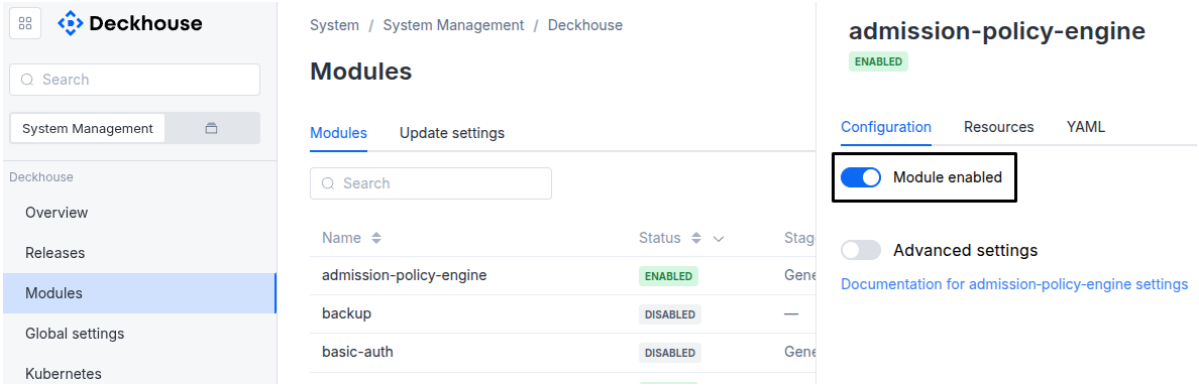
  License: Apache License 2.0

  Kubernetes autoscaler that automatically adjusts the size of the cluster.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability



The module has 60 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

  ```
  d8 system module enable node-manager
  ```

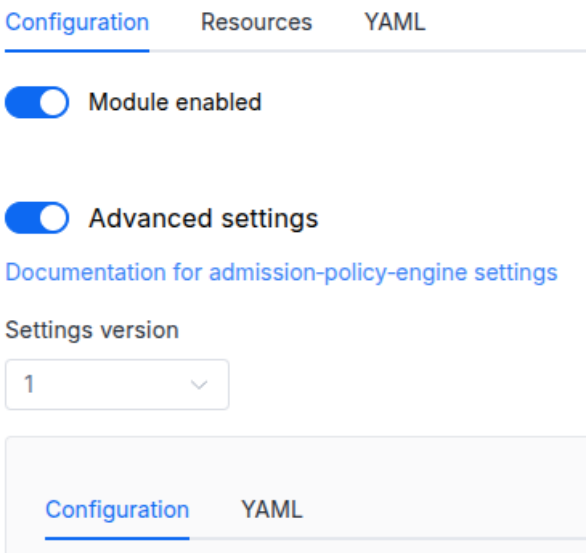
- **Using ModuleConfig `node-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `node-manager` (create it if necessary);

  Example of a manifest to enable module `node-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: node-manager
  spec:
    enabled: true
  ```

How to configure the module...



You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-`

`manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `node-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `node-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `node-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc node-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `node-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `node-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: node-manager
  spec:
    version: 3
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

Delete `allowedKubernetesVersions` and `allowedBundles`.

- Updates from version **2** to **3**:

  Delete `earlyOomEnabled`.

Parameters

Schema version: 3

- **settings**
  object
  - **settings.capiEmergencyBrake**
    boolean

    Set to ‘true’ to disable CAPI in case of potentially cluster-damaging changes.

    > **Warning.** Use this flag only if you fully understand the consequences.

    Default: `false`

    Example:

    ```
    capiEmergencyBrake: false
    ```

  - **settings.fencing**
    object

    Available in editions: Ultimate/EE

    Fencing settings.

    - **settings.fencing.systemNetworkFallback**
      object

      Settings of the second network of the fencing agents.

      - **settings.fencing.systemNetworkFallback.systemNetworkName**
        string

        The name of the SystemNetwork object for the second network of the fencing agents. Currently the agents do not exchange messages through this network.

        An empty value or no value disables the second network.

        Deckhouse checks that the SystemNetwork object exists when you set or change the value. If you delete the object later, the `D8FencingSystemNetworkNotFound` alert rises.

        Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)?$`

        Maximum length: `253`

        Example:

        ```
        systemNetworkName: sysnet-a
        ```

  - **settings.instancePrefix**
    string

    The prefix to use when creating instances via the corresponding cloud provider module.

    The default value can be calculated based on the `ClusterConfiguration` struct if the cluster is installed via the Deckhouse installer.

    Example:

    ```
    instancePrefix: kube
    ```

  - **settings.mcmEmergencyBrake**
    boolean

Available in editions: Open/CE, BE, SE, SE+, Ultimate/EE

Set to ‘true’ to disable machine-controller-manager in case of potentially cluster-damaging changes.

> **Warning.** Use this flag only if you fully understand the consequences.

Default: `false`

Example:

```
mcmEmergencyBrake: false
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

FencingFailedNodeState

Short names: ffns

Scope: Cluster
Version: v1alpha1

Fencing incident of one node.

The name of the object is the name of the failed node. The object has exactly one owner reference to this node. When the Node object is deleted, the Kubernetes garbage collector deletes this object too. The controller does nothing for an object whose owner reference does not have the UID of the node with this name, for example after the node is created again with the same name. A healthy node has no `FencingFailedNodeState`: the object exists only while the node has an active incident.

A fencing agent creates the object. The agent of any node can create it, also the agent on a node of a group in the `Disabled` mode. The creator writes `spec`. Nobody can change `spec` after that. Each part of `status` has one owner. The fencing controller reads the object and decides if it must evacuate the node.

The object is deleted in these cases:

- The failed node comes back with the same boot ID before the phase `Proven`. Then the fencing agents delete the object.
- The Node is `Ready` and has a new boot ID. Then the fencing controller removes the `node.kubernetes.io/out-of-service` taint from the Node and deletes the object.
- The Node object is deleted. Then the Kubernetes garbage collector deletes the object.

Do not create the object manually. Do not edit `spec` or `status`.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Required value

  Immutable description of the incident. The creator of the object writes it at creation. You cannot change it after that.

  - **spec.armed**
    boolean

    Required value

    `true` if the watchdog of the failed node was armed at the time of the failure. A fencing agent takes the value from the memberlist metadata of the node.

  - **spec.bootID**
    string

Required value

Boot ID of the failed node at the time of the failure. A fencing agent takes it from the memberlist metadata of the node. For the `NodeLeaseStale` source, the controller takes it from `status.nodeInfo.bootID` of the Node.

- **spec.detectedAt**
  string

  Required value

  Time when the creator detected the failure, with microsecond precision.

  The value is for reference only. The fencing controller counts its deadlines from its own observations.

  Pattern: `^[0-9]{4}-[0-9]{2}-[0-9]{2}T[0-9]{2}:[0-9]{2}:[0-9]{2}\.[0-9]{6}(Z|[+-][0-9]{2}:[0-9]{2})$`

- **spec.detectedBy**
  string

  Required value

  Name of the node whose agent created the object. If the fencing controller created the object, the value is `fencing-controller`.

- **spec.profileRef**
  object

  SLA profile of the node group of the failed node at the time when the object was created. The group is the value of the `node.deckhouse.io/group` label of the Node. The mode of the group selects the profile. If the group is in the `Disabled` mode, the value is the profile of the memberlist network of the cluster.

  The field is set only if `armed` is `true`. The fencing controller takes the timings of the failed node only from this profile.

  - **spec.profileRef.name**
    string

    Required value

    Name of the built-in SLA profile. The value can be only the name of a built-in profile.

    The name of the related `FencingSLAProfile` object is this value in lower case, because the name of a Kubernetes object cannot have capital letters. To find the profile, the controller changes this value to lower case.

    Allowed values: `Critical`, `Normal`, `Slow`

- **spec.source**
  string

  Required value

  Source of the incident. It tells who created the object:

  - `MemberlistDead`: a fencing agent that saw the node as dead in the memberlist network of the cluster.
  - `DeclareSuicide`: a fencing agent that received the `DeclareSuicide` message of the node. This agent is the witness.
  - `NodeLeaseStale`: the fencing controller, because the Lease of the node is stale. The current version of the controller does not create objects with this source.

  Allowed values: `MemberlistDead`, `DeclareSuicide`, `NodeLeaseStale`

- **status**
  object

  Observed state of the incident. Each part of the status has one owner:

  - `attestation`: the fencing agent of the witness node.
  - `contact`: the fencing agent that received a report of a contact with the failed node. The current version of the agent does not write this section.
  - `fallback`: the fencing agent of the failed node.
  - `phase`, `correlation` and `conditions`: the fencing controller. The current version of the controller does not write `correlation`.

The status is a subresource. The creator of the object cannot set it in the create request.

- **status.attestation**
  object

  Attestation of the failure. The witness is a node whose agent received the `DeclareSuicide` message of the failed node. The agent of the witness writes the name of its own node.

  - **status.attestation.at**
    string

    Required value

    Time of the attestation, with microsecond precision.

    Pattern: `^[0-9]{4}-[0-9]{2}-[0-9]{2}T[0-9]{2}:[0-9]{2}:[0-9]{2}\.[0-9]{6}(Z|[+-][0-9]{2}:[0-9]{2})$`

  - **status.attestation.witness**
    string

    Required value

    Name of the witness node.

- **status.conditions**
  array of objects

  Conditions of the incident. A condition does not replace the phase, so the controller can report the same problem in any phase.

  The controller sets `ConfigurationError` with the status `True` and the reason `ProfileUnavailable` while it cannot read the timings that it needs from the SLA profile in `spec.profileRef.name`. The message of the condition tells the cause. In this state, the controller does not evacuate the node. The status `False` with the reason `ProfileResolved` tells that the controller found the profile. An incident with `armed: false` needs no profile and also has this status.

  The `Queued` condition with the status `True` tells why the evacuation waits in the `Queued` phase. The reasons are `ConcurrencyLimit` and `MassFailure`. The current version of the controller does not use this condition.

  The controller sets `Progressing` with the status `False` when the evacuation in the `Evicting` phase is not complete after 60 seconds. The controller continues to examine the node. The `reason` tells what stops the evacuation now, and the `message` gives the details:

  - `VolumesAttached`: the node still has `VolumeAttachment` objects, so the volumes of its pods are not free for other nodes. The message gives their names.
  - `PodsRemaining`: the controller could not delete pods of the node, or another error of the API stops the evacuation. The message gives the pods and the errors.
  - `TooManyUnhealthyMachines`: the controller does not delete the Node of a cloud CAPI machine, because the MachineHealthCheck does not replace the machine now: more than 50 % of the machines are unhealthy, or the cluster has no MachineHealthCheck that reports its machines. The message gives the numbers.

  When the evacuation is complete, the phase is `Evicted`, and the controller removes the `Progressing` condition.

  - **status.conditions.lastTransitionTime**
    string

    Required value

    Time the condition last changed its status.

  - **status.conditions.message**
    string

    Human-readable description of the last transition.

  - **status.conditions.observedGeneration**
    integer

    Generation of the resource the condition was set from.

    Allowed values: `0 <= X`

  - **status.conditions.reason**

string

Required value

Machine-readable reason for the last transition.

- **status.conditions.status**
  string

  Required value

  Condition status.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  Condition type.

- **status.contact**
  object

  Last contact with the failed node. A fencing agent that received a report of a contact with the node writes this section.

  - **status.contact.at**
    string

    Required value

    Time of the last contact with the failed node, with microsecond precision.

    Pattern: `^[0-9]{4}-[0-9]{2}-[0-9]{2}T[0-9]{2}:[0-9]{2}:[0-9]{2}\.[0-9]{6}(Z|[+-][0-9]{2}:[0-9]{2})$`

  - **status.contact.reportedBy**
    string

    Required value

    Name of the node that reported the contact.

- **status.correlation**
  object

  Correlation of the incident with the incidents of other nodes. The current version of the controller does not write this section.

  - **status.correlation.episode**
    string

    Identifier of the episode of correlated failures that includes this incident.

- **status.fallback**
  object

  Liveness evidence from the failed node. Only the fencing agent of the failed node writes this section, and only through the Kubernetes API. Thus the section exists only if the node reached the API.

  The fencing controller keeps the `FallbackAlive` phase while the last heartbeat is not older than `2 * heartbeat.interval + heartbeat.apiTimeout` of the profile.

  - **status.fallback.lastHeartbeatAt**
    string

    Required value

    Time of the last heartbeat of the node, with microsecond precision.

    When fresh heartbeats stop, this is the signal that the node cannot reach the API.

    Pattern: `^[0-9]{4}-[0-9]{2}-[0-9]{2}T[0-9]{2}:[0-9]{2}:[0-9]{2}\.[0-9]{6}(Z|[+-][0-9]{2}:[0-9]{2})$`

- **status.phase**

string

Phase of the incident:

- `Suspected`: a failure of the node is suspected.
- `FallbackAlive`: the node writes heartbeats through the Kubernetes API. For example, an ACL or a firewall blocks the network between the nodes, but the node can reach the API.
- `Proven`: the failure is proven. The controller proves a failure in one of two ways:
  - attestation: a witness confirmed the stop of the node, and the time `watchdog.timeout` + `watchdog.margin` of the profile passed after the controller saw the attestation. The node did not send a heartbeat after the attestation;
  - silence of the node: the time `controlPlaneLostAfter` + 0.2s + `watchdog.timeout` + `watchdog.margin` + 0.9s of the profile passed after the last sign of life of the node. The last sign of life is the later of two moments: when the controller saw the object first, and when it saw the last heartbeat plus `heartbeat.interval`.

  While the `Fencing` condition of the Node is not `True`, the controller does not write `Proven`, and the object stays in the phase `Suspected`.

- `Unproven`: the failure is a part of a correlated failure and has no attestation. The current version of the controller does not set this phase.
- `Queued`: the evacuation waits. The `Queued` condition tells the reason. The current version of the controller does not use this phase.
- `Evicting`: the node has the `node.kubernetes.io/out-of-service` taint, and the evacuation is in progress. If the evacuation is not complete after 60 seconds, the `Progressing` condition tells the reason.
- `Evicted`: the evacuation is complete: the controller deleted the pods of the node, and the node has no `VolumeAttachment` objects.

The controller writes `Evicted` before it deletes the Node or the Machine of a node that the cloud replaces. The deletion of the Node also deletes this object. If the write of `Evicted` fails, the controller does not delete the Node or the Machine. If the deletion fails, the controller sends it again in the `Evicted` phase.

An object with `armed: false` never gets the phase `Proven`. It stays in the phase `Suspected` or `FallbackAlive`, and the node never gets the taint.

An empty phase means that the controller did not process the object yet. Read it as `Suspected`.

An error is not a phase. The controller reports an error in `conditions` and keeps the phase.

Allowed values: `Suspected`, `FallbackAlive`, `Proven`, `Unproven`, `Queued`, `Evicting`, `Evicted`

FencingSLAProfile

Short names: fsp

Scope: Cluster
Version: v1alpha1

SLA profile of fencing. A profile holds only timings. Correlation, the brake and the eviction limit are settings of the module, not of a profile.

The module ships three profiles: `critical`, `normal` and `slow`. Community Edition (CE) has no `critical` profile, because the `Critical` mode is available only in the commercial editions. Only Deckhouse can change the profiles. NodeGroup `spec.fencing.mode` selects the profile of a group. The mode name in lower case is the name of the object, because the name of a Kubernetes object cannot have capital letters.

All agents of the cluster run one memberlist network. They use the `memberlist` and `rejoin` sections of the profile of the fastest group that is not `Disabled`. An agent of a group that is not `Disabled` takes the other sections from the profile of its own group.

A profile is a cluster-scoped object. It has no state, so the resource has no `status`.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object

- **spec**
  object

  Required value

  Timings of the profile. Every value is a duration or a count. The CEL rules of this object check the inequalities of one profile; the agent checks the others.

  The profile has no probe timings of kubernetes-api-proxy. The proxy uses the same fixed values on all nodes:

  - probe interval: 1.2s at most (1s with a jitter of 20 %);
  - probe timeout: 0.5s;
  - no retry of a failed probe.

  The largest age of a probe is 1.7s (1.2s + 0.5s).

  The profile has no timeouts of the poll of the control plane state and no read period of kubernetes-api-proxy. These timings are the same for all profiles: they are internal values of the module.

  - **spec.controlPlaneLostAfter**
    string

    Required value

    Maximum age of the last successful control plane probe. The node sees the control plane while the last `Ready` answer of any apiserver upstream is not older than this value.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

  - **spec.eviction**
    object

    Required value

    Parameters of the creation of `FencingFailedNodeState` objects.

    The profile has no delay before the taint of a silent node, a node without signs of life. The fencing controller calculates it from the other values of the profile: `controlPlaneLostAfter` + 0.2s + `watchdog.timeout` + `watchdog.margin` + 0.9s. The controller counts the delay from the last sign of life of the node.

    - **spec.eviction.writerWaveInterval**
      string

      Required value

      Interval between the waves of the agents that create `FencingFailedNodeState` objects.

      Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

      Maximum length: `32`

  - **spec.heartbeat**
    object

    Required value

    Parameters of the heartbeat that a failed node writes through the Kubernetes API.

    - **spec.heartbeat.apiTimeout**
      string

      Required value

      Timeout of one request of the agent to the Kubernetes API. The memberlist TCP timeout uses it too.

      Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

      Maximum length: `32`

    - **spec.heartbeat.interval**
      string

      Required value

Interval between the heartbeat writes of a failed node into its own `FencingFailedNodeState`.

Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

Maximum length: `32`

- **spec.memberlist**
  object

  Required value

  Parameters of memberlist and Lifeguard. All agents of the cluster use this section of the fastest profile among the node groups that are not `Disabled`.

  - **spec.memberlist.awarenessMaxMultiplier**
    integer

    Required value

    Maximum slowdown of the probe interval of a locally degraded agent (Lifeguard awareness).

    Allowed values: `1 <= X`

  - **spec.memberlist.deadNodeReclaimTime**
    string

    Required value

    Time after which a new node can take the name or the address of a dead node.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

  - **spec.memberlist.gossipInterval**
    string

    Required value

    Interval between gossip messages.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

  - **spec.memberlist.gossipNodes**
    integer

    Required value

    Number of peers that receive gossip in each gossip interval.

    Allowed values: `1 <= X`

  - **spec.memberlist.gossipToTheDeadTime**
    string

    Required value

    Time during which a dead node still receives gossip. The node can refute the dead state after it recovers.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

  - **spec.memberlist.indirectChecks**
    integer

    Required value

    Number of indirect checks when the direct probe of a peer fails.

    Allowed values: `1 <= X`

  - **spec.memberlist.probeInterval**
    string

Required value

Interval between probes of one peer. A shorter interval gives faster detection and more probe traffic. The value must be at least twice `probeTimeout`.

Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

Maximum length: `32`

- **spec.memberlist.probeTimeout**
  string

  Required value

  Time to wait for the answer to a probe. The value must be at most half of `probeInterval`.

  Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

  Maximum length: `32`

- **spec.memberlist.retransmitMult**
  integer

  Required value

  Retransmit multiplier of gossip broadcasts: `retransmitMult * ceil(log10(nodeCount + 1))`, where `nodeCount` is the number of nodes.

  Allowed values: `1 <= X`

- **spec.memberlist.suspicionMaxTimeoutMult**
  integer

  Required value

  Upper bound of the suspicion timer when no confirmations arrive.

  Allowed values: `1 <= X`

- **spec.memberlist.suspicionMult**
  integer

  Required value

  Multiplier of the suspicion window before memberlist marks a peer as dead. The value must be at least 3.

  Allowed values: `1 <= X`

- **spec.poll**
  object

  Required value

  Parameters of the poll of the control plane state between agents.

  - **spec.poll.witnessFresherBy**
    string

    Required value

    Minimum gap between the own last successful probe and the probe of the answering node. An answer with a smaller gap is not a witness.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

- **spec.rejoin**
  object

  Required value

  Parameters of the join attempts of the agent. All agents of the cluster use this section of the fastest profile among the node groups that are not `Disabled`.

  - **spec.rejoin.interval**
    string

Required value

Interval between the join attempts of the agent. The agent repeats the attempt at this fixed interval while some nodes are missing from the memberlist network.

Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

Maximum length: `32`

- **spec.watchdog**
  object

  Required value

  Parameters of the watchdog of the node.

  - **spec.watchdog.feedInterval**
    string

    Required value

    Interval between two feeds of the watchdog. The value must be at most a quarter of `timeout`.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

  - **spec.watchdog.margin**
    string

    Required value

    Reserve that is added to `timeout`. The value must be at least 300ms and at least 5 % of `timeout`.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

  - **spec.watchdog.timeout**
    string

    Required value

    Timeout of the watchdog. The node panics when the agent does not feed the watchdog for this time. The value is a whole number of seconds, because the watchdog device takes whole seconds.

    Pattern: `^([0-9]+(\.[0-9]+)?(ms|s|m|h))+$`

    Maximum length: `32`

Instance

Scope: Cluster

- v1alpha2
- v1alpha1

Instance describes the full lifecycle of a server in Deckhouse Platform, aggregating status from the Machine object (infrastructure) and Bashible service on the node (configuration).

- **spec**
  object

  Specification of the Instance, including references to related resources.

  - **spec.classReference**
    object

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` or `infra-provider-*` module.

    - **spec.classReference.kind**
      string

      The object type (e.g., `OpenStackInstanceClass`). The object type is specified in the

documentation of the corresponding cloud or infrastructure provider module.

- **spec.classReference.name**
  string

  The name of the required `InstanceClass` object (e.g., `finland-medium`).

- **spec.machineRef**
  object

  Reference to instance in the cloud.

  - **spec.machineRef.apiVersion**
    string

    APIVersion defines the versioned schema of this representation of an reference object.

  - **spec.machineRef.kind**
    string

    Kind is a string value representing the REST resource referenced object represents.

  - **spec.machineRef.name**
    string

    Name of referenced object.

  - **spec.machineRef.namespace**
    string

    Namespace of referenced object.

- **spec.nodeGroupRef**
  object

  Reference to the NodeGroup that ordered this instance. It is known before the node joins the cluster.

  - **spec.nodeGroupRef.name**
    string

    NodeGroup name.

- **spec.nodeRef**
  object

  Reference to the kubernetes node object.

  - **spec.nodeRef.name**
    string

    Node name.

- **status**
  object

  Most recently observed status of the Instance.

  - **status.bashibleStatus**
    string

    Aggregated status of the bashible configuration process.

    Derived from `BashibleReady` condition.

    Allowed values: `Error`, `Unknown`, `Ready`, `WaitingApproval`

  - **status.bootstrapStatus**
    object

    Information about instance bootstrapping process.

    - **status.bootstrapStatus.description**
      string

      Description about getting logs.

    - **status.bootstrapStatus.logsEndpoint**
      string

http endpoint for getting bootstrap logs.

- **status.conditions**
  array of objects

  Detailed conditions of the instance (`MachineReady`, `BashibleReady`, etc.).

  On a node that has a NodeConfig, `NodeAgentReady` is `True` while the node agent reports and `Unknown` with reason `NoReport` after 10 minutes without a report.

  - **status.conditions.lastHeartbeatTime**
    string

    Last time the condition heartbeat was updated by its source.

  - **status.conditions.lastTransitionTime**
    string

    Last time the condition transitioned from one status to another.

  - **status.conditions.message**
    string

    A human-readable message indicating details about the transition.

  - **status.conditions.observedGeneration**
    integer

    The generation observed by the controller.

  - **status.conditions.reason**
    string

    Required value

    The reason for the condition’s last transition.

  - **status.conditions.severity**
    string

    Severity of the condition (`Error`, `Warning`, `Info`).

  - **status.conditions.status**
    string

    Required value

    Status of the condition (`True`, `False`, `Unknown`).

  - **status.conditions.type**
    string

    Required value

    Type of the condition (e.g., `MachineReady`, `BashibleReady`).

- **status.machineStatus**
  string

  Aggregated status of the infrastructure machine.

  Derived from `MachineReady` condition.

  Allowed values: `Progressing`, `Error`, `Ready`, `Blocked`, `Rebooting`

- **status.message**
  string

  A human-readable message indicating details about the current status or error.

  Displayed in CLI only when using `-o wide` for `d8 k`.

- **status.phase**
  string

  The high-level lifecycle phase of the Instance.

  Mapping: Pending -> Provisioning -> Provisioned -> Running -> Terminating.

Allowed values: `Pending`, `Provisioning`, `Provisioned`, `Running`, `Terminating`, `Unknown`

Describes an implementation-independent ephemeral machine resource.

- **status**
  object
  - **status.bootstrapStatus**
    object

    Information about instance bootstrapping process.

    - **status.bootstrapStatus.description**
      string

      Description about getting logs.

    - **status.bootstrapStatus.logsEndpoint**
      string

      http endpoint for getting bootstrap logs.

  - **status.classReference**
    object

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

    - **status.classReference.kind**
      string

      The object type (e.g., `OpenStackInstanceClass`). The object type is specified in the documentation of the corresponding `cloud-provider-` module.

      Allowed values: `OpenStackInstanceClass`, `GCPInstanceClass`, `VsphereInstanceClass`, `AWSInstanceClass`, `YandexInstanceClass`, `AzureInstanceClass`, `VCDInstanceClass`, `ZvirtInstanceClass`, `DynamixInstanceClass`, `HuaweiCloudInstanceClass`, `DVPInstanceClass`, `BareMetalInstanceClass`

    - **status.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

  - **status.currentStatus**
    object

    Current status of the instance object.

    - **status.currentStatus.lastUpdateTime**
      string

      Last update time of current status.

    - **status.currentStatus.phase**
      string

      InstancePhase is a label for the condition of a instance at the current time.

  - **status.lastOperation**
    object

    Last operation refers to the status of the last operation performed.

    - **status.lastOperation.description**
      string

      Description of the current operation.

    - **status.lastOperation.lastUpdateTime**
      string

      Last update time of current operation.

    - **status.lastOperation.state**
      string

      State of operation.

        - **status.lastOperation.type**
          string

          Type of operation.

    - **status.machineRef**
      object

      Reference to instance in the cloud.

        - **status.machineRef.apiVersion**
          string

          APIVersion defines the versioned schema of this representation of an reference object.

        - **status.machineRef.kind**
          string

          Kind is a string value representing the REST resource referenced object represents.

        - **status.machineRef.name**
          string

          Name of referenced object.

        - **status.machineRef.namespace**
          string

          Namespace of referenced object.

    - **status.nodeRef**
      object

      Reference to the kubernetes node object.

        - **status.nodeRef.name**
          string

          Node name.

InstanceTypesCatalog

Scope: Cluster
Version: v1alpha1

Contains information about discovered data from cloud.

- **instanceTypes**
  array of objects

  Required value

  List of available instance types.

    - **instanceTypes.cpu**
      integer or string

      Required value

      The number of CPUs for the instance type.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

    - **instanceTypes.memory**
      integer or string

      Required value

      The amount of RAM a instance type has.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

    - **instanceTypes.name**
      string

      Instance type name.

- **instanceTypes.rootDisk**
  integer or string

  Root disk size.

  Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

NodeGroup

Short names: ng

Scope: Cluster

- v1
- v1alpha2
- v1alpha1

Describes the runtime parameters of the node group.

Example:

```
# NodeGroup for cloud nodes in AWS.
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: test
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    zones:
      - eu-west-1a
      - eu-west-1b
    minPerZone: 1
    maxPerZone: 2
    classReference:
      kind: AWSInstanceClass
      name: test
  nodeTemplate:
    labels:
      tier: test
---
# NodeGroup for static nodes on bare metal servers (or VMs).
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
```

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `42`

- **spec**
  object

  Required value

  - **spec.chaos**
    object

    Chaos monkey settings.

Example:

```
chaos:
  mode: DrainAndDelete
  period: 24h
```

- **spec.chaos.mode**
  string

  The chaos monkey mode:

  - `DrainAndDelete` — drains and deletes a node when triggered;
  - `Disabled` — leaves this NodeGroup intact.

  Default: `Disabled`

  Allowed values: `Disabled`, `DrainAndDelete`

- **spec.chaos.period**
  string

  The time interval to use for the chaos monkey.

  It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

  Default: `6h`

  Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

- **spec.cloudInstances**
  object

  Parameters of the node group cloud virtual machines.

  The `cloudInstances` parameter is used for `CloudEphemeral` nodes. When the cloud provider is configured through ModuleConfig, it is also used for `CloudPermanent` nodes, including master nodes. In this case, `classReference` specifies the instance class with the virtual machine parameters.

  - **spec.cloudInstances.classReference**
    object

    Required value

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

    - **spec.cloudInstances.classReference.kind**
      string

      The kind of the `InstanceClass` object (e.g., `OpenStackInstanceClass`). Supported kinds are defined by the installed cloud provider modules and specified in their documentation.

    - **spec.cloudInstances.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

  - **spec.cloudInstances.maxPerZone**
    integer

    Required value

    For `CloudEphemeral` nodes, sets the maximum number of nodes in each zone and the upper bound for autoscaling.

    For `CloudPermanent` nodes, the field is required when `cloudInstances` is set. Specify a value greater than or equal to `minPerZone`.

    Allowed values: `0 <= X`

  - **spec.cloudInstances.maxSurgePerZone**
    integer

    The maximum number of instances the platform creates in each zone above the desired

number while it replaces the instances of the group.

Replacement happens when parameters that require recreating a virtual machine change, for example in the InstanceClass. The parameter does not limit the number of instances that the cluster autoscaler orders when it scales the group up. For details on what NodeGroup parameters affect, see NodeGroup parameters and their result.

The value `0` is treated as if the parameter is not set, so the default value applies.

Default: `1`

Allowed values: `0 <= X`

- **spec.cloudInstances.maxUnavailablePerZone**
  integer

  The maximum number of unavailable instances (during rollout) in the group in each zone.

  Default: `0`

  Allowed values: `0 <= X`

- **spec.cloudInstances.minPerZone**
  integer

  Required value

  For `CloudEphemeral` nodes, sets the minimum number of nodes in each zone and the lower bound for autoscaling.

  For `CloudPermanent` nodes with a ModuleConfig-based provider configuration, sets the desired number of nodes in the group.

  Allowed values: `0 <= X`

- **spec.cloudInstances.priority**
  integer

  Priority of the node group.

  When scaling a cluster, the autoscaler will first select node groups with a higher priority set. If several node groups have the same priority, the autoscaler randomly selects a group of them. You can control the rate at which nodes are switched to lower-priority groups on demand (for more details, see the FAQ).

  Using priorities can be convenient to prefer ordering cheaper nodes (for example, spot instances) over more expensive ones.

- **spec.cloudInstances.quickShutdown**
  Deprecated
  boolean

  Lowers CloudEphemeral machine drain timeout to 5 minutes.

- **spec.cloudInstances.standby**
  integer or string

  The summary number of overprovisioned nodes for this `NodeGroup` in all zones.

  An overprovisioned node is a cluster node on which resources are reserved that are available at any time for scaling. The presence of such a node allows the cluster autoscaler not to wait for node initialization (which may take several minutes), but to immediately place a load on it.

  The value can be an absolute number (for example, 2) or a percentage of desired nodes (for example, 10%). If a percentage is specified, the absolute number is calculated based on the percentage of the maximum number of nodes (the maxPerZone parameter) rounded down, but not less than one.

  Pattern: `^[0-9]+%?$`

- **spec.cloudInstances.standbyHolder**
  object

  Amount of reserved resources.

  Used to determine whether to order overprovisioned nodes.

- **spec.cloudInstances.standbyHolder.notHeldResources**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Use the `overprovisioningRate` parameter.

  Describes the resources that will not be held (consumed) by the standby holder.

  - **spec.cloudInstances.standbyHolder.notHeldResources.cpu**
    integer or string

    Describes the amount of CPU that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of cpus (for example, 2) as well as a milli representation (for example, 1500m).

    Pattern: `^[0-9]+m?$`

  - **spec.cloudInstances.standbyHolder.notHeldResources.memory**
    integer or string

    Describes the amount of memory that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of bytes (for example, 128974848) as well as a fixed-point number using one of memory suffixes: G, Gi, M, Mi.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.cloudInstances.standbyHolder.overprovisioningRate**
  integer

  Percentage of reserved resources calculated from the capacity of a node of a `NodeGroup`.

  Default: `50`

  Allowed values: `1 <= X <= 80`

- **spec.cloudInstances.zones**
  array of strings

  List of availability zones to create instances in.

  The default value depends on the cloud provider selected and usually corresponds to all zones of the region being used.

  Example:

  ```
  zones:
  - Helsinki
  - Espoo
  - Tampere
  ```

- **spec.cri**
  object

  Container runtime parameters.

  - **spec.cri.containerd**
    object

    Containerd runtime parameters.

    If used, `cri.type` must be set to `Containerd`.

    - **spec.cri.containerd.maxConcurrentDownloads**
      integer

      Set the max concurrent downloads for each pull.

      Default: `3`

  - **spec.cri.containerdV2**
    object

ContainerdV2 runtime parameters.

If used, `cri.type` must be set to `ContainerdV2`.

When using `ContainerdV2`, `CgroupsV2` will be used (providing improved security and resource management).

To use `ContainerdV2` as a container runtime, the nodes in the group must meet the following requirements:

- Support for `CgroupsV2`.
- Linux kernel version `5.8` or newer.
- Systemd version `244` or newer.
- Support for `erofs` kernel module.
- **spec.cri.containerdV2.maxConcurrentDownloads**
  integer

  Set the max concurrent downloads for each pull.

  Default: `3`

- **spec.cri.docker**
  Deprecated
  object

  Docker settings for nodes.

  - **spec.cri.docker.manage**
    boolean

    Enable Docker maintenance from bashible.

    Default: `true`

  - **spec.cri.docker.maxConcurrentDownloads**
    integer

    Set the max concurrent downloads for each pull.

    Default: `3`

- **spec.cri.notManaged**
  object

  Settings for not managed CRI for nodes.

  - **spec.cri.notManaged.criSocketPath**
    string

    Path to CRI socket.

- **spec.cri.type**
  string

  Container runtime type.

  If not specified, the `defaultCRI` parameter value of ClusterConfiguration is used.

  > **Note.** Docker support is deprecated.

  > **Note.** The CSE edition supports containerd v2 only.

  Allowed values: `Docker`, `Containerd`, `ContainerdV2`, `NotManaged`

- **spec.disruptions**
  object

  Disruptions settings for nodes.

  Example:

```
disruptions:
  approvalMode: Automatic
  automatic:
    drainBeforeApproval: false
    windows:
    - from: '06:00'
      to: '08:00'
      days:
      - Tue
      - Sun
```

- **spec.disruptions.approvalMode**
  string

  The approval mode for disruptive updates:

  - `Manual` — disable automatic disruption approval; the alert will be displayed if disruption is needed. Nodes are not drained automatically in `Manual` mode. If necessary, manually drain nodes before setting the `update.node.deckhouse.io/disruption-approved=` annotation. **Caution.** The `master` node group update mode must be `Manual` to avoid issues with draining.
  - `Automatic` — automatically approve disruption-involving updates. Nodes could be drained automatically before reboot, as configured by the drainBeforeApproval option.
  - `RollingUpdate` — in this mode, a **new** node with new settings will be created; then, the old node will be deleted. Available only for cloud nodes.

  If the `RollingUpdate` mode is not used, when updating, the node is first drained and then updated (rebooted) and put back into operation (uncordoned). Note that in this case, the cluster must have sufficient resources to accommodate the load while the node being updated is unavailable. In the `RollingUpdate` mode, the node is **replaced** by the updated node, i.e., an extra node appears in the cluster for the duration of the update. In cloud infrastructures, the `RollingUpdate` mode is convenient, for example, if there are no resources in the cluster to temporarily host the load from the node being updated.

  Default: `Automatic`

  Allowed values: `Manual`, `Automatic`, `RollingUpdate`

- **spec.disruptions.automatic**
  object

  Additional parameters for the `Automatic` mode.

  - **spec.disruptions.automatic.drainBeforeApproval**
    boolean

    Drain Pods from the nodes before approving disruption.

    Caution. This setting ignores (nodes will be approved without draining Pods):

    - for the nodeGroup `master` with a single node;
    - for a single `ready` node in a nodeGroup picked out for Deckhouse placement.

    Default: `true`

  - **spec.disruptions.automatic.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.automatic.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

```
days: Wed
```

- **Element of the array**
  string

  Day of the week.

  Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

- **spec.disruptions.automatic.windows.from**
  string

  Required value

  Start time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

```
from: '13:00'
```

- **spec.disruptions.automatic.windows.to**
  string

  Required value

  End time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

```
to: '18:30'
```

- **spec.disruptions.rollingUpdate**
  object

  Additional parameters for the `RollingUpdate` mode.

  - **spec.disruptions.rollingUpdate.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.rollingUpdate.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

```
days: Mon
```

```
days: Wed
```

      - **Element of the array**
        string

        Day of the week.

        Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

    - **spec.disruptions.rollingUpdate.windows.from**
      string

      Required value

      Start time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

```
from: '13:00'
```

- **spec.disruptions.rollingUpdate.windows.to**
  string

  Required value

  End time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

  ```
  to: '18:30'
  ```

- **spec.fencing**
  object

  Fencing settings for the node group.

  - **spec.fencing.mode**
    string

    Fencing mode of the node group. Every mode except `Disabled` selects the built-in FencingSLAProfile with the reaction timings of the group:

    - `Disabled`: fencing is off for the node group. A node group without `fencing` is in this mode too.
    - `Critical`: the `critical` profile, reaction in about 12 seconds. Available only in the commercial editions. In Community Edition (CE), Deckhouse does not let you set this mode. A group that already has this mode works as `Normal`.
    - `Normal`: the `normal` profile, reaction in about 30 seconds.
    - `Slow`: the `slow` profile, reaction in about 60 seconds.
    - `Watchdog`: deprecated. This mode works as `Slow`. Use `Normal`, `Slow`, or `Critical` (`Critical` is available only in the commercial editions).

    When at least one node group has a mode other than `Disabled`, the fencing-agent runs on every node of the cluster. If all node groups are `Disabled`, Deckhouse does not deploy the fencing-agent.

    In a cluster with one master, Deckhouse does not let you turn on fencing of an existing node group and shows a warning when you create a node group with fencing, because a failure or a restart of this master stops all nodes with fencing.

    How the fencing-agent works:

    - The agents of all cluster nodes form a single gossip network (`memberlist`). Every agent uses the timings of the fastest mode of the node groups in this network. The memberlist protocol detects failures correctly only when all members have the same timings.
    - On the nodes of a group with a mode other than `Disabled`, the agent arms the `/dev/watchdog` device with the watchdog timeout of the profile of the group. While the agent runs, it resets the timer. If the node or the agent hangs, the timer expires and the kernel panics.
    - When the node does not see the control plane for longer than `controlPlaneLostAfter` of the profile, the agent stops the reset of the timer at once. When the watchdog timeout expires, the node stops. If the control plane is available again before the timeout expires, the agent resets the timer again, and the node continues to work. Thus, a short pause of the control plane does not stop the nodes.
    - After the stop of the reset, the agent asks the agents of the other nodes for a witness, that is, a node that sees the control plane. The witness writes an attestation of the stop. After that, the stop is final.
    - On the nodes of a `Disabled` group, the agent only takes part in failure detection. The agent does not arm the watchdog.
    - The agent respects maintenance annotations `node-manager.deckhouse.io/fencing-disable`, `update.node.deckhouse.io/approved`, and `update.node.deckhouse.io/disruption-approved`, temporarily disabling the watchdog during planned operations.

    For a mode other than `Disabled`, the NodeGroupConfiguration script loads the `softdog` kernel module with `soft_panic=1`. The fencing-agent applies the watchdog timeout when it arms the device.

On nodes of a group with `systemType: Immutable` (Deckhouse Engine), the NodeGroupConfiguration script does not run. On these nodes, `softdog` is built into the kernel and starts with `soft panic=1`. The operating system image sets the permissions on `/dev/watchdog`. The fencing-agent applies the timeout of the profile in the same way as on other nodes. If you installed a node before the Deckhouse Engine release with `softdog` in the kernel, the node does not have `softdog`. The node gets it only after a reinstall or an update of the boot partition.

For a mode other than `Disabled`, Deckhouse disables the automatic reboot of the node after a kernel panic at the OS level. This prevents a node from returning in an undefined state: the stopped node stays down until you restore it manually.

When the stop of the node is certain, the fencing-controller sets the `node.kubernetes.io/out-of-service` taint on the node. After the taint, the controller sets the `Failed` phase and the `DisruptionTarget` condition on the pods of the node and deletes the pods immediately. This includes the pods that tolerate the taint. The controller does not delete the pods of DaemonSets and the static pods. The controller does not remove the finalizers of the pods: a pod with a finalizer stays in the API until the owner of the finalizer removes it. For such a pod of a StatefulSet, the controller sends a warning event with the names of the finalizers. The evacuation is complete when the node has no `VolumeAttachment` objects. If the evacuation is not complete after 60 seconds, the incident stays in the `Evicting` phase and gets the `Progressing` condition with the status `False` and the reason. The controller continues to examine the node. After the evacuation, Deckhouse acts on the node as follows:

- For a node of a `CloudPermanent`, `CloudStatic`, or `Static` group (this includes a `Static` group with `staticInstances`, that is, CAPS), for a master node, and for an etcd arbiter node, Deckhouse only keeps the taint. It never deletes the Node object.
- For a node of a `CloudEphemeral` group with `status.engine: CAPI`, Deckhouse deletes the Node object only when the MachineHealthCheck of the Cluster API cluster reports its machines and 50 percent or fewer of them are unhealthy. Deckhouse counts the stopped machine as unhealthy. MachineHealthCheck then sets the `HealthCheckSucceeded` condition of the Machine to `False` with the `NodeDeleted` reason and replaces the machine. If more than 50 percent of the machines are unhealthy, or the MachineHealthCheck does not report its machines yet, Deckhouse does not delete the Node object yet. The controller continues to examine the machines. When 50 percent or fewer of them are unhealthy, the controller deletes the Node object and completes the evacuation.
- For a node of a `CloudEphemeral` group with `status.engine: MCM`, Deckhouse deletes the `Machine` (`machine.sapcloud.io`). Machine Controller Manager creates a new machine.

When the node returns (the Node is `Ready` and it has a new boot ID), the fencing-controller removes the taint automatically. The controller works only while at least one node group has a mode other than `Disabled`. If you turn fencing off in all node groups, the taint stays on the node, and you must remove it manually.

The stop is certain in one of two cases: a witness confirmed the stop and `watchdog.timeout` + `watchdog.margin` of the profile passed, or the node is silent for `controlPlaneLostAfter` + 0.2s + `watchdog.timeout` + `watchdog.margin` + 0.9s of the profile after its last sign of life. The controller does not set the taint while the `Fencing` condition of the Node is not `True`.

If the fencing-controller does not set the taint, Kubernetes evicts the pods of the node after the time in the `failedNodePodEvictionTimeoutSeconds` parameter of the `control-plane-manager` module (300 seconds by default).

For details on how fencing handles a failed node, see FAQ.

Default: `Disabled`

Allowed values: `Disabled` — Fencing is off for the node group. A node group without fencing is in this mode too.
`Normal` — The normal profile, reaction in about 30 seconds.
`Slow` — The slow profile, reaction in about 60 seconds.
`Critical` — The critical profile, reaction in about 12 seconds. Available only in the commercial editions.
`Watchdog` — Deprecated. Works as Slow. Use Normal, Slow, or Critical (Critical is available only in the commercial editions).

- **spec.fencing.watchdog**
  object

  Deprecated. Deckhouse keeps the settings of fencing 1.0 only for compatibility and

ignores them.

- **spec.fencing.watchdog.timeout**
  string

  Deprecated. Deckhouse ignores this field. The watchdog timeout comes from the profile of the fencing mode.

  Pattern: `^[0-9]+[smh]{1}$`

- **spec.gpu**
  object

  Available in editions: Ultimate/EE

  GPU parameters.

  - **spec.gpu.exclusive**
    object

    Without GPU sharing.

  - **spec.gpu.mig**
    object

    `MIG` sharing strategy parameters.

    - **spec.gpu.mig.customConfigs**
      array of objects

      Custom MIG partitioning by GPU index.

      Used only when `partedConfig: custom` is set.

      Represents an array of devices (a map keyed by `index`), where each entry refers to a GPU by its index and describes the slices to be created.

      Examples:

      ```
      customConfigs:
        profile: 3g.40gb
        count: 2
      ```

      ```
      customConfigs:
        profile: 1g.10gb.me
        count: 1
      ```

      - **spec.gpu.mig.customConfigs.index**
        integer

        Required value

        GPU index on the node.

        Allowed values: `0 <= X`

      - **spec.gpu.mig.customConfigs.slices**
        array of objects

        Required value

        List of MIG slices to create.

        - **spec.gpu.mig.customConfigs.slices.count**
          integer

          Required value

          Number of slices in the selected profile.

          Default: `1`

          Allowed values: `1 <= X <= 7`

        - **spec.gpu.mig.customConfigs.slices.profile**
          string

Required value

MIG profile name.

Pattern: `^[0-9]+g\.[0-9]+gb(\.me)?$`

Examples:

```
profile: 3g.40gb
```

```
profile: 1g.10gb
```

```
profile: 1g.10gb.me
```

- **spec.gpu.mig.partedConfig**
  string

  MIG configuration name.

  Standard `all-*` profiles are supported (the same partitioning applied to all GPUs), as well as the `custom` value, which allows defining partitioning individually for each GPU.

  Default: `all-1g.5gb`

- **spec.gpu.sharing**
  string

  GPU sharing strategy:

  - `Exclusive` — no sharing (each GPU is fully allocated to a single Pod).
  - `TimeSlicing` — time-sliced sharing (multiple Pods can share one GPU concurrently by splitting GPU time).
  - `MIG` — use NVIDIA Multi-Instance GPU (MIG) to split each GPU into multiple instances (if supported by hardware).

  Allowed values: `TimeSlicing`, `MIG`, `Exclusive`

- **spec.gpu.timeSlicing**
  object

  `TimeSlicing` sharing strategy parameters.

  - **spec.gpu.timeSlicing.partitionCount**
    number

    Count of partition per GPU.

    Default: `4`

    Allowed values: `1 <= X <= 100`

- **spec.kubelet**
  object

  Kubelet settings for nodes.

  - **spec.kubelet.containerLogMaxFiles**
    integer

    How many rotated log files to store before deleting them.

    Default: `4`

    Allowed values: `2 <= X <= 20`

  - **spec.kubelet.containerLogMaxSize**
    string

    Maximum log file size before it is rotated.

    Default: `50Mi`

    Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

  - **spec.kubelet.maxPods**

integer

Set the max count of pods per node for given NodeGroup. When left unspecified, the system automatically determines this limit according to the value of the `podSubnetNodeCIDRPrefix` parameter of the `control-plane-manager` module:

- `120` pods for `podSubnetNodeCIDRPrefix` ≥ `24`;
- `250` pods for `podSubnetNodeCIDRPrefix` = `23`;
- `500` pods for `podSubnetNodeCIDRPrefix` = `22`;
- `1000` pods for `podSubnetNodeCIDRPrefix` ≤ `21`.

- **spec.kubelet.memorySwap**
  object

  Configuration of swap memory usage for kubelet.

  - **spec.kubelet.memorySwap.limitedSwap**
    object

    Configuration for the limited swap mode. Required when `swapBehavior` is set to `LimitedSwap`.

    - **spec.kubelet.memorySwap.limitedSwap.size**
      string

      Required value

      Size of the swap file to create, specified in GB (for example, “2G”, “4G”).

      Pattern: `^\d+G$`

      Example:

      ```
      size: 1G
      ```

  - **spec.kubelet.memorySwap.swapBehavior**
    string

    Defines how swap memory is handled on the node:

    - `NoSwap`: Swap is disabled. This is the traditional Kubernetes behavior.
    - `LimitedSwap`: Kubelet can use swap memory up to the limit specified in `limitedSwap.size`.

    For details on swap memory usage on nodes, refer to Kubernetes documentation.

    Allowed values: `NoSwap`, `LimitedSwap`

  - **spec.kubelet.memorySwap.swappiness**
    integer

    Defines the kernel’s tendency to use the swap.

    - `0`: Minimal swap usage (only to avoid OOM).
    - `60`: Default balanced behavior.
    - `100`: Aggressive swap usage.

    This value is set via `vm.swappiness` sysctl parameter.

    Default: `60`

    Allowed values: `0 <= X <= 100`

- **spec.kubelet.resourceReservation**
  object

  Management of resource reservation for system daemons on a node.

  More info in the Kubernetes documentation.

  - **spec.kubelet.resourceReservation.mode**
    string

    Defines the system resource reservation mode:

    - `Off` — disables resource reservation.
    - `Auto` — reserves resources based on the Node capacity.
    - `Static` — reserves resources based on the values provided by the user via

the `static` parameter.

Note that currently we do not use a dedicated group `cgroup` for resource reservation (`-system-reserved-cgroup` is not used).

Default: `Auto`

- **spec.kubelet.resourceReservation.static**
  object

  Resource reservation parameters for the 'Static' mode.

  - **spec.kubelet.resourceReservation.static.cpu**
    integer or string

    Pattern: `\d+[m]`

  - **spec.kubelet.resourceReservation.static.ephemeralStorage**
    integer or string

    Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

  - **spec.kubelet.resourceReservation.static.memory**
    integer or string

    Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

- **spec.kubelet.rootDir**
  string

  Directory path for managing kubelet files (volume mounts,etc).

  Default: `/var/lib/kubelet`

- **spec.kubelet.seccompDefault**
  boolean

  Use `RuntimeDefault` seccomp profile for workloads that don't specify seccomp profile explicitly.

- **spec.kubelet.topologyManager**
  object

  Controls the kubelet resource managers on NUMA nodes: the CPU manager, the memory manager and the topology manager.

  With a policy other than `None`, containers of Guaranteed pods with an integer CPU request get exclusive CPUs, and the memory of Guaranteed pods is bound to NUMA nodes. With `Restricted` and `SingleNumaNode`, they get whole physical cores. Deckhouse calculates NUMA-dependent kubelet settings on each node of the group: it splits `reservedMemory` between NUMA nodes and sets `max-allowable-numa-nodes` on nodes with more than 8 NUMA nodes.

  A policy other than `None` requires `resourceReservation.mode` `Auto`, or `Static` with a positive `static.cpu`. Changing the settings restarts the kubelet and can require a disruption on nodes with Guaranteed pods. See How do I give pods dedicated CPUs and NUMA alignment?

  For more information, see the Kubernetes documentation.

  - **spec.kubelet.topologyManager.enabled**
    Deprecated
    boolean

    Deprecated, has no effect. The resource managers are controlled by `policy` alone.

  - **spec.kubelet.topologyManager.policy**
    string

    Resource alignment policy and the related kubelet settings:

    - `None`: no alignment. The CPU and memory managers are not used.
    - `BestEffort`: Guaranteed pods get exclusive CPUs and NUMA-bound memory. Resources are aligned to NUMA nodes when possible; a pod is admitted even if they cannot be aligned, but it is rejected if its memory cannot be placed.
    - `Restricted`: Guaranteed pods get exclusive whole physical cores and

NUMA-bound memory. A pod is rejected if its resources cannot be aligned; when a pod needs several NUMA nodes, the closest ones are preferred.
- `SingleNumaNode`: as `Restricted`, but all resources of a pod (or of a container, see `scope`) must come from one NUMA node.

More information can be found in the Kubernetes documentation.

Default: `None`

Allowed values: `None`, `BestEffort`, `Restricted`, `SingleNumaNode`

- **spec.kubelet.topologyManager.scope**
  string

  Defines granularity with which resources are aligned:

  - `Container`: resources are aligned for each container separately.
  - `Pod`: all containers of a pod are aligned together.

  Default: `Pod`

  Allowed values: `Container`, `Pod`

- **spec.nodeDrainTimeoutSecond**
  integer

  Maximum duration (in seconds) for which the controller attempts to reschedule pods to a new machine during node draining.

  When a machine is deleted, the `Drain` operation evicts the pods for this long. Then the machine is deleted anyway. In a `Static` or `CloudStatic` NodeGroup without this field, the `Drain` of a deleted machine has no time limit.

  The range is the one the module's own settings have always enforced. A value outside it used to be accepted here and then rejected when the module read it, which stopped node-manager reconciling anything at all.

  Allowed values: `30 <= X <= 7200`

- **spec.nodeTemplate**
  object

  Specification of some of the fields that will be maintained in all nodes of the group.

  Example:

```
nodeTemplate:
  labels:
    environment: production
    app: warp-drive-ai
  annotations:
    ai.fleet.com/discombobulate: 'true'
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
```

  - **spec.nodeTemplate.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

```
annotations:
  ai.fleet.com/discombobulate: 'true'
```

  - **spec.nodeTemplate.labels**
    object

    Similar to the standard `metadata.labels` field.

    Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

- **spec.nodeTemplate.taints**
  array of objects

  Similar to the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **spec.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.nodeTemplate.taints.key**
    string
  - **spec.nodeTemplate.taints.value**
    string

- **spec.nodeType**
  string

  Required value

  The type of nodes this group provides:

  - `CloudEphemeral` — nodes for this group will be automatically created (and deleted) in the cloud of the specified cloud provider;
  - `CloudPermanent`. Nodes are created and deleted using `dhctl`. Virtual machine parameters are set in the cloud provider configuration. When the provider is configured through ModuleConfig, the parameters are set in the instance class referenced by `cloudInstances.classReference`;
  - `CloudStatic` — a static node (created manually or using any external tools) hosted in the cloud integrated with one of the cloud providers. This node has the CSI running, and it is managed by the cloud-controller-manager: the `Node` object automatically gets the information about the zone and region based on the cloud data; if a node gets deleted from the cloud, its corresponding Node object will be deleted in Kubernetes;
  - `Static` — a static node hosted on a bare metal or virtual machine. The cloud-controller-manager does not manage the node even if one of the cloud providers is enabled.

  Allowed values: `CloudEphemeral`, `CloudPermanent`, `CloudStatic`, `Static`

- **spec.operatingSystem**
  object

  Operating System settings for nodes.

  - **spec.operatingSystem.manageKernel**
    Deprecated
    boolean

    This parameter has no effect. Earlier, it enabled kernel maintenance on behalf of bashible.

    Default: `true`

- **spec.providerType**
  string

  Cloud provider type of the node group. `None` or an empty value — for a static node group.

- **spec.staticInstances**

object

Parameter for provisioning static machines to the cluster.

- **spec.staticInstances.count**
  integer

  Target number of StaticInstance resources (matching the `labelSelector`) that DP bootstraps and adds into the cluster.

  In a NodeGroup with Static or CloudStatic nodes, this parameter sets the expected number of nodes. DP uses this value for state control and automation purposes.

  > **Warning.** Set this parameter explicitly. The default value is `0`, which means DP won't bootstrap any StaticInstance resource or add any node to the group unless this value is modified. To add static nodes, specify the required number here (greater than `0`).

  Default: `0`

  Allowed values: `0 <= X`

- **spec.staticInstances.labelSelector**
  object

  Label selector for choosing the StaticInstance resources the node group uses.

  If both `matchLabels` and `matchExpressions` are set, a StaticInstance resource must satisfy all the conditions at once.

  An empty selector (`{}`) chooses every StaticInstance resource. If the selector is not set, the node group chooses no StaticInstance resources.

  Warning. A selector with at least one condition cannot be modified or removed. To change it, create a new node group and move the static nodes to it.

  Adding a selector to a node group that already uses StaticInstance resources is possible only when the labels of all those resources satisfy the new selector. Otherwise the webhook rejects the change and lists the resources that do not match the selector in the error message.

  After the selector is added, existing static nodes are not recreated and keep their previous configuration, but the platform applies the selector to every new node. A StaticInstance resource that does not match the selector cannot be reused, so the node group ends up with fewer nodes than the `count` parameter specifies.

  To add a selector:

  - Label all the StaticInstance resources of the node group with the `d8 k label staticinstance <STATIC_INSTANCE> <KEY>=<VALUE>` command.
  - Set the selector in the `spec.staticInstances` parameter of the NodeGroup resource.
  - **spec.staticInstances.labelSelector.matchExpressions**
    array of objects

    A list of label selector requirements. The requirements are ANDed.

    A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

    - **spec.staticInstances.labelSelector.matchExpressions.key**
      string

      key is the label key that the selector applies to.

    - **spec.staticInstances.labelSelector.matchExpressions.operator**
      string

      operator represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

    - **spec.staticInstances.labelSelector.matchExpressions.values**
      array of strings

      values is an array of string values. If the operator is In or NotIn, the values

array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **Element of the array**
  string

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

- **spec.staticInstances.labelSelector.matchLabels**
  object

  matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **spec.systemType**
  string

  How the nodes of the group are managed.

  - `GenericOS`: Generic OS nodes, configured by bashible on the fly. An unset field means the same.
  - `DeckhouseEngine`: Deckhouse Engine nodes. The node agent brings the node to the state described in a NodeConfig object, without bashible. The machine must boot from a Deckhouse Engine image.

  `DeckhouseEngine` is supported for:

  - `Static`: Machines must be added with `d8 node add`. `staticInstances` cannot be used.
  - `CloudEphemeral`: Machines must be created by the cloud provider through Cluster API (CAPI).
  - `CloudPermanent`: Machines are created by dhctl.

  `DeckhouseEngine` is not supported for `CloudStatic` groups.

  A group can become `DeckhouseEngine` only while bashible has configured none of its nodes. `DeckhouseEngine` cannot be removed or changed to `GenericOS`.

  Allowed values: `GenericOS`, `DeckhouseEngine`

- **spec.update**
  object
  - **spec.update.maxConcurrent**
    integer or string

    Maximum number of concurrently updating nodes.

    Can be set as absolute count or as a percent of total nodes.

    Default: `1`

    Pattern: `^[1-9][0-9]*%?$`

- **status**
  object
  - **status.conditionSummary**
    object
    - **status.conditionSummary.ready**
      string

      Status of the condition summary.

      Allowed values: `True`, `False`

    - **status.conditionSummary.statusMessage**
      string

      Status message about group handling.

  - **status.conditions**
    array of objects
    - **status.conditions.lastTransitionTime**
      string

Last time the condition transit from one status to another.

- **status.conditions.message**
  string

  Human readable message indicating details about last transition.

- **status.conditions.status**
  string

  Required value

  Status of the condition, one of True, False.

- **status.conditions.type**
  string

  Required value

  Type of node group condition.

- **status.deckhouse**
  object
  - **status.deckhouse.observed**
    object

    Contains last timestamp when the resource change was noted by the operator and its checksum.

    - **status.deckhouse.observed.checkSum**
      string

      The checksum of the last observed resource.

    - **status.deckhouse.observed.lastTimestamp**
      string

      Last timestamp when a change of the resource was noted by the operator.

  - **status.deckhouse.processed**
    object

    Contains last timestamp when the resource was applied in the cluster by the operator and its checksum.

    - **status.deckhouse.processed.checkSum**
      string

      The checksum of the last applied resource.

    - **status.deckhouse.processed.lastTimestamp**
      string

      Last timestamp when the resource was applied in the cluster.

  - **status.deckhouse.synced**
    string

    True if last observed version of the resource was successfully applied in the cluster.

- **status.desired**
  integer

  Number of desired machines in the group.

- **status.engine**
  string

  Machinery used to manage nodes in this group.

  The field value indicates which component manages the nodes:

  - `None` — nodes in the group are not managed by Machine Controller Manager or CAPI.
  - `MCM` — nodes in the group are managed by Machine Controller Manager.
  - `CAPI` — nodes in the group are managed by Cluster API.

  Allowed values: `None`, `MCM`, `CAPI`

- **status.error**

string

Error message about possible problems with the group handling.

- **status.instances**
  integer

  Number of instances (in any state) in the group.

- **status.kubernetesVersion**
  string

  The current version of kubernetes on the nodes, or the version to which the nodes will be upgraded.

- **status.lastMachineFailures**
  array of objects
  - **status.lastMachineFailures.lastOperation**
    object
    - **status.lastMachineFailures.lastOperation.description**
      string

      Last operation’s description.

    - **status.lastMachineFailures.lastOperation.lastUpdateTime**
      string

      Timestamp of last status update for operation.

    - **status.lastMachineFailures.lastOperation.state**
      string

      Machine’s operation state.

    - **status.lastMachineFailures.lastOperation.type**
      string

      Type of operation.

  - **status.lastMachineFailures.name**
    string

    Machine’s name.

  - **status.lastMachineFailures.ownerRef**
    string

    Machine owner’s name.

  - **status.lastMachineFailures.providerID**
    string

    Machine’s ProviderID.

- **status.max**
  integer

  Maximum amount of instances in the group.

- **status.min**
  integer

  Minimal amount of instances in the group.

- **status.nodes**
  integer

  Number of Kubernetes nodes (in any state) in the group.

- **status.ready**
  integer

  Number of ready Kubernetes nodes in the group.

- **status.standby**
  integer

  Number of overprovisioned instances in the group.

- **status.upToDate**
  integer

  Number of up-to-date nodes in the group.

Describes the runtime parameters of the node group.

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `42`
- **spec**
  object

  Required value

  - **spec.chaos**
    object

    Chaos monkey settings.

    Example:

    ```
    chaos:
      mode: DrainAndDelete
      period: 24h
    ```

    - **spec.chaos.mode**
      string

      The chaos monkey mode:

      - `DrainAndDelete` — drains and deletes a node when triggered;
      - `Disabled` — leaves this NodeGroup intact.

      Default: `Disabled`

      Allowed values: `Disabled`, `DrainAndDelete`
    - **spec.chaos.period**
      string

      The time interval to use for the chaos monkey (can be specified in the Go format).

      Default: `6h`

      Pattern: `^[0-9]+[mh]{1}$`
  - **spec.cloudInstances**
    object

    Parameter for provisioning the cloud-based VMs.

    > **i** **Caution.** Can only be used together with `nodeType: CloudEphemeral`.

    - **spec.cloudInstances.classReference**
      object

      Required value

      The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

      - **spec.cloudInstances.classReference.kind**
        string

        The kind of the `InstanceClass` object (e.g., `OpenStackInstanceClass`). Supported kinds are defined by the installed cloud provider modules and specified in their documentation.

    - **spec.cloudInstances.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

- **spec.cloudInstances.maxPerZone**
  integer

  Required value

  The maximum number of instances for the group in each zone.

  This value is used as the upper bound in cluster-autoscaler.

  Allowed values: `0 <= X`

- **spec.cloudInstances.maxSurgePerZone**
  integer

  The maximum number of instances the platform creates in each zone above the desired number while it replaces the instances of the group.

  Replacement happens when parameters that require recreating a virtual machine change, for example in the InstanceClass. The parameter does not limit the number of instances that the cluster autoscaler orders when it scales the group up. For details on what NodeGroup parameters affect, see NodeGroup parameters and their result.

  The value `0` is treated as if the parameter is not set, so the default value applies.

  Default: `1`

  Allowed values: `0 <= X`

- **spec.cloudInstances.maxUnavailablePerZone**
  integer

  The maximum number of unavailable instances (during rollout) in the group in each zone.

  Default: `0`

  Allowed values: `0 <= X`

- **spec.cloudInstances.minPerZone**
  integer

  Required value

  The minimum number of instances for the group in each zone.

  This value is used in the `MachineDeployment` object and as a lower bound in cluster-autoscaler.

  Allowed values: `0 <= X`

- **spec.cloudInstances.standby**
  integer or string

  The summary number of overprovisioned nodes for this `NodeGroup` in all zones.

  An overprovisioned node is a cluster node on which resources are reserved that are available at any time for scaling. The presence of such a node allows the cluster autoscaler not to wait for node initialization (which may take several minutes), but to immediately place a load on it.

  The value can be an absolute number (for example, 2) or a percentage of desired nodes (for example, 10%). If a percentage is specified, the absolute number is calculated based on the percentage of the maximum number of nodes (the maxPerZone parameter) rounded down, but not less than one.

  Pattern: `^[0-9]+%?$`

- **spec.cloudInstances.standbyHolder**
  object

  Amount of reserved resources.

  Used to determine whether to order overprovisioned nodes.

- **spec.cloudInstances.standbyHolder.notHeldResources**
  object

  Describes the resources that will not be held (consumed) by the standby holder.

  - **spec.cloudInstances.standbyHolder.notHeldResources.cpu**
    integer or string

    Describes the amount of CPU that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of cpus (for example, 2) as well as a milli representation (for example, 1500m).

    Pattern: `^[0-9]+m?$`

  - **spec.cloudInstances.standbyHolder.notHeldResources.memory**
    integer or string

    Describes the amount of memory that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of bytes (for example, 128974848) as well as a fixed-point number using one of memory suffixes: G, Gi, M, Mi.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.cloudInstances.zones**
  array of strings

  List of availability zones to create instances in.

  The default value depends on the cloud provider selected and usually corresponds to all zones of the region being used.

  Example:

  ```
  zones:
  - Helsinki
  - Espoo
  - Tampere
  ```

- **spec.cri**
  object

  Container runtime parameters.

  - **spec.cri.containerd**
    object

    Containerd runtime parameters.

    If used, `cri.type` must be set to `Containerd`.

    - **spec.cri.containerd.maxConcurrentDownloads**
      integer

      Set the max concurrent downloads for each pull.

      Default: `3`

  - **spec.cri.docker**
    object

    Docker settings for nodes.

    > **Note.** the `Docker` is deprecated.

    - **spec.cri.docker.manage**
      boolean

      Enable Docker maintenance from bashible.

      Default: `true`

        - **spec.cri.docker.maxConcurrentDownloads**
          integer

          Set the max concurrent downloads for each pull.

          Default: `3`

    - **spec.cri.notManaged**
      object

      Settings for not managed CRI for nodes.

        - **spec.cri.notManaged.criSocketPath**
          string

          Path to CRI socket.

    - **spec.cri.type**
      string

      Container runtime type.

      Value `defaultCRI` from the initial cluster configration (`cluster-configuration.yaml` parameter from the `d8-cluster-configuration` secret in the `kube-system` namespace) is used if not specified.

      > **i** **Note.** Docker support is deprecated.

      Allowed values: `Docker`, `Containerd`, `NotManaged`

- **spec.disruptions**
  object

  Disruptions settings for nodes.

  Example:

  ```
  disruptions:
    approvalMode: Automatic
    automatic:
      drainBeforeApproval: false
      windows:
      - from: '06:00'
        to: '08:00'
        days:
        - Tue
        - Sun
  ```

    - **spec.disruptions.approvalMode**
      string

      The approval mode for disruptive updates:

        - `Manual` — disable automatic disruption approval; the alert will be displayed if disruption is needed. **Caution.** The `master` node group update mode must be `Manual` to avoid issues with draining.
        - `Automatic` — automatically approve disruption-involving updates.
        - `RollingUpdate` — in this mode, a **new** node with new settings will be created; then, the old node will be deleted. Available only for cloud nodes.

      If the `RollingUpdate` mode is not used, when updating, the node is first drained and then updated (rebooted) and put back into operation (uncordoned). Note that in this case, the cluster must have sufficient resources to accommodate the load while the node being updated is unavailable. In the `RollingUpdate` mode, the node is **replaced** by the updated node, i.e., an extra node appears in the cluster for the duration of the update. In cloud infrastructures, the `RollingUpdate` mode is convenient, for example, if there are no resources in the cluster to temporarily host the load from the node being updated.

      Default: `Automatic`

      Allowed values: `Manual`, `Automatic`, `RollingUpdate`

- **spec.disruptions.automatic**
  object

  Additional parameters for the `Automatic` mode.

  - **spec.disruptions.automatic.drainBeforeApproval**
    boolean

    Drain Pods from the nodes before approving disruption.

    Caution. This setting ignores (nodes will be approved without draining Pods):

    - for the nodeGroup `master` with a single node;
    - for a single `ready` node in a nodeGroup picked out for Deckhouse placement.

    Default: `true`

  - **spec.disruptions.automatic.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.automatic.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

      ```
      days: Wed
      ```

      - **Element of the array**
        string

        Day of the week.

        Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

    - **spec.disruptions.automatic.windows.from**
      string

      Required value

      Start time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      from: '13:00'
      ```

    - **spec.disruptions.automatic.windows.to**
      string

      Required value

      End time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      to: '18:30'
      ```

- **spec.disruptions.rollingUpdate**
  object

  Additional parameters for the `RollingUpdate` mode.

  - **spec.disruptions.rollingUpdate.windows**
    array of objects

    Time windows for node disruptive updates

Time windows for node disruptive updates.

- **spec.disruptions.rollingUpdate.windows.days**
  array of strings

  Days of the week when node could be updated.

  Examples:

  ```
  days: Mon
  ```

  ```
  days: Wed
  ```

  - **Element of the array**
    string

    Day of the week.

    Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

- **spec.disruptions.rollingUpdate.windows.from**
  string

  Required value

  Start time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

  ```
  from: '13:00'
  ```

- **spec.disruptions.rollingUpdate.windows.to**
  string

  Required value

  End time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

  ```
  to: '18:30'
  ```

- **spec.kubelet**
  object

  Kubelet settings for nodes.

  - **spec.kubelet.containerLogMaxFiles**
    integer

    How many rotated log files to store before deleting them.

    > **Warning.** This parameter does nothing if CRI type is `Docker`.

    Default: `4`

    Allowed values: `2 <= X <= 20`

  - **spec.kubelet.containerLogMaxSize**
    string

    Maximum log file size before it is rotated.

    > **Warning.** This parameter does nothing if CRI type is `Docker`.

    Default: `50Mi`

Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

- **spec.kubelet.maxPods**
  integer

  Set the max count of pods per node for given NodeGroup. When left unspecified, the system automatically determines this limit according to the value of the `podSubnetNodeCIDRPrefix` parameter of the `control-plane-manager` module:

  - `120` pods for `podSubnetNodeCIDRPrefix` ≥ `24`;
  - `250` pods for `podSubnetNodeCIDRPrefix` = `23`;
  - `500` pods for `podSubnetNodeCIDRPrefix` = `22`;
  - `1000` pods for `podSubnetNodeCIDRPrefix` ≤ `21`.
- **spec.kubelet.rootDir**
  string

  Directory path for managing kubelet files (volume mounts,etc).

  Default: `/var/lib/kubelet`

- **spec.kubelet.seccompDefault**
  boolean

  Use `RuntimeDefault` seccomp profile for workloads that don’t specify seccomp profile explicitly.

- **spec.nodeTemplate**
  object

  Specification of some of the fields that will be maintained in all nodes of the group.

  Example:

  ```
  nodeTemplate:
    labels:
      environment: production
      app: warp-drive-ai
    annotations:
      ai.fleet.com/discombobulate: 'true'
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
  ```

  - **spec.nodeTemplate.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **spec.nodeTemplate.labels**
    object

    Similar to the standard `metadata.labels` field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **spec.nodeTemplate.taints**
    array of objects

    Similar to the `.spec.taints` field of the Node object.

> **i** Available fields: `effect`, `key`, and `values`.

Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

- **spec.nodeTemplate.taints.effect**
  string

  Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
- **spec.nodeTemplate.taints.key**
  string
- **spec.nodeTemplate.taints.value**
  string

- **spec.nodeType**
  string

  Required value

  The type of nodes this group provides.

  - `Cloud` — nodes for this group will be automatically created (and deleted) in the cloud of the specified cloud provider;
  - `Static` — a static node hosted on a bare metal or virtual machine. The cloud-controller-manager does not manage the node even of one of the cloud providers is enabled;
  - `Hybrid` — a static node (created manually or using any external tools) hosted in the cloud integrated with one of the cloud provider. This node has the CSI running, and it is managed by the cloud-controller-manager: the Node object automatically gets the information about the zone and region based on the cloud data; if a node gets deleted from the cloud, its corresponding Node object will be deleted in Kubernetes.

  Allowed values: `Cloud`, `Static`, `Hybrid`

- **spec.operatingSystem**
  object

  Operating System settings for nodes.

  - **spec.operatingSystem.manageKernel**
    boolean

    Enable kernel maintenance from bashible.

    Default: `true`

- **spec.providerType**
  string

  Cloud provider type of the node group. `None` or an empty value — for a static node group.

- **spec.systemType**
  string

  How the nodes of the group are managed.

  - `GenericOS`: Generic OS nodes, configured by bashible on the fly. An unset field means the same.
  - `DeckhouseEngine`: Deckhouse Engine nodes. The node agent brings the node to the state described in a NodeConfig object, without bashible. The machine must boot from a Deckhouse Engine image.

  `DeckhouseEngine` is supported for:

  - `Static`: Machines must be added with `d8 node add`.
  - `Cloud`: Machines must be created by the cloud provider through Cluster API (CAPI).
  - `Hybrid`: Machines must be created by dhctl (`CloudPermanent` in `deckhouse.io/v1`).

  `DeckhouseEngine` is not supported for other `Hybrid` groups (`CloudStatic` in

`deckhouse.io/v1`).

A group can become `DeckhouseEngine` only while bashible has configured none of its nodes. `DeckhouseEngine` cannot be removed or changed to `GenericOS`.

Allowed values: `GenericOS`, `DeckhouseEngine`

- **status**
  object
  - **status.conditionSummary**
    object
    - **status.conditionSummary.ready**
      string

      Status of the condition summary.

      Allowed values: `True`, `False`

    - **status.conditionSummary.statusMessage**
      string

      Status message about group handling.

  - **status.desired**
    integer

    Number of desired machines in the group.

  - **status.engine**
    string

    Machinery used to manage nodes in this group.

    The field value indicates which component manages the nodes:

    - `None` — nodes in the group are not managed by MCM or CAPI.
    - `MCM` — nodes in the group are managed by machine-controller-manager.
    - `CAPI` — nodes in the group are managed by Cluster API.

    Allowed values: `None`, `MCM`, `CAPI`

  - **status.error**
    string

    Error message about possible problems with the group handling.

  - **status.instances**
    integer

    Number of instances (in any state) in the group.

  - **status.kubernetesVersion**
    string

    The current version of kubernetes on the nodes, or the version to which the nodes will be upgraded.

  - **status.lastMachineFailures**
    array of objects
    - **status.lastMachineFailures.lastOperation**
      object
      - **status.lastMachineFailures.lastOperation.description**
        string

        Last operation’s description.

      - **status.lastMachineFailures.lastOperation.lastUpdateTime**
        string

        Timestamp of last status update for operation.

      - **status.lastMachineFailures.lastOperation.state**
        string

        Machine’s operation state.

      - **status.lastMachineFailures.lastOperation.type**
        string

Type of operation.

- **status.lastMachineFailures.name**
  string

  Machine’s name.

- **status.lastMachineFailures.ownerRef**
  string

  Machine owner’s name.

- **status.lastMachineFailures.providerID**
  string

  Machine’s ProviderID.

- **status.max**
  integer

  Maximum amount of instances in the group.

- **status.min**
  integer

  Minimal amount of instances in the group.

- **status.nodes**
  integer

  Number of Kubernetes nodes (in any state) in the group.

- **status.ready**
  integer

  Number of ready Kubernetes nodes in the group.

- **status.standby**
  integer

  Number of overprovisioned instances in the group.

- **status.upToDate**
  integer

  Number of up-to-date nodes in the group.

Defines the runtime parameters of a node group.

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `42`

- **spec**
  object

  Required value

  - **spec.chaos**
    object

    Chaos monkey settings.

    Example:

    ```
    chaos:
      mode: DrainAndDelete
      period: 24h
    ```

    - **spec.chaos.mode**
      string

      The chaos monkey mode:

The chaos monkey mode:

- `DrainAndDelete` — drains and deletes a node when triggered;
- `Disabled` — leaves this NodeGroup intact.

Default: `Disabled`

Allowed values: `Disabled`, `DrainAndDelete`

- **spec.chaos.period**
  string

  The time interval to use for the chaos monkey (can be specified in the Go format).

  Default: `6h`

  Pattern: `^[0-9]+[mh]{1}$`

- **spec.cloudInstances**
  object

  Parameter for provisioning the cloud-based VMs.

  > **Caution.** Can only be used together with `nodeType: CloudEphemeral`.

  - **spec.cloudInstances.classReference**
    object

    Required value

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

    - **spec.cloudInstances.classReference.kind**
      string

      The kind of the `InstanceClass` object (e.g., `OpenStackInstanceClass`). Supported kinds are defined by the installed cloud provider modules and specified in their documentation.

    - **spec.cloudInstances.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

  - **spec.cloudInstances.maxPerZone**
    integer

    Required value

    The maximum number of instances for the group in each zone.

    This value is used as the upper bound in cluster-autoscaler.

    With a value of 0, you need to set capacity for some `InstanceClass`. Get more details in the description of the necessary `InstanceClass`.

    Allowed values: `0 <= X`

  - **spec.cloudInstances.maxSurgePerZone**
    integer

    The maximum number of instances the platform creates in each zone above the desired number while it replaces the instances of the group.

    Replacement happens when parameters that require recreating a virtual machine change, for example in the InstanceClass. The parameter does not limit the number of instances that the cluster autoscaler orders when it scales the group up. For details on what NodeGroup parameters affect, see NodeGroup parameters and their result.

    The value `0` is treated as if the parameter is not set, so the default value applies.

    Default: `1`

    Allowed values: `0 <= X`

  - **spec.cloudInstances.maxUnavailablePerZone**

integer

The maximum number of unavailable instances (during rollout) in the group in each zone.

Default: `0`

Allowed values: `0 <= X`

- **spec.cloudInstances.minPerZone**
  integer

  Required value

  The minimum number of instances for the group in each zone.

  This value is used in the `MachineDeployment` object and as a lower bound in cluster-autoscaler.

  Allowed values: `0 <= X`

- **spec.cloudInstances.standby**
  integer or string

  The summary number of overprovisioned nodes for this `NodeGroup` all zones.

  An overprovisioned node is a cluster node on which resources are reserved that are available at any time for scaling. The presence of such a node allows the cluster autoscaler not to wait for node initialization (which may take several minutes), but to immediately place a load on it.

  The value can be an absolute number (for example, 2) or a percentage of desired nodes (for example, 10%). If a percentage is specified, the absolute number is calculated based on the percentage of the maximum number of nodes (the maxPerZone parameter) rounded down, but not less than one.

  Pattern: `^[0-9]+%?$`

- **spec.cloudInstances.standbyHolder**
  object

  Amount of reserved resources.

  Used to determine whether to order overprovisioned nodes.

  - **spec.cloudInstances.standbyHolder.notHeldResources**
    object

    Describes the resources that will not be held (consumed) by the standby holder.

    - **spec.cloudInstances.standbyHolder.notHeldResources.cpu**
      integer or string

      Describes the amount of CPU that will not be held by standby holder on Nodes from this NodeGroup.

      The value can be an absolute number of cpus (for example, 2) as well as a milli representation (for example, 1500m).

      Pattern: `^[0-9]+m?$`

    - **spec.cloudInstances.standbyHolder.notHeldResources.memory**
      integer or string

      Describes the amount of memory that will not be held by standby holder on Nodes from this NodeGroup.

      The value can be an absolute number of bytes (for example, 128974848) as well as a fixed-point number using one of memory suffixes: G, Gi, M, Mi.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.cloudInstances.zones**
  array of strings

  List of availability zones to create instances in.

  The default value depends on the cloud provider selected and usually corresponds to all zones of the region being used.

Example:

```
zones:
- Helsinki
- Espoo
- Tampere
```

- **spec.cri**
  object

  Container runtime parameters.

  - **spec.cri.containerd**
    object

    Containerd runtime parameters.

    If used, `cri.type` must be set to `Containerd`.

    - **spec.cri.containerd.maxConcurrentDownloads**
      integer

      Set the max concurrent downloads for each pull.

      Default: `3`

  - **spec.cri.type**
    string

    Container runtime type.

    If not specified, the `defaultCRI` parameter value of ClusterConfiguration is used.

    > **Note.** Docker support is deprecated.

    Allowed values: `Docker`, `Containerd`, `NotManaged`

- **spec.disruptions**
  object

  Disruptions settings for nodes.

  Example:

```
disruptions:
  approvalMode: Automatic
  automatic:
    drainBeforeApproval: false
    windows:
    - from: '06:00'
      to: '08:00'
      days:
      - Tue
      - Sun
```

  - **spec.disruptions.approvalMode**
    string

    The approval mode for disruptive updates:

    - `Manual` — disable automatic disruption approval; the alert will be displayed if disruption is needed. **Caution.** The `master` node group update mode must be `Manual` to avoid issues with draining.
    - `Automatic` — automatically approve disruption-involving updates.
    - `RollingUpdate` — in this mode, a **new** node with new settings will be created; then, the old node will be deleted. Available only for cloud nodes.

    If the `RollingUpdate` mode is not used, when updating, the node is first drained and then updated (rebooted) and put back into operation (uncordoned). Note that in this case, the cluster must have sufficient resources to accommodate the load while the

node being updated is unavailable. In the `RollingUpdate` mode, the node is **replaced** by the updated node, i.e., an extra node appears in the cluster for the duration of the update. In cloud infrastructures, the `RollingUpdate` mode is convenient, for example, if there are no resources in the cluster to temporarily host the load from the node being updated.

Default: `Automatic`

Allowed values: `Manual`, `Automatic`, `RollingUpdate`

- **spec.disruptions.automatic**
  object

  Additional parameters for the `Automatic` mode.

  - **spec.disruptions.automatic.drainBeforeApproval**
    boolean

    Drain Pods from the nodes before approving disruption.

    Caution. This setting ignores (nodes will be approved without draining Pods):

    - for the nodeGroup `master` with a single node;
    - for a single `ready` node in a nodeGroup picked out for Deckhouse placement.

    Default: `true`

  - **spec.disruptions.automatic.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.automatic.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

      ```
      days: Wed
      ```

      - **Element of the array**
        string

        Day of the week.

        Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

    - **spec.disruptions.automatic.windows.from**
      string

      Required value

      Start time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      from: '13:00'
      ```

    - **spec.disruptions.automatic.windows.to**
      string

      Required value

      End time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

```
to: '18:30'
```

- **spec.disruptions.rollingUpdate**
  object

  Additional parameters for the `RollingUpdate` mode.

  - **spec.disruptions.rollingUpdate.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.rollingUpdate.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

      ```
      days: Wed
      ```

      - **Element of the array**
        string

        Day of the week.

        Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

    - **spec.disruptions.rollingUpdate.windows.from**
      string

      Required value

      Start time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      from: '13:00'
      ```

    - **spec.disruptions.rollingUpdate.windows.to**
      string

      Required value

      End time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      to: '18:30'
      ```

- **spec.docker**
  object

  Docker settings for nodes.

  If used, `cri.type` must be set to `Docker`.

  > **i** **Note.** the `Docker` is deprecated.

  - **spec.docker.manage**
    boolean

    Enable Docker maintenance from bashible.

    Default: `true`

- **spec.docker.maxConcurrentDownloads**
  integer

  Set the max concurrent downloads for each pull.

  Default: `3`

- **spec.kubelet**
  object

  Kubelet settings for nodes.

  - **spec.kubelet.containerLogMaxFiles**
    integer

    How many rotated log files to store before deleting them.

    > **Warning.** This parameter does nothing if CRI type is `Docker`.

    Default: `4`

    Allowed values: `2 <= X <= 20`

  - **spec.kubelet.containerLogMaxSize**
    string

    Maximum log file size before it is rotated.

    > **Warning.** This parameter does nothing if CRI type is `Docker`.

    Default: `50Mi`

    Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

  - **spec.kubelet.maxPods**
    integer

    Set the max count of pods per node for given NodeGroup. When left unspecified, the system automatically determines this limit according to the value of the `podSubnetNodeCIDRPrefix` parameter of the `control-plane-manager` module:

    - `120` pods for `podSubnetNodeCIDRPrefix` ≥ `24`;
    - `250` pods for `podSubnetNodeCIDRPrefix` = `23`;
    - `500` pods for `podSubnetNodeCIDRPrefix` = `22`;
    - `1000` pods for `podSubnetNodeCIDRPrefix` ≤ `21`.

  - **spec.kubelet.rootDir**
    string

    Directory path for managing kubelet files (volume mounts,etc).

    Default: `/var/lib/kubelet`

  - **spec.kubelet.seccompDefault**
    boolean

    Use `RuntimeDefault` seccomp profile for workloads that don’t specify seccomp profile explicitly.

- **spec.kubernetesVersion**
  string

  The desired minor version of Kubernetes.

  By default, it corresponds to the version selected for the cluster globally (see installation documentation) or to the current version of the control plane (if the global version is not defined).

  Allowed values: `1.33`, `1.34`, `1.35`, `1.36`, `1.37`

  Example:

  ```
  kubernetesVersion: '1.33'
  ```

- **spec.nodeTemplate**
  object

  Specification of some of the fields that will be maintained in all nodes of the group.

  Example:

  ```
  nodeTemplate:
    labels:
      environment: production
      app: warp-drive-ai
    annotations:
      ai.fleet.com/discombobulate: 'true'
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
  ```

  - **spec.nodeTemplate.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **spec.nodeTemplate.labels**
    object

    Similar to the standard `metadata.labels` field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **spec.nodeTemplate.taints**
    array of objects

    Similar to the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **spec.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **spec.nodeTemplate.taints.key**
      string
    - **spec.nodeTemplate.taints.value**
      string
- **spec.nodeType**
  string

  Required value

  The type of nodes this group provides.

- `Cloud` — nodes for this group will be automatically created (and deleted) in the cloud of the specified cloud provider;
- `Static` — a static node hosted on a bare metal or virtual machine. The cloud-controller-manager does not manage the node even of one of the cloud providers is enabled;
- `Hybrid` — a static node (created manually or using any external tools) hosted in the cloud integrated with one of the cloud provider. This node has the CSI running, and it is managed by the cloud-controller-manager: the Node object automatically gets the information about the zone and region based on the cloud data; if a node gets deleted from the cloud, its corresponding Node object will be deleted in Kubernetes.

Allowed values: `Cloud`, `Static`, `Hybrid`

- **spec.operatingSystem**
  Deprecated
  object

  Operating System settings for nodes.

  - **spec.operatingSystem.manageKernel**
    Deprecated
    boolean

    Enable kernel maintenance from bashible.

    Default: `true`

- **spec.providerType**
  string

  Cloud provider type of the node group. `None` or an empty value — for a static node group.

- **spec.static**
  object

  Static node parameters

  - **spec.static.internalNetworkCIDRs**
    array of strings

    Subnet CIDR

- **spec.systemType**
  string

  How the nodes of the group are managed.

  - `GenericOS`: Generic OS nodes, configured by bashible on the fly. An unset field means the same.
  - `DeckhouseEngine`: Deckhouse Engine nodes. The node agent brings the node to the state described in a NodeConfig object, without bashible. The machine must boot from a Deckhouse Engine image.

  `DeckhouseEngine` is supported for:

  - `Static`: Machines must be added with `d8 node add`.
  - `Cloud`: Machines must be created by the cloud provider through Cluster API (CAPI).
  - `Hybrid`: Machines must be created by dhctl (`CloudPermanent` in `deckhouse.io/v1`).

  `DeckhouseEngine` is not supported for other `Hybrid` groups (`CloudStatic` in `deckhouse.io/v1`).

  A group can become `DeckhouseEngine` only while bashible has configured none of its nodes. `DeckhouseEngine` cannot be removed or changed to `GenericOS`.

  Allowed values: `GenericOS`, `DeckhouseEngine`

- **status**
  object
  - **status.conditionSummary**
    object
    - **status.conditionSummary.ready**
      string

      Status of the condition summary.

      Allowed values: `True`, `False`

        - **status.conditionSummary.statusMessage**
          string

          Status message about group handling.

    - **status.desired**
      integer

      Number of desired machines in the group.

    - **status.engine**
      string

      Machinery used to manage nodes in this group.

      The field value indicates which component manages the nodes:

      - `None` — nodes in the group are not managed by Machine Controller Manager or CAPI.
      - `MCM` — nodes in the group are managed by Machine Controller Manager.
      - `CAPI` — nodes in the group are managed by Cluster API.

      Allowed values: `None`, `MCM`, `CAPI`

    - **status.error**
      string

      Error message about possible problems with the group handling.

    - **status.instances**
      integer

      Number of instances (in any state) in the group.

    - **status.kubernetesVersion**
      string

      The current version of kubernetes on the nodes, or the version to which the nodes will be upgraded.

    - **status.lastMachineFailures**
      array of objects
        - **status.lastMachineFailures.lastOperation**
          object
            - **status.lastMachineFailures.lastOperation.description**
              string

              Last operation’s description.

            - **status.lastMachineFailures.lastOperation.lastUpdateTime**
              string

              Timestamp of last status update for operation.

            - **status.lastMachineFailures.lastOperation.state**
              string

              Machine’s operation state.

            - **status.lastMachineFailures.lastOperation.type**
              string

              Type of operation.

        - **status.lastMachineFailures.name**
          string

          Machine’s name.

        - **status.lastMachineFailures.ownerRef**
          string

          Machine owner’s name.

        - **status.lastMachineFailures.providerID**
          string

          Machine’s ProviderID.

    - **status.max**

integer

Maximum amount of instances in the group.

- **status.min**
  integer

  Minimal amount of instances in the group.

- **status.nodes**
  integer

  Number of Kubernetes nodes (in any state) in the group.

- **status.ready**
  integer

  Number of ready Kubernetes nodes in the group.

- **status.standby**
  integer

  Number of overprovisioned instances in the group.

- **status.upToDate**
  integer

  Number of up-to-date nodes in the group.

NodeConfig

Short names: nc

Scope: Cluster
Version: v1alpha1

NodeConfig is the desired state of one node and the node agent’s report on it.

The node agent (nodelet) applies `spec`.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  Required value

  Desired state of the node.

  - **spec.apiServerEndpoints**
    array of strings

    Kubernetes API server URLs with scheme and port, for example `https://10.0.0.1:6443`.

    - **Element of the array**
      string

      Pattern: `^https://(\[[0-9A-Fa-f:]+\]|[A-Za-z0-9]([-A-Za-z0-9]*[A-Za-z0-9])?([.][A-Za-z0-9]([-A-Za-z0-9]*[A-Za-z0-9])?)*):(6553[0-5]|655[0-2][0-9]|65[0-4][0-9]{2}|6[0-4][0-9]{3}|[1-5][0-9]{4}|[1-9][0-9]{0,3})/?$`

      Maximum length: `253`

- **spec.containerRuntime**
  object

  ContainerRuntime holds containerd configuration.

  - **spec.containerRuntime.maxConcurrentDownloads**
    integer

    Maximum number of image layers downloaded in parallel.

    `0` means no limit. Defaults to `8` when unset.

    Allowed values: `0 <= X`

  - **spec.containerRuntime.registryConfigOwner**
    string

    Component that writes the containerd `registry.d` directory.

    - `Nodelet`: The node agent writes the configuration from `spec.registry` to the directory and removes everything else in it, except the route directories of `spec.registry.upstreams`.
    - `RegistryAgent`: The registry agent static pod owns the directory. The node agent writes nothing there and only removes the directories it wrote before.

    Defaults to `Nodelet` when unset. Set by `node-manager`.

    Allowed values: `Nodelet`, `RegistryAgent`

  - **spec.containerRuntime.sandboxImage**
    string

    The `pause` image used for pod sandboxes.

    If not specified, the pause image imported by the containerd system extension is used.

    Pattern: `^[^[:space:]]+$`

    Maximum length: `1024`

- **spec.extensions**
  array of objects

  Extensions the node installs, each pinned by digest.

  On a Deckhouse Engine node an entry is a signed dm-verity system extension image. On a Generic OS node an entry is a registry package: the node agent runs the package's own `install` script as root.

  An entry named `nodelet` updates the node agent itself.

  Extension is a signed verity sysext built from a release channel, fetched from the registry-packages-proxy by digest. Optional repository selects the proxy's per-registry config; optional path is its "path" parameter.

  - **spec.extensions.digest**
    string

    Required value

    Digest is the sha256 digest of the sysext image.

    Pattern: `^sha256:[a-f0-9]{64}$`

  - **spec.extensions.name**
    string

    Required value

    Name is the extension name (also the sysext image basename).

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Length: `1..63`

  - **spec.extensions.path**
    string

    Path to the artifact inside the registry.

Maximum length: `512`

- **spec.extensions.repository**
  string

  Repository optionally selects the proxy’s per-registry client config.

  Pattern: `^[^[:space:]]+$`

  Maximum length: `1024`

- **spec.extensions.requestedBy**
  object

  Object that requested the extension.

  Unset for an extension of the platform itself.

  - **spec.extensions.requestedBy.kind**
    string

    Required value

    Kind of the object.

    Allowed values: `NodeExtensionRequest`, `NodeStaticPodRequest`, `RegistryUpstream`, `ModuleSource`

  - **spec.extensions.requestedBy.name**
    string

    Required value

    Name of the object.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Length: `1..253`

- **spec.featureGates**
  object

  Node agent features to switch on or off, keyed by feature name.

  A feature missing from this map is on for a Deckhouse Engine node if the node type supports it, and off for a Generic OS node. A Generic OS node runs only the features switched on here.

  The node rejects a document that names an unknown feature or switches on a feature its node type does not support.

  Set by node-controller.

- **spec.internalNetworkCIDRs**
  array of strings

  InternalNetworkCIDRs are the subnets the cluster’s own traffic runs on. The node picks the interface holding an address inside one of them and registers with that address; a node with one NIC needs none of this. IPv4 only.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

    Maximum length: `43`

- **spec.kernel**
  object

  Kernel holds sysctl settings and kernel modules to load.

  - **spec.kernel.modules**
    array of objects

    Kernel modules to load, in this order.

    Dependencies are not loaded automatically: list each module after the modules it

depends on. Do not list a driver built into the kernel: `KernelModulesLoaded` becomes `False`.

A module added to the list is loaded only after the disruption is approved.

KernelModule is a module to load with optional parameters.

- **spec.kernel.modules.name**
  string

  Required value

  Module name, as `lsmod` lists it. A `-` and a `_` in the name are the same.

  Length: `1..64`

- **spec.kernel.modules.params**
  array of strings

  Module parameters, passed to `insmod` in this order, for example `debug=1`.

  A changed list applies the next time the module loads: a loaded module is not reloaded.

  - **Element of the array**
    string

    Maximum length: `256`

- **spec.kernel.sysctl**
  object

  Kernel parameters the node sets at runtime, keyed by their dotted name, for example `net.ipv4.ip_forward`.

  A key the kernel does not have is skipped. The keys the node agent requires keep its values, and `vm.overcommit_memory` can only be `1`. The size of the connection tracking table, which the node computes from its cores, yields to a value set here.

- **spec.kubelet**
  object

  Kubelet holds kubelet configuration parameters.

  - **spec.kubelet.bootstrapToken**
    string

    BootstrapToken is the bootstrap token used by kubelet to obtain its client certificate on first boot.

    Maximum length: `4096`

  - **spec.kubelet.clusterCABundle**
    string

    PEM bundle of the cluster CA.

    Maximum length: `65536`

  - **spec.kubelet.clusterDNS**
    array of strings

    ClusterDNS is the list of DNS server IP addresses for the cluster.

    - **Element of the array**
      string

      Maximum length: `45`

  - **spec.kubelet.clusterDomain**
    string

    ClusterDomain is the DNS domain for this cluster (e.g. “cluster.local”).

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

  - **spec.kubelet.containerLogMaxFiles**

integer

Number of rotated log files kept per container.

Defaults to `4` when unset.

Allowed values: `2 <= X <= 1000`

- **spec.kubelet.containerLogMaxSize**
  string

  Maximum size of a container log file before it is rotated.

  Defaults to `50Mi` when unset.

  Maximum length: `64`

- **spec.kubelet.externalCloudProvider**
  boolean

  ExternalCloudProvider enables –cloud-provider=external so the cloud-controller-manager manages the node (zone, region, providerID).

- **spec.kubelet.kubernetesVersion**
  string

  KubernetesVersion is the cluster’s minor version, e.g. “1.34”. It decides which feature gates kubelet is started with (bashible turns DRA gates on by version); without it DRA workloads cannot run on Deckhouse Engine nodes.

  Pattern: `^[0-9]+\.[0-9]+$`

  Maximum length: `16`

- **spec.kubelet.maxPods**
  integer

  Maximum number of pods on the node.

  Defaults to `120` when unset.

  Allowed values: `1 <= X <= 1000`

- **spec.kubelet.nodeLabels**
  object

  NodeLabels are labels added to the node object when kubelet registers. A NodeGroup caps neither their number nor their shape, so neither does this.

- **spec.kubelet.registerWithTaints**
  array of objects

  RegisterWithTaints is a list of taints to add to the node object when kubelet registers itself. Only takes effect on initial registration.

  Taint represents a Kubernetes taint applied to a node during registration. Key, value and effect take what a NodeGroup takes: bare strings and an optional effect, so a taint copied from one still fits.

  - **spec.kubelet.registerWithTaints.effect**
    string

    Taint effect. A taint without an effect is skipped: kubelet registers a taint only with one of these.

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.kubelet.registerWithTaints.key**
    string

    Required value

    Taint key. A taint kubelet cannot register, such as one whose key is not a qualified name, is skipped, and the other taints are registered.

  - **spec.kubelet.registerWithTaints.value**
    string

    Taint value.

- **spec.kubelet.resourceReservation**
  object

  ResourceReservation controls how much CPU, memory and disk are held back from pods for the system itself (systemReserved).

  - **spec.kubelet.resourceReservation.mode**
    string

    Reservation policy.

    - `Auto`: Computed from the node’s capacity.
    - `Off`: Nothing is reserved.

    Defaults to `Auto` when unset.

    Allowed values: `Auto`, `Off`

- **spec.kubelet.serverTLSBootstrap**
  boolean

  ServerTLSBootstrap makes kubelet request a serving certificate from the cluster instead of signing its own.

  Defaults to `true` when unset.

- **spec.network**
  object

  Network holds hostname, DNS, NTP, interfaces and routes.

  - **spec.network.dns**
    object

    DNS resolver configuration.

    - **spec.network.dns.search**
      array of strings

      Search domains for host names that are not fully qualified, tried in this order.

      - **Element of the array**
        string

        Maximum length: `253`

    - **spec.network.dns.servers**
      array of strings

      Name server IP addresses.

      - **Element of the array**
        string

        Maximum length: `45`

  - **spec.network.hostname**
    string

    Host name of the node.

    Maximum length: `253`

  - **spec.network.interfaces**
    array of objects

    Network interfaces, keyed by name.

    NetworkInterface describes a single NIC.

    - **spec.network.interfaces.addresses**
      array of strings

      Static addresses in CIDR notation, used when `dhcp` is `false`.

      - **Element of the array**
        string

        Maximum length: `43`

- **spec.network.interfaces.cluster**
  boolean

  Cluster names this NIC the one the cluster’s traffic runs on, for a machine whose addressing spec.internalNetworkCIDRs cannot tell apart.

- **spec.network.interfaces.dhcp**
  boolean

  Required value

  DHCP enables DHCPv4 on the interface.

- **spec.network.interfaces.gateway**
  string

  Default gateway IP address.

  Maximum length: `45`

- **spec.network.interfaces.name**
  string

  Required value

  Interface name, for example `eth0`.

  Length: `1..253`

- **spec.network.ntp**
  object

  NTP time-sync configuration.

  - **spec.network.ntp.servers**
    array of strings

    NTP servers, each a host name or an IPv4 address. On Immutable nodes the time-sync feature checks them once per boot, before kubelet starts, and waits at most 30 seconds for a usable answer. The deckhouse chrony module keeps the clock in time after that.

    - **Element of the array**
      string

      Maximum length: `253`

- **spec.network.routes**
  array of objects

  Static routes, added on every interface listed in `interfaces`.

  Route is a static route.

  - **spec.network.routes.gateway**
    string

    Gateway IP address.

    Maximum length: `45`

  - **spec.network.routes.name**
    string

    Label for the route. It does not change how the route is applied.

    Maximum length: `253`

  - **spec.network.routes.networks**
    array of strings

    Destination networks in CIDR notation.

    - **Element of the array**
      string

      Maximum length: `43`

- **spec.nodeName**

string

Required value

Name of the Kubernetes node this configuration applies to.

Equals `metadata.name` and cannot be changed.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

Length: `1..253`

- **spec.osImage**
  object

  Operating system image to use on the node.

  To determine whether an update is required, the node compares the image `digest` with the value saved to `/config/os-digest` during installation. The digest identifies a specific image publication and may change when the same content is republished.

  Required when `systemType` is `DeckhouseEngine` or its former name `Immutable`.

  - **spec.osImage.digest**
    string

    Required value

    Operating system image digest.

    Identifies a specific image and is used by the node to determine whether an update is required. During installation, the node saves the digest and compares it with the specified value during subsequent checks.

    Pattern: `^sha256:[a-f0-9]{64}$`

  - **spec.osImage.path**
    string

    Path to the image inside the registry.

    Maximum length: `512`

  - **spec.osImage.repository**
    string

    Address of the container registry from which the operating system image is downloaded.

    The value is passed to `registry-packages-proxy` as the `repository` parameter.

    If the parameter is not specified, `repository` is not passed and `registry-packages-proxy` uses its default container registry.

    Pattern: `^[^[:space:]]+$`

    Maximum length: `1024`

  - **spec.osImage.rootHash**
    string

    Dm-verity root hash of the root filesystem inside the image, in ASCII hexadecimal format.

    Used to determine whether the actual image content has changed. Unlike `digest`, which may change when an image is republished, `rootHash` remains the same if the root filesystem content has not changed.

    Deckhouse Platform obtains the value from an image label. If the value cannot be obtained from the label, the node determines the root hash after downloading the image.

    Pattern: `^[a-f0-9]{64}$`

- **spec.registry**
  object

  Registry is the container registry the node talks to directly, without the registry-packages-proxy. A node bootstrapping a control plane has no proxy yet but must pull images and

sysexts. `upstreams` lists the additional registries containerd routes pulls to.

On a Generic OS node bashible configures containerd for the registry itself, and the node agent writes only the `upstreams` routes, with the `registry-routes` feature on. It reads only `address` there, which no route may take over, and never downloads from the registry directly.

- **spec.registry.address**
  string

  Required value

  Address is the registry host, optionally with a port, e.g. “registry.deckhouse.io” or “registry.example.com:5000”.

  Pattern: `^[^[:space:]]+$`

  Length: `1..1024`

- **spec.registry.auth**
  string

  Auth is the base64-encoded “user:password” pair, as it appears in the “auth” field of a docker config.

  Maximum length: `4096`

- **spec.registry.caBundle**
  string

  PEM bundle of the CA certificates the registry is verified with.

  Maximum length: `65536`

- **spec.registry.path**
  string

  Path is the repository path within the registry, e.g. “/deckhouse/ce”.

  Maximum length: `1024`

- **spec.registry.scheme**
  string

  Protocol the node uses to connect to the registry.

  Defaults to `HTTPS` when unset.

  Allowed values: `HTTPS`, `HTTP`

- **spec.registry.upstreams**
  array of objects

  Additional registries the node routes pulls to: each entry sends the pulls of one registry host to another registry and its mirrors.

  The node writes one containerd host directory per entry, named after `match` in lower case, and removes the directories of entries that are gone. A route change does not restart containerd. An entry the node cannot apply is skipped and reported in the `RegistryRoutesReady` condition; the other entries are still applied.

  The `registry-routes` feature applies this list. It is on by default on a Deckhouse Engine node; a Generic OS node applies the list only when `featureGates` switch the feature on. With the feature off, the node leaves the directories it wrote before as they are.

  Set by node-controller from the accepted RegistryUpstream objects and the CAs of ModuleSource objects. On a Deckhouse Engine node the list is empty while the registry module’s agent configures containerd. On a Generic OS node the list is always set but has no ModuleSource entry, since bashible writes those CAs itself, and the node writes no route while the agent’s `default` directory is listed in bashible’s `deckhouse_hosts_state.json`.

  RegistryUpstream is one route of spec.registry.upstreams.

  - **spec.registry.upstreams.match**
    string

Required value

Registry host, optionally with a port, whose pulls the route takes over. The name of the containerd host directory.

Pattern: `^[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?(\.[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?)*(:[0-9]{1,5})?$`

Length: `1..255`

- **spec.registry.upstreams.requestedBy**
  object

  Required value

  Object the route comes from: a RegistryUpstream, or a ModuleSource whose registry needs its own CA.

  - **spec.registry.upstreams.requestedBy.kind**
    string

    Required value

    Kind of the object.

    Allowed values: `NodeExtensionRequest`, `NodeStaticPodRequest`, `RegistryUpstream`, `ModuleSource`

  - **spec.registry.upstreams.requestedBy.name**
    string

    Required value

    Name of the object.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Length: `1..253`

- **spec.registry.upstreams.upstream**
  object

  Required value

  Registry the pulls are sent to, and its mirrors.

  - **spec.registry.upstreams.upstream.auth**
    object

    Credentials for the registry.

    - **spec.registry.upstreams.upstream.auth.auth**
      string

      Base64-encoded `username:password` pair. Takes precedence over `username` and `password` when set.

      Maximum length: `4096`

    - **spec.registry.upstreams.upstream.auth.password**
      string

      Password for basic authentication.

      Maximum length: `4096`

    - **spec.registry.upstreams.upstream.auth.username**
      string

      Username for basic authentication.

      Maximum length: `1024`

  - **spec.registry.upstreams.upstream.ca**
    string

    PEM bundle of the CA certificates the registry is verified with over `HTTPS`. The node skips the route unless the bundle is only CERTIFICATE blocks that

all parse.

Maximum length: `65536`

- **spec.registry.upstreams.upstream.host**
  string

  Required value

  Registry host, optionally with a port.

  Length: `1..255`

- **spec.registry.upstreams.upstream.mirrors**
  array of objects

  Additional addresses serving the same content, tried after the registry in the listed order.

  RegistryEndpoint is one address of a route.

  - **spec.registry.upstreams.upstream.mirrors.auth**
    object

    Credentials for the registry.

    - **spec.registry.upstreams.upstream.mirrors.auth.auth**
      string

      Base64-encoded `username:password` pair. Takes precedence over `username` and `password` when set.

      Maximum length: `4096`

    - **spec.registry.upstreams.upstream.mirrors.auth.password**
      string

      Password for basic authentication.

      Maximum length: `4096`

    - **spec.registry.upstreams.upstream.mirrors.auth.username**
      string

      Username for basic authentication.

      Maximum length: `1024`

  - **spec.registry.upstreams.upstream.mirrors.ca**
    string

    PEM bundle of the CA certificates the registry is verified with over `HTTPS`. The node skips the route unless the bundle is only CERTIFICATE blocks that all parse.

    Maximum length: `65536`

  - **spec.registry.upstreams.upstream.mirrors.host**
    string

    Required value

    Registry host, optionally with a port.

    Length: `1..255`

  - **spec.registry.upstreams.upstream.mirrors.path**
    string

    Repository prefix inside the registry, for example `/virtualization`. The node prepends it to every repository it pulls through this address.

    Maximum length: `1024`

  - **spec.registry.upstreams.upstream.mirrors.scheme**
    string

    Protocol the node uses to connect to the registry.

Defaults to `HTTPS` when unset.

Allowed values: `HTTP`, `HTTPS`

- **spec.registry.upstreams.upstream.path**
  string

  Repository prefix inside the registry, for example `/virtualization`. The node prepends it to every repository it pulls through this address.

  Maximum length: `1024`

- **spec.registry.upstreams.upstream.scheme**
  string

  Protocol the node uses to connect to the registry.

  Defaults to `HTTPS` when unset.

  Allowed values: `HTTP`, `HTTPS`

- **spec.registryPackagesProxy**
  object

  How the node reaches `registry-packages-proxy`, which serves it extensions and operating system images.

  - **spec.registryPackagesProxy.accessToken**
    string

    Bearer token the node presents to the proxy.

    Base64-encoded in the object.

    Maximum length: `4096`

  - **spec.registryPackagesProxy.endpoints**
    array of strings

    `registry-packages-proxy` URLs with scheme and port.

    When unset, the node uses port `4219` of the `apiServerEndpoints` hosts. Set only in the initial configuration of the first master node.

    - **Element of the array**
      string

      Pattern: `^https?://(\[[0-9A-Fa-f:]+\]|[A-Za-z0-9]([-A-Za-z0-9]*[A-Za-z0-9])?([.][A-Za-z0-9]([-A-Za-z0-9]*[A-Za-z0-9])?)*):(6553[0-5]|655[0-2][0-9]|65[0-4][0-9]{2}|6[0-4][0-9]{3}|[1-5][0-9]{4}|[1-9][0-9]{0,3})/?$`

      Maximum length: `253`

- **spec.staticPods**
  array of objects

  Manifests of static pods that kubelet runs without using the Kubernetes scheduler.

  The node writes the manifests to `/etc/kubernetes/manifests`. Static pods must obtain any other required resources on their own. For example, a pod can issue its own certificates, use the node's kubeconfig, and mount directories for persistent state using `hostPath` with the `DirectoryOrCreate` type.

  Control plane component manifests created by the node agent are not included in `spec.staticPods` and are not modified when this parameter is processed.

  Static pod.

  - **spec.staticPods.manifest**
    string

    Required value

    Complete pod manifest.

    When the manifest is written to disk, the `$MY_IP` substring is replaced with the node's IP address, similarly to control plane component manifests.

Length: `1..32768`

- **spec.staticPods.name**
  string

  Required value

  Manifest file name without an extension.

  Used as the list item key and is independent of `metadata.name` of the pod in the manifest. Kubelet determines the mirror pod name from the manifest rather than the file name.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

  Length: `1..63`

- **spec.staticPods.requestedBy**
  object

  Object that requested the static pod.

  Unset for a static pod of the platform itself.

  - **spec.staticPods.requestedBy.kind**
    string

    Required value

    Kind of the object.

    Allowed values: `NodeExtensionRequest`, `NodeStaticPodRequest`, `RegistryUpstream`, `ModuleSource`

  - **spec.staticPods.requestedBy.name**
    string

    Required value

    Name of the object.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Length: `1..253`

- **spec.statusToken**
  string

  StatusToken is the bearer presented to the node’s :50000 status port. Whoever writes the document mints it (dhctl, or the NodeConfigTemplate render for a hand-installed machine); the cluster carries it over untouched, having no way to tell the node a new one.

  Maximum length: `4096`

- **spec.storage**
  object

  Disk the operating system is installed on, and additional filesystems.

  The installation disk cannot be changed once set.

  - **spec.storage.device**
    string

    Device is the whole-disk block device to install onto, e.g. “/dev/sda”, “/dev/nvme0n1”, or a stable “/dev/disk/by-id/…” path. Ignored when diskSelector is set.

    Pattern: `^/dev/[A-Za-z0-9._/-]+$`

    Maximum length: `1024`

  - **spec.storage.diskSelector**
    object

    Selects the installation disk by attributes instead of a fixed path.

    All specified fields must match.

- **spec.storage.diskSelector.busPath**
  string

  BusPath matches the hardware bus path (glob).

  Maximum length: `253`

- **spec.storage.diskSelector.model**
  string

  Model matches the device model (glob), e.g. “Samsung*”.

  Maximum length: `253`

- **spec.storage.diskSelector.name**
  string

  Name matches the kernel device name (glob), e.g. “nvme0n1”.

  Maximum length: `253`

- **spec.storage.diskSelector.rotational**
  boolean

  Rotational matches spinning (true) vs solid-state (false) disks.

- **spec.storage.diskSelector.serial**
  string

  Serial matches the disk serial number (glob).

  Maximum length: `253`

- **spec.storage.diskSelector.size**
  string

  Size matches the disk capacity, optionally with a comparison operator, e.g. “>=100Gi”, “>1Ti”, “512Gi”.

  Maximum length: `253`

- **spec.storage.diskSelector.type**
  string

  Type matches the disk kind.

  Allowed values: `SSD`, `HDD`, `NVMe`, `SD`

- **spec.storage.diskSelector.wwid**
  string

  WWID matches the World Wide Identifier (glob).

  Maximum length: `253`

- **spec.storage.mounts**
  array of objects

  Mounts are additional filesystems the node makes available, at /mnt/ or wherever bindTo names. Nothing here is partitioned: only existing partitions and blank whole disks are formatted (when empty) and mounted.

  Mount is one additional filesystem, at /mnt/ unless bindTo says otherwise. Exactly one of device or partitionSelector names the partition; an empty one is formatted (label = name), an existing filesystem mounted as is.

  - **spec.storage.mounts.bindTo**
    string

    BindTo mounts the filesystem at this path instead of /mnt/, for a directory something else knows by name (/var/lib/etcd). The directory must be empty: mounting over files hides them, and hidden etcd data is lost data.

    Pattern: `^/[A-Za-z0-9._/-]+$`

    Maximum length: `1024`

  - **spec.storage.mounts.device**
    string

Device is the partition to use, e.g. “/dev/sdb1” or a stable “/dev/disk/by-id/...-part1” path.

Pattern: `^/dev/[A-Za-z0-9._/-]+$`

Maximum length: `1024`

- **spec.storage.mounts.filesystem**
  string

  Filesystem to create on an empty partition.

  Defaults to `Ext4` when unset.

  Allowed values: `Ext4`

- **spec.storage.mounts.mode**
  string

  Mode is the mode of the filesystem root after mounting, as an octal string, e.g. “0700”. Left alone when unset. A freshly made ext4 has its root at 0755, which is a mode etcd refuses to start on.

  Pattern: `^0[0-7]{3}$`

- **spec.storage.mounts.name**
  string

  Required value

  Name identifies the mount, and is both the mount point (/mnt/) and the filesystem label written when this node formats the partition. Capped at 16 characters because that is the size of the ext4 volume label field.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

  Length: `1..16`

- **spec.storage.mounts.partitionSelector**
  object

  PartitionSelector picks the partition by attributes instead of a fixed path.

  - **spec.storage.mounts.partitionSelector.blank**
    boolean

    Blank makes whole disks selectable, and only ones that carry nothing: no partition table, no filesystem — a cloud disk never touched. Without it a selector sees partitions only; a whole disk is where somebody’s layout lives.

  - **spec.storage.mounts.partitionSelector.fsType**
    string

    FSType matches the type of the filesystem already present (glob).

    Maximum length: `253`

  - **spec.storage.mounts.partitionSelector.label**
    string

    Label matches the filesystem label (glob).

    Maximum length: `253`

  - **spec.storage.mounts.partitionSelector.name**
    string

    Name matches the kernel device name (glob), e.g. “sdb1” or “nvme0n1p*”.

    Maximum length: `253`

  - **spec.storage.mounts.partitionSelector.partLabel**
    string

    PartLabel matches the GPT partition name (glob).

    Maximum length: `253`

  - **spec.storage.mounts.partitionSelector.partUUID**

string

PartUUID matches the GPT partition UUID exactly, ignoring case.

Maximum length: `253`

- **spec.storage.mounts.partitionSelector.size**
  string

  Size matches the size, optionally with a comparison operator, e.g. “>=100Gi”, “>1Ti”, “512Gi”. Without an operator the comparison is “>=”; “=” allows 1%, since a disk rarely reports an exact round size.

  Maximum length: `253`

- **spec.storage.mounts.partitionSelector.uuid**
  string

  UUID matches the filesystem UUID exactly, ignoring case.

  Maximum length: `253`

- **spec.storage.wipe**
  boolean

  Wipe controls whether an already-provisioned disk is wiped and re-partitioned. Default false: only an unprovisioned (or non-matching) disk is set up, so an existing layout stays and a reboot never destroys data.

- **spec.systemType**
  string

  Required value

  How the node is managed.

  - `DeckhouseEngine`: a Deckhouse Engine node. The node agent configures the whole node.
  - `GenericOS`: a node configured by bashible. The node agent manages only what `featureGates` turn on.

  The former names `Immutable` (for `DeckhouseEngine`) and `Mutable` (for `GenericOS`) are deprecated and accepted during the transition period.

  The node type cannot be changed. Replacing a former name with the new name of the same type, or back, is allowed.

  Allowed values: `Immutable`, `Mutable`, `DeckhouseEngine`, `GenericOS`

- **spec.updatePolicy**
  object

  UpdatePolicy controls how and when the node is updated.

  - **spec.updatePolicy.mode**
    string

    Update mode.

    The node checks the value and does not act on it: in either mode it updates within `windows`.

    Allowed values: `Manual`, `Automatic`

  - **spec.updatePolicy.windows**
    array of objects

    Time windows in UTC when the node may download and apply updates.

    An update is allowed if any window matches. Without windows, updates are allowed at any time.

    One update window, in UTC.

    - **spec.updatePolicy.windows.days**
      array of strings

      Days of the week the window applies to, as calendar days in UTC.

A time matches when its own day is listed, also in the part of a window that runs past midnight. When empty, the window applies every day.

- **Element of the array**
  string

  Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

- **spec.updatePolicy.windows.from**
  string

  Required value

  Start of the window, `H:MM` or `HH:MM` (24-hour, UTC).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

- **spec.updatePolicy.windows.to**
  string

  Required value

  End of the window, same format as `from`.

  A window whose end is before its start runs over midnight. The part after midnight belongs to its own calendar day: with `days: [Sat]`, a window from `22:00` to `04:00` allows Saturday 00:00 to 04:00 and Saturday 22:00 to midnight, and not Sunday 01:00.

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

- **status**
  object

  Status is reported by the on-node agent after each reconcile pass.

  - **status.agent**
    object

    Node agent build that wrote this status.

    - **status.agent.version**
      string

      Build version of the node agent.

  - **status.appliedGeneration**
    integer

    AppliedGeneration is the spec generation the node has applied.

    The node has applied the current spec when AppliedGeneration equals metadata.generation and ConfigurationApplied is True at that generation. The value stays behind while a disruptive change waits for approval, and while a new agent build installed for this generation has not applied it yet.

  - **status.conditions**
    array of objects

    Conditions of the node.

    A `False` condition whose reason ends with `Pending` is a wait. Any other `False` reason and `Unknown` mean a failure. `AddressResolved` does not affect `phase`.

    In `Ready`, `ConfigurationApplied` and `DisruptionApproved`, `observedGeneration` is the generation the node has processed. In the other conditions, it is the generation the node runs.

    Condition types:

    - `Ready`: `True` with reason `ReconcileSucceeded` when `phase` is `Ready`. Otherwise `False`, with the phase as the reason. The message names the condition that determined the phase.
    - `ConfigurationApplied`: `True` when the node runs the published configuration.

      With `True`, the reason is `ReconcileSucceeded`, or `UnknownFields` when the object has fields unknown to this agent build. The message lists them.

Reasons with `False` that mean a wait:

- `DisruptionApprovalPending`
- `Pending`
- `RestartPending`

Reasons with `False` that mean a failure:

- `Rejected`
- `RolledBackToLastKnownGood`
- `RollbackFailed`
- `PartiallyApplied`
- `FieldsNotApplicable`

- `DisruptionApproved`: Whether the interruption that the configuration of the node needs is approved.

  Reasons:

  - `ApprovalPending` (`False`): A configuration that interrupts the node waits for approval.
  - `AttemptsExhausted` (`False`): The interruptions `node-manager` attempted failed, and it makes no new attempt for now.
  - `Approved` (`True`): The interruption is approved.
  - `NoDisruptionPending` (`True`): Nothing waits for approval.

- `AddressResolved`: Whether the node has determined the address it registers with.

  Reasons with `False`:

  - `NoneInCIDR`, `Ambiguous`: The node cannot choose an address.
  - `AddressDrift`: The node keeps the address it registered with, but that address is no longer on the machine or the configuration now selects another one.

- Subsystem conditions, one per subsystem the pass ran or skipped:

  - `BootTimeSyncConfigured`
  - `APIEndpointsReachable`
  - `SysctlApplied`
  - `KernelModulesLoaded`
  - `MountsReady`
  - `ExtensionsReady`
  - `ContainerdReady`
  - `KubeletReady`
  - `StaticPodsReady`
  - `RegistryRoutesReady`
  - `UnitsRunning`
  - `OSImageUpToDate`
  - `ControlPlaneBootstrapped`

  Values of a subsystem condition:

  - `True`: The reason is `ReconcileSucceeded`, or a specific reason of the subsystem listed below.
  - `False`: The message gives the cause. The reason is `Pending` while the subsystem waits for something outside the node, otherwise `ReconcileFailed` or a more specific reason of the subsystem listed below.
  - `Unknown`: The subsystem did not run in this pass. The reason is `ReconcileSkipped`.

  Specific reasons with `True`:

  - `OwnedByRegistryAgent` (`RegistryRoutesReady`): The registry agent configures containerd’s registry hosts on this Generic OS node. The node writes no route and has removed the ones it wrote.

  Specific reasons with `False` that mean a failure:

  - `StaticPodFailed` (`StaticPodsReady`): A static pod manifest is not written or not removed. The `staticPods` entry gives the cause.
  - `OSImageRolledBack` (`OSImageUpToDate`): The node rolled back from the image or refused it before. The image is not tried again.
  - `OSImageRejected` (`OSImageUpToDate`): The kernel refused the root hash signature of the image. The image is not tried again.
  - `OSImageRootHashMismatch` (`OSImageUpToDate`): The image does not carry the root hash the configuration declares. The image is not tried again.

- `OSImageDownloadFailed` (`OSImageUpToDate`): The node could not download the image. The node retries.
- `OSImageStaged` (`OSImageUpToDate`): The image is staged for the next boot, but the node could not request the reboot.
- `OSImageOnTrial` (`OSImageUpToDate`): The node did not confirm the new image in time and could not request the reboot that tries it again.

Waits of `OSImageUpToDate` are published with the reason `Pending`, and the message tells them apart:

- `OSImageBaselineUnknown`: The node has no record of the image it runs and cannot update it until it is reinstalled.
- `OSImageUpdateDeferred`: The update waits for the update window.
- `OSImageStaged`, `OSImageOnTrial`: The node reboots into the new image or waits for its subsystems before it confirms the image.

Condition contains details for one aspect of the current state of this API Resource.

- **status.conditions.lastTransitionTime**
  string

  Required value

  lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

- **status.conditions.message**
  string

  Required value

  message is a human readable message indicating details about the transition. This may be an empty string.

  Maximum length: `32768`

- **status.conditions.observedGeneration**
  integer

  observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

  Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  reason contains a programmatic identifier indicating the reason for the condition’s last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  status of the condition, one of True, False, Unknown.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  type of condition in CamelCase or in foo.example.com/CamelCase.

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-`

`9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

Maximum length: `316`

- **status.extensions**
  array of objects

  Extensions is the outcome of each configured system extension, one entry per extension. Republished on every pass, empty when the pass checked nothing — never “the previous outcome still holds”.

  ExtensionStatus is the reconcile outcome of one system extension.

  - **status.extensions.digest**
    string

    Digest depends on State.

    - Ready: the digest installed on the node.
    - Pending: the digest being installed. For the agent’s own entry, the digest installed and waiting for the new build to start.
    - Failed: the digest the node refused or could not install.
  - **status.extensions.message**
    string

    Message carries the cause when State is Failed.

  - **status.extensions.name**
    string

    Required value

    Name is the extension name: a spec.extensions[].name, or the name of an extension removed from spec whose uninstall failed on a Generic OS node.

  - **status.extensions.state**
    string

    Required value

    State of the extension.

    - Ready: the extension is installed (on a Deckhouse Engine node, also merged).
    - Pending: the extension is being fetched or waits for the update window, or the agent restarts with a new build of itself (reason RestartPending).
    - Failed: the cause is in Message.

    Allowed values: `Ready`, `Pending`, `Failed`

- **status.features**
  array of strings

  Features that ran on the node during its last reconciliation, sorted by name: the gates switched on in spec.featureGates plus the defaults of the node type.

  On a Deckhouse Engine node spec.featureGates is usually empty because unset gates are on there. This list shows what actually runs on the node.

- **status.lastReconcileTime**
  string

  LastReconcileTime is when the node last finished a reconcile pass — the only thing in the status that ages, so it is what tells a dead agent from a healthy one. Republished coarsely: judge staleness in tens of minutes.

- **status.maintenanceToken**
  string

  MaintenanceToken is the bearer token an operator presents to the node’s :50000 config-push port once the node has lost the API. Root-equivalent, so the apiserver keeps it out of every answer without the sensitive subresource, which nodes are not granted.

- **status.network**
  object

  Network is what the node resolved for itself: the interface it took its cluster address from, and that address. Written by the node alone.

        - **status.network.address**
          string

          Address is the address kubelet registered the node with.

        - **status.network.clusterInterface**
          string

          ClusterInterface is the NIC the address was taken from.

    - **status.observedGeneration**
      integer

      ObservedGeneration is the latest spec generation the node has processed: it reaches the newest generation as soon as the node has looked at it, even while it is still held for approval (see AppliedGeneration).

    - **status.osImage**
      object

      Status of the operating system image on the node. Filled in by the node.

        - **status.osImage.attemptsLeft**
          integer

          Number of remaining boot attempts with the image being verified before initramfs automatically rolls back to the previous image.

        - **status.osImage.digest**
          string

          Digest of the operating system image currently used by the node. The value is read from the node configuration partition.

          May be absent on nodes installed before the digest persistence mechanism was introduced.

        - **status.osImage.failedDigest**
          string

          Digest of an image that caused the node to roll back after booting. No further attempts are made to boot this image.

          Because a digest uniquely identifies immutable image content, a fixed version of the image has a different digest.

        - **status.osImage.rootHash**
          string

          Dm-verity root hash of the image currently used by the node. The value is read from the active A/B slot.

          Used to identify the actual root filesystem content independently of the image digest. For example, the digests of the desired and currently used images may differ after republishing, while identical `rootHash` values indicate that the root filesystem content has not changed.

        - **status.osImage.slot**
          string

          A/B slot (`a` or `b`) containing the image currently used by the node.

        - **status.osImage.trialDigest**
          string

          Digest of the image prepared for the next boot or being verified during the current boot.

          Set only during an update, while `digest` still contains the digest of the previous image.

    - **status.phase**
      string

      Summary of the node.

        - `Ready`: The node runs the published configuration and every subsystem is healthy.
        - `Pending`: The node is healthy but does not run the published configuration yet.
        - `Degraded`: At least one condition other than `AddressResolved` reports a failure.

Allowed values: `Ready`, `Pending`, `Degraded`

- **status.staticPods**
  array of objects

  Results of processing static pods. A separate entry is created for each pod.

  Value is regenerated on each reconciliation and remains empty if no static pods were checked during the reconciliation.

  Processing result for a single static pod.

  - **status.staticPods.manifestDigest**
    string

    sha256 of the manifest as published in `spec`, in the form `sha256:<hex>`.

    Set when `state` is `Written`.

  - **status.staticPods.message**
    string

    Detailed information about the error when `state` is `Failed`.

  - **status.staticPods.name**
    string

    Required value

    Static pod name corresponding to `spec.staticPods[].name`.

  - **status.staticPods.reason**
    string

    Reason for the `Failed` state.

    Possible values:

    - `ManifestRejected`: Node rejected the manifest. The manifest in the resource must be corrected.
    - `WriteFailed`: Manifest file could not be written to the node. Check the node state.
    - `RemoveFailed`: Static pod was removed from `spec`, but the corresponding manifest file could not be removed from the node. The pod continues to run.

    Allowed values: `ManifestRejected`, `WriteFailed`, `RemoveFailed`

  - **status.staticPods.state**
    string

    Required value

    Manifest processing state.

    Possible values:

    - `Written`: File on disk matches the manifest from `spec`.
    - `Failed`: File does not match the manifest from `spec`, or the required operation could not be completed. The reason is specified in `reason`.

    Allowed values: `Written`, `Failed`

- **status.units**
  array of objects

  Units is the outcome of each managed systemd unit (containerd, kubelet and every unit an extension ships), one entry per unit. Republished on every pass like Extensions, and empty when the pass checked nothing.

  UnitStatus is the reconcile outcome of one managed systemd unit.

  - **status.units.message**
    string

    Message carries the cause when State is Failed.

  - **status.units.name**
    string

Required value

Name is the systemd unit name (e.g. containerd.service).

- **status.units.state**
  string

  Required value

  State is Active when the unit is running, Pending when it is queued to be started later this pass, or Failed with the cause in Message.

  Allowed values: `Active`, `Pending`, `Failed`

NodeExtensionRequest

Short names: ner

Scope: Cluster
Version: v1alpha1

Request to install an extension on the selected nodes: a system extension (a sysext image, optionally with kernel modules) or a registry package.

The requester sets the kind in `spec.extension.kind`. A registry package (`Package`) is installed on the selected nodes that bashible configures. A system extension (`SystemExtension`) is installed on the selected Deckhouse Engine nodes. The kind is never inferred from the image. If none of the selected groups installs extensions of this kind, the `Accepted` condition reports the `NotDeliverable` reason.

The image is addressed the same way as any package in the registry-packages-proxy: a name, a digest, and an optional repository and path. node-controller copies these fields unchanged into `spec.extensions` of the NodeConfig, and the node agent installs the extension. node-controller does not look up the image by module or ModuleSource.

Example:

```
# A system extension with kernel modules, fetched from the registry of a
ModuleSource.
apiVersion: deckhouse.io/v1alpha1
kind: NodeExtensionRequest
metadata:
  name: drbd
spec:
  extension:
    name: drbd
    digest: sha256:4f53cda18c2baa0c0354bb5f9a3ecbe5ed12ab4d8e11ba873c2f11161202b945
    kind: SystemExtension
    repository: registry.example.com/deckhouse/modules
    path: drbd/extensions
    kernelModules:
      - name: drbd
        params:
          - usermode_helper=disabled
      - name: drbd_transport_tcp
  nodeGroupSelector:
    matchNames:
      - worker
---
# A registry package from the cluster's main registry, on the nodes of every
# group bashible configures that carry the label.
apiVersion: deckhouse.io/v1alpha1
kind: NodeExtensionRequest
metadata:
  name: nvme-cli
spec:
  extension:
    name: nvme-cli
    digest: sha256:9b2a6f2bb7e3c5f6d1a0e4c8b7d6e5f4a3b2c1d0e9f8a7b6c5d4e3f2a1b0c9d8
    kind: Package
  nodeSelector:
    matchLabels:
      storage.example.com/nvme: "true"
```

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Required value

  - **spec.extension**
    object

    Required value

    Image to install and its kind. The image is addressed the same way as any package in the registry-packages-proxy.

    - **spec.extension.digest**
      string

      Required value

      Image manifest digest.

      Pattern: `^sha256:[a-f0-9]{64}$`

    - **spec.extension.kernelModules**
      array of objects

Kernel modules the node agent loads after merging the system extension, in the listed order. Allowed only with the `SystemExtension` kind. Each module is listed once.

Dependencies are not loaded automatically: list every module the extension needs, each one after the modules it depends on.

Adding a module interrupts each selected node: the node waits for an approved `Disruption` NodeOperation.

- **spec.extension.kernelModules.name**
  string

  Required value

  Kernel module name.

  Pattern: `^[a-zA-Z0-9][a-zA-Z0-9_-]*$`

  Length: `1..64`

- **spec.extension.kernelModules.params**
  array of strings

  Module parameters, passed as `key=value` strings.

  - **Element of the array**
    string

    Maximum length: `256`

- **spec.extension.kind**
  string

  Required value

  Image kind.

  - `Package`: a registry package. The node agent installs it on the selected nodes that bashible configures.
  - `SystemExtension`: a system extension. The node agent merges it on the selected Deckhouse Engine nodes.

  Nodes of groups of the other type do not receive the image. If none of the selected groups installs extensions of this kind, the `Accepted` condition reports the `NotDeliverable` reason.

  Cannot be changed after creation. To change the kind, delete the request and create it again.

  Allowed values: `Package`, `SystemExtension`

- **spec.extension.name**
  string

  Required value

  Extension name.

  The image of a system extension must contain the extension-release file for this name.

  The names `containerd`, `kubelet`, `kubernetes-cni`, `nodelet` and `qemu-guest-agent` belong to platform extensions and are not accepted.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

  Length: `1..63`

- **spec.extension.path**
  string

  The image's path within the repository (the proxy's `--rpp-path`). Left empty, the repository root is used.

  Maximum length: `512`

- **spec.extension.repository**
  string

  The key the registry-packages-proxy resolves credentials by (its `--rpp-repository`).

The key the registry packages proxy resolves credentials by (its `spec.registry.repo`), for example a ModuleSource's `spec.registry.repo`. Left empty, the image is pulled from the cluster's main registry.

Pattern: `^[^[:space:]]+$`

Maximum length: `1024`

- **spec.nodeGroupSelector**
  object

  Narrows the extension to nodes of the named NodeGroups.

  - **spec.nodeGroupSelector.matchNames**
    array of strings

    The set of NodeGroup names the extension applies to.

    - **Element of the array**
      string

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

      Maximum length: `63`

- **spec.nodeSelector**
  object

  Narrows the extension to nodes carrying the given labels.

  - **spec.nodeSelector.matchLabels**
    object

    The set of node labels a node must carry to be selected.

- **status**
  object
  - **status.appliedNodes**
    integer

    Number of selected nodes that report the extension installed at the digest of this request.

    Allowed values: `0 <= X`

  - **status.conditions**
    array of objects

    Conditions of the request: `Accepted` and `Ready`.

    `Accepted` shows whether `node-manager` accepted the request. It is `True` with the `Accepted` reason or `False` with one of these reasons:

    - `InvalidExtension`: The extension has no name or no digest.
    - `ReservedName`: The name belongs to a platform extension.
    - `Conflict`: An older request of the same kind already uses this name or digest, or the platform installs a registry package with this name or digest on the same nodes.
    - `KernelModuleConflict`: An older request already loads one of the kernel modules with different parameters.
    - `NotDeliverable`: None of the selected NodeGroups installs extensions of this kind.

    `Ready` shows whether the selected nodes run the request's digest:

    - `True` with the `AllNodesApplied` reason: Every selected node runs it.
    - `True` with the `NoNodesSelected` reason: The request selects no node. The selected NodeGroups do not exist, have no nodes, or have no nodes that match `nodeSelector`.
    - `False` with the `RolloutInProgress` reason: Some selected nodes do not run it yet.
    - `False` with the `RefusedByNodes` reason: At least one node refused the extension.
    - `False` with the `NotAccepted` reason: The `Accepted` condition is `False`.
    - **status.conditions.lastTransitionTime**
      string

      Required value

    - **status.conditions.message**
      string

      Required value

      Maximum length: `32768`

- **status.conditions.observedGeneration**
  integer

  Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.failedNodes**
  integer

  Number of selected nodes that refused the extension at the request’s digest.

  Allowed values: `0 <= X`

- **status.matchedNodeGroups**
  array of strings

  The selected NodeGroups whose nodes install this kind of image: Deckhouse Engine groups for a system extension, groups bashible manages for a registry package.

- **status.matchedNodes**
  integer

  Number of nodes in `matchedNodeGroups` that the selectors pick.

  Allowed values: `0 <= X`

- **status.nodes**
  array of objects

  Selected nodes that have not applied the request, at most 32.

  - **status.nodes.message**
    string

    Why the node refused the request or what it waits for.

    Maximum length: `4096`

  - **status.nodes.name**
    string

    Required value

    Node name.

  - **status.nodes.state**
    string

    Required value

    `Failed` if the node refused the request or `Pending` if it has not answered yet.

    Allowed values: `Pending`, `Failed`

- **status.observedGeneration**

integer

The generation of the spec this status reflects.

Allowed values: `0 <= X`

- **status.pendingNodes**
  integer

  Number of selected nodes that have reported neither the extension installed at the request's digest nor a refusal yet.

  Allowed values: `0 <= X`

- **status.phase**
  string

  Summary of the conditions.

  - `Pending`: The selected nodes are still installing the extension (the `Ready` condition has the `RolloutInProgress` reason).
  - `Ready`: The `Ready` condition is `True`.
  - `Degraded`: `node-manager` did not accept the request (the `Accepted` condition is `False`), or nodes refused the extension (the `Ready` condition has the `RefusedByNodes` reason).

  Allowed values: `Pending`, `Ready`, `Degraded`

NodeGroupConfiguration

Short names: ngc

Scope: Cluster
Version: v1alpha1

Executes bash scripts on nodes.

Read more in the module documentation.

- **spec**
  object

  Required value

  - **spec.bundles**
    array of strings

    Required value

    Bundles for step execution. You can set `'*'` for selecting all bundles.

    Examples:

    ```
    bundles:
    - ubuntu-lts
    - centos-7
    ```

    ```
    bundles:
    - ubuntu-lts
    ```

    ```
    bundles:
    - "*"
    ```

    - **Element of the array**
      string

      Allowed values: `ubuntu-lts`, `centos`, `debian`, `redos`, `rosa`, `astra`, `altlinux`, `opensuse`, `*`

  - **spec.content**
    string

    Required value

A bash script that does the same things you would do in a configuration step.

You can use Go Template to generate a script.

The list of parameters available for use in templates can be retrieved from the `bashible-apiserver-context` Secret as follows:

```
d8 k -n d8-cloud-instance-manager get secrets bashible-apiserver-context -o
jsonpath='{.data.input\.yaml}'| base64 -d
```

For example:

```
{{- range .nodeUsers }}
echo 'Tuning environment for user {{ .name }}'
# Some code for tuning user environment
{{- end }}
```

You can also use the pre-defined bashbooster commands in the script. For example:

```
bb-event-on 'bb-package-installed' 'post-install'
post-install() {
  bb-log-info "Setting reboot flag due to kernel was updated"
  bb-flag-set reboot
}
```

Example of using the proxy parameters of ClusterConfiguration resource:

```
bb-set-proxy
curl -I https://google.com
bb-unset-proxy
```

```
test-function-with-proxy() {
  bb-set-proxy
  trap bb-unset-proxy RETURN
  curl -I https://google.com
}
test-function-with-proxy
```

- **spec.nodeGroups**
  array of strings

  Required value

  List of NodeGroups to apply the step for. You can set `'*'` for selecting all NodeGroups.

  Examples:

  ```
  nodeGroups:
  - master
  - worker
  ```

  ```
  nodeGroups:
  - worker
  ```

  ```
  nodeGroups:
  - "*"
  ```

- **spec.weight**
  integer

  Order of the step execution.

  Default: `100`

NodeOperation

Short names: nop

Scope: Cluster
Version: v1alpha1

Describes an operation on a node that interrupts its work.

The `spec` of an existing operation cannot be changed, except `.spec.approved`. To approve a `Disruption` operation, run:

```
d8 k patch nodeoperation <OPERATION_NAME> --type=merge -p '{"spec":{"approved":true}}'
```

In the command, replace `<OPERATION_NAME>` with the name of the operation.

Operations for a deleted Cluster API Machine carry the label `node-manager.deckhouse.io/machine-uid`. Only `node-manager` can set it.

Example:

```
# Reboot a node.
apiVersion: deckhouse.io/v1alpha1
kind: NodeOperation
metadata:
  name: reboot-worker-1
spec:
  type: Reboot
  nodeName: worker-1
```

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Required value

  - **spec.approved**
    boolean

    Whether the interruption may go ahead. If the field is not set, the operation is not approved.

    Only meaningful for `Disruption`. `Reboot` and `Drain` ignore it.

    In the `Manual` approval mode of the NodeGroup (`spec.disruptions.approvalMode`), `node-manager` sets it to `false`, and an operator sets it to `true`. In the other modes, `node-manager` sets it to `true` on creation. An approval cannot be withdrawn.

  - **spec.cause**
    string

    Why the node is interrupted.

    For a `Disruption`, `node-manager` sets it on creation. For `Reboot` and `Drain`, an operator may set it.

    Maximum length: `1024`

  - **spec.configGeneration**
    integer

    Revision of the node's NodeConfig this disruption is for (`.metadata.generation` of the NodeConfig object).

    Allowed only for `Disruption`. The API server rejects the field for other types. If the NodeConfig moves to a newer generation before the operation is approved, `node-manager` deletes the operation.

    Allowed values: `1 <= X`

  - **spec.drain**

object

How to evict the workload before the node is interrupted.

Allowed for `Reboot` and `Disruption`. The API server rejects the field for `Drain`.

- **spec.drain.skip**
  boolean

  Interrupt the node without evicting its workload first.

  When `node-manager` creates a `Disruption`, it sets the field to `true` for these nodes:

  - The single node of the `master` NodeGroup
  - The node of the Deckhouse pod, while fewer than two nodes of its group are `Ready`
  - Every node of a NodeGroup with `spec.disruptions.automatic.drainBeforeApproval: false`

  Default: `false`

- **spec.nodeConfigUID**
  string

  NodeConfig object this disruption is for (`.metadata.uid` of the node's NodeConfig).

  Only meaningful for `Disruption`. Other types ignore it.

  Maximum length: `36`

- **spec.nodeName**
  string

  Required value

  The name of the node the operation applies to.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Length: `1..253`

- **spec.type**
  string

  Required value

  Operation to perform on the node.

  - `Reboot`: Reboot the node. Only the nodes of a NodeGroup with `systemType: DeckhouseEngine` perform this operation. A node that bashible manages refuses it, and the operation fails with the reason `NodeRefused`.
  - `Drain`: Evict the workload from the node. The node stays unschedulable until an operator makes it schedulable again. `node-manager` also creates a `Drain` for the node of a deleted Cluster API Machine. `.spec.cause` names the machine.

    To cancel a running `Drain`, delete it. `node-manager` withdraws its eviction request from the node before the object is gone. The cordon the eviction placed stays: make the node schedulable again yourself.
  - `Disruption`: Interrupt the node's work so that the node can apply a new configuration.

  `node-manager` creates `Disruption` operations. Creating one by hand is refused. `Reboot` and `Drain` are meant for an operator.

  Allowed values: `Reboot`, `Drain`, `Disruption`

- **status**
  object
  - **status.bootID**
    string

    Boot ID of the node (`status.nodeInfo.bootID` of the Node object) when the reboot started.

    Maximum length: `64`

  - **status.conditions**
    array of objects

    Latest details of the operation's progress:

Latest details of the operation's progress:

- `Drained`: Written by `node-manager`. While the workload is being evicted, the condition is `False` with the reason `Draining`. Once the workload has left, it is `True` with the reason `Drained`. When the operation skips the eviction, it is `True` with the reason `DrainSkipped`.
- `EvictionBlocked`: Written by `node-manager` while evictions of the workload are refused, for example by a PodDisruptionBudget. The condition is `True` with the reason `EvictionRefused`, and its `message` lists the refusals as the eviction reports them, one per pod. The same text is in the operation's `message`. The condition is removed once the refusals stop or the eviction ends. A finished operation keeps the refusals it ended on.
- `NodeReported`: Written by the node. The condition is `True` with the reason `Succeeded`, `Released`, `Failed`, `Refused` or `RebootStarted`.
- `Retry`: Written by `node-manager` on a failed `Disruption`. The condition says whether `node-manager` makes another attempt for the same NodeConfig revision.

Reasons of the `Retry` condition:

- `Created` (`True`): The next attempt exists, and `message` names it.
- `Scheduled` (`True`): `node-manager` creates the next attempt at the time given in `message`.
- `AttemptsExhausted` (`False`): 3 attempts for the same revision have failed. `node-manager` makes no new attempt until the NodeConfig changes or the oldest failed attempt is deleted.
- `Superseded` (`False`): The NodeConfig has moved to another generation or has been recreated.
- `NotRequested` (`False`): The node no longer asks to be interrupted for this revision.
- **status.conditions.lastTransitionTime**
  string

  Required value
- **status.conditions.message**
  string

  Required value

  Maximum length: `32768`
- **status.conditions.observedGeneration**
  integer

  Allowed values: `0 <= X`
- **status.conditions.reason**
  string

  Required value

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`
- **status.conditions.status**
  string

  Required value

  Allowed values: `True`, `False`, `Unknown`
- **status.conditions.type**
  string

  Required value

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.deadline**
  string

  Time when the current stage of the operation times out and the operation fails.

  The node gets 30 minutes from `startedAt` to report the result or to come back after a reboot. The eviction gets the drain timeout of the NodeGroup (`nodeDrainTimeoutSecond`)

plus 30 minutes.

- **status.drainDeadline**
  string

  When the eviction this operation asked for runs out of the time it was given.

  On the `Drain` of a deleted machine, the operation fails with `PreparationTimedOut` at this moment, and the machine is deleted with the pods that did not leave. The field is not set for a `Static` or `CloudStatic` NodeGroup without `nodeDrainTimeoutSecond`, and such a `Drain` has no time limit.

  It is pinned at the moment the eviction is requested, from the NodeGroup's `nodeDrainTimeoutSecond` as it stood then, because that is the bound the draining controller itself started running to. Deriving it again later would let a change to the NodeGroup cut short a drain that is still running.

- **status.eviction**
  object

  Progress of the eviction this operation asked for, written by `node-manager` while the eviction runs.

  The field appears once the pods to evict are listed and is updated every few seconds. It is removed when the eviction ends. A failed operation keeps the progress it ended on.

  - **status.eviction.remainingPods**
    integer

    Required value

    How many of the pods the eviction listed are still on the node, including the terminating ones. The eviction leaves DaemonSet pods, static pods and finished pods on the node, and they are not counted.

    Allowed values: `0 <= X`

  - **status.eviction.terminatingPods**
    array of strings

    Pods that have been evicted and have not stopped yet, as `<namespace>/<name>`.

- **status.finishedAt**
  string

  When the operation reached a terminal phase. A finished operation is kept as the record of what was done to the node and is collected once it is a day old.

- **status.message**
  string

  Human-readable explanation of `reason`.

  Maximum length: `32768`

- **status.nodeWasUnschedulable**
  boolean

  Whether the node was already out of the scheduler when the operation reached it.

  Releasing the node at the end of the operation restores this value instead of making the node schedulable, so an operation does not quietly undo a cordon an operator put there by hand.

- **status.phase**
  string

  Current phase of the operation, set by `node-manager`.

  - `Pending`: The operation is queued or waits for approval.
  - `Approved`: The operation may go ahead. The workload is being evicted from the node before the node receives the operation.
  - `InProgress`: For `Drain`, the workload is being evicted. For the other types, the node has been prepared and can perform the operation.
  - `Completed`: The operation finished successfully.
  - `Failed`: The operation failed.

  Allowed values: `Pending`, `Approved`, `InProgress`, `Completed`, `Failed`

- **status.reason**
  string

  Reason for the current phase of the operation.

  - `Pending`: `Queued` (nothing has been done yet), `WaitingForApproval`.
  - `Approved`: `Draining` (the workload is being evicted from the node), `WaitingForOperation` (another eviction of the node is running, and `message` names who requested it).
  - `InProgress`: `Draining` and `WaitingForOperation` (for `Drain`), `WaitingForNode` (the node has received the operation and has not reported yet), `Rebooting` (the node is rebooting and has not come back yet).
  - `Completed`: `Succeeded`, `Released` (the node gave up on the NodeConfig revision the `Disruption` is for), `Drained` (for `Drain`).
  - `Failed`: `NodeFailed` and `NodeRefused` (reported by the node), `PreparationTimedOut` (the workload did not leave the node in time), `NodeTimedOut` (the node did not report back or did not come back after a reboot in time), `NodeNotFound`, `NodeGroupMissing`, `MachineDeleted` (the machine of the node is being deleted).

  Pattern: `^[A-Za-z][A-Za-z0-9]*$`

  Maximum length: `128`

- **status.startedAt**
  string

  When the node was handed the operation. The wait for the node is measured from here.

NodeStaticPodRequest

Short names: nspr

Scope: Cluster
Version: v1alpha1

Request to run a static pod on the selected nodes without using the Kubernetes scheduler.

`node-manager` adds the manifest to `spec.staticPods` of the NodeConfig of each selected node. The node writes the manifest to disk, and kubelet runs the pod from it. The request reports whether the nodes wrote the manifest. It does not report whether the pod runs.

A user with permission to create NodeStaticPodRequests can run arbitrary manifests with root privileges on all selected nodes.

Example:

```
# A node-local agent on the nodes of the worker NodeGroup.
apiVersion: deckhouse.io/v1alpha1
kind: NodeStaticPodRequest
metadata:
  name: node-local-agent
spec:
  nodeGroupSelector:
    matchNames:
      - worker
  manifest: |
    apiVersion: v1
    kind: Pod
    metadata:
      name: node-local-agent
      namespace: kube-system
    spec:
      hostNetwork: true
      priorityClassName: system-node-critical
      containers:
        - name: agent
          image: deckhouse.local/images:node-local-agent
          args:
            - --listen-address=$MY_IP:5002
          env:
            - name: NODE_NAME
              valueFrom:
                fieldRef:
                  fieldPath: spec.nodeName
          volumeMounts:
            - name: state
              mountPath: /var/lib/node-local-agent
      volumes:
        - name: state
          hostPath:
            path: /var/lib/node-local-agent
            type: DirectoryOrCreate
```

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Required value

  - **spec.manifest**
    string

    Required value

    Complete pod manifest.

    Requirements for the manifest:

    - `metadata.name` is a DNS subdomain (RFC 1123), `metadata.namespace` is a DNS label (RFC 1123).
    - The namespace is `kube-system` or starts with `d8-`.
    - `spec.nodeName` is not set.
    - The pod does not reference API objects. Not allowed: `spec.serviceAccountName`, volumes of the `secret`, `configMap`, `persistentVolumeClaim` and `projected` types, `envFrom` and `env[].valueFrom` with `secretKeyRef` or `configMapKeyRef` in containers and init containers.

    A manifest that does not meet these requirements is rejected on creation and update.

When the manifest is written to disk, the `$MY_IP` substring is replaced with the node's IP address.

Maximum manifest size is 32 KiB. A node can run no more than 16 static pods defined by NodeStaticPodRequests.

Length: `1..32768`

- **spec.nodeGroupSelector**
  object

  Restricts the pod to nodes in the specified NodeGroups. If no groups are specified, all NodeGroups are selected.

  The node agent writes the manifest from the NodeConfig of each selected node. On nodes managed by bashible, a resource named `registry-agent` or describing the `kube-system/registry-agent` pod is not applied, because bashible writes that manifest itself. If the resource reaches no other node, the `Ready` condition reports the `ServedByBashible` reason.

  - **spec.nodeGroupSelector.matchNames**
    array of strings

    Names of NodeGroups on whose nodes the pod must run.

    - **Element of the array**
      string

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

      Maximum length: `63`

- **status**
  object
  - **status.appliedNodes**
    integer

    Number of selected nodes that reported the current manifest written.

    Allowed values: `0 <= X`

  - **status.conditions**
    array of objects

    Conditions of the request: `Accepted` and `Ready`.

    `Accepted` shows whether `node-manager` accepted the request. It is `True` with the `Accepted` reason or `False` with one of these reasons:

    - `InvalidName`: The request name is not a DNS label (RFC 1123) of at most 63 characters.
    - `ReservedName`: The request name, or the `metadata.namespace` and `metadata.name` of the pod, is already used by a static pod of the platform.
    - `InvalidManifest`: The manifest does not meet the requirements of `spec.manifest`.
    - `Conflict`: An older request already defines a pod with the same `metadata.namespace` and `metadata.name`.
    - `LimitExceeded`: At least one selected NodeGroup already has 16 static pods from older requests. Only the nodes of the other selected NodeGroups get the manifest.

    `Ready` shows whether the selected nodes wrote the current manifest:

    - `True` with the `AllNodesApplied` reason: Every selected node wrote it.
    - `True` with the `NoNodesSelected` reason: The selector matches no existing NodeGroup, or the selected NodeGroups have no nodes.
    - `True` with the `ServedByBashible` reason: The selected NodeGroups are managed by bashible, which writes the `registry-agent` manifest on their nodes itself.
    - `False` with the `RolloutInProgress` reason: Some selected nodes have not written the current manifest yet.
    - `False` with the `RefusedByNodes` reason: At least one node refused the manifest.
    - `False` with the `NotAccepted` reason: The `Accepted` condition is `False`.
    - **status.conditions.lastTransitionTime**
      string

      Required value

    - **status.conditions.message**
      string

Required value

Maximum length: `32768`

- **status.conditions.observedGeneration**
  integer

  Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.failedNodes**
  integer

  Number of selected nodes that refused the manifest.

  Allowed values: `0 <= X`

- **status.matchedNodeGroups**
  array of strings

  NodeGroups that match the current selector.

- **status.matchedNodes**
  integer

  Number of nodes in the selected NodeGroups to which the node agent writes the manifest. Nodes of NodeGroups on which bashible writes the manifest itself are not counted.

  Allowed values: `0 <= X`

- **status.nodes**
  array of objects

  Selected nodes that have not written the current manifest, at most 32.

  - **status.nodes.message**
    string

    Why the node refused the manifest or what it waits for.

    Maximum length: `4096`

  - **status.nodes.name**
    string

    Required value

    Node name.

  - **status.nodes.state**
    string

    Required value

`Failed` if the node refused the manifest or `Pending` if it has not answered yet.

Allowed values: `Pending`, `Failed`

- **status.observedGeneration**
  integer

  Generation of `spec` that corresponds to the current `status`.

  Allowed values: `0 <= X`

- **status.pendingNodes**
  integer

  Number of selected nodes that have not yet reported either the current manifest written or a failure.

  Allowed values: `0 <= X`

- **status.phase**
  string

  Summary of the conditions.

  - `Pending`: The selected nodes are still writing the manifest (the `Ready` condition has the `RolloutInProgress` reason).
  - `Ready`: The `Ready` condition is `True`.
  - `Degraded`: `node-manager` did not accept the request (the `Accepted` condition is `False`), or nodes refused the manifest (the `Ready` condition has the `RefusedByNodes` reason).

  Allowed values: `Pending`, `Ready`, `Degraded`

NodeUser

Scope: Cluster

- v1
- v1alpha1

Defines the linux users to create on all nodes.

The user's home directory is created in the `/home/deckhouse/` directory.

- **spec**
  object

  Required value

  - **spec.extraGroups**
    array of strings

    Node user additional system groups.

    Examples:

    ```
    extraGroups:
    - docker
    ```

    ```
    extraGroups:
    - docker
    - ftp
    ```

  - **spec.isSudoer**
    boolean

    Persistence of node user in sudo group.

    Default: `false`

    Example:

    ```
    isSudoer: true
    ```

- **spec.nodeGroups**
  array of strings

  List of NodeGroups to apply the user for.

  Default: `["*"]`

  Examples:

  ```
  nodeGroups:
  - master
  - worker
  ```

  ```
  nodeGroups:
  - worker
  ```

  ```
  nodeGroups:
  - "*"
  ```

- **spec.passwordHash**
  string

  Hashed user password.

  The format corresponds to the password hashes in `/etc/shadow`. You can get it using the following command: `openssl passwd -6`.

  If the caller is not allowed to read the `nodeusers/sensitive` subresource, the API returns `<omitted>` instead of the value.

  Example:

  ```
  passwordHash:
  "$2a$10$F9ey7zW.sVliT224RFxpWeMsgzO.D9YRG54a8T36/K2MCiT41nzmC"
  ```

- **spec.sshPublicKey**
  Deprecated
  string

  Node user SSH public key.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKey: ssh-rsa AAABBB
  ```

- **spec.sshPublicKeys**
  array of strings

  Node user SSH public keys.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKeys:
  - ssh-rsa AAABBB
  - cert-authority,principals="name" ssh-rsa BBBCCC
  ```

- **spec.uid**
  number

  Required value

  Node user ID.

  We recommend using the values `>= 1100` to avoid conflicts with manually created users.

  This parameter does not change during the entire resource life.

Allowed values: `1001 <= X`

Example:

```
uid: 1100
```

- **status**
  object

  User creation status information

  - **status.errors**
    object

    List of user creation errors on each node

Deprecated resource. Support for the resource might be removed in a later release.

Defines the linux users to create on all nodes.

The user's home directory is created in the `/home/deckhouse/` directory.

- **spec**
  object

  Required value

  - **spec.extraGroups**
    array of strings

    Node user additional system groups.

    Examples:

    ```
    extraGroups:
    - docker
    ```

    ```
    extraGroups:
    - docker
    - ftp
    ```

  - **spec.isSudoer**
    boolean

    Persistence of node user in sudo group.

    Default: `false`

    Example:

    ```
    isSudoer: true
    ```

  - **spec.nodeGroups**
    array of strings

    List of NodeGroups to apply the user for.

    Default: `["*"]`

    Examples:

    ```
    nodeGroups:
    - master
    - worker
    ```

    ```
    nodeGroups:
    - worker
    ```

```
nodeGroups:
- "*"
```

- **spec.passwordHash**
  string

  Hashed user password.

  The format corresponds to the password hashes in `/etc/shadow`. You can get it using the following command: `openssl passwd -6`.

  If the caller is not allowed to read the `nodeusers/sensitive` subresource, the API returns `<omitted>` instead of the value.

  Example:

  ```
  passwordHash:
  "$2a$10$F9ey7zW.sVliT224RFxpWeMsgzO.D9YRG54a8T36/K2MCiT41nzmC"
  ```

- **spec.sshPublicKey**
  Deprecated
  string

  Node user SSH public key.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKey: ssh-rsa AAABBB
  ```

- **spec.sshPublicKeys**
  array of strings

  Node user SSH public keys.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKeys:
  - ssh-rsa AAABBB
  - cert-authority,principals="name" ssh-rsa BBBCCC
  ```

- **spec.uid**
  number

  Required value

  Node user ID.

  We recommend using the values `>= 1100` to avoid conflicts with manually created users.

  This parameter does not change during the entire resource life.

  Allowed values: `1001 <= X`

  Example:

  ```
  uid: 1100
  ```

SSHCredentials

Scope: Cluster

- v1alpha2
- v1alpha1

Contains credentials required by Cluster API Provider Static (CAPS) to connect over SSH. CAPS connects to the server (virtual machine) defined in the StaticInstance custom resource to manage its state.

A reference to this resource is specified in the credentialsRef parameter of the `StaticInstance` resource.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  SSHCredentialsSpec defines the desired state of SSHCredentials.

  - **spec.privateSSHKey**
    string

    Private SSH key in PEM format encoded as base64 string.

    If the user does not have permission to view sensitive SSHCredentials data, the API returns instead of the actual value.

  - **spec.sshExtraArgs**
    string

    A list of additional arguments to pass to the openssh command.

    Examples:

    ```
    sshExtraArgs: "-vvv"
    ```

    ```
    sshExtraArgs: "-c chacha20-poly1305@openssh.com"
    ```

    ```
    sshExtraArgs: "-c aes256-gcm@openssh.com"
    ```

    ```
    sshExtraArgs: "-m umac-64-etm@openssh.com"
    ```

    ```
    sshExtraArgs: "-m hmac-sha2-512-etm@openssh.com"
    ```

  - **spec.sshPort**
    integer

    A port to connect to the host via SSH.

    Default: `22`

    Allowed values: `1 <= X <= 65535`

  - **spec.sudoPasswordEncoded**
    string

    Base64 encoded sudo password for the user.

    If the user does not have permission to view sensitive SSHCredentials data, the API returns instead of the actual value.

  - **spec.user**
    string

    Required value

    A username to connect to the host via SSH.

Contains credentials required by Cluster API Provider Static (CAPS) to connect over SSH. CAPS connects to the server (virtual machine) defined in the StaticInstance custom resource to manage its state.

A reference to this resource is specified in the credentialsRef parameter of the `StaticInstance` resource.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  SSHCredentialsSpec defines the desired state of SSHCredentials.

  - **spec.privateSSHKey**
    string

    Private SSH key in PEM format encoded as base64 string.

    If the user does not have permission to view sensitive SSHCredentials data, the API returns instead of the actual value.

  - **spec.sshExtraArgs**
    string

    A list of additional arguments to pass to the openssh command.

    Examples:

    ```
    sshExtraArgs: "-vvv"
    ```

    ```
    sshExtraArgs: "-c chacha20-poly1305@openssh.com"
    ```

    ```
    sshExtraArgs: "-c aes256-gcm@openssh.com"
    ```

    ```
    sshExtraArgs: "-m umac-64-etm@openssh.com"
    ```

    ```
    sshExtraArgs: "-m hmac-sha2-512-etm@openssh.com"
    ```

  - **spec.sshPort**
    integer

    A port to connect to the host via SSH.

    Default: `22`

    Allowed values: `1 <= X <= 65535`

  - **spec.sudoPassword**
    string

    A sudo password for the user.

    If the user does not have permission to view sensitive SSHCredentials data, the API returns instead of the actual value.

  - **spec.user**
    string

Required value

A username to connect to the host via SSH.

StaticInstance

Scope: Cluster

- v1alpha2
- v1alpha1

StaticInstance describes a machine for the Cluster API Provider Static.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  StaticInstanceSpec defines the desired state of StaticInstance.

  - **spec.address**
    string

    Required value

    The IP address of the host.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **spec.credentialsRef**
    object

    Required value

    The reference to the `SSHCredentials` object.

    - **spec.credentialsRef.apiVersion**
      string

      API version of the referent.

    - **spec.credentialsRef.fieldPath**
      string

      If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

    - **spec.credentialsRef.kind**
      string

      Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

    - **spec.credentialsRef.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-

with-objects/names/#names

- **spec.credentialsRef.namespace**
  string

  Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

- **spec.credentialsRef.resourceVersion**
  string

  Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

- **spec.credentialsRef.uid**
  string

  UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status**
  object

  StaticInstanceStatus defines the observed state of StaticInstance.

  - **status.conditions**
    array of objects

    Conditions defines current service state of the StaticInstance.

    Condition contains details for one aspect of the current state of this API Resource.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

    - **status.conditions.message**
      string

      Required value

      message is a human readable message indicating details about the transition. This may be an empty string.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

      Allowed values: `0 <= X`

    - **status.conditions.reason**
      string

      Required value

      reason contains a programmatic identifier indicating the reason for the condition’s last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

      Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

      Length: `1..1024`

    - **status.conditions.status**
      string

Required value

status of the condition, one of True, False, Unknown.

Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  type of condition in CamelCase or in foo.example.com/CamelCase.

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.currentStatus**
  object
  - **status.currentStatus.lastUpdateTime**
    string
  - **status.currentStatus.phase**
    string

    Allowed values: `Error`, `Pending`, `Bootstrapping`, `Running`, `Cleaning`

- **status.machineRef**
  object

  The reference to the `StaticMachine` object.

  - **status.machineRef.apiVersion**
    string

    API version of the referent.

  - **status.machineRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **status.machineRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

  - **status.machineRef.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **status.machineRef.namespace**
    string

    Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

  - **status.machineRef.resourceVersion**
    string

    Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

  - **status.machineRef.uid**
    string

    UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status.nodeRef**
  object

  The reference to the `Node` object.

  - **status.nodeRef.apiVersion**
    string

    API version of the referent.

  - **status.nodeRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **status.nodeRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

  - **status.nodeRef.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **status.nodeRef.namespace**
    string

    Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

  - **status.nodeRef.resourceVersion**
    string

    Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

  - **status.nodeRef.uid**
    string

    UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

StaticInstance describes a machine for the Cluster API Provider Static.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  StaticInstanceSpec defines the desired state of StaticInstance.

  - **spec.address**

string

Required value

The IP address of the host.

Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **spec.credentialsRef**
  object

  Required value

  The reference to the `SSHCredentials` object.

  - **spec.credentialsRef.apiVersion**
    string

    API version of the referent.

  - **spec.credentialsRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **spec.credentialsRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

  - **spec.credentialsRef.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.credentialsRef.namespace**
    string

    Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

  - **spec.credentialsRef.resourceVersion**
    string

    Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

  - **spec.credentialsRef.uid**
    string

    UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status**
  object

  StaticInstanceStatus defines the observed state of StaticInstance.

  - **status.conditions**
    array of objects

    Conditions defines current service state of the StaticInstance.

    Condition contains details for one aspect of the current state of this API Resource.

    - **status.conditions.lastTransitionTime**
      string

      Required value

lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

- **status.conditions.message**
  string

  Required value

  message is a human readable message indicating details about the transition. This may be an empty string.

  Maximum length: `32768`

- **status.conditions.observedGeneration**
  integer

  observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

  Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  status of the condition, one of True, False, Unknown.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  type of condition in CamelCase or in foo.example.com/CamelCase.

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.currentStatus**
  object
  - **status.currentStatus.lastUpdateTime**
    string
  - **status.currentStatus.phase**
    string

    Allowed values: `Error`, `Pending`, `Bootstrapping`, `Running`, `Cleaning`

- **status.machineRef**
  object

  The reference to the `StaticMachine` object.

  - **status.machineRef.apiVersion**
    string

    API version of the referent.

- **status.machineRef.fieldPath**
  string

  If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

- **status.machineRef.kind**
  string

  Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **status.machineRef.name**
  string

  Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **status.machineRef.namespace**
  string

  Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

- **status.machineRef.resourceVersion**
  string

  Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

- **status.machineRef.uid**
  string

  UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status.nodeRef**
  object

  The reference to the `Node` object.

  - **status.nodeRef.apiVersion**
    string

    API version of the referent.

  - **status.nodeRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **status.nodeRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

  - **status.nodeRef.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **status.nodeRef.namespace**
    string

Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

- **status.nodeRef.resourceVersion**
  string

  Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

- **status.nodeRef.uid**
  string

  UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

How do I add master nodes to a cloud cluster?

For the procedure of converting a cluster with a single master node to a multi-master cluster, refer to the FAQ of the `control-plane-manager` module.

How do I reduce the number of master nodes in a cloud cluster?

For the procedure of converting a multi-master cluster to a cluster with a single master node, refer to the FAQ of the `control-plane-manager` module.

Static nodes

You can add a static node to the cluster manually (an example) or by using Cluster API Provider Static.

How do I add a static node to a cluster (Cluster API Provider Static)?

To add a static node to a cluster (bare metal server or virtual machine), follow these steps:

1. Prepare the required resources:
   - Allocate a server or virtual machine and ensure that the node has the necessary network connectivity with the cluster.
   - If necessary, install additional operating system packages and configure the mount points that will be used on the node.
2. Create a user with `sudo` privileges:
   - Add a new user (in this example, `caps`) with `sudo` privileges:

     ```
     useradd -m -s /bin/bash caps
     usermod -aG sudo caps
     ```

   - Allow the user to run `sudo` commands without having to enter a password. For this, add the following line to the `sudo` configuration on the server (you can either edit the `/etc/sudoers` file, or run the `sudo visudo` command, or use some other method):

     ```
     caps ALL=(ALL) NOPASSWD: ALL
     ```

3. Set `UsePAM` to `yes` in `/etc/ssh/sshd_config` on server and restart sshd service:

   ```
   sudo systemctl restart sshd
   ```

4. Generate a pair of SSH keys with an empty passphrase on the server:

   ```
   ssh-keygen -t ed25519 -f caps-id -C "" -N ""
   ```

   The public and private keys of the caps user will be stored in the `caps-id.pub` and `caps-id` files in the current directory on the server.

5. Add the generated public key to the `/home/caps/.ssh/authorized_keys` file of the `caps` user by executing the following commands in the keys directory on the server:

   ```
   mkdir -p /home/caps/.ssh
   cat caps-id.pub >> /home/caps/.ssh/authorized_keys
   chmod 700 /home/caps/.ssh
   chmod 600 /home/caps/.ssh/authorized_keys
   chown -R caps:caps /home/caps/
   ```

6. Create the SSHCredentials resource.
7. Create the StaticInstance resource.
8. Create the NodeGroup resource with the `Static` nodeType, specify the desired number of nodes in the group and, if necessary, the filter for `StaticInstance`.

An example of adding a static node.

How do I add a batch of static nodes to a cluster manually?

Use an existing one or create a new NodeGroup custom resource (example of the `NodeGroup` called `worker`). The nodeType parameter for static nodes in the NodeGroup must be `Static` or `CloudStatic`.

You can automate the bootstrap process with any automation platform you prefer. The following is an example for Ansible.

1. Pick up one of Kubernetes API Server endpoints. Note that this IP must be accessible from nodes that are being added to the cluster:

   ```
   d8 k -n default get ep kubernetes -o json | jq '.subsets[0].addresses[0].ip + ":" +
   (.subsets[0].ports[0].port | tostring)' -r
   ```

   Check the K8s version. If the version >= 1.25, create `node-group` token:

   ```
   d8 k create token node-group --namespace d8-cloud-instance-manager --duration 1h
   ```

   Save the token you got and add it to the `token:` field of the Ansible playbook in the next steps.

2. If the Kubernetes version is smaller than 1.25, get a Kubernetes API token for a special ServiceAccount that Deckhouse manages:

   ```
   d8 k -n d8-cloud-instance-manager get $(d8 k -n d8-cloud-instance-manager get secret -o name |
   grep node-group-token) \
     -o json | jq '.data.token' -r | base64 -d && echo ""
   ```

3. Create Ansible playbook with `vars` replaced with values from previous steps:

```
- hosts: all
  become: yes
  gather_facts: no
  vars:
    kube_apiserver: <KUBE_APISERVER>
    token: <TOKEN>
  tasks:
    - name: Check if node is already bootsrapped
      stat:
        path: /var/lib/bashible
      register: bootstrapped
    - name: Get bootstrap secret
      uri:
        url: "https://{{ kube_apiserver }}/api/v1/namespaces/d8-cloud-instance-
manager/secrets/manual-bootstrap-for-{{ node_group }}"
        return_content: yes
        method: GET
        status_code: 200
        body_format: json
        headers:
          Authorization: "Bearer {{ token }}"
        validate_certs: no
      register: bootstrap_secret
      when: bootstrapped.stat.exists == False
    - name: Run bootstrap.sh
      shell: "{{ bootstrap_secret.json.data['bootstrap.sh'] | b64decode }}"
      args:
        executable: /bin/bash
      ignore_errors: yes
      when: bootstrapped.stat.exists == False
    - name: wait
      wait_for_connection:
        delay: 30
      when: bootstrapped.stat.exists == False
```

4. Specify one more `node_group` variable. This variable must be the same as the name of `NodeGroup` to which node will belong. Variable can be passed in different ways, for example, by using an inventory file.:

```
[system]
system-0
system-1

[system:vars]
node_group=system

[worker]
worker-0
worker-1

[worker:vars]
node_group=worker
```

5. Run the playbook with the inventory file.

How do I clean up a static node manually?

> **i** This method is valid for both manually configured nodes (using the bootstrap script) and nodes configured using CAPS.

To decommission a node from the cluster and clean up the server (VM), run the following command on the node:

For all nodes except the control-plane

1. Delete a node from the Kubernetes cluster:

```
d8 k drain <node>
d8 k drain <node> --ignore-daemonsets --delete-emptydir-data
d8 k delete pods --all-namespaces --field-selector spec.nodeName=<node> --force
d8 k delete node <node>
```

2. Run the cleanup script on the node:

```
bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
```

3. After restarting the node run the script `bootstrap.sh`.

For control-plane nodes

1. Remove the labels `node-role.kubernetes.io/control-plane`, `node-role.kubernetes.io/master`, and `node.deckhouse.io/group` from the node:

```
d8 k label node <node> node-role.kubernetes.io/control-plane- node-role.kubernetes.io/master-
node.deckhouse.io/group-
```

2. Make sure the removed node with control-plane has disappeared from the list of etcd cluster members:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name | head -n1) -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key --endpoints https://127.0.0.1:2379/ member list -w table
```

3. Delete a node from the Kubernetes cluster:

```
d8 k drain <node>
d8 k drain <node> --ignore-daemonsets --delete-emptydir-data
d8 k delete pods --all-namespaces --field-selector spec.nodeName=<node> --force
d8 k delete node <node>
```

4. Run the cleanup script on the node:

```
bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
```

5. After restarting the node run the script `bootstrap.sh`.
6. Wait for the Deckhouse queues to be processed and ensure that the etcd cluster member has reappeared in the list:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name | head -n1) -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key --endpoints https://127.0.0.1:2379/ member list -w table
```

Can I delete a StaticInstance?

A StaticInstance that is in the `Pending` state can be deleted with no adverse effects.

To delete a StaticInstance in any state other than `Pending` (`Running`, `Cleaning`, `Bootstrapping`), you need to:

1. Add the label `"node.deckhouse.io/allow-bootstrap": "false"` to the StaticInstance.

   Example command for adding a label:

```
d8 k label staticinstance d8cluster-worker node.deckhouse.io/allow-bootstrap=false
```

2. Wait until the StaticInstance status becomes `Pending`.

   To check the status of StaticInstance, use the command:

   ```
   d8 k get staticinstances
   ```

3. Delete the StaticInstance.

   Example command for deleting StaticInstance:

   ```
   d8 k delete staticinstance d8cluster-worker
   ```

4. Decrease the `NodeGroup.spec.staticInstances.count` field by 1.

How do I change the IP address of a StaticInstance?

You cannot change the IP address in the `StaticInstance` resource. If an incorrect address is specified in `StaticInstance`, you have to delete the StaticInstance and create a new one.

How do I migrate a manually configured static node under CAPS control?

You need to clean up the node, then hand over the node under CAPS control.

Why are the SSH key and the sudo password of SSHCredentials shown as `<omitted>`?

The `privateSSHKey`, `sudoPassword` (`v1alpha1`), and `sudoPasswordEncoded` (`v1alpha2`) fields of the SSHCredentials resource contain sensitive data and are protected from viewing.

If a user has no permissions to read sensitive SSHCredentials data, the API returns `<omitted>` instead of the actual value. The other fields — `user`, `sshPort`, `sshExtraArgs` — and the resource metadata remain available to users who are allowed to read SSHCredentials.

Additionally, kube-apiserver protects this data as follows:

- removes the `kubectl.kubernetes.io/last-applied-configuration` annotation from API responses if it may contain a copy of sensitive values;
- replaces sensitive values with `"******"` in audit events, regardless of user permissions and audit level;
- encrypts the resource in etcd using the same mechanism as for Kubernetes Secrets, if the `apiserver.encryptionEnabled` parameter of the `control-plane-manager` module is enabled.

Unmasked values are available to the CAPS controller, which needs them to connect to the node over SSH, as well as to users with the `SuperAdmin` access level and members of the `kubeadm:cluster-admins` group.

The `d8:subsystem:cluster:viewer` and `d8:subsystem:cluster:manager` roles allow reading the SSHCredentials resource, but do not grant access to the SSH key or the sudo password.

To check whether a user can read sensitive SSHCredentials data, run:

```
d8 k auth can-i get sshcredentials/sensitive --as=<user>
```

The `<omitted>` value means the actual value is hidden from the current user. This behavior applies to both `v1alpha1` and `v1alpha2`, so using a different API version does not reveal the hidden data.

How do I change the NodeGroup of a static node?

Note that if a node is under CAPS control, you **cannot** change the `NodeGroup` membership of such a node. The only alternative is to delete StaticInstance and create a new one.

To switch an existing manually created static node to another `NodeGroup`, you need to change its group label:

```
d8 k label node --overwrite <node_name> node.deckhouse.io/group=<new_node_group_name>
d8 k label node <node_name> node-role.kubernetes.io/<old_node_group_name>-
```

Applying the changes will take some time.

How to clean up a node for adding to the cluster?

This is only needed if you have to move a static node from one cluster to another. Be aware these operations remove local storage data. If you just need to change a NodeGroup, follow this instruction.

> ⚠ Evict resources from the node and remove the node from LINSTOR/DRBD using the instruction if the node you are cleaning up has LINSTOR/DRBD storage pools.

1. Delete the node from the Kubernetes cluster:

   ```
   d8 k drain <node> --ignore-daemonsets --delete-emptydir-data
   d8 k delete node <node>
   ```

2. Run cleanup script on the node:

   ```
   bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
   ```

3. Run the `bootstrap.sh` script after reboot of the node.

How do I know if something went wrong?

If a node in a nodeGroup is not updated (the value of `UPTODATE` when executing the `d8 k get nodegroup` command is less than the value of `NODES`) or you assume some other problems that may be related to the `node-manager` module, then you need to look at the logs of the `bashible` service. The `bashible` service runs on each node managed by the `node-manager` module.

To view the logs of the `bashible` service on a specific node, run the following command:

```
journalctl -fu bashible
```

Example of output when the `bashible` service has performed all necessary actions:

```
May 25 04:39:16 kube-master-0 systemd[1]: Started Bashible service.
May 25 04:39:16 kube-master-0 bashible.sh[1976339]: Configuration is in sync,
nothing to do.
May 25 04:39:16 kube-master-0 systemd[1]: bashible.service: Succeeded.
```

How do I know what is running on a node while it is being created?

You can analyze `cloud-init` to find out what's happening on a node during the bootstrapping process:

1. Find the node that is currently bootstrapping:

   ```
   d8 k get instances | grep Pending
   ```

   An example:

   ```
   d8 k get instances | grep Pending
   dev-worker-2a6158ff-6764d-nrtbj   Pending   46s
   ```

2. Get information about connection parameters for viewing logs:

   ```
   d8 k get instances dev-worker-2a6158ff-6764d-nrtbj -o yaml | grep 'bootstrapStatus' -B0 -A2
   ```

   An example:

```
d8 k get instances dev-worker-2a6158ff-6764d-nrtbj -o yaml | grep 'bootstrapStatus' -B0 -A2
bootstrapStatus:
  description: Use 'curl -N http://192.168.199.158:8000' to get bootstrap logs.
  logsEndpoint: http://192.168.199.158:8000
```

3. Run the command you got (`curl -N http://192.168.199.158:8000` according to the example above) to see `cloud-init` logs and determine the cause of the problem on the node.

The logs of the initial node configuration are located at `/var/log/cloud-init-output.log`.

How do I update kernel on nodes?

Debian-based distros

Create a `Node Group Configuration` resource by specifying the desired kernel version in the `desired_version` variable of the shell script (the resource's spec.content parameter):

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: install-kernel.sh
spec:
  bundles:
    - '*'
  nodeGroups:
    - '*'
  weight: 32
  content: |
    # Copyright 2022 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    desired_version="5.15.0-53-generic"

    bb-event-on 'bb-package-installed' 'post-install'
    post-install() {
      bb-log-info "Setting reboot flag due to kernel was updated"
      bb-flag-set reboot
    }

    version_in_use="$(uname -r)"

    if [[ "$version_in_use" == "$desired_version" ]]; then
      exit 0
    fi

    bb-deckhouse-get-disruptive-update-approval
    bb-apt-install "linux-image-${desired_version}"
```

CentOS-based distros

Create a `Node Group Configuration` resource by specifying the desired kernel version in the `desired_version` variable of the shell script (the resource's spec.content parameter):

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: install-kernel.sh
spec:
  bundles:
    - '*'
  nodeGroups:
    - '*'
  weight: 32
  content: |
    # Copyright 2022 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    desired_version="3.10.0-1160.42.2.el7.x86_64"

    bb-event-on 'bb-package-installed' 'post-install'
    post-install() {
      bb-log-info "Setting reboot flag due to kernel was updated"
      bb-flag-set reboot
    }

    version_in_use="$(uname -r)"

    if [[ "$version_in_use" == "$desired_version" ]]; then
      exit 0
    fi

    bb-deckhouse-get-disruptive-update-approval
    bb-dnf-install "kernel-${desired_version}"
```

NodeGroup parameters and their result

The NodeGroup parameter	Disruption update	Node provisioning	Kubelet restart
chaos	-	-	-
cloudInstances.classReference	-	+	-
cloudInstances.maxSurgePerZone	-	-	-
cri.containerd.maxConcurrentDownloads	-	-	+
cri.type	- (NotManaged) / + (other)	-	-
disruptions	-	-	-
kubelet.maxPods	-	-	+
kubelet.rootDir	-	-	+

The NodeGroup parameter	Disruption update	Node provisioning	Kubelet restart
kubelet.topologyManager	+ (policy other than `None`, details)	-	+
kubernetesVersion	-	-	+
nodeTemplate	-	-	-
static	-	-	+
update.maxConcurrent	-	-	-

Refer to the description of the NodeGroup custom resource for more information about the parameters.

When the `InstanceClass` or `instancePrefix` parameters are modified, the process is similar to updating a Deployment in Kubernetes (changing `InstanceClass` results in creating a new MachineSet, and changing `instancePrefix` results in creating a new MachineDeployment). New instances will be created according to the value of the `cloudInstances.maxSurgePerZone` parameter. As the new instances are created, the old ones will be gradually removed, with a drain operation performed beforehand.

During the disruption update, an evict of the pods from the node is performed. If any pod fails to evict, the evict is repeated every 20 seconds until a global timeout of 5 minutes is reached. After that, the pods that failed to evict are removed.

How do I redeploy ephemeral machines in the cloud with a new configuration?

If the Deckhouse configuration is changed (both in the node-manager module and in any of the cloud providers), the VMs will not be redeployed. The redeployment is performed only in response to changing `InstanceClass` or `NodeGroup` objects.

To force the redeployment of all Machines, you need to add/modify the `manual-rollout-id` annotation to the `NodeGroup`: `d8 k annotate NodeGroup name_ng "manual-rollout-id=$(uuidgen)" --overwrite`.

How do I allocate nodes to specific loads?

⚠ You cannot use the `deckhouse.io` domain in `labels` and `taints` keys of the `NodeGroup`. It is reserved for Deckhouse components. Please, use the `dedicated` or `dedicated.client.com` keys.

There are two ways to solve this problem:

1. You can set labels to `NodeGroup`'s `spec.nodeTemplate.labels`, to use them in the `Pod`'s spec.nodeSelector or spec.affinity.nodeAffinity parameters. In this case, you select nodes that the scheduler will use for running the target application.
2. You cat set taints to `NodeGroup`'s `spec.nodeTemplate.taints` and then remove them via the `Pod`'s spec.tolerations parameter. In this case, you disallow running applications on these nodes unless those applications are explicitly allowed.

i Deckhouse tolerates the `dedicated` by default, so we recommend using the `dedicated` key with any `value` for taints on your dedicated nodes.

To use custom keys for `taints` (e.g., `dedicated.client.com`), you must add the key's value to the array `.spec.settings.modules.placement.customTolerationKeys` parameters. This way, deckhouse can deploy system components (e.g., `cni-flannel`) to these dedicated nodes.

How do I give pods dedicated CPUs and NUMA alignment?

Use the `spec.kubelet.topologyManager` parameter of the NodeGroup. Deckhouse configures the CPU, memory and topology managers of the kubelet and calculates NUMA-dependent values on each node of the group.

The result depends on `policy`:

policy	What pods get	kubelet settings
`None` (default)	Nothing, all pods share all CPUs	Not set, the kubelet defaults are used
`BestEffort`	Exclusive CPUs for containers of Guaranteed pods that request a whole number of CPUs, NUMA-bound memory. NUMA alignment of CPUs, memory and devices when possible	`cpuManagerPolicy: static`, `memoryManagerPolicy: Static`, `topologyManagerPolicy: best-effort`
`Restricted`	Exclusive whole physical cores. The pod gets CPUs, memory and devices from the smallest possible set of NUMA nodes, otherwise it is rejected	`cpuManagerPolicy: static` with `full-pcpus-only`, `memoryManagerPolicy: Static`, `topologyManagerPolicy: restricted`
`SingleNumaNode`	Exclusive whole physical cores. CPUs, memory and devices come from one NUMA node, otherwise the pod is rejected	`cpuManagerPolicy: static` with `full-pcpus-only`, `memoryManagerPolicy: Static`, `topologyManagerPolicy: single-numa-node`

The `scope` parameter sets what is aligned for every policy except `None`: `Pod` (default) aligns all containers of a pod together, `Container` aligns each container separately.

The `enabled` parameter is deprecated and has no effect: the managers are controlled by `policy` alone. To turn them off, set `policy: None`.

For every policy except `None`, Deckhouse also:

- splits `reservedMemory` between NUMA nodes in proportion to their memory without hugepages;
- sets `prefer-closest-numa-nodes` for `Restricted` if the node reports a full NUMA distance table and its NUMA node IDs are consecutive from 0;
- sets `max-allowable-numa-nodes` if the node has more than 8 NUMA nodes.

The policies `BestEffort`, `Restricted` and `SingleNumaNode` require `resourceReservation.mode` `Auto`, or `Static` with a positive `static.cpu`.

With every policy except `None`, the memory of a Guaranteed pod is bound to the NUMA nodes chosen at admission, `BestEffort` included. A pod whose memory cannot be placed is rejected with `UnexpectedAdmissionError`. A container can be killed by the OOM killer when its NUMA nodes run out of memory, even if other NUMA nodes have free memory.

Exclusive CPUs are taken from the shared pool. Burstable and BestEffort pods, including system components, run on the CPUs that remain. This matters for pods that use more CPU than they request: without exclusive CPUs they use idle time of all cores, with exclusive CPUs they share the remaining CPUs. With `Auto`, the shared pool can shrink to 1 CPU. If needed, use `Static` with a larger `static.cpu`.

The following NodeGroup gives Guaranteed pods on the `worker-dpdk` nodes exclusive whole cores on one NUMA node:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker-dpdk
spec:
  nodeType: Static
  kubelet:
    topologyManager:
      policy: SingleNumaNode
    resourceReservation:
      mode: Auto
```

Only containers of Guaranteed pods with a whole number of CPUs get exclusive CPUs: requests are equal to limits for CPU and memory in every container, and the CPU value is an integer:

```
apiVersion: v1
kind: Pod
metadata:
  name: dpdk-app
spec:
  containers:
  - name: app
    image: registry.example.com/dpdk-app:latest
    resources:
      requests:
        cpu: "4"
        memory: 8Gi
      limits:
        cpu: "4"
        memory: 8Gi
```

Rules of the Restricted and SingleNumaNode policies

- The number of CPUs of a container must be a multiple of the number of threads per core. With SMT (Hyper-Threading) enabled, an odd number of CPUs is rejected with `SMTAlignmentError`.
- With `SingleNumaNode`, the pod (with `scope: Pod`) or each container (with `scope: Container`) must fit into one NUMA node. Size pods by the smallest NUMA node in the group.
- A pod that cannot be aligned is rejected: with `TopologyAffinityError` if its CPUs do not fit, with `UnexpectedAdmissionError` if its memory does not fit.
- The scheduler does not know about NUMA nodes. It can place a pod on a node where the pod is then rejected. The controller of the pod (for example, a Deployment or a StatefulSet) creates a new pod, which can be rejected again.

Changing the settings

Changing `policy`, or `scope` with a policy other than `None`, restarts the kubelet on the nodes of the group.

The node requests a disruption if all of the following is true:

- the new kubelet configuration uses a policy other than `None`;
- the kubelet CPU or memory settings change, for example `policy`, `scope`, the CPU or memory reservation in `resourceReservation`, or the amount of memory or hugepages on the node. Other reservations, such as `ephemeralStorage`, do not cause a disruption;
- the node runs Guaranteed pods. DaemonSet and static pods are not counted, because a drain does not evict them.

The disruption is handled according to the `disruptions` settings of the group:

- with `approvalMode: Automatic` the node is drained and then gets the new configuration;
- with `approvalMode: Automatic` and `automatic.drainBeforeApproval: false` the node is not drained. After the kubelet restart, running pods that do not fit the new policy are stopped;
- with `approvalMode: Manual` the node is not drained automatically. Drain it, then run `d8 k annotate node <NODE NAME> update.node.deckhouse.io/disruption-approved=`;
- with `approvalMode: RollingUpdate` (cloud nodes only) the node is replaced with a new one.

Switching to `None` does not drain nodes: running containers keep their CPUs and the NUMA node of their memory until they are recreated. To spread them over all CPUs, restart the workloads, for example with `d8 k rollout restart`.

Limitations

- Nodes with more than 8 NUMA nodes are supported, but pod admission takes longer.
- Nodes in one group may have different NUMA layouts. Each node gets its own values, but the pod size limit is set by the smallest NUMA node.
- NodeGroupConfiguration scripts must not change reservations or manager policies in `/var/lib/kubelet/config.yaml`.
- Allocate hugepages before the kubelet is configured. Steps of NodeGroupConfiguration run in the order of `weight` together with the built-in steps, and the kubelet is configured at step 64, so use a `weight` below 64. The NUMA split of the reservation counts hugepages allocated at that moment. Hugepages allocated later change the split and can cause one more drain if the node runs Guaranteed pods.

How to allocate nodes to system components?

Frontend

For Ingress controllers, use the `NodeGroup` with the following configuration:

```
nodeTemplate:
  labels:
    node-role.deckhouse.io/frontend: ""
  taints:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      value: frontend
```

System components

`NodeGroup` for components of Deckhouse subsystems will look as follows:

```
nodeTemplate:
  labels:
    node-role.deckhouse.io/system: ""
  taints:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      value: system
```

How do I speed up node provisioning on the cloud when scaling applications horizontally?

The most efficient way is to have some extra nodes “ready”. In this case, you can run new application replicas on them almost instantaneously. The obvious disadvantage of this approach is the additional maintenance costs related to these nodes.

Here is how you should configure the target `NodeGroup`:

1. Specify the number of “ready” nodes (or a percentage of the maximum number of nodes in the group) using the `cloudInstances.standby` parameter.
2. If there are additional service components on nodes that are not handled by Deckhouse (e.g., the `filebeat` DaemonSet), you can specify the percentage of node resources they can consume via the `standbyHolder.overprovisioningRate` parameter.
3. This feature requires that at least one group node is already running in the cluster. In other words, there must be either a single replica of the application, or the `cloudInstances.minPerZone` parameter must be set to `1`.

An example:

```
cloudInstances:
  maxPerZone: 10
  minPerZone: 1
  standby: 10%
  standbyHolder:
    overprovisioningRate: 30%
```

How do I disable machine-controller-manager/CAPI in the case of potentially cluster-damaging changes?

> ✖ Use this switch only if you know what you are doing and clearly understand the consequences.

Set the `mcmEmergencyBrake` parameter to true:

```
mcmEmergencyBrake: true
```

For disabling CAPI, set the `capiEmergencyBrake` parameter to true:

```
capiEmergencyBrake: true
```

How do I restore the master node if kubelet cannot load the control plane components?

Such a situation may occur if images of the control plane components on the master were deleted in a cluster that has a single master node (e.g., the directory `/var/lib/containerd` was deleted). In this case, kubelet cannot pull images of the control plane components when restarted since the master node lacks authorization parameters required for accessing `registry.deckhouse.io`.

Below is an instruction on how you can restore the master node.

containerd

Execute the following command to restore the master node in any cluster running under Deckhouse:

```
d8 k -n d8-system get secrets deckhouse-registry -o json |
jq -r '.data.".dockerconfigjson"' | base64 -d |
jq -r '.auths."registry.deckhouse.io".auth'
```

Copy the command's output and use it for setting the `AUTH` variable on the corrupted master.

Next, you need to pull images of `control plane` components to the corrupted master:

```
for image in $(grep "image:" /etc/kubernetes/manifests/* | awk '{print $3}'); do
  crictl pull --auth $AUTH $image
done
```

You need to restart `kubelet` after pulling the images.

How to change CRI for NodeGroup?

> ⚠ CRI can only be switched from `Containerd` to `NotManaged` and back (the cri.type parameter).

Set NodeGroup `cri.type` to `Containerd` or `NotManaged`.

NodeGroup YAML example:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  cri:
    type: Containerd
```

Also, this operation can be done with patch:

- For `Containerd`:

  ```
  d8 k patch nodegroup <NodeGroup name> --type merge -p '{"spec":{"cri":
  {"type":"Containerd"}}}'
  ```

- For `NotManaged`:

  ```
  d8 k patch nodegroup <NodeGroup name> --type merge -p '{"spec":{"cri":
  {"type":"NotManaged"}}}'
  ```

> ⚠ While changing `cri.type` for NodeGroups, created using `dhctl`, you must change it in `dhctl config edit provider-cluster-configuration` and in `NodeGroup` object.

After setting up a new CRI for NodeGroup, the node-manager module drains nodes one by one and installs a new CRI on them. Node update is accompanied by downtime (disruption). Depending on the `disruption` setting for NodeGroup, the node-manager module either automatically allows node updates or requires manual confirmation.

Why might the CRI change not apply?

When attempting to switch the CRI, the changes may not take effect. The most common reason is the presence of special node labels: `node.deckhouse.io/containerd-v2-unsupported` and `node.deckhouse.io/containerd-config=custom`.

The `node.deckhouse.io/containerd-v2-unsupported` label is set to a node if at least one of the following conditions is true:

- Kernel version lower than 5.8
- Linux kernel version is in the range 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS)
- systemd version lower than 244
- cgroup v2 is disabled
- EROFS file system is unavailable.

The `node.deckhouse.io/containerd-config=custom` label is set if the node contains `.toml` files in the `/etc/containerd/conf.d/` (if CRI containerd v1 is used on the cluster nodes) or `/etc/containerd/conf2.d/` (if CRI containerd v2 is used on the cluster nodes) directories. In this case, you should remove such files (provided this will not have critical impact on running containers) and delete the corresponding NodeGroupConfiguration (NGC) resources through which they may have been added.

If the Deckhouse Virtualization Platform is used, an additional reason why the CRI may fail to switch can be the `containerd-dvcr-config.sh` NGC. If the virtualization platform is already installed and running, this NGC can be removed.

If you cannot remove the NodeGroupConfiguration resource that modifies the containerd configuration and is incompatible with containerd v2, use the universal template:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
spec:
  bundles:
  - '*'
  content: |
    {{- if eq .cri "ContainerdV2" }}
  # <Script to modify the configuration for ContainerdV2>.
    {{- else }}
  # <Script to modify the configuration for ContainerdV1>.
    {{- end }}
  nodeGroups:
  - '*'
  weight: 31
```

Additionally, to switch the CRI you may need to remove the custom label `node.deckhouse.io/containerd-config=custom`. You can do this with the following command:

```
for node in $(d8 k get nodes -l node-role.kubernetes.io/<Name of NodeGroup where CRI is changed>=);
do kubectl label $node node.deckhouse.io/containerd-config-; done
```

How to change CRI for the whole cluster?

> ⚠ CRI can only be switched from `Containerd` to `NotManaged` and back (the cri.type parameter).

It is necessary to use the `dhctl` utility to edit the `defaultCRI` parameter in the `cluster-configuration` config.

Also, this operation can be done with the following patch:

- For `Containerd`:

```
data="$(d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r
'.data."cluster-configuration.yaml"' | base64 -d | sed "s/NotManaged/Containerd/"
| base64 -w0)"
d8 k -n kube-system patch secret d8-cluster-configuration -p "{\"data\":{\"cluster-
configuration.yaml\":\"$data\"}}"
```

- For `NotManaged`:

```
data="$(d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r
'.data."cluster-configuration.yaml"' | base64 -d | sed "s/Containerd/NotManaged/"
| base64 -w0)"
d8 k -n kube-system patch secret d8-cluster-configuration -p "{\"data\":{\"cluster-
configuration.yaml\":\"$data\"}}"
```

If it is necessary to leave some NodeGroup on another CRI, then before changing the `defaultCRI` it is necessary to set CRI for this NodeGroup, as described here.

✖ Changing `defaultCRI` entails changing CRI on all nodes, including master nodes. If there is only one master node, this operation is dangerous and can lead to a complete failure of the cluster! The preferred option is to make a multi-master and change the CRI type.

When changing the CRI in the cluster, additional steps are required for the master nodes:

1. Deckhouse updates nodes in master NodeGroup one by one, so you need to discover which node is updating right now:

```
d8 k get nodes -l node-role.kubernetes.io/control-plane="" -o json | jq '.items[] |
select(.metadata.annotations."update.node.deckhouse.io/approved"=="") |
.metadata.name' -r
```

2. Confirm the disruption of the master node that was discovered in the previous step:

```
d8 k annotate node <master node name> update.node.deckhouse.io/disruption-approved=
```

3. Wait for the updated master node to switch to `Ready` state. Repeat steps for the next master node.

How to add node configuration step?

Additional node configuration steps are set via the NodeGroupConfiguration custom resource.

How to automatically put custom labels on the node?

1. On the node, create the directory `/var/lib/node_labels`.
2. Create a file or files containing the necessary labels in it. The number of files can be any, as well as the number of subdirectories containing them.
3. Add the necessary labels to the files in the `key=value` format. For example:

```
example-label=test
```

4. Save the files.

When adding a node to the cluster, the labels specified in the files will be automatically affixed to the node.

⚠ Please note that it is not possible to add labels used in DP in this way. This method will only work with custom labels that do not overlap with those reserved for Deckhouse.

How to deploy custom containerd configuration?

ℹ The example of `NodeGroupConfiguration` uses functions of the script 032_configure_containerd.sh.

✖ Adding custom settings causes a restart of the containerd service.

Bashible on nodes merges main DP containerd configuration with the following configuration files:

- `/etc/containerd/conf.d/*.toml`: If containerd v1 is used as the CRI on the cluster nodes.
- `/etc/containerd/conf2.d/*.toml`: If containerd v2 is used as the CRI on the cluster nodes.

⚠ You can override the values of the parameters that are specified in the file `/etc/containerd/deckhouse.toml`, but you will have to ensure their functionality on your own. Also, it is better not to change the configuration for the master nodes (nodeGroup `master`).

The following are configuration examples of the NodeGroupConfiguration resources adding a custom configuration file for a corresponding containerd version.

- For containerd v1
- For containerd v2

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-option-config.sh
spec:
  bundles:
    - '*'

    mkdir -p /etc/containerd/conf2.d
    bb-sync-file /etc/containerd/conf2.d/runtimeclass.toml - << "EOF"
    [plugins."io.containerd.cri.v1.runtime".containerd.runtimes.gpu-large-shm]
      runtime_type = "io.containerd.runc.v2"
      [plugins."io.containerd.cri.v1.runtime".containerd.runtimes.gpu-large-
shm.options]
        BinaryName = ""
        SystemdCgroup = true
        ShmSize = 17179869184
    EOF
  nodeGroups:
    - "worker"
  weight: 31
```

How to add configuration for an additional registry?

Containerd supports two methods for registry configuration: the **deprecated** method and the **actual** method.

To check for the presence of the **deprecated** configuration method, run the following commands on the cluster nodes:

```
cat /etc/containerd/config.toml | grep
'plugins."io.containerd.grpc.v1.cri".registry.mirrors'
cat /etc/containerd/config.toml | grep
'plugins."io.containerd.grpc.v1.cri".registry.configs'

# Example output:
# [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
#   [plugins."io.containerd.grpc.v1.cri".registry.mirrors."<REGISTRY_URL>"]
# [plugins."io.containerd.grpc.v1.cri".registry.configs]
#   [plugins."io.containerd.grpc.v1.cri".registry.configs."<REGISTRY_URL>".auth]
```

To check for the presence of the **actual** configuration method, run the following command on the cluster nodes:

```
cat /etc/containerd/config.toml | grep '/etc/containerd/registry.d'

# Example output:
# config_path = "/etc/containerd/registry.d"
```

Old Method

⚠ This containerd configuration format is deprecated.

i Used in containerd v1 when Deckhouse is not managed by the Registry module.

The configuration is described in the main containerd configuration file `/etc/containerd/config.toml`.

Adding custom configuration is carried out through the `toml merge` mechanism. Configuration files from the `/etc/containerd/conf.d` directory are merged with the main file `/etc/containerd/config.toml`. The merge takes place during the execution of the `032_configure_containerd.sh` script, so the corresponding files must be added in advance.

Example configuration file for the `/etc/containerd/conf.d/` directory:

```
[plugins]
  [plugins."io.containerd.grpc.v1.cri"]
    [plugins."io.containerd.grpc.v1.cri".registry]
      [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
        [plugins."io.containerd.grpc.v1.cri".registry.mirrors."${REGISTRY_URL}"]
          endpoint = ["https://${REGISTRY_URL}"]
      [plugins."io.containerd.grpc.v1.cri".registry.configs]
        [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".auth]
          auth = "${BASE_64_AUTH}"
          username = "${USERNAME}"
          password = "${PASSWORD}"
        [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".tls]
          ca_file = "${CERT_DIR}/${CERT_NAME}.crt"
          insecure_skip_verify = true
```

✖ Adding custom settings through the `toml merge` mechanism causes the containerd service to restart.

How to add additional registry auth (deprecated method)?

Example of adding authorization to a additional registry when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step.
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."${REGISTRY_URL}"]
              endpoint = ["https://${REGISTRY_URL}"]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]

[plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".auth]
              username = "username"
              password = "password"
              # OR
              auth = "dXNlcm5hbWU6cGFzc3dvcmQ="
    EOF
```

How to configure a certificate for an additional registry (deprecated method)?

Example of configuring a certificate for an additional registry when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-tls.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step.
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example
    CERT_FILE_NAME=${REGISTRY_URL}
    CERTS_FOLDER="/var/lib/containerd/certs/"

    mkdir -p ${CERTS_FOLDER}
    bb-sync-file "${CERTS_FOLDER}/${CERT_FILE_NAME}.crt" - << EOF
    -----BEGIN CERTIFICATE-----
    ...
    -----END CERTIFICATE-----
    EOF

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]

[plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".tls]
            ca_file = "${CERTS_FOLDER}/${CERT_FILE_NAME}.crt"
    EOF
```

> **i** In addition to containerd, the certificate can be added into the OS.

How to add TLS skip verify (deprecated method)?

Example of adding TLS skip verify when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-skip-tls.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step.
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]

[plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".tls]
            insecure_skip_verify = true
    EOF
```

After applying the configuration file, verify access to the registry from the nodes using the command:

```
# Via the CRI interface
crictl pull private.registry.example/image/repo:tag
```

How to set up a mirror for public image registries (deprecated method)?

Example of configuring a mirror for public image registries when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: mirror-to-harbor.sh
spec:
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC

    sed -i '/endpoint = \["https:\/\/registry-1.docker.io"\]/d'
/var/lib/bashible/bundle_steps/032_configure_containerd.sh
    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/mirror-to-harbor.toml - << "EOF"
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."docker.io"]
              endpoint = ["https://registry.private.network/v2/dockerhub-proxy/"]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."gcr.io"]
              endpoint = ["https://registry.private.network/v2/YOUR_GCR_PROXY_REPO/"]
    EOF
```

New Method

> **i** Used in containerd v2.
>
> Used in containerd v1 when managed through the `registry` module (for example, in `Direct` mode).

The configuration is defined in the `/etc/containerd/registry.d` directory.
Configuration is specified by creating subdirectories named after the registry address:

```
/etc/containerd/registry.d
├── private.registry.example:5001
│   ├── ca.crt
│   └── hosts.toml
└── registry.deckhouse.io
    ├── ca.crt
    └── hosts.toml
```

Example contents of the `hosts.toml` file:

```
[host]
  # Mirror 1.
  [host."https://${REGISTRY_URL_1}"]
    capabilities = ["pull", "resolve"]
    ca = ["${CERT_DIR}/${CERT_NAME}.crt"]

    [host."https://${REGISTRY_URL_1}".auth]
      username = "${USERNAME}"
      password = "${PASSWORD}"

  # Mirror 2.
  [host."http://${REGISTRY_URL_2}"]
    capabilities = ["pull", "resolve"]
    skip_verify = true
```

> **i** Configuration changes do not cause the containerd service to restart.

How to add additional registry auth (actual method)?

Example of adding authorization to a additional registry when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required.
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        [host."https://${REGISTRY_URL}".auth]
          username = "username"
          password = "password"
    EOF
```

How to configure a certificate for an additional registry (actual method)?

Example of configuring a certificate for an additional registry when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-tls.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required.
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"

    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/ca.crt" - << EOF
    -----BEGIN CERTIFICATE-----
    ...
    -----END CERTIFICATE-----
    EOF

    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        ca = ["/etc/containerd/registry.d/${REGISTRY_URL}/ca.crt"]
    EOF
```

i In addition to containerd, the certificate can be added into the OS.

How to add TLS skip verify (actual method)?

Example of adding TLS skip verify when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-skip-tls.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required.
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        skip_verify = true
    EOF
```

After applying the configuration file, check access to the registry from the nodes using the following commands:

```
# Via the CRI interface.
crictl pull private.registry.example/image/repo:tag

# Via ctr with the configuration directory specified.
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/
private.registry.example/image/repo:tag

# Via ctr for an HTTP registry.
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/ --plain-http
private.registry.example/image/repo:tag
```

How to set up a mirror for public image registries (actual method)?

Example of configuring a mirror for public image registries when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: mirror-to-harbor.sh
spec:
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY1_URL=docker.io
    mkdir -p "/etc/containerd/registry.d/${REGISTRY1_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY1_URL}/hosts.toml" - << EOF
    [host."https://registry.private.network/v2/dockerhub-proxy/"]
      capabilities = ["pull", "resolve"]
      override_path = true
    EOF
    REGISTRY2_URL=gcr.io
    mkdir -p "/etc/containerd/registry.d/${REGISTRY2_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY2_URL}/hosts.toml" - << EOF
    [host."https://registry.private.network/v2/dockerhub-proxy/"]
      capabilities = ["pull", "resolve"]
      override_path = true
    EOF
```

How to use NodeGroup’s priority feature

The priority field of the `NodeGroup` CustomResource allows you to define the order in which nodes will be provisioned in the cluster. For example, `cluster-autoscaler` can first provision *spot-nodes* and switch to regular ones when they run out. Or it can provision larger nodes when there are plenty of resources in the cluster and then switch to smaller nodes once cluster resources run out.

Here is an example of creating two `NodeGroups` using spot-node nodes:

```
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker-spot
spec:
  cloudInstances:
    classReference:
      kind: AWSInstanceClass
      name: worker-spot
    maxPerZone: 5
    minPerZone: 0
    priority: 50
  nodeType: CloudEphemeral
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  cloudInstances:
    classReference:
      kind: AWSInstanceClass
      name: worker
    maxPerZone: 5
    minPerZone: 0
    priority: 30
  nodeType: CloudEphemeral
```

In the above example, `cluster-autoscaler` will first try to provision a spot-node. If it fails to add such a node to the cluster within 15 minutes, the `worker-spot` NodeGroup will be paused (for 20 minutes), and `cluster-autoscaler` will start provisioning nodes from the `worker` NodeGroup. If, after 30 minutes, another node needs to be deployed in the cluster, `cluster-autoscaler` will first attempt to provision a node from the `worker-spot` NodeGroup before provisioning one from the `worker` NodeGroup.

Once the `worker-spot` NodeGroup reaches its maximum (5 nodes in the example above), the nodes will be provisioned from the `worker` NodeGroup.

Note that node templates (labels/taints) for `worker` and `worker-spot` NodeGroups must be the same (or at least suitable for the load that triggers the cluster scaling process).

How to interpret Node Group states?

Ready — the node group contains the minimum required number of scheduled nodes with the status `Ready` for all zones.

Example 1. A group of nodes in the `Ready` state:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: ng1
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    maxPerZone: 5
    minPerZone: 1
status:
  conditions:
  - status: "True"
    type: Ready
---
apiVersion: v1
kind: Node
metadata:
  name: node1
  labels:
    node.deckhouse.io/group: ng1
status:
  conditions:
  - status: "True"
    type: Ready
```

Example 2. A group of nodes in the `Not Ready` state:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: ng1
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    maxPerZone: 5
    minPerZone: 2
status:
  conditions:
  - status: "False"
    type: Ready
---
apiVersion: v1
kind: Node
metadata:
  name: node1
  labels:
    node.deckhouse.io/group: ng1
status:
  conditions:
  - status: "True"
    type: Ready
```

Updating — a node group contains at least one node in which there is an annotation with the prefix `update.node.deckhouse.io` (for example, `update.node.deckhouse.io/waiting-for-approval`).

WaitingForDisruptiveApproval - a node group contains at least one node that has an annotation `update.node.deckhouse.io/disruption-required` and there is no annotation `update.node.deckhouse.io/disruption-approved`.

Scaling — calculated only for node groups with the type `CloudEphemeral`. The state `True` can be in two cases:

1. When the number of nodes is less than the *desired number of nodes* in the group, i.e. when it is

necessary to increase the number of nodes in the group.
2. When a node is marked for deletion or the number of nodes is greater than the *desired number of nodes*, i.e. when it is necessary to reduce the number of nodes in the group.

The *desired number of nodes* is the sum of all replicas in the node group.

Example. The desired number of nodes is 2:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: ng1
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    maxPerZone: 5
    minPerZone: 2
status:
...
  desired: 2
...
```

Error — contains the last error that occurred when creating a node in a node group.

How do I make werf ignore the Ready conditions in a node group?

werf checks the `Ready` status of resources and, if available, waits for the value to become `True`.

Creating (updating) a nodeGroup resource in a cluster can take a significant amount of time to create the required number of nodes. When deploying such a resource in a cluster using werf (e.g., as part of a CI/CD process), deployment may terminate when resource readiness timeout is exceeded. To make werf ignore the nodeGroup status, the following `nodeGroup` annotations must be added:

```
metadata:
  annotations:
    werf.io/fail-mode: IgnoreAndContinueDeployProcess
    werf.io/track-termination-mode: NonBlocking
```

What is an Instance resource?

An Instance resource contains a description of an implementation-independent ephemeral machine resource. For example, machines created by MachineControllerManager or Cluster API Provider Static will have a corresponding Instance resource.

The object does not contain a specification. The status contains:

1. A link to the InstanceClass if it exists for this implementation;
2. A link to the Kubernetes Node object;
3. Current machine status;
4. Information on how to view machine creation logs (at the machine creation stage).

When a machine is created/deleted, the Instance object is created/deleted accordingly. You cannot create an Instance resource yourself, but you can delete it. In this case, the machine will be removed from the cluster (the removal process depends on implementation details).

When is a node reboot required?

Node reboots may be required after configuration changes. For example, after changing certain sysctl settings, specifically when modifying the `kernel.yama.ptrace_scope` parameter (e.g., using `astra-ptrace-lock enable/disable` in the Astra Linux distribution).

How to enable a delay before a node shutdown or restart while critical pods are running on it?

> ⚠ To decide whether to block a node shutdown, DP additionally queries the NodeGroup. If the current node belongs to the `master` group and it is the only master node in the cluster, the shutdown block will not be applied to it.

To enable the mechanism that delays a pod's restart or shutdown, add the label `pod.deckhouse.io/inhibit-node-shutdown` to the Pod (for a Deployment, specify the label in the pod template).

Example of a Pod manifest with the `pod.deckhouse.io/inhibit-node-shutdown` label:

```
apiVersion: v1
kind: Pod
metadata:
  name: my-stateful-app
  labels:
    app: my-stateful-app
    pod.deckhouse.io/inhibit-node-shutdown: "true"
spec:
  containers:
    - name: app
      image: my-registry/my-app:1.0.0
```

> ⚠ The block only applies to pods labeled with `pod.deckhouse.io/inhibit-node-shutdown` that are in the `Running` phase on the node. Kubelet shuts down the pods without this label according to the standard graceful shutdown process.

Searching pods that prevent shutdown and performing the node troubleshooting

To search the pods that are preventing a node shutdown, use the following command:

```
d8 k get po -A -l pod.deckhouse.io/inhibit-node-shutdown -o wide
```

To view the `GracefulShutdownPostpone` condition on a node, use the following command:

```
d8 k get node <NODE_NAME> -o jsonpath='{range .status.conditions[?
(@.type=="GracefulShutdownPostpone")]}{.type}{"\t"}{.status}{"\t"}{.reason}{"\t"}
{.message}{"\n"}{end}'
```

Possible values of the `reason` field:

- `WaitingForShutdownSignal`: The shutdown blocking mechanism is running on the node, but the blocking has not yet begun.
- `PodsWithLabelAreRunningOnNode`: The shutdown has been blocked because there are pods with the label `pod.deckhouse.io/inhibit-node-shutdown` still running on the node.
- `NoRunningPodsWithLabel`: The blocking has been released and the shutdown can continue.

How do I set up fencing for a node group?

Fencing protects the cluster from nodes that lost the connection to it. A node that cannot reach the cluster stops its own work with a kernel panic. After that, Kubernetes can safely move the workloads to other nodes.

Set the fencing mode in the `spec.fencing.mode` parameter of the NodeGroup resource:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  fencing:
    mode: Normal
```

Each mode selects a built-in FencingSLAProfile. The profile sets the timings of the failure detection and the watchdog timeout:

Mode	Profile	Time to consider the control plane lost (`controlPlaneLostAfter`)	Watchdog timeout	Reaction to a failure
`Disabled`	none	none	none	Fencing is off. This is the default mode.
`Critical`	`critical`	4.15 s	5 s	About 12 s
`Normal`	`normal`	9.1 s	15 s	About 30 s
`Slow`	`slow`	20.2 s	30 s	About 60 s

The reaction time is a target. The tolerance is ±20 %. A failed node stops not later than `controlPlaneLostAfter` + 0.2 s + the watchdog timeout after the failure: 9.35 s with `Critical`, 24.3 s with `Normal` and 50.4 s with `Slow`.

A short timeout gives a fast reaction. But a short timeout also gives a higher risk of a false panic when the cluster is slow. Use `Slow` for groups with an unstable network or a heavy load. Use `Critical` only when a fast reaction is more important than the risk of a false panic.

Note the following:

- The `Watchdog` value of the `spec.fencing.mode` parameter is deprecated. It works as `Slow`. Use `Normal`, `Slow`, or `Critical` (`Critical` is available only in the commercial editions).
- The `spec.fencing.watchdog.timeout` parameter is deprecated. Deckhouse ignores it. The watchdog timeout comes from the profile of the mode.
- In a cluster with one master node, Deckhouse does not let you turn on fencing. Refer to Fencing in a cluster with one master node.
- Deckhouse does not let you change the mode of a node group while a node of the group has a FencingFailedNodeState object. Refer to Known limitations of the evacuation.
- The fencing agent runs on all nodes of the cluster when at least one node group has a mode other than `Disabled`. On the nodes of a `Disabled` group, the agent only takes part in the failure detection. It does not arm the watchdog.
- Fencing sets the `kernel.panic` kernel parameter to `0` on the nodes of the groups with a mode other than `Disabled`. A node does not restart by itself after a fencing panic.
- When you set a mode other than `Disabled` for a group, the new agent pod on a node starts only after bashible loads `softdog` and `/dev/watchdog` appears. Until then, the pod stays in the `ContainerCreating` state with the `FailedMount` event, and the agent does not work on the node. If the group already has agent pods, the DaemonSet replaces them by 10 percent of the nodes at a time. On Deckhouse Engine nodes, `softdog` is built into the kernel, and the pod does not wait. If a node waits for more than 5 minutes, the `D8FencingAgentDown` alert rises. When bashible loads `softdog`, the pod starts and the alert stops. No action is necessary. If the pod does not start, check the bashible logs on the node.

How do I check the fencing state of the nodes?

Run the following command:

```
d8 k get nodes -o custom-columns='NAME:.metadata.name,READY:.status.conditions[?
(@.type=="Ready")].status,FENCING:.status.conditions[?
(@.type=="Fencing")].reason,PROFILE:.metadata.annotations.node-
manager\.deckhouse\.io/fencing-profile'
```

The `READY` column shows the status of the `Ready` condition of the node. The `FENCING` column shows the reason of the `Fencing` condition, for example, `Armed` or `GroupDisabled`. The `PROFILE` column shows the `node-manager.deckhouse.io/fencing-profile` annotation of the node. The annotation has the FencingSLAProfile of the node group mode (`slow` for the deprecated `Watchdog` mode). This is also true when the watchdog of the node is not armed. If the group has the `Disabled` mode, the annotation is `disabled`. If the fencing agent does not run on the node, the `FENCING` and `PROFILE` columns show `<none>`. For example, this occurs when all node groups have the `Disabled` mode.

When fencing stops a node after the loss of the connection to the API server, the node cannot update its `Fencing` condition. Until the node restarts and the agent starts again, the `FENCING` column can still show `Armed`. To find a stopped node, look at the `READY` column: its value is not `True`.

What happens when the fencing agent restarts?

- A planned stop of the agent, for example, an update of the DaemonSet, a deletion of the pod or a shutdown of the node, disarms the watchdog. The node does not stop. If the agent has already stopped the reset of the timer after the loss of the control plane, the watchdog stays armed.
- If the agent crashes or is killed, the watchdog stays armed. The watchdog timeout starts when the agent process stops. At the start, the new agent process checks whether the control plane is available:
  - If the control plane is available, the agent disarms the watchdog. Then the agent arms the watchdog again, as at a usual start. Until then, the reason of the `Fencing` condition is not `Armed`.
  - If the control plane is not available, the agent does not disarm the watchdog. If the agent does not arm the watchdog again before the timeout expires, the node stops.
- If the agent crashes at each start and the control plane is available, the node usually continues to work, but its watchdog is not armed. The `D8FencingAgentRestarted` alert rises, and the reason of the `Fencing` condition is not `Armed`. Read the logs of the agent and remove the cause of the crashes.

What are the limits of softdog?

Fencing uses the `softdog` kernel module as the watchdog. Deckhouse loads the module with the `soft_panic=1` parameter. If the fencing agent does not reset the timer, the timer expires and the kernel panics.

`softdog` is a timer of the same kernel that it must protect. If the kernel has a hard lockup, the timer does not work and the node does not panic. If the node has a hardware watchdog, use it instead of `softdog`. A hardware watchdog works also when the kernel hangs.

Deckhouse Engine nodes

On nodes of groups with `systemType: Immutable` (Deckhouse Engine), `softdog` is built into the kernel. The NodeGroupConfiguration script does not run on these nodes.

If you installed a node before the Deckhouse Engine release with the built-in `softdog`, the node does not have the built-in `softdog`. The node gets `softdog` only after you reinstall it or update its boot partition.

How does fencing work on master nodes?

The fencing agent treats master nodes in the same way as worker nodes. The same modes and conditions apply. There is no special rule for the `master` group.

Note the following:

- After a fencing panic, a master node does not start again by itself. Return the node to the cluster manually. If etcd runs on the node, return the node to the etcd cluster manually.
- When a master node fails, the taint comes later than on a worker node, usually by 10–20 seconds. kube-apiserver on the other master nodes also sends requests to etcd on the failed master node and waits for an answer for approximately 10 seconds. The requests of the fencing-controller wait too. No action is necessary.
- The fencing-controller runs on the master nodes. If the master node of the controller fails or is not ready, Kubernetes evicts the controller pod from it at once, and the controller starts on another master node. In this case, the taint of a failed node comes later. The delay is the time in which Kubernetes marks the master node as unreachable (`nodeMonitorGracePeriodSeconds` of the `control-plane-manager` module, 40 seconds by default), plus the time to start the pod. In a cluster without the high availability mode, the controller has one replica.

Fencing in a cluster with one master node

A node with fencing stops when it loses the control plane. In a cluster with one master node, a failure or a restart of this master node stops all nodes with fencing. Also, when the master node stops, no component remains to set the taint and to move the workloads. Thus, Deckhouse does not let you turn on fencing in a cluster with one master node:

- Deckhouse refuses a change of a NodeGroup that turns fencing on, that is, a change of `spec.fencing.mode` from `Disabled` to another mode.
- When you create a NodeGroup with a mode other than `Disabled`, Deckhouse only shows a warning. This does not stop the installation of a cluster with fencing in its resources.
- A NodeGroup that already has fencing on stays editable. Deckhouse does not turn off fencing that is already on.

Deckhouse counts the master nodes as follows. It counts the nodes with the `node-role.kubernetes.io/control-plane` label. If there are no such nodes, it counts the system nodes with the `node-role.deckhouse.io/master` label.

Until the installation of the cluster is complete, Deckhouse only shows a warning also when you turn fencing on. For this check, the installation is complete when the first node that is not a master node becomes `Ready`. Thus, in a cluster of one master node without other nodes, Deckhouse only shows a warning.

To turn on fencing in the `master` node group, first add master nodes to the cluster. Then set the mode of the group.

Which network ports does fencing need?

The fencing agents on all nodes connect to each other on port 8500. Open the following access rules before you enable fencing:

- Port 8500 TCP and UDP between the InternalIP addresses of all cluster nodes.
- Port 8500 UDP between the addresses of the SystemNetwork on all nodes. This rule is necessary only if you use the second network (the `settings.fencing.systemNetworkFallback.systemNetworkName` parameter of the `node-manager` module). TCP is not necessary for this network. Currently the agents do not exchange messages through the second network. Open the rule in advance for the fallback through the SystemNetwork.

What does the D8FencingSystemNetworkNotFound alert mean?

The alert means that the `settings.fencing.systemNetworkFallback.systemNetworkName` parameter of the `node-manager` module names a SystemNetwork that does not exist in the cluster. The agents cannot use the second network. Deckhouse does not change the parameter.

To fix the problem, do one of the following:

- Create the SystemNetwork.
- Set the name of an existing network.
- Delete the name from the parameter.

Note the following:

- Deckhouse checks that the SystemNetwork exists when you set `systemNetworkName` to a new non-empty value. Deckhouse can reject only this change. Deckhouse always accepts the deletion of the value and the changes of the other ModuleConfig fields, also when the check is not available.
- During `dhctl bootstrap`, the check is not active. Deckhouse accepts the parameter without the check. If the network does not exist, the alert rises after the module starts.
- The alert stops about 10 minutes after you restore the network.
- While all node groups have the `Disabled` mode, the alert does not rise. The agents do not use the second network in this case. The alert rises when you enable fencing.

How does fencing protect the network key?

The fencing agents use a shared key to encrypt the messages between them. The key is in the `fencing-memberlist-key` Secret in the `d8-cloud-instance-manager` namespace. If you delete the Secret, Deckhouse generates a new key and the `D8FencingKeyRegenerated` alert rises.

When an agent gets a new key, it keeps the old key and starts to use the new key after 2 minutes. This delay lets the kubelet on all nodes update the Secret. The agent removes the old key after the same delay.

How do I rotate the fencing network key?

The `fencing-memberlist-key` Secret in the `d8-cloud-instance-manager` namespace has two keys in the `data` field:

- `primary`: the agents use this key to encrypt the messages. It is necessary.
- `secondary`: the agents use this key only to decrypt the messages. It is optional.

Each key is exactly 32 random bytes. In the `data` field, the value is these 32 bytes encoded in base64. Do not write a base64 string into the `stringData` field: the agents then get a key of a wrong length.

To rotate the key, do the following steps:

1. Make a new key, write it into `primary` and move the current key to `secondary`. The key stays in a shell variable only, so it does not appear in the output and in the shell history:

   ```
   NEW_KEY=$(head -c 32 /dev/urandom | base64)
   d8 k -n d8-cloud-instance-manager patch secret fencing-memberlist-key --type=json -p "
   [{\"op\":\"copy\",\"from\":\"/data/primary\",\"path\":\"/data/secondary\"},
   {\"op\":\"replace\",\"path\":\"/data/primary\",\"value\":\"${NEW_KEY}\"}]"
   unset NEW_KEY
   ```

   The kubelet updates the Secret on the nodes, usually in approximately 1 minute. Each agent keeps the current key, adds the new key and starts to use the new key after 2 minutes. During the rotation, the agents with the old key and the agents with the new key decrypt the messages of each other.

2. Wait at least 10 minutes. Then all agents use the new key. Remove the old key from the Secret:

   ```
   d8 k -n d8-cloud-instance-manager patch secret fencing-memberlist-key --type=json -p '[
     {"op": "remove", "path": "/data/secondary"}
   ]'
   ```

Do not delete the Secret to rotate the key. Deckhouse then makes a new key without the old key, and the `D8FencingKeyRegenerated` alert rises.

If the key has a wrong format, the agents that run continue to use their current keys and ignore the wrong key. The `d8_fencing_agent config_invalid{parameter="key"}` metric of these agents is `1`. An agent that starts with a wrong `primary` key cannot connect to the other agents and does not arm the watchdog. The `Fencing` condition of its node is `False` with the `InvalidKey` reason, and after 10 minutes the `D8FencingAgentInvalidKey` alert rises. To find these nodes, use the command from How do I check the fencing state of the nodes?. To check the length of the `primary` key, run the following command. It must show `32`:

```
d8 k -n d8-cloud-instance-manager get secret fencing-memberlist-key -o jsonpath='{.data.primary}'
| base64 -d | wc -c
```

How the fencing mechanism handles different node types?

The fencing mechanism stops a node that lost the connection with the cluster. It protects the cluster from “zombie” nodes in an undefined state.

A node with an armed watchdog works only while it sees the control plane. When the node does not see the control plane for longer than `controlPlaneLostAfter` of the profile, the fencing-agent stops the reset of the watchdog timer (the `softdog` kernel module) at once. When the timeout expires, a kernel panic occurs. This guarantees that no workloads remain running on the node.

While the node has a FencingFailedNodeState object, the node sees the control plane only when it can write its heartbeat through the API server. A node that cannot write its heartbeat stops in the same way.

After the agent stops the reset of the timer, it continues to check the control plane:

- If the control plane is available again before the watchdog timeout expires, the agent resets the timer again, and the node continues to work. Thus, a short pause of the control plane does not stop the nodes.
- The agent also asks the agents of the other nodes. It looks for a witness, that is, a node that sees the control plane. The agent sends a stop message to the witness, and the witness writes an attestation into the FencingFailedNodeState object of the node. After this message, the stop is final: the agent does not reset the timer again. The stop is also final when the FencingFailedNodeState object of the node is in the `Proven` phase.

A pause of the control plane in the whole cluster affects all nodes with an armed watchdog at the same time. Measurements on a cluster show that all nodes survive a pause of up to the following time:

Mode	Pause that the nodes survive
`Critical`	7.35 s
`Normal`	21.6 s
`Slow`	45.7 s

If the pause is longer, some or all nodes with an armed watchdog can stop.

For more details on how the fencing-agent works, refer to the description of the `spec.fencing.mode` parameter of the NodeGroup resource.

After the node stops, the behavior depends on the type of the node group (the `node.deckhouse.io/type` label) and its engine (`status.engine`):

1. The node stays down. Deckhouse disables the automatic reboot after a kernel panic at the OS level. This applies to all nodes of the groups with a fencing mode other than `Disabled`. This prevents a node from rejoining the cluster in an undefined state.
2. When the stop of the node is certain, the fencing-controller sets the `node.kubernetes.io/out-of-service` taint on the Node. The stop is certain when a witness confirmed it and the watchdog timeout of the node passed, or when the node is silent for the time that it needs to stop. For the times and for the cases when the controller does not set the taint, refer to When the controller sets the taint. After the taint, the controller sets the `Failed` phase and the `DisruptionTarget` condition on the pods of the node and deletes the pods immediately. This includes the pods that tolerate the taint. The controller does not delete the pods of DaemonSets and the static pods. The controller does not remove the finalizers of the pods: a pod with a finalizer stays in the API until the owner of the finalizer removes it. Pods of a StatefulSet and pods with ReadWriteOnce volumes start on other nodes. The evacuation is complete when the node has no `VolumeAttachment` objects. If the evacuation is not complete after 60 seconds, the incident stays in the `Evicting` phase and gets the `Progressing` condition with the status `False`. The reason of the condition tells what stops the evacuation now: `VolumesAttached`, `PodsRemaining` or `TooManyUnhealthyMachines`. The controller continues to examine the node and completes the evacuation when the cause is gone.
3. After the evacuation, Deckhouse acts on the node as follows:
   - For a node of a `CloudPermanent`, `CloudStatic`, or `Static` group (this includes a `Static` group with `staticInstances`, that is, CAPS), for a master node, and for an etcd arbiter node, Deckhouse only keeps the taint. It never deletes the Node object.
   - For a node of a `CloudEphemeral` group with `status.engine: CAPI`, Deckhouse deletes the Node object only when the MachineHealthCheck of the Cluster API cluster reports its machines and 50 percent or fewer of them are unhealthy. Deckhouse counts the stopped machine as unhealthy. MachineHealthCheck then sets the `HealthCheckSucceeded` condition of the Machine to `False` with the `NodeDeleted` reason and replaces the machine. If more than 50 percent of the machines are unhealthy, or the MachineHealthCheck does not report its machines yet, Deckhouse does not delete the Node object yet. The controller continues to examine the machines. When 50 percent or fewer of them are unhealthy, the controller deletes the Node object and completes the evacuation.
   - For a node of a `CloudEphemeral` group with `status.engine: MCM`, Deckhouse deletes the `Machine` (`machine.sapcloud.io`). Machine Controller Manager creates a new machine.
4. A node that Deckhouse does not replace stays down until you start it. When the node returns (the Node is `Ready` and it has a new boot ID), the fencing-controller removes the taint automatically. The controller works only while at least one node group has a mode other than `Disabled`. If you turn fencing off in all node groups, the taint stays on the node. Refer to What to do with the out-of-service taint before you turn fencing off in all node groups?

If the fencing-controller does not set the taint, Kubernetes sets the `node.kubernetes.io/unreachable` taint on the Node and evicts the pods of the node after the time in the `failedNodePodEvictionTimeoutSeconds` parameter of the `control-plane-manager` module (300 seconds by default).

A node of a group with fencing can return to the cluster in a way that is different from the behavior above. If this occurs, contact the support. Your report helps to clarify the sequence of checks and protection mechanisms.

When the controller sets the taint

The controller sets the `node.kubernetes.io/out-of-service` taint only on a node that is stopped. The controller proves the stop in one of two ways:

- Attestation of a witness. The witness is a node whose agent received the stop message of the

failed node. The agent of the witness writes the attestation into the FencingFailedNodeState object of the failed node. After the controller sees the attestation, it waits for `watchdog.timeout` + `watchdog.margin` of the profile. During this time, the watchdog of the failed node expires.
- Silence of the node. For example, the node is off or lost all networks, and no witness can confirm its stop. The controller waits for `controlPlaneLostAfter` + 0.2 s + `watchdog.timeout` + `watchdog.margin` + 0.9 s of the profile after the last sign of life of the node. The last sign of life is the later of two moments: when the controller saw the FencingFailedNodeState object first, and when it saw the last heartbeat of the node plus `heartbeat.interval`. During this time, the node detects the loss of the control plane and its watchdog expires.

The controller uses the way that gives the proof first:

Mode	Profile	Time after the attestation	Time after the last sign of life
`Critical`	`critical`	5.3 s	10.55 s
`Normal`	`normal`	15.75 s	25.95 s
`Slow`	`slow`	31.5 s	52.8 s

When the incident gets the `Proven` phase, the controller writes an event. The event tells the way of the proof and the time.

The controller takes the profile from the `spec.profileRef.name` field of the FencingFailedNodeState object. The agent that creates the object writes the slower of two profiles: the profile that the failed node applied, and the profile of the node group at the time of the creation of the object. Deckhouse does not let you change the mode of the group while a node of the group has a FencingFailedNodeState object. Refer to Known limitations of the evacuation.

The controller does not set the taint in these cases:

- The watchdog of the node was not armed (`spec.armed` is `false`). For example, the node is in a group with the `Disabled` mode.
- The `Fencing` condition of the Node is not `True`, that is, the agent of the node did not report that the watchdog is armed. The controller does not prove the failure, and the incident stays in the `Suspected` phase. The controller examines the node again every 5 seconds.
- The node sends heartbeats. The controller counts the time after the last sign of life again from each new heartbeat. A heartbeat after the attestation also cancels the proof by this attestation, and the `D8FencingNodeAliveAfterAttestation` alert rises.
- The node has one of the maintenance annotations `node-manager.deckhouse.io/fencing-disable`, `update.node.deckhouse.io/approved` or `update.node.deckhouse.io/disruption-approved`, or the agent of the node stops by plan. The controller examines the node again every 5 seconds.
- The owner reference of the FencingFailedNodeState object does not have the UID of the node with this name, for example after the node is created again with the same name. The controller does nothing for such an object.
- The controller cannot use the profile. The `D8FencingProfileIsUnavailable` alert rises.

Phases of a fencing incident

The controller writes the phase of the incident into the `status.phase` field of the FencingFailedNodeState object. The name of the object is the name of the node. To see the incidents, run the following command:

```
d8 k get fencingfailednodestates
```

The phases:

- `Suspected`: an agent found the failure of the node. The controller waits for the proof of the failure.
- `FallbackAlive`: the node sends its heartbeat through the API server. The node works, but the agents of other nodes cannot connect to it.
- `Proven`: the controller proved the failure by the attestation of a witness or by the silence of the node. Refer to When the controller sets the taint.
- `Evicting`: the node has the taint. The controller deletes the pods and waits until the node has no `VolumeAttachment` objects.
- `Evicted`: the evacuation is complete. The controller writes this phase first. Then it deletes the Node or the `Machine` of a node that the cloud replaces.

For the description of all fields, refer to FencingFailedNodeState.

Fencing alerts

The fencing-controller gives these alerts:

- `D8FencingNodeFailed`: a node with an armed watchdog has an incident.
- `D8FencingNodeIsolatedFromPeers`: the incident is in the `FallbackAlive` phase for 1 minute. The node works, but the network between this node and the other nodes is broken. Usually a firewall rule or an ACL stops the traffic of the agents.
- `D8FencingNodeAliveAfterAttestation`: the node sent a heartbeat after the attestation. The controller does not set the taint on this node while the node sends heartbeats. Examine the node.
- `D8FencingEvictionNotProgressing`: the evacuation is not complete after 60 seconds. The `reason` label tells the reason of the `Progressing` condition.
- `D8NodeOutOfServiceTainted`: a node has the `node.kubernetes.io/out-of-service` taint for 30 minutes. Start the node again or remove it from the cluster.
- `D8FencingProfileIsUnavailable`: the controller cannot use the profile of the incident and does not set the taint.

The alerts of the controller exist only while the controller works, that is, while at least one node group has a mode other than `Disabled`.

The `D8FencingWatchdogDeviceMissing` alert of the fencing agent rises when the agent has no watchdog device for 30 minutes. The agent does not arm the watchdog, so the controller never sets the taint on this node. Usually the DaemonSet of the node group did not replace the agent pod of the previous revision yet.

Known limitations of the evacuation

The fencing-controller runs on the master nodes. In a cluster with several master nodes, the controller has several replicas, and only the leader of the replicas works. A new leader counts the times of the incidents again from what it sees. Thus, if the leader changes during an incident, the taint comes later by up to approximately 20 seconds plus the time after the last sign of life from the table in When the controller sets the taint. No action is necessary. The leader can change in these cases:

- The master node of the leader fails.
- kubernetes-api-proxy restarts with a new manifest on the master node of the leader, for example, during an update of Deckhouse. The controller connects to the API server through this proxy.

On the master nodes of Deckhouse Engine (`systemType: Immutable`), and when the `control-plane-manager` module is disabled, the controller connects to the API server through the ClusterIP of the `kubernetes` Service. When a master node fails, the requests of the controller can go to the failed master node for some seconds. Then the taint of the failed node comes later, and the leader can change.

When the master node of the controller fails, the controller starts on another master node only after Kubernetes marks the failed master node as unreachable. Until then, the controller does not set the taint. Refer to How does fencing work on master nodes?

Deckhouse does not let you change the mode of a node group while a node of the group has a FencingFailedNodeState object. The controller calculates the times of an incident from the profile in the object, but the watchdog of the node can already use the times of the new mode. The error message names the nodes that have the objects. Wait until the incidents end, then change the mode. An incident ends when the node comes back after a reboot, or when its Node object is deleted. To find the objects:

```
d8 k get fencingfailednodestates
```

Change the mode of a node group only when all nodes of the group work correctly.

After switching the edition to CE, a FencingFailedNodeState object with the `critical` profile stays in the cluster, because CE has no such profile. The object gets the `ConfigurationError` condition, the `D8FencingProfileIsUnavailable` alert rises, and the controller does not evacuate the node. When the node comes back, that is, the Node is `Ready` and has a new boot ID, the controller deletes the object. In other cases, make sure that the node works or is off. Then delete the object:

```
d8 k delete fencingfailednodestate <NODE_NAME>
```

If the node fails again, the agents create a new object with the profile of the current mode. If the node has the `node.kubernetes.io/out-of-service` taint, the taint stays after the deletion. Remove the taint when the node works again:

```
d8 k taint node <NODE_NAME> node.kubernetes.io/out-of-service-
```

A node with an armed watchdog stops when it does not see the control plane. If the network separates

a part of the cluster from the control plane, all nodes with an armed watchdog in this part stop, also when they work correctly.

The controller knows that the watchdog of a node is armed only from the `Fencing` condition of the Node. The agent writes this condition after it arms or disarms the watchdog. Between these two moments, the condition can be incorrect. This gives two known cases:

- The agent armed the watchdog, but the `True` status of the condition did not reach the API server, and at this moment the node failed. For example, this can occur when the node fails during the restart of the agent. The controller does not set the taint on this node until the node comes back.
- The agent crashed, and the new agent process disarmed the watchdog. Then the node lost the control plane before the agent wrote the `False` status of the condition. The node works and its watchdog is not armed, but the condition stays `True`. The controller does not set the taint on this node: if the node gets a FencingFailedNodeState object, the object has `spec.armed: false`.

A rollback of Deckhouse to a version with fencing 1.0 is not supported. If you do a rollback, unload the `softdog` kernel module on the nodes. If you do not, the module keeps the timeout of fencing 2.0 (5 seconds for the `Critical` profile), the agent of fencing 1.0 resets the timer less frequently, and the node goes into a kernel panic.

What to do with the out-of-service taint before you turn fencing off in all node groups?

Only the fencing-controller removes the `node.kubernetes.io/out-of-service` taint from a node that came back. When the last node group gets the `Disabled` mode, Deckhouse deletes the controller together with the fencing agents. If a node has the taint at this time, the taint stays on the node. Deckhouse does not remove it, and no fencing alert rises after that. Kubernetes does not run pods on this node.

The same occurs when you disable the `node-manager` module, because Deckhouse deletes the controller together with the module. Deckhouse disables the module only after you confirm it with the `modules.deckhouse.io/allow-disabling=true` annotation on the ModuleConfig. Before you confirm, set the `Disabled` mode in all node groups and wait until no `fencing-agent` pods are left in the `d8-cloud-instance-manager` namespace. If you do not, an agent can fail to report its stop, and the watchdog stops its node. Also do the steps below before you set the `Disabled` mode in the last node group.

Before you set the `Disabled` mode in the last node group, do these steps:

1. Find the nodes with the taint and the fencing incidents:

   ```
   d8 k get nodes -o custom-columns='NAME:.metadata.name,TAINTS:.spec.taints[*].key' |
   grep -E '^NAME|node.kubernetes.io/out-of-service'
   d8 k get fencingfailednodestates
   ```

2. For each node with the taint, make sure that the node works again or that you replaced it. Then remove the taint:

   ```
   d8 k taint node <NODE_NAME> node.kubernetes.io/out-of-service-
   ```

   If the node is still stopped, you can turn fencing off. But then you must remove the taint manually after you start the node.

If you turn fencing on again, the controller removes the taint by the usual rule. It removes the taint when the Node is `Ready`, has a new boot ID and still has its FencingFailedNodeState object.

How do I work with GPU nodes?

Step-by-step procedure for adding a GPU node to the cluster

Starting with Deckhouse 1.71, if a NodeGroup resource contains the `spec.gpu` section, the `node-manager` module **automatically**:

- Configures containerd with `default_runtime = "nvidia"`.
- Applies the required system settings (including fixes for the NVIDIA Container Toolkit).
- Deploys the following system components:
  - NFD
  - GFD
  - NVIDIA Device Plugin
  - DCGM Exporter
  - MIG Manager (if needed)

For the list of platforms supported by NVIDIA Container Toolkit, see the official documentation.

> **i** To ensure correct operation, clearly specify the GPU sharing strategy in the `spec.gpu.sharing` parameter (`Exclusive`, `TimeSlicing`, or `MIG`).
>
> Containerd on GPU nodes is configured automatically. Do not change its configuration manually (for example, via the NodeGroupConfiguration resource or a configuration on the node).

> **i** If a GPU is used in a single-node cluster and the `MIG` strategy is selected, an additional manual procedure is required after each node reboot to reapply the MIG configuration. For details, see MIG in a single-node cluster section.

To add a GPU node to the cluster, perform the following steps:

1. Create a NodeGroup resource for GPU nodes.

   An example with **TimeSlicing** enabled (`partitionCount: 4`) and typical `taints` and `labels`:

   ```
   apiVersion: deckhouse.io/v1
   kind: NodeGroup
   metadata:
     name: gpu
   spec:
     nodeType: CloudStatic  # Can also be Static or CloudEphemeral — depending on
   your infrastructure.
     gpu:
       sharing: TimeSlicing
       timeSlicing:
         partitionCount: 4
     nodeTemplate:
       labels:
         node-role/gpu: ""
       taints:
       - key: node-role
         value: gpu
         effect: NoSchedule
   ```

   > **i** If you use custom taint keys, ensure they are allowed in the ModuleConfig `global` in the array `.spec.settings.modules.placement.customTolerationKeys`, so that workloads can add the corresponding `tolerations`.

   A full field schema is available in the NodeGroup custom resource reference.

2. Install the NVIDIA driver and NVIDIA Container Toolkit.

   Install the NVIDIA driver and NVIDIA Container Toolkit directly on the nodes, either manually or via the NodeGroupConfiguration resource. Current NodeGroupConfiguration examples for the `gpu` NodeGroup (Ubuntu, Debian, CentOS) are available in the `gpu` module FAQ.

3. After the configuration is applied, perform a bootstrap and reboot the nodes so that settings are applied and the drivers get installed.

4. Verify installation on the node using the command:

   ```
   nvidia-smi
   ```

> ⚠ If the GPU node was prepared in advance, shipped with preinstalled NVIDIA drivers, or runs an OS with a graphical environment, make sure that the GPU is not being used by third-party processes.
>
> In the `nvidia-smi` output, the `Processes` section must not contain third-party processes using the GPU. On nodes with a graphical environment, these may include, for example, graphical session or display manager processes: `Xorg`, `gnome-shell`, `gdm`, `sddm`, `lightdm`, and others. Such processes can consume GPU memory and interfere with correct workload operation as well as MIG configuration.

Expected proper output (example):

```
root@k8s-dvp-w1-gpu:~# nvidia-smi
Tue Aug  5 07:08:48 2025

5. Verify infrastructure components in the cluster.

   NVIDIA Pods in the `d8-nvidia-gpu` namespace:

   ```
   d8 k -n d8-nvidia-gpu get pod
   ```

   Expected proper output (example):

   ```
   NAME                                  READY   STATUS    RESTARTS   AGE
   gpu-feature-discovery-80ceb7d-r842q   2/2     Running   0          2m53s
   nvidia-dcgm-exporter-w9v9h            1/1     Running   0          2m53s
   nvidia-dcgm-njqqb                     1/1     Running   0          2m53s
   nvidia-device-plugin-80ceb7d-8xt8g    2/2     Running   0          2m53s
   ```

   NFD Pods in the `d8-cloud-instance-manager` namespace:

```
d8 k -n d8-cloud-instance-manager get pods | egrep '^(NAME|node-feature-discovery)'
```

Expected proper output (example):

```
NAME                                          READY   STATUS      RESTARTS
AGE
node-feature-discovery-gc-6d845765df-45vpj    1/1     Running     0
3m6s
node-feature-discovery-master-74696fd9d5-wkjk4   1/1     Running     0
3m6s
node-feature-discovery-worker-5f4kv           1/1     Running     0
3m8s
```

Resource exposure on the node:

```
d8 k describe node <node-name>
```

Output snippet (example):

```
Capacity:
  cpu:                40
  memory:             263566308Ki
  nvidia.com/gpu:     4
Allocatable:
  cpu:                39930m
  memory:             262648294441
  nvidia.com/gpu:     4
```

6. Run functional tests.

   Option A. Invoke `nvidia-smi` from inside a container.

   1. Create a Job:

      ```
      apiVersion: batch/v1
      kind: Job
      metadata:
        name: nvidia-cuda-test
        namespace: default
      spec:
        completions: 1
        template:
          spec:
            restartPolicy: Never
            nodeSelector:
              node.deckhouse.io/group: gpu
              node-role/gpu: ""
            tolerations:
              - key: "node-role"
                operator: "Equal"
                value: "gpu"
                effect: "NoSchedule"
            containers:
              - name: nvidia-cuda-test
                image: nvidia/cuda:11.6.2-base-ubuntu20.04
                imagePullPolicy: "IfNotPresent"
                command:
                  - nvidia-smi
      ```

   2. Check the logs using the command:

```
d8 k logs job/nvidia-cuda-test
```

Output example:

```
Tue Aug  5 07:48:02 2025
+-----------------------------------------------------------------------------

```

Option B. CUDA sample (vectoradd).

1. Create a Job:

```
apiVersion: batch/v1
kind: Job
metadata:
  name: gpu-operator-test
  namespace: default
spec:
  completions: 1
  template:
    spec:
      restartPolicy: Never
      nodeSelector:
        node.deckhouse.io/group: gpu
      tolerations:
        - key: "node-role"
          operator: "Equal"
          value: "gpu"
          effect: "NoSchedule"
      containers:
        - name: gpu-operator-test
          image: nvidia/samples:vectoradd-cuda10.2
          imagePullPolicy: "IfNotPresent"
```

2. Check the logs using the command:

```
d8 k logs job/gpu-operator-test
```

Output example:

```
[Vector addition of 50000 elements]
Copy input data from the host memory to the CUDA device
CUDA kernel launch with 196 blocks of 256 threads
Copy output data from the CUDA device to the host memory
Test PASSED
Done
```

How to monitor GPUs?

Deckhouse Platform automatically deploys **DCGM Exporter**; GPU metrics are scraped by Prometheus and available in Grafana.

Which GPU modes are supported?

- **Exclusive** — the node exposes the `nvidia.com/gpu` resource; each Pod receives an entire GPU.
- **TimeSlicing** — time-sharing a single GPU among multiple Pods (default `partitionCount: 4`); Pods still request `nvidia.com/gpu`.
- **MIG (Multi-Instance GPU)** — hardware partitioning of supported GPUs into independent instances; with the `all-1g.5gb` profile the cluster exposes resources like `nvidia.com/mig-1g.5gb`.

See examples in Managing nodes: examples section.

How to view available MIG profiles in the cluster?

Pre-defined profiles are stored in the **`mig-parted-config`** ConfigMap inside the **`d8-nvidia-gpu`** namespace and can be viewed with the command:

```
d8 k -n d8-nvidia-gpu get cm mig-parted-config -o json | jq -r '.data["config.yaml"]'
```

The `mig-configs:` section lists the **GPU models (by PCI ID) and the MIG profiles each card supports**—for example `all-1g.5gb`, `all-2g.10gb`, `all-balanced`. Select the profile that matches your accelerator and set its name in `spec.gpu.mig.partedConfig` of the NodeGroup.

How to set a custom per-GPU MIG layout on a node?

Set the `partedConfig` parameter in NodeGroup to `custom` and define MIG partitioning per GPU index:

```
spec:
  gpu:
    sharing: MIG
    mig:
      partedConfig: custom
      customConfigs:
        - index: 0
          slices:
            - profile: 7g.80gb
              count: 1   # Can be in the range from 1 to 7.
        - index: 1
          slices:
            - profile: 3g.40gb
              count: 2
            - profile: 1g.10gb
              count: 1
        # Add more indexes as needed.
```

As a result, the `node-manager` module automatically:

- Adds a configuration named `custom-<node-group-name>-<hash>` into the `mig-parted-config` ConfigMap, where `<hash>` is calculated based on the partitioning scheme (long NodeGroup names are truncated with a hash suffix to fit into a label).
- Sets the label `nvidia.com/mig.config=custom-<node-group-name>-<hash>` to the nodes in the corresponding group.

A separate `custom-<ng>-<hash>` configuration is created for each group of nodes, and configuration names do not overlap.

MIG profile does not activate — what to check?

1. Check the GPU model. MIG is supported in the H100/A100/A30 models and **not** supported in V100/T4. To verify the support in a model, refer to profile tables in the NVIDIA MIG guide.
2. Ensure the GPU is not being used by OS processes or user applications. If a graphical environment, display manager, or other GPU-consuming processes are running on the node, applying the MIG configuration may fail or may not take effect until the GPU is released. Check this with the following command:

   ```
   nvidia-smi
   ```

3. Check the NodeGroup configuration:

   ```
   gpu:
     sharing: MIG
     mig:
       partedConfig: all-1g.5gb
   ```

4. Wait until `nvidia-mig-manager` completes the **drain** of the node and reconfigures the GPU.

   This process can take several minutes.

   While it is running, the node is tainted with `mig-reconfigure`. When the operation succeeds, that taint is removed.

5. Track the progress via the `nvidia.com/mig.config.state` label on the node:

   `pending`, `rebooting`, `success` (or `error` if something goes wrong).

6. If `nvidia.com/mig-*` resources are still missing, check:

   ```
   d8 k -n d8-nvidia-gpu logs daemonset/nvidia-mig-manager
   nvidia-smi -L
   ```

Are AMD or Intel GPUs supported?

At this time, Deckhouse Platform automatically configures **NVIDIA GPUs only**. Support for **AMD (ROCm)** and **Intel GPUs** is being worked on and is planned for future releases.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Below are some examples of NodeGroup description, as well as installing the cert-manager plugin for `kubectl` and setting the `sysctl` parameter.

Examples of the `NodeGroup` configuration

Cloud nodes

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: test
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    zones:
      - eu-west-1a
      - eu-west-1b
    minPerZone: 1
    maxPerZone: 2
    classReference:
      kind: AWSInstanceClass
      name: test
  nodeTemplate:
    labels:
      tier: test
```

Static nodes

Use `nodeType: Static` for physical servers and VMs on Hypervisors.

An example:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
```

Adding nodes to such a group is done manually using the pre-made scripts.

You can also use a method that adds static nodes using the Cluster API Provider Static.

System nodes

Below is an example of a system node group manifest.

When describing a NodeGroup with Static nodes, specify the value `Static` in the `nodeType` field and use the `staticInstances` field to describe the parameters for provisioning static machines to the cluster.

When describing a NodeGroup with CloudEphemeral type cloud nodes, specify the value `CloudEphemeral` in the `nodeType` field and use the `cloudInstances` field to describe the parameters for provisioning the cloud-based VMs.

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: system
spec:
  nodeTemplate:
    labels:
      node-role.deckhouse.io/system: ""
    taints:
      - effect: NoExecute
        key: dedicated.deckhouse.io
        value: system
  # Example for Static nodes.
  nodeType: Static
  staticInstances:
    count: 2
    labelSelector:
      matchLabels:
        role: system
  # Example for CloudEphemeral nodes.
  # nodeType: CloudEphemeral
  # cloudInstances:
  #   classReference:
  #     kind: YandexInstanceClass
  #     name: large
  #   maxPerZone: 2
  #   minPerZone: 1
  #   zones:
  #   - ru-central1-d
```

Nodes with GPU

GPU nodes require the **NVIDIA driver** and the **NVIDIA Container Toolkit**. There are two ways to install the driver:

1. **Manual installation** — the administrator installs the driver before the node joins the cluster.
2. **Automation via `NodeGroupConfiguration`** (more details in the Step-by-step procedure for adding a GPU node to the cluster section).

After the driver is detected and the NodeGroup includes the `spec.gpu` section, `node-manager` enables full GPU support by deploying **NFD**, **GFD**, **NVIDIA Device Plugin**, **DCGM Exporter**, and, if required, **MIG Manager**.

> **i** GPU nodes are usually tainted (e.g. `node-role=gpu:NoSchedule`) so that regular workloads don’t land there by accident. A workload that needs a GPU just adds the matching `tolerations` and `nodeSelector`.

See the full field reference in the NodeGroup custom resource documentation.

Below are examples of NodeGroup manifests for typical GPU operating modes (Exclusive, TimeSlicing, MIG).

Exclusive mode (one Pod — one GPU)

Each Pod gets an entire physical GPU; the cluster exposes the `nvidia.com/gpu` resource.

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: gpu-exclusive
spec:
  nodeType: Static
  gpu:
    sharing: Exclusive
  nodeTemplate:
    labels:
      node-role/gpu: ""
    taints:
    - key: node-role
      value: gpu
      effect: NoSchedule
```

Time-slicing (4 partitions)

The GPU is time-sliced: up to four Pods can share one card sequentially. Suitable for experiments, CI, and light inference workloads.

Pods still request the `nvidia.com/gpu` resource.

```
spec:
  gpu:
    sharing: TimeSlicing
    timeSlicing:
      partitionCount: 4
```

MIG (`all-1g.5gb` profile)

A hardware-partitioned GPU (A100, A30, etc.) is split into independent instances. The scheduler exposes resources like `nvidia.com/mig-1g.5gb`.

For a complete list of supported GPUs and their profiles you can see it by using instruction.

```
spec:
  gpu:
    sharing: MIG
    mig:
      partedConfig: all-1g.5gb
```

Smoke-test Job (CUDA vectoradd)

```
apiVersion: batch/v1
kind: Job
metadata:
  name: cuda-vectoradd
spec:
  template:
    spec:
      restartPolicy: OnFailure
      nodeSelector:
        node-role/gpu: ""
      tolerations:
      - key: node-role
        value: gpu
        effect: NoSchedule
      containers:
      - name: cuda-vectoradd
        image: nvcr.io/nvidia/k8s/cuda-sample:vectoradd-cuda11.7.1-ubuntu20.04
        resources:
          limits:
            nvidia.com/gpu: 1
```

This Job runs NVIDIA's **vectoradd** CUDA sample. If the Pod finishes with `Succeeded`, the GPU is present and configured correctly.

Adding a static node to a cluster

Adding a static node can be done manually or using the Cluster API Provider Static.

Manually

Follow the steps below to add a new static node (e.g., VM or bare metal server) to the cluster:

1. For CloudStatic nodes in the following cloud providers, refer to the steps outlined in the documentation:
   - For AWS
   - For GCP
   - For YC
2. Use the existing one or create a new NodeGroup custom resource (see the example for the `NodeGroup` called `worker`). The nodeType parameter for static nodes in the NodeGroup must be `Static` or `CloudStatic`.
3. Get the Base64-encoded script code to add and configure the node.

   Here is how you can get Base64-encoded script code to add a node to the `worker` NodeGroup:

   ```
   NODE_GROUP=worker
   d8 k -n d8-cloud-instance-manager get secret manual-bootstrap-for-${NODE_GROUP} -o json | jq '.data."bootstrap.sh"' -r
   ```
4. Pre-configure the new node according to the specifics of your environment. For example:
   - Add all the necessary mount points to the `/etc/fstab` file (NFS, Ceph, etc.).
   - Install the necessary packages.
   - Configure network connectivity between the new node and the other nodes of the cluster.
5. Connect to the new node over SSH and run the following command, inserting the Base64 string you got in step 3:

   ```
   echo <Base64-CODE> | base64 -d | bash
   ```

Using the Cluster API Provider Static

> ⚠ If you have previously increased the number of master nodes in the cluster in the NodeGroup `master` (parameter `spec.staticInstances.count`), before adding regular nodes using CAPS, make sure that they will not be “captured”.

A brief example of adding a static node to a cluster using Cluster API Provider Static (CAPS):

1. Prepare the necessary resources.
   - Allocate a server (or a virtual machine), configure networking, etc. If required, install specific OS packages and add the mount points on the node.
   - Create a user (`caps` in the example below) and add it to sudoers by running the following command **on the server**:

     ```
     useradd -m -s /bin/bash caps
     usermod -aG sudo caps
     ```

   - Allow the user to run sudo commands without having to enter a password. For this, add the following line to the sudo configuration **on the server** (you can either edit the `/etc/sudoers` file, or run the `sudo visudo` command, or use some other method):

     ```
     caps ALL=(ALL) NOPASSWD: ALL
     ```

   - Generate a pair of SSH keys with an empty passphrase **on the server**:

     ```
     ssh-keygen -t  -f caps-id -C "" -N ""
     ```

     The public and private keys of the `caps` user will be stored in the `caps-id.pub` and `caps-id` files in the current directory on the server.
   - Add the generated public key to the `/home/caps/.ssh/authorized_keys` file of the `caps` user by executing the following commands in the keys directory **on the server**:

     ```
     mkdir -p /home/caps/.ssh
     cat caps-id.pub >> /home/caps/.ssh/authorized_keys
     chmod 700 /home/caps/.ssh
     chmod 600 /home/caps/.ssh/authorized_keys
     chown -R caps:caps /home/caps/
     ```

2. Create a SSHCredentials resource in the cluster:

   Run the following command in the user key directory **on the server** to encode the private key to Base64:

   ```
   base64 -w0 caps-id
   ```

   On any computer with `kubectl` configured to manage the cluster, create an environment variable with the value of the Base64-encoded private key you generated in the previous step:

   ```
   CAPS_PRIVATE_KEY_BASE64=<BASE64-ENCODED PRIVATE KEY>
   ```

   Create a `SSHCredentials` resource in the cluster (note that from this point on, you have to use `kubectl` configured to manage the cluster):

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1alpha1
kind: SSHCredentials
metadata:
  name: credentials
spec:
  user: caps
  privateSSHKey: "${CAPS_PRIVATE_KEY_BASE64}"
EOF
```

3. Create a StaticInstance resource in the cluster; specify the IP address of the static node server:

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-worker-1
  labels:
    role: worker
spec:
  # Specify the IP address of the static node server.
  address: "<SERVER-IP>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
EOF
```

4. Create a NodeGroup resource in the cluster. Value of `count` defines number of `staticInstances` which fall under the `labelSelector` that will be bootstrapped and joined into the `nodeGroup`, in this example this is `1`:

> **i** The `labelSelector` field in the `NodeGroup` resource is immutable. To update the `labelSelector`, you need to create a new `NodeGroup` and move the static nodes into it by changing their labels.

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: worker
EOF
```

> **i** If it is necessary to add nodes to an existing node group, specify the desired number in the `.spec.count` field of the NodeGroup.

Using Cluster API Provider Static for multiple node groups

This example shows how you can use filters in the StaticInstance label selector to group static nodes and use them in different NodeGroups. Here, two node groups (`front` and `worker`) are used for different tasks. Each group includes nodes with different characteristics — the `front` group has two servers and the `worker` group has one.

1. Prepare the required resources (3 servers or virtual machines) and create the `SSHCredentials` resource in the same way as step 1 and step 2 of the example.
2. Create two NodeGroup in the cluster (from this point on, use `kubectl` configured to manage the cluster):

   > **i** The `labelSelector` field in the `NodeGroup` resource is immutable. To update the `labelSelector`, you need to create a new `NodeGroup` and move the static nodes into it by changing their labels.

   ```
   d8 k create -f - <<EOF
   apiVersion: deckhouse.io/v1
   kind: NodeGroup
   metadata:
     name: front
   spec:
     nodeType: Static
     staticInstances:
       count: 2
       labelSelector:
         matchLabels:
           role: front
   ---
   apiVersion: deckhouse.io/v1
   kind: NodeGroup
   metadata:
     name: worker
   spec:
     nodeType: Static
     staticInstances:
       count: 1
       labelSelector:
         matchLabels:
           role: worker
   EOF
   ```

3. Create StaticInstance resources in the cluster and specify the valid IP addresses of the servers:

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-front-1
  labels:
    role: front
spec:
  address: "<SERVER-FRONT-IP1>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
---
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-front-2
  labels:
    role: front
spec:
  address: "<SERVER-FRONT-IP2>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
---
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-worker-1
  labels:
    role: worker
spec:
  address: "<SERVER-WORKER-IP>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
EOF
```

Cluster API Provider Static: Moving Instances Between Node Groups

⚠ During the process of transferring instances between node groups, the instance will be cleaned and re-bootstrapped, and the `Node` object will be recreated.

This section describes the process of moving static instances between different node groups (NodeGroup) using the Cluster API Provider Static (CAPS). The process involves modifying the NodeGroup configuration and updating the labels of the corresponding StaticInstance.

Initial Configuration

Assume that there is already a NodeGroup named `worker` in the cluster, configured to manage one static instance with the label `role: worker`.

`NodeGroup` worker:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: worker
```

`StaticInstance` static-worker-1:

```
apiVersion: deckhouse.io/v1alpha2
kind: StaticInstance
metadata:
  name: static-worker-1
  labels:
    role: worker
spec:
  address: "192.168.1.100"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
```

Steps to Move an Instance Between Node Groups

1. Create a New `NodeGroup` for the Target Node Group

Create a new NodeGroup resource, for example, named `front`, which will manage a static instance with the label `role: front`.

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: front
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: front
EOF
```

2. Update the Label on the `StaticInstance`

Change the `role` label of the existing StaticInstance from `worker` to `front`. This will allow the new NodeGroup `front` to manage this instance.

```
d8 k label staticinstance static-worker-1 role=front --overwrite
```

3. Decrease the Number of Static Instances in the Original `NodeGroup`

Update the NodeGroup resource `worker` by reducing the `count` parameter from `1` to `0`.

```
d8 k patch nodegroup worker -p '{"spec": {"staticInstances": {"count": 0}}}' --type=merge
```

An example of the `NodeUser` configuration

```
apiVersion: deckhouse.io/v1
kind: NodeUser
metadata:
  name: testuser
spec:
  uid: 1100
  sshPublicKeys:
    - "<SSH_PUBLIC_KEY>"
  passwordHash: <PASSWORD_HASH>
  isSudoer: true
```

An example of the `NodeGroupConfiguration` configuration

Installing the cert-manager plugin for kubectl on master nodes

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: add-cert-manager-plugin.sh
spec:
  weight: 100
  bundles:
  - "*"
  nodeGroups:
  - "master"
  content: |
    if [ -x /usr/local/bin/kubectl-cert_manager ]; then
      exit 0
    fi
    curl -L https://github.com/cert-manager/cert-
manager/releases/download/v1.7.1/kubectl-cert_manager-linux-amd64.tar.gz -o - | tar
-zxvf - kubectl-cert_manager
    mv kubectl-cert_manager /usr/local/bin
```

Tuning sysctl parameters

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: sysctl-tune.sh
spec:
  weight: 100
  bundles:
  - "*"
  nodeGroups:
  - "*"
  content: |
    sysctl -w vm.max_map_count=262144
```

Adding a root certificate to the host

⚠ Example is given for Ubuntu OS.
The method of adding certificates to the store may differ depending on the OS.

Change the bundles and content parameters to adapt the script to a different OS.

⚠ To use the certificate in `containerd` (including pulling containers from a private repository), a restart of the service is required after adding the certificate.

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: add-custom-ca.sh
spec:
  weight: 31
  nodeGroups:
  - '*'
  bundles:
  - 'ubuntu-lts'
  content: |-
    CERT_FILE_NAME=example_ca
    CERTS_FOLDER="/usr/local/share/ca-certificates"
    CERT_CONTENT=$(cat <<EOF
    -----BEGIN CERTIFICATE-----
    MIIDSjCCAjKgAwIBAgIRAJ4RR/WDuAym7M11JA8W7D0wDQYJKoZIhvcNAQELBQAw

Adding the ability to download images from insecure container registry to containerd

The ability to download images from an insecure container registry is enabled using the `insecure_skip_verify` parameter in the containerd configuration file. For more information, see the How to add configuration for an additional registry.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The okmeter module

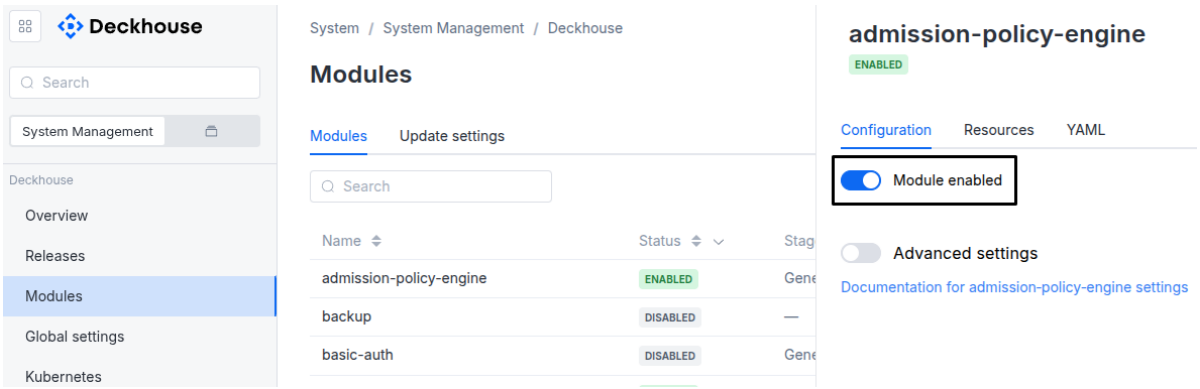
> The module lifecycle stage: General Availability

The `okmeter` module installs the Okmeter agent as a `daemonset` in the `d8-okmeter` namespace, and deletes `okmeter` installed manually.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability



The module has 1 alert.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `okmeter` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

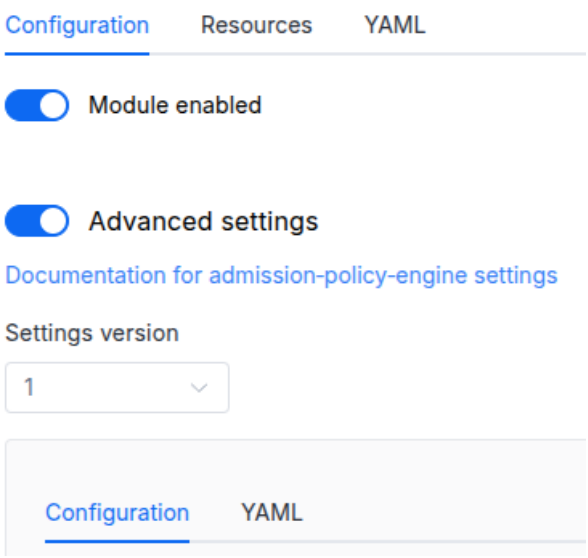
  ```
  d8 system module enable okmeter
  ```

- **Using ModuleConfig `okmeter`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `okmeter` (create it if necessary);

  Example of a manifest to enable module `okmeter`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: okmeter
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `okmeter` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `okmeter` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module

`okmeter`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `okmeter` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc okmeter
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `okmeter` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `okmeter`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: okmeter
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.apiKey**
    string

    Required value

    Key to access Okmeter API.

    You can get the key from your personal Okmeter account (`OKMETER_API_TOKEN`).

    Example:

    ```
    apiKey: 5ff9z2a3-9127-1sh4-2192-06a3fc6e13e3
    ```

  - **settings.disableAutoDiscovery**

    Disables okagent autodiscovery. Setting this option to `true` will leave only basic host monitoring, all other plugins (postgresql/mysql/redis/etc.) will be disabled. Default value is `false`

  - **settings.image**
    object
    - **settings.image.repository**
      string

      Required value

      Docker repository for okmeter agent image.

      Default: `registry.okmeter.io/agent/okagent`

    - **settings.image.tag**
      string

Required value

Okmeter agent image tag.

Default: `latest`

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    test: test
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

> The module lifecycle stage: General Availability

Example

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: okmeter
spec:
  version: 1
  enabled: true
  settings:
    apiKey: dh-test-secret-0123456789abcdef
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The openvpn module

> The module lifecycle stage: General Availability

> Web interfaces associated with the module: openvpn-admin

The openvpn module allows peers to authenticate each other using certificates and provides a simple web interface.

Using the web interface, you can:

- Issue certificates.
- Revoke certificates.
- Cancel certificate revocation.
- Get a ready-to-use custom configuration file.

Integrating with the user-authn module lets you manage user access to the web interface.

Exposing the VPN service

1. Select one or more external IP addresses for connection.
2. Use one of the connection methods:
   - By external IP address (`ExternalIP`) - if there are nodes with public IP addresses.
   - Using `LoadBalancer` - for all cloud providers and their placement schemes that support LoadBalancer ordering.
   - `Direct` - configure the traffic path manually: from the entry point to the cluster to the pod with OpenVPN.

Available cluster resources after connecting to the VPN

The following parameters are pushed to the user's computer after connecting to the VPN:

- The `kube-dns` address is added to the client's DNS servers to allow direct access to Kubernetes services via FQDN.
- A route to the local network.
- A route to the cluster service network.
- A route to the Pod network.

User's traffic audit

The module can log user's activity via VPN in JSON format. Traffic is grouped by `src_ip`, `dst_ip`, `src_port`, `dst_port`, `ip_proto` fields. Using the log-shipper module, container logs can be collected and stored for later auditing.

Third-party components

List of third-party software used in the `openvpn` module:

- OpenVPN 2.6.12

  License: Mixed

  A secure tunneling daemon.

- OpenSSL 3.3.2

  License: Apache License 2.0

  TLS/SSL and crypto library.

- Libcap-ng 0.8.5

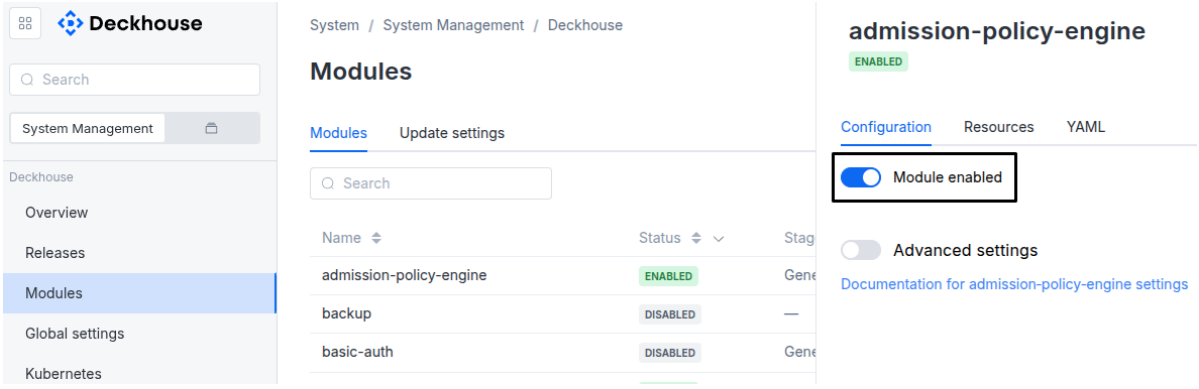
  License: GNU General Public License v2.0

  Libcap-ng is a library for Linux that makes using posix capabilities easy..

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability



The module has 9 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `openvpn` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

  ```
  d8 system module enable openvpn
  ```

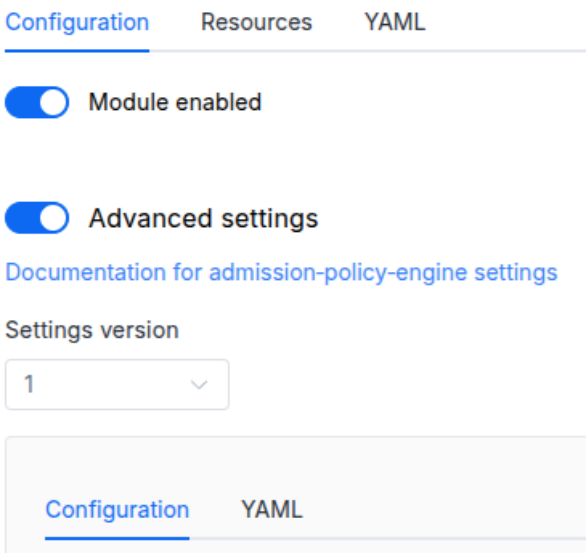
- **Using ModuleConfig `openvpn`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `openvpn` (create it if necessary);

  Example of a manifest to enable module `openvpn`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: openvpn
  spec:
    enabled: true
  ```

How to configure the module...



You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `openvpn` module and enable the “Advanced Settings” switch. Fill in the required fields in the

"Configuration" tab or specify the module settings in YAML format on the "YAML" tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `openvpn` on the "YAML" tab in the module settings window ("System" → "System Management" → "Deckhouse" → "Modules", open the module `openvpn`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `openvpn` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc openvpn
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `openvpn` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `openvpn`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: openvpn
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Conversion description is missing.

Actions performed by the conversion (jq syntax)...

- `del(.auth.password) | if .auth == {} then del(.auth) end`
- `del(.storageClass)`

Parameters

Schema version: 2

- **settings**
  object
  - **settings.auth**
    object

    Options related to authentication or authorization in the application.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module's public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

      An array of user groups that can access the OpenVPN admin panel.

      This parameter is used if the user-authn module is enabled or the externalAuthentication parameter is set.

      > **Caution!** Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

    - **settings.auth.externalAuthentication**
      object

      Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

      > **Note!** External authentication is enabled automatically if the user-authn module is enabled.

      - **settings.auth.externalAuthentication.authSignInURL**
        string

        The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

      - **settings.auth.externalAuthentication.authURL**
        string

        The URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

    - **settings.auth.whitelistSourceRanges**
      array of strings

      The CIDR range for which authentication to access the OpenVPN is allowed.

  - **settings.clientCertExpirationDays**
    integer

    Certificate client expired period for OpenVPN in days. Specifies the number of days for which a client certificate generated using EasyRSA will be issued.

    Client certificate lifetime must be at least 1 day and no more than 10 years.

    Default: `3650`

    Allowed values: `1 <= X <= 3650`

- **settings.externalHost**
  string

  An IP address or a domain clients use to connect to the OpenVPN server.

  By default, data from an `openvpn-external` service are used.

- **settings.externalIP**
  string

  The IP address of a cluster node to connect OpenVPN clients.

  It is only required if the `ExternalIP` inlet is used.

- **settings.externalPort**
  integer

  The port to expose on the `externalIP` or load balancer.

  Default: `5416`

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

- **settings.hostPort**
  integer

  Port to connect to the OpenVPN server, which will be available on the node where it is scheduled.

  The parameter is available when selecting inlet `HostPort`.

  Default: `5416`

- **settings.https**
  object

  What certificate type to use with the OpenVPN admin panel.

  This parameter completely overrides the `global.modules.https` settings.

  Example:

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object
    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for the OpenVPN admin panel (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.https.customCertificate**
    object
    - **settings.https.customCertificate.secretName**
      string

      The name of the Secret in the `d8-system` namespace to use with the OpenVPN admin panel (this Secret must have the kubernetes.io/tls format).

      Default: `false`

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager` — the OpenVPN admin panel will use HTTPS and get a certificate from the ClusterIssuer defined in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate` — the OpenVPN admin panel will use the certificate from the `d8-system` namespace for HTTPS.
  - `Disabled` — in this mode, the OpenVPN admin panel works over HTTP only.
  - `OnlyInURI` — the OpenVPN admin panel will work over HTTP (thinking that there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). All the links in the user-authn will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for the OpenVPN admin panel.

  By default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.inlet**
  string

  The way the connection is implemented.

  The following inlet types are supported:

  - `ExternalIP` — when there are nodes with public IPs. It is used together with the `externalIP` parameter.
  - `LoadBalancer` — for all cloud providers and cloud-based placement strategies that support the provision of LoadBalancers.
  - `HostPort` — the port of the OpenVPN server will be available on the node where it is scheduled. The port can be configured in the `hostPort` parameter.
  - `Direct` — for non-standard cases. You need to create a service called `openvpn-external` in the `d8-openvpn` namespace. It will route traffic to the Pod with the `app: openvpn` label to the port called `ovpn-tcp` (or just 1194). This service provides the externalIP, the IP address of the balancer or its host. If none of these are present, you need to specify the `externalHost` parameter.

  Allowed values: `ExternalIP`, `LoadBalancer`, `HostPort`, `Direct`

- **settings.loadBalancer**
  object

  A section of optional parameters of the `LoadBalancer` inlet.

  - **settings.loadBalancer.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

    > **i** **Note** that module does not take into account the specifics of setting annotations in different clouds. If annotations for the provision of the load balancer are only used when the service is being created, then you need to restart the module (disable/enable it) to update them.

  - **settings.loadBalancer.sourceRanges**
    array of strings

    A list of CIDRs that are allowed to connect to the Load Balancer.

    The cloud provider may not support this option or ignore it.

- **settings.nodeSelector**
  object

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

If the parameter is omitted or `false`, it will be determined automatically.

- **settings.pmacctEnabled**
  boolean

  Enable logging of user's activity via VPN in JSON format.

  All connections within `tun` interfaces will be collected via `libpcap` and logged as `{"event_type": "purge", "ip_src": "172.25.175.10", "ip_dst": "10.222.0.10", "port_src": 32172, "port_dst": 53, "ip_proto": "udp", "packets": 1, "bytes": 53}`

  Default: `false`

- **settings.pushDefaultGatewayToClient**
  boolean

  Routing all client traffic through the VPN. A default route will be added to clients.

  Default: `false`

- **settings.pushToClientDNS**
  string

  The IP address of the DNS server to send to clients upon connection.

  By default, the IP address of the `kube-system/kube-dns` service is used.

- **settings.pushToClientRoutes**
  array of strings

  A list of routes to send to clients upon their connection.

  By default, this list is generated automatically using the local cluster network, service subnet, and Pod subnet.

  Example:

  ```
  pushToClientRoutes:
  - 172.25.176.0/24
  - 172.25.178.0/255.255.255.0
  ```

- **settings.pushToClientSearchDomains**
  array of strings

  A list of search domains to send to clients upon connection.

  The default value is a value from the `global.discovery.clusterDomain` variable.

- **settings.tcpEnabled**
  boolean

  Default: `true`

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string
- **settings.tunnelNetwork**
  string

  Tunnel network for OpenVPN server.

Default: `172.25.175.0/24`

Examples:

```
tunnelNetwork: 172.25.175.0/24
```

```
tunnelNetwork: 172.25.178.0/255.255.255.0
```

- **settings.udpEnabled**
  boolean

  Default: `false`

Authentication

user-authn module provides authentication by default. You can also configure authentication using the externalAuthentication parameter. If these options are disabled, the module will use basic auth with the auto-generated password.

To view the generated password, run the command:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values openvpn -o json | jq '.openvpn.internal.auth.password'
```

To generate a new password, delete the Secret:

```
d8 k -n d8-openvpn delete secret/basic-auth
```

> The `auth.password` parameter is deprecated.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

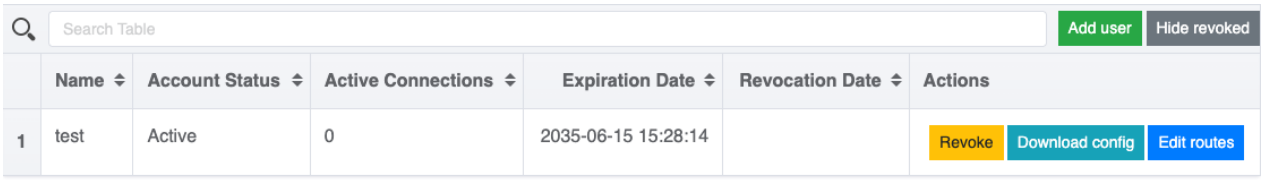
Why doesn’t automatic DNS server configuration work when connecting to macOS and Linux using the OpenVPN client

Due to the architectural features of the Linux and macOS operating systems, automatic DNS server configuration when using the official OpenVPN client is not possible.

To configure the DNS server on such operating systems, the service provides the ability to use third-party scripts that run when the client connects or disconnects.

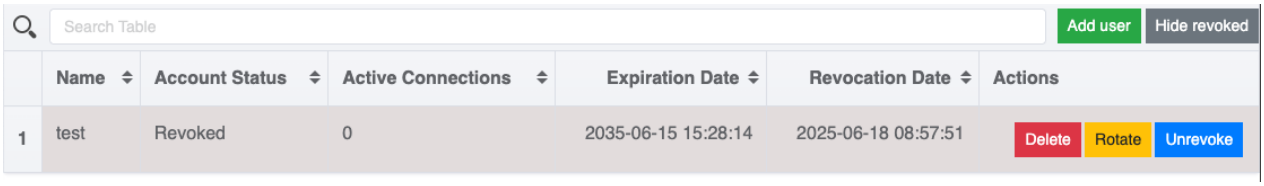
In the client configurations generated by the module, the blocks responsible for these settings are predefined and commented out:

```
# Uncomment the lines below for use with Linux
#script-security 2
# If you use resolved
#up /etc/openvpn/update-resolv-conf
#down /etc/openvpn/update-resolv-conf
# If you use systemd-resolved, first install the openvpn-systemd-resolved package
#up /etc/openvpn/update-systemd-resolved
#down /etc/openvpn/update-systemd-resolved
```



To use these code blocks, uncomment them (remove the initial `#` symbol), and specify the correct paths to the scripts.

You can either prepare the scripts yourself or use ready-made scripts from the official OpenVPN Community (for Linux). For macOS, you can use a third-party script.



⚠ Scripts must have execution permissions.

How to revoke, rotate or delete a user certificate

All operations with client certificates are performed via the openvpn-admin web interface. Buttons for managing certificates are available to the right of each user's name:

To rotate (issue a new certificate) or delete a client, you must first revoke their current certificate:

Once revoked, the Renew (rotation) and Delete (removal) actions become available.

How to rotate a server certificate

The server certificate is rotated automatically several days before it expires.

If you need to rotate the certificate manually (e.g., due to certificate corruption or an unscheduled replacement), follow these steps:

1. Delete the secret `openvpn-pki-server` in the namespace `d8-openvpn`:

   ```
   d8 k -n d8-openvpn delete secrets openvpn-pki-server
   ```

2. Restart the OpenVPN pods to trigger the generation of a new certificate:

   ```
   d8 k -n d8-openvpn rollout restart sts openvpn
   ```

A new certificate will be generated automatically when the pods start.

How to rotate a root certificate (CA)

The root certificate (CA) and server certificate are rotated automatically 1 day before expiration. Automatic rotation of clients certificates is not provided. The root certificate (CA) is used to sign all certificates in OpenVPN — both server and client. Therefore, when replacing the CA, you must reissue all dependent certificates.

Steps to rotate the root certificate:

1. Revoke or delete all active client certificates using the openvpn-admin web interface. If you choose to revoke certificates, you can rotate them later (Renew) after the CA is replaced, without recreating the clients.
2. Delete secrets `openvpn-pki-ca` and `openvpn-pki-server` in the namespace `d8-openvpn`:

   ```
   d8 k -n d8-openvpn delete secrets openvpn-pki-ca openvpn-pki-server
   ```

3. Restart OpenVPN pods:

   ```
   d8 k -n d8-openvpn rollout restart sts openvpn
   ```

4. Rotate certificates of revoked users, or create new ones.
5. Delete all revoked certificate secrets:

   ```
   d8 k -n d8-openvpn delete secrets -l revokedForever=true
   ```

  name: openvpn
spec:
  version: 2
  enabled: true
  settings:
   inlet: ExternalIP
   externalIP: 5.4.54.4
```

An example for AWS & Google Cloud

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: openvpn
spec:
  version: 2
  enabled: true
  settings:
    inlet: LoadBalancer
```

An example for an external load balancer with a public IP address

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: openvpn
spec:
  version: 2
  enabled: true
  settings:
    externalHost: 5.4.54.4
    externalIP: 192.168.0.30 # The internal IP address to forward the external LB's
traffic to.
    inlet: ExternalIP
    nodeSelector:
      kubernetes.io/hostname: node
```

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Registry Module

Included in extensions: **Advanced Infrastructure Security, Billing**

⚠ The module lifecycle stage: Preview

The module is used to manage the pull paths for container images of Deckhouse Platform (DP) components, and for images from additional registries (vendor or your own).

The current implementation of the module and the v1 implementation, used in DP up to and including 1.77, are described below.

A cluster where the v1 implementation of this module has never run uses the current one right away. A cluster where the v1 implementation has run keeps using it until it is switched to the `Unmanaged` state, after which the migration completes on its own. The process is described in How does the migration to the registry module work.

Current implementation

Modes of operation

The module can run in one of the following modes (selected with the `mode` parameter):

- `Unmanaged` (the default mode). In this mode the module does not manage the pull paths of DP components. With `mode: Unmanaged` the cluster keeps pulling images from the registry it was installed with (set during cluster bootstrap in the `deckhouse` parameter in InitConfiguration). None of the module's components are created in this mode.
- `Managed`. In this mode the module manages the pull paths for container images. The cluster administrator hands the pull path to the module by setting the `mode: Managed` parameter.

  In this mode (when the module manages the pull paths) the following independent settings are used:

  - `primary.upstream` — the registry images are pulled from. If not set, the cluster is considered air-gapped: the only source becomes the in-cluster cache, filled with the `d8 mirror push` command.
  - `storage.cache` — controls the in-cluster cache on the control-plane nodes. If set, a registry is deployed on the control-plane nodes. All nodes pull images from it, with the upstream

staying a fallback path while the cache is being filled.

Turning the cache on or off, changing the registry, changing credentials — each of these is an ordinary reconfiguration, possible at any time and in any order. Exactly one change has a condition attached: when the upstream is removed to go air-gapped, the module waits until the in-cluster cache holds the whole expected image set and no workload in the `kube-system` and `d8-*` namespaces references the upstream any more — only then do images stop being pulled from the registry set in `primary.upstream`. Workloads in other namespaces are not counted: move the ones whose images reference the upstream address onto the in-cluster address before removing the upstream. While this is in progress, the `D8RegistryAirGapTransitionHeld` alert fires. If the switch to the in-cluster cache happened right after the upstream was removed, every node could be left with nowhere to pull images from.

The cache reclaims its own disk space. Nothing else ever removes data from it — every release adds a slice of the repository — so a sweep removes the slices of releases the cluster has already passed through, keeping the deployed release and the one before it. It runs on a schedule (nightly by default), once the cache holds a new image set — after a Deckhouse Platform update, or after a module is enabled or updated — and when the store refuses writes. A sweep does not interrupt serving, but it pauses filling the replica's store and can fail a `d8 mirror push` started during it, which is why it defaults to a nighttime hour. It can also be run right away with a RegistryOperation object. For details, see the `storage.garbageCollection` parameter and the FAQ section The cache keeps growing. What reclaims it.

The `primary.upstream` and `storage.cache` parameters together cover every supported configuration:

primary.upstream	storage.cache	What the cluster does
set	`false`	Nodes pull images directly from the upstream. Nothing is deployed on the control-plane nodes
set	`true`	The cache acts as a pass-through: filled from the upstream on demand and ahead of time
not set	`true`	Air-gapped. The cache is the only source, and `d8 mirror push` is the only way in
not set	`false`	The configuration is rejected: nodes would have nowhere to pull images from

Installer behavior when no container image registry is configured

The installer creates the `registry` ModuleConfig with `mode: Managed` and `primary.upstream` pointing to the public Deckhouse Open/CE registry `registry.deckhouse.io/deckhouse/ce`, and warns about it in its output when the installation configuration specifies no container image registry in any of the following places:

- InitConfiguration
- The `registry` section of the `deckhouse` ModuleConfig
- The `registry` ModuleConfig (the ModuleConfig is absent)

This applies only when the installation configuration contains a ClusterConfiguration and the container runtime is managed by Deckhouse Platform (`defaultCRI` is `Containerd` or `ContainerdV2`). In a Managed Kubernetes cluster (without ClusterConfiguration) and with `defaultCRI: NotManaged`, the installer does not create this ModuleConfig.

Under the same conditions, the installer rejects a configuration in which the `registry` ModuleConfig sets `mode: Unmanaged` (or omits `mode`, which means the same) or `enabled: false` and no registry is specified elsewhere. In this case, the nodes would have nowhere to pull images from. Specify the registry from which nodes pull images directly in one of the following ways:

- Via the `deckhouse` parameter in InitConfiguration (`imagesRepo` and `registryDockerCfg`).
- By setting `mode: Managed` with `primary.upstream` in the `registry` ModuleConfig. A private or mirror registry populated with `d8 mirror push` can serve as `primary.upstream`. To install an air-gapped cluster from an image bundle instead, set `enabled: true` and `mode: Managed` with `storage.cache: true` and `storage.source`, without `primary.upstream`, and pass the bundle to the installer with the `--img-bundle-path` flag.

The installer also refuses a `registry` ModuleConfig that specifies `primary` or `storage` without `mode: Managed`, as the module's schema does: in the default `Unmanaged` mode these settings would have no effect.

Additional registries

`primary.upstream` is deliberately the only registry configurable through the module. It is used for the images of DP components. Additional registries (a vendor's, needed by some module, or your own) are declared as a separate RegistryUpstream resource. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryUpstream
metadata:
  name: virtualization-images
spec:
  match: images.virtualization.example.com
  upstream:
    host: vendor.example.com
    path: /virtualization
    auth:
      username: robot
      password: <PASSWORD>
```

This approach — declaring an additional registry as a separate resource — was chosen because a module or a user adding their own registry should not have to edit a ModuleConfig they don't own. Such registries are always transit: pulls are routed through the node agent so that credentials and CA certificates live in one place, but nothing from them is ever cached.

Architecture

The node agent

On every node of the cluster, an agent (registry-agent) is deployed as a static pod. The container runtime is pointed at it (`127.0.0.1:5001`, through containerd's `_default` fallback directory) and gets access to registries through it, passing the original registry name along in the request.

This achieves the following:

- **Node configuration is static.** Adding a registry, turning the in-cluster cache on, rotating credentials — none of this changes the configuration on any node, because the container runtime accesses registries through the agent.
- **Registry credentials stay out of the runtime's configuration files.** They are held by the agent and attached to every request.
- **Credentials are not stored in the module's resources.** A RegistryNode, a RegistryStorage, and the recorded effective upstream name a key in one Secret instead of carrying the credential itself. These are cluster-scoped resources, and the permission to read them is granted to every node, so a credential inside any of them would be readable through the API by every kubelet in the cluster. Each component's access is narrowed to that one Secret by name, and the credential it resolved is kept together with its own copy of the routing.
- **Pulling images works when the API server is unavailable.** The agent keeps a copy of its routing on disk and falls back to it, because the images it serves include the ones needed to repair a broken control plane. A node that could not reach the API server uses the routing it was installed with.

An unconfigured registry is proxied untouched, along with whatever credentials the request already carried — so an ordinary `imagePullSecret` for a third-party registry keeps working, with nothing needing to be declared for it.

The in-cluster cache

With `storage.cache` enabled, a registry runs on each control-plane node. It stores blobs (the files an image is made of) in the cache directory: `/var/lib/deckhouse/registry` when the master NodeGroup has `systemType: DeckhouseEngine`, `/opt/deckhouse/registry` otherwise. One control-plane node holds the lease and fills from the upstream; the others replicate data from the leading replica (the one holding the lease) ahead of time, so losing the leader does not mean filling from scratch. For details on how the leading replica is chosen, see Leader election.

Agents reach a replica by the node's address, not by the service name `registry.d8-`

`system.svc:5001`. `registry.d8-system.svc:5001` is what every image reference in the cluster is built from, and what a request is matched against. But the agent runs in the host's network namespace, where the cluster DNS name does not resolve.

A replica serves on port `4281/TCP` of its control-plane node: the agents of every node connect to it, and so do the other replicas when they replicate. The publication endpoint behind the Ingress is port `4283/TCP` of the same nodes, reached from the nodes running the ingress controller. Both are in the 4200-4299 range and are listed in "Network interaction of the platform components". The `5001` in the service name is not the cache's port: on every node, `127.0.0.1:5001` is the agent.

That address (which agents use to reach a replica) takes effect in two steps, and the order matters. Nodes are given it as soon as the module starts managing the pull path, through the same bashible rollout that installs the agent. The image references of the platform's own components move only after every node's agent has applied the configuration it was given: no node resolves this address except through the agent, so re-rendering the cluster onto it any earlier would point every workload at something that cannot be pulled yet. Until then, references keep naming the registry the cluster was installed with — which is also where they return if the module is set to `Unmanaged` or disabled. Whether this step has happened is visible from the presence of the ConfigMap `registry-image-address` in `d8-system`.

The Deckhouse controller pulls through the same agent — at `127.0.0.1:5001` — its own release channel and the module sources it owns. A different address, but the same agent: the controller is a process and has to dial a connection, whereas an image reference is resolved by the container runtime, which a drop-in redirects to the agent, so it can name a service that nothing ever connects to. This is exactly what makes changing the registry a single change: the configuration is edited in one place, the agents are reconfigured, and both what the nodes pull and what the controller fetches follow — with no registry address for the controller written down anywhere, and so none that could be left pointing at the old one.

> ⚠ Use a separate disk for the cache directory and for etcd data. Sharing one disk degrades etcd while the cache is being filled.

The expected image set

The cache holds the expected image set: the images of the deployed DP release and of the previous one (for a rollback), the images of the modules the cluster runs, and the catalog of modules the module sources offer. Updates the cluster lists as pending — of DP and of modules — are copied too, ahead of time: the replicas receive an update before it is deployed, in an air-gapped cluster as soon as `d8 mirror push` has put it into the store. An update the source does not hold yet does not hold the cache back; it is copied when it is deployed at the latest. The replicas copy only while one of them is short of the set or a pending update has appeared; after that, nothing is copied until the set changes again.

Replication

The followers copy from the leader's read port, the one the nodes pull through. A follower writes only into its own store, through its own write port, and no replica uses another replica's write port, so between control-plane nodes replication needs only the read port. The leader's write port still has to be reachable from the nodes that run the ingress controller: the publication endpoint forwards `d8 mirror push` to it (see Air-gapped clusters). What a follower can get from the leader's read port depends on whether an upstream is set:

- With an upstream, the leader's read port is a pull-through cache for the upstream's images: an image the leader does not hold yet, it fetches from the upstream to answer the follower, and keeps. A follower therefore does not wait for the leader to finish filling. An image that a replication pass still leaves missing (`pending_on_the_leader` in the syncer's `the replication finished` log line) is one the leader has not got yet: for example, a module from another module source, which the leader fills from that source's own registry rather than through the upstream, or an image the upstream could not serve at that moment. A later pass picks it up.
- Without an upstream, the leader serves only what it holds. An image missing on the leader is missing at the source: `d8 mirror push` has not brought it yet.

Only the copy ahead of pending updates is rate-limited: it reads from its source at no more than 16 MiB/s, so that it does not take a control-plane node's CPU away from etcd and the API server. The leader's fill of the expected set and the followers' replication of it are not limited: until a store holds the set, nodes pull through the upstream, and a follower without the set is a replica the cluster cannot fall back on (in an air-gapped cluster, there is nothing else to fall back on). The followers replicate independently of each other, so all of them read from the leader at the same time, each copying

several layers at once, on top of the nodes' own pulls. None of this is configurable in the ModuleConfig.

Leader election

The leader fills the store and is the source the other replicas copy from, so the lease is not handed out by a plain election:

- When some replica holds the whole expected image set, a leader that cannot complete the set by itself steps aside for that replica. A leader cannot complete the set by itself when there is no upstream, when its last pass failed, when its store refuses writes, or when it has stopped renewing the lease.
- A leader that is still completing the set from the upstream keeps the lease even if a follower finishes first: the follower copies from the leader, and moving the lease would gain nothing.
- While no replica holds the whole set, as in a new cluster, the lease does not move: every move would start the fill over on another replica. If there is no leader at all, the lease goes to the replica that holds the most verified images; ties are broken by node name. A replica whose registry does not answer or whose disk refuses writes is passed over, and so is one whose store is out of room while another replica has room. A failed pass alone does not pass a replica over: what it holds is still counted from its store.

So an incomplete replica can be the leader, either while no replica is full or while it is filling from the upstream. The fields that show this are described in the FAQ.

The rule that a full replica takes over matters most in an air-gapped cluster. There the leader gets images only from `d8 mirror push`, which always lands on the leader, and the followers copy only what the leader holds. An incomplete leader beside a full follower (for example, a leader whose store was lost) could not complete the set, the followers would replicate its gaps, and the images on the full replica would reach nobody.

A replica whose node has been reported unreachable for a minute (about two minutes after the node stops responding) is not counted in the election, so the replicas that are left do not wait for a leader whose node is gone. A replica whose registry stops answering or whose disk stops accepting writes reports an error and hands the lease over to a replica that holds the full expected image set, if there is one; otherwise it keeps the lease and only reports the error.

After the leader's node fails, a new leader takes over in about a minute in an air-gapped cluster and in two to three minutes in a cluster with an upstream. While no replica holds the full expected image set yet, it can take up to about three and a half minutes, and two minutes more if the replica holding the most images does not take the lease. Nodes pull from the leader only, so until the new leader takes over and the nodes' configuration follows it, they pull from the upstream if one is configured; in an air-gapped cluster, pulls of images that are not already on the node wait for the new leader. The other replicas keep their data, so a new leader that holds the full expected image set fills nothing again.

While no replica holds the full expected image set, the replica that takes the lease may hold fewer images than another one, or none: the replica holding the most images is passed over if its node is unreachable or if it does not take the lease within two minutes. The new leader then fills what it lacks again, from the upstream, or, in an air-gapped cluster, from what is pushed again with `d8 mirror push`. It keeps the lease until some replica holds the full expected image set, even after the replica holding more images comes back.

A leader whose store has lost the expected image set, for example after the cache directory on its node was wiped, gives up the lease while another replica holds the whole set: it checks the deployed release and a sample of the set on its own disk about once a minute, and at startup. It reports `full: false` and `verifiedDigests: 0`, the replica that holds the set becomes the leader, and the former leader copies the set from it like any other replica. If no other replica holds the whole set, the leader keeps the lease, since it is still the one that fills the set, but reports `full: false` and `verifiedDigests: 0` all the same: `safeToDropUpstream` becomes `false`, and the leader fills the set again from the upstream (in an air-gapped cluster, counts its store again).

A replica whose store holds at most half as many manifests as its `verifiedDigests` (by `totalDigests`) stops reporting the set within about a minute and a half of the loss: the leader as described above, and a replica that does not hold the lease by reporting `full: false` and reading its store again. A smaller loss on a replica that does not hold the lease is reported no later than at its next periodic check of its store, every six hours by default. After the leader's syncer restarts, `safeToDropUpstream` stays `false` until the running syncer has read its store, normally at its first pass, within about two minutes, so a report left by the previous process cannot drop the upstream.

What protects the ports on control-plane nodes

The cache runs in the host network, so its ports are open on the address of every control-plane node, to

anything that can reach that address: other nodes, pods, and hosts outside the cluster if the network lets them through. The module ships no host firewall policy for these ports (for example, Cilium host policies). Restricting who can reach a control-plane node at the network level is left to the cluster's own firewall. Each port protects itself as follows:

Port	Purpose	Protection
`4281/TCP`	Reading: the agents of all nodes pull through it, the other replicas replicate from it.	TLS with the module's own certificate authority. Every request needs a token from the module's token service. The read credentials, which every node uses to get one, are on every node, so whoever has taken them from any node and can reach this port can pull everything the cache holds. The port does not accept writes, whatever the credentials: a push or a delete is refused, in an air-gapped cluster as well, where the port serves the store itself rather than a cache in front of an upstream. The store accepts writes only on `4283/TCP`, which requires a client certificate.
`4283/TCP`	Writing: `d8 mirror push` through the Ingress, and the replica's own filling, replication and garbage collection.	Mutual TLS. The connection is refused during the TLS handshake unless the client presents a certificate issued by the module's certificate authority to the ingress controller or to the cache's own pod. After that, the write credentials are checked. `whitelistSourceRanges` is applied by the Ingress only: the port does not filter by source address. A connection made directly to the port, or to the `registry-push` Service inside the cluster, without such a certificate fails at TLS.
`4285/TCP`	Metrics.	`kube-rbac-proxy`: a request needs a token of a subject allowed to get the `prometheus-metrics` subresource of the `registry-storage` StatefulSet in `d8-system`. The registry's own metrics and debug listeners are behind it, on the loopback.

The ingress controller presents its certificate for any Ingress that names the `d8-system/registry-storage-ingress-client` secret, not only for the module's own. An ingress-nginx controller that lets an Ingress use a secret of another namespace (the `allow-cross-namespace-resources` option, enabled by default in controller versions before 1.12, 1.10 among them) therefore lets anyone who can create an Ingress and a Service in any namespace reach `4283/TCP` through them, outside `whitelistSourceRanges`. The write credentials are still checked on that path. To close it, turn `allow-cross-namespace-resources` off in the controller's configuration: the module's own Ingress is in `d8-system`, beside the secret, and keeps working.

A replica whose pod was created before `4281/TCP` started refusing writes still accepts a push on that port in an air-gapped cluster, until the pod is replaced. The `registry-storage` StatefulSet is updated with `OnDelete`: the module replaces the pods one at a time, each only while something else can serve the nodes in its place: another replica, the upstream, or, for the only replica of an air-gapped cache, its new images already held on its master node (see How is the cache updated?). While a replacement waits, the module records an `UpdateBlocked` event on the `d8-system/registry-storage` StatefulSet.

Do not delete the pod to hurry this along. The new pod pulls its images from the store it is itself part of:

deleted before they are on its node, the only replica of an air-gapped cache stays in `ImagePullBackOff`, and until it is back no node of the cluster can pull any image.

Air-gapped clusters

If no upstream is set in `primary.upstream`, the in-cluster cache is the only source of images, and images get into it only with `d8 mirror push`.

`d8 mirror push` writes through the publication endpoint: the `registry-push` Ingress in the `d8-system` namespace, at the `registry` domain built from publicDomainTemplate. The endpoint exists whenever the cache is enabled, `publicDomainTemplate` is set and the `cert-manager` module is enabled, including while an upstream is set, so that the images can be pushed before the upstream is removed. A push always lands on the leader; while there is no leader, it is refused.

This is the one path that can replace an image, so a push needs both credentials with write access — the account in the `registry-storage-push` Secret in `d8-system`, meant for `d8 mirror push` — and the client certificate the ingress presents to the storage: a leaked password alone is not enough. The certificate is also what tells the storage that the client address passed by the ingress can be trusted. To limit who can reach the endpoint, set `whitelistSourceRanges`. A push sent straight to a control-plane node, around the endpoint, is refused on either port of the cache. For what protects each port, including on a replica whose pod has not been replaced yet after an update, see What protects the ports on control-plane nodes.

If `publicDomainTemplate` is not set or the `cert-manager` module is disabled, an air-gapped cluster has no way to write into the store: `4281/TCP` refuses writes, and `4283/TCP` admits only the ingress controller and the cache itself. To bring images in, either set `publicDomainTemplate` and enable `cert-manager` (the endpoint appears on the next run of the module), or set `primary.upstream` to a registry the cluster can reach that holds the images, let the cache fill from it, and remove the upstream again.

Installing from a bundle

An air-gapped cluster can also be installed straight from a bundle made with `d8 mirror pull`. To do so, set `mode: Managed` in the `registry` ModuleConfig, enable `storage.cache` with its `storage.size`, describe the bundle in `storage.source`, set no `primary.upstream`, and pass the bundle to the installer with `--img-bundle-path`:

```
spec:
  enabled: true
  settings:
    mode: Managed
    storage:
      cache: true
      size: 50Gi
      source:
        bundleRef: d8-mirror-bundle
        expectedDigests: 459
```

A temporary registry on the first control-plane node serves the bundle until the in-cluster cache starts on that node, and the installer then hands the node over to the cache.

Installing from a bundle has the following limitations:

- In a cloud cluster, the `cloud-controller-manager` must be able to initialize the first control-plane node, which means the cloud API must be reachable from the cluster. Until the node loses the `node.cloudprovider.kubernetes.io/uninitialized` taint, the cache cannot be placed on it. The installer waits for that, and if it does not happen, it stops with an error naming the node and keeps the temporary registry, so that the node is not left with nothing to pull images from.
- A master NodeGroup with `systemType: DeckhouseEngine` does not support installing from a bundle: such a node runs none of the steps that set up the temporary registry. The installer refuses this combination before it creates any infrastructure. To install such a cluster without internet access, push the bundle with `d8 mirror push` into a registry inside your perimeter, and set `mode: Managed` with `primary.upstream` pointing at that registry.

Requirements for using the module

Before enabling the `registry` module to manage the pull paths for container images, make sure the cluster meets the following requirements:

- Nodes use containerd or containerd v2, set with the `defaultCRI` parameter in ClusterConfiguration.
- The cluster is fully managed by DP. The module does not work in Managed Kubernetes.
- The in-cluster cache uses disks on the control-plane nodes, in static and cloud clusters alike. In a cloud cluster that is the control-plane node's root disk unless another one is mounted at the cache directory (`/var/lib/deckhouse/registry` when the master NodeGroup has `systemType: DeckhouseEngine`, `/opt/deckhouse/registry` otherwise). That disk must hold `storage.size` plus the reserve the store keeps free for the node, on top of what the node itself uses. Size `storage.size` for three releases of the image set together with the modules and the module catalog; see What happens when the cache's store is full?.

The v1 implementation

The v1 implementation of the module, used in DP up to and including 1.77, is described below. DP 1.78 no longer contains it; the description is kept because clusters are still running on it, and moving to the new configuration is work for the administrator that has to be done before the cluster is upgraded, not after.

✖ Prepare the cluster BEFORE upgrading to DP 1.78: the upgrade is blocked while the cluster uses the v1 implementation and the module is running in `Proxy` or `Local` mode, or in `Direct` mode without a configured `registry` ModuleConfig.

Installing DP 1.78 or later, or upgrading to it, does not create any objects of the v1 implementation. A new installation with `Proxy` or `Local` in the `deckhouse` ModuleConfig is refused by the installer: configure this module instead. The v1 implementation's modes are switched only by the code of DP 1.77 and earlier — so all preparation happens before upgrading to DP 1.78. Preparation has the following specifics:

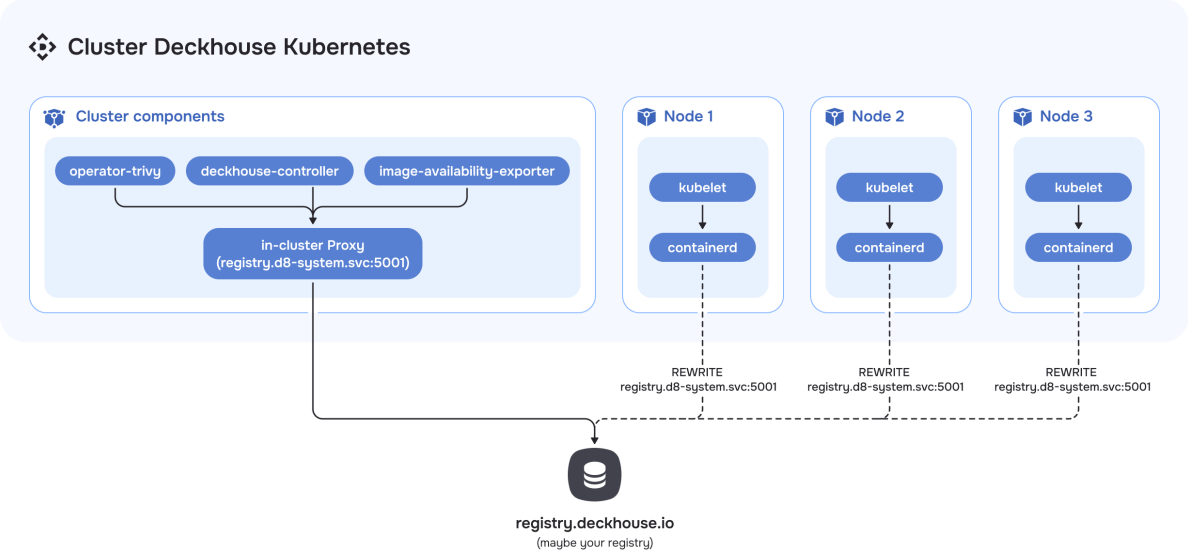
- If the cluster uses the v1 implementation of the `registry` module running in `Proxy` mode, it must be switched to `Unmanaged` mode.
- If a cluster with the v1 implementation of the `registry` module is air-gapped (the module runs in `Local` mode), switching straight to `Unmanaged` mode does not work. Air-gapped clusters have a separate procedure, described in How do I migrate an air-gapped cluster from Local mode.
- If the cluster uses the v1 implementation of the `registry` module running in `Direct` mode, no mode switch is needed — only this module's configuration, written before the upgrade. Its objects are kept deliberately — DP 1.77 marks them to survive the removal of the v1 implementation — and they keep serving the in-cluster address nodes pull through, until this module's agent has taken that address over. The procedure is described in migrating from Direct mode.

In the v1 implementation of the module, working with the registry is configured not through the module's own settings, but through the `deckhouse` ModuleConfig, and it works as a state machine with four modes:

- `Direct` — direct access to an external registry through the fixed address `registry.d8-system.svc:5001/system/deckhouse`. The fixed address is what keeps Deckhouse images from being re-downloaded, and components from restarting, when registry parameters change.
- `Proxy` — an internal caching proxy registry on the control-plane nodes, reachable at that same fixed address; it reduces the number of requests to the external registry.
- `Local` — a full local copy of the registry inside the cluster, for air-gapped environments.
- `Unmanaged` — no in-cluster registry; the cluster reaches the external one directly. Comes in a configurable form, managed through the `deckhouse` ModuleConfig, and a deprecated non-configurable form, set at installation.

Of the four v1 modes listed above, two survive an upgrade to DP 1.78, for different reasons. `Unmanaged` is the mode whose objects served nothing to begin with, so removing them takes nothing away, and the handover happens on its own. `Direct` survives because the address its nodes pull images through is also served by the `registry` module: DP 1.77 marks the objects behind that address so that they outlive the removal of the v1 implementation, and they keep serving it until the agent takes it over — meaning such a cluster needs this module's configuration rather than a mode switch. Both paths are described in how does the migration to the `registry` module work. The two implementations never manage a cluster at the same time: whichever one is active decides what gets created at all, so there is no state where both configure the same node.

`Proxy` and `Local` modes leave nodes in a state that DP 1.78 and later cannot correctly account for or carry over. So the v1 implementation running in these modes is switched to `Unmanaged` first. That switch is only possible on DP 1.77 or earlier — that is, before upgrading to DP 1.78, which no longer contains the v1 implementation.

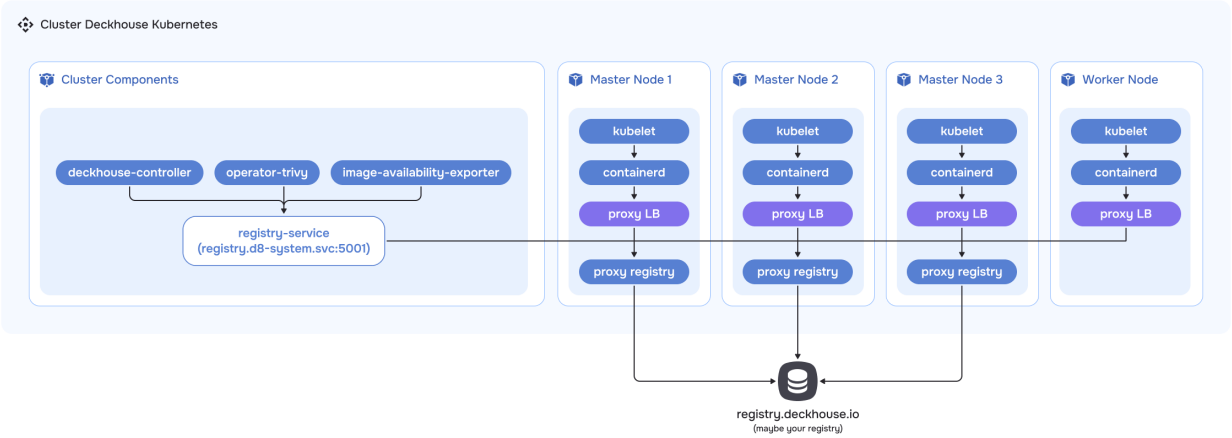


Mode switching restrictions

The restrictions on switching modes in the v1 implementation are as follows:

- Changing registry parameters and switching modes is only available after the bootstrap phase is fully complete.
- For the first switch, migrate the user's registry configurations first — the procedure is described in the FAQ.
- Switching to the non-configurable `Unmanaged` mode is only available from `Unmanaged`.

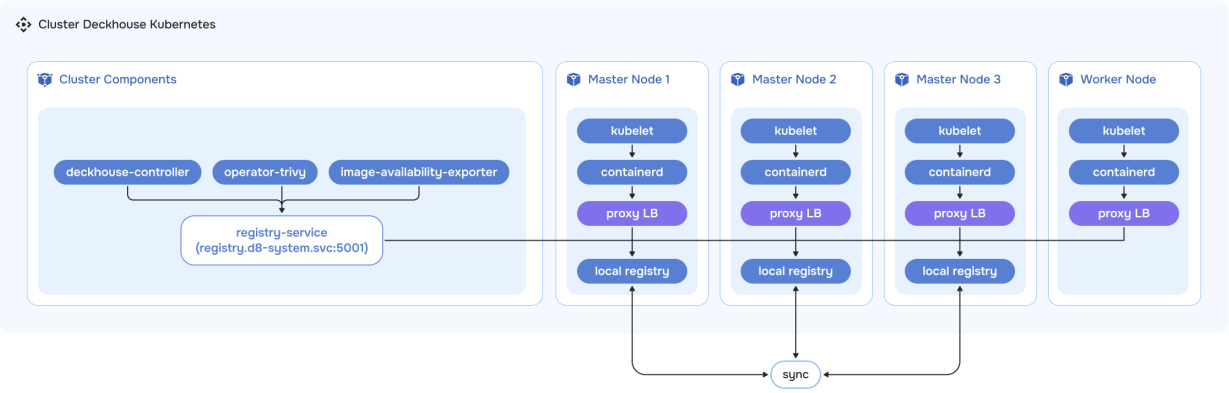
Direct mode architecture



In `Direct` mode, requests to the registry are processed without intermediate caching. CRI requests are redirected based on the containerd configuration. Components that access the registry directly — `operator-trivy`, `image-availability-exporter`, `deckhouse-controller`, and others — go through the in-cluster proxy on the control-plane nodes.

Proxy mode architecture

> ⚠ It is recommended to use separate disks for storing registry data (`/opt/deckhouse/registry`) and etcd data. Using a single disk may lead to etcd performance degradation while the registry is operating.



The caching proxy registry runs as static pods on the control-plane nodes and stores cached data in `/opt/deckhouse/registry`. A load balancer sits in front of it on each node, and the containerd configuration points at that load balancer. Components that access the registry directly go through the caching proxy registry.

Local mode architecture

⚠ It is recommended to use separate disks for storing registry data (`/opt/deckhouse/registry`) and etcd data. Using a single disk may lead to etcd performance degradation while the registry is operating.

`Local` mode keeps a full copy of the registry inside the cluster, synchronized between replicas on the control-plane nodes and populated with the `d8` tool using `d8 mirror push`/`d8 mirror pull`. Otherwise it works the same way as the caching proxy.

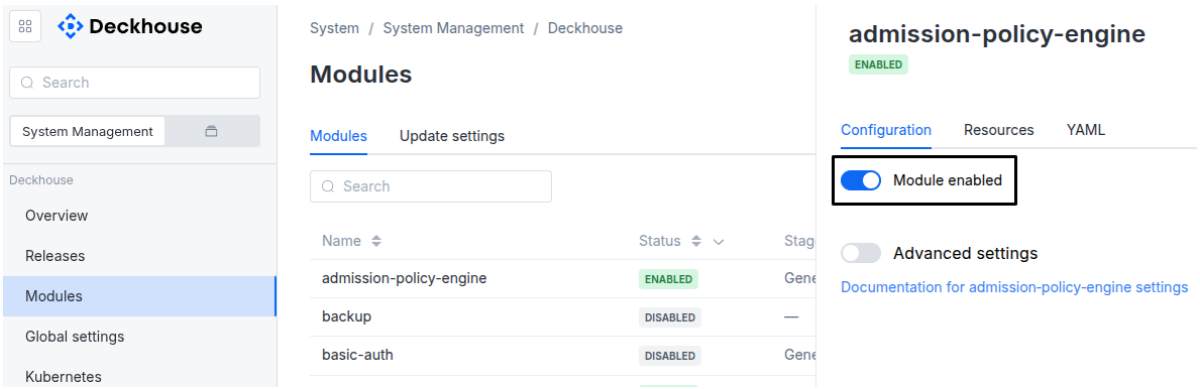
ℹ **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Module registry: configuration

ℹ Included in extensions: **Advanced Infrastructure Security, Billing**

⚠ The module lifecycle stage: Preview



The module has 21 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

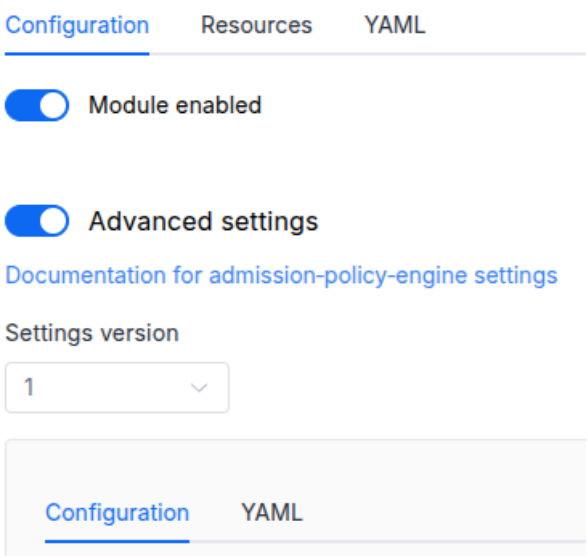
  ```
  d8 system module enable registry
  ```

- **Using ModuleConfig `registry`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `registry` (create it if necessary);

  Example of a manifest to enable module `registry`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: registry
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `registry` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module

`registry`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `registry` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc registry
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `registry` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `registry`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: registry
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.https**
    object

    What certificate type to use.

    This parameter completely overrides the `global.modules.https` settings.

    Examples:

    ```
    https:
      mode: Disabled
    ```

    ```
    https:
      mode: OnlyInURI
    ```

    ```
    https:
      mode: CustomCertificate
      customCertificate:
        secretName: foobar
    ```

    ```
    https:
      mode: CertManager
      certManager:
        clusterIssuerName: letsencrypt
    ```

    - **settings.https.certManager**
      object

Parameters for certmanager.

- **settings.https.certManager.clusterIssuerName**
  string

  What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

  Default: `letsencrypt`

  Example:

  ```
  clusterIssuerName: letsencrypt
  ```

- **settings.https.customCertificate**
  object

  Parameters for custom certificate usage.

  - **settings.https.customCertificate.secretName**
    string

    The name of the secret in the `d8-system` namespace to use with the registry ingress.

    This secret must have the kubernetes.io/tls format.

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager`: The registry ingress is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate`: The registry ingress is accessed over HTTPS using a certificate from the `d8-system` namespace.
  - `Disabled`: In this mode, the registry ingress can only be accessed over HTTP.
  - `OnlyInURI`: The registry ingress will work over HTTP (thinking that there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). Load balancer should provide a redirect from HTTP to HTTPS.

  Default: `CertManager`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for the registry.

  Optional. By default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.mode**
  string

  Whether the module manages how the cluster pulls images.

  - `Unmanaged` — the module manages nothing. No components are created and no node configuration is written; the cluster keeps pulling from the registry it was installed with. This is the default, so enabling the module changes nothing on its own.

    Asking for `Unmanaged` on a cluster the module was managing does not take effect instantly: image references all over the cluster name the in-cluster registry, and they move to the upstream one only as each module's release is rendered again. So the module stops advertising its address at once and keeps serving it until nothing names it any more, which normally takes a few minutes. On a cluster that was installed with the module already managing, it also writes the registry it was fetching from back into the cluster's registry credentials — otherwise nothing would remember where images come from, since the installer had put the in-cluster registry there. Until then its components are still running, and `D8RegistryDrainStuck` reports a withdrawal that cannot finish.

  - `Managed` — the module owns the pull path: it configures the container runtime on every

node through its node agent, and optionally runs an in-cluster cache.

There is no choice of implementation. A cluster that has never run the v1 implementation of this module (DP up to and including 1.77) always uses the current one; a cluster that has runs the v1 implementation until it is brought to its `Unmanaged` state, after which the migration completes on its own.

Default: `Unmanaged`

Allowed values: `Managed`, `Unmanaged`

- **settings.primary**
  object

  The single authoritative source of Deckhouse component images. Applies only when `mode` is `Managed`.

  Additional registries are declared as separate RegistryUpstream resources rather than here: a module or a user bringing their own registry must not have to edit a ModuleConfig owned by someone else.

  - **settings.primary.upstream**
    object

    The registry to pull Deckhouse component images from.

    If omitted, the cluster is air-gapped: the in-cluster cache becomes authoritative and is populated with `d8 mirror push`. Omitting it requires `storage.cache: true` and `storage.source`.

    Example:

    ```
    upstream:
      host: registry.deckhouse.io
      path: "/deckhouse/ee"
      scheme: HTTPS
      auth:
        license: DECKHOUSE_LICENSE_KEY
    ```

    - **settings.primary.upstream.auth**
      object

      Credentials for the registry.

      - **settings.primary.upstream.auth.license**
        string

        The Deckhouse license key.

        A shorthand for the `username`/`password` pair used with `registry.deckhouse.io`. Mutually exclusive with them.

        Changing the license changes the registry credentials, so it goes through the same preflight probe as an address change: the new credentials are verified before the cluster is switched over, and the last known good ones are kept if the probe fails.

      - **settings.primary.upstream.auth.password**
        string

        The password for basic authentication.

      - **settings.primary.upstream.auth.username**
        string

        The username for basic authentication.

    - **settings.primary.upstream.ca**
      string

      A PEM-encoded certificate authority bundle used to verify the registry when `scheme` is `HTTPS`.

      If not specified, the system trust store is used.

    - **settings.primary.upstream.host**

string

Required value

The registry host, optionally with a port.

Without a protocol and repository prefix, they are specified in `scheme` and `path`, respectively.

Pattern: `^[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?(\.[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?)*(:[0-9]{1,5})?$`

Length: `1..255`

Examples:

```
host: registry.deckhouse.io
```

```
host: my-private-registry.com:5000
```

- **settings.primary.upstream.mirrors**
  array of objects

  Additional addresses serving **the same** content as the primary registry, used for failover and load balancing.

  Mirrors are not separate sources: the cache holds one de-duplicated set regardless of which mirror the images came from. A registry with different content is an additional upstream and belongs in a RegistryUpstream resource.

  - **settings.primary.upstream.mirrors.auth**
    object

    Credentials for the registry.

    - **settings.primary.upstream.mirrors.auth.license**
      string

      The Deckhouse license key.

      A shorthand for the `username`/`password` pair used with `registry.deckhouse.io`. Mutually exclusive with them.

      Changing the license changes the registry credentials, so it goes through the same preflight probe as an address change: the new credentials are verified before the cluster is switched over, and the last known good ones are kept if the probe fails.

    - **settings.primary.upstream.mirrors.auth.password**
      string

      The password for basic authentication.

    - **settings.primary.upstream.mirrors.auth.username**
      string

      The username for basic authentication.

  - **settings.primary.upstream.mirrors.ca**
    string

    A PEM-encoded certificate authority bundle used to verify the mirror.

  - **settings.primary.upstream.mirrors.host**
    string

    Required value

    The mirror host, optionally with a port.

    Without a protocol and repository prefix, they are specified in `scheme` and `path`, respectively.

    Pattern: `^[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?(\.[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?)*(:[0-9]{1,5})?$`

Length: `1..255`

- **settings.primary.upstream.mirrors.path**
  string

  The repository prefix inside the mirror.

- **settings.primary.upstream.mirrors.scheme**
  string

  The protocol used to reach the mirror.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **settings.primary.upstream.path**
  string

  The repository prefix inside the registry.

  Example:

  ```
  path: "/deckhouse/ee"
  ```

- **settings.primary.upstream.scheme**
  string

  The protocol used to reach the registry.

  Use `HTTP` only for insecure, trusted registries.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **settings.storage**
  object

  The in-cluster registry cache. Applies only when `mode` is `Managed`.

  - **settings.storage.cache**
    boolean

    Whether pulls go through the in-cluster cache on the master nodes.

    This is one of the two configuration axes; the other is whether `primary.upstream` is set. Together they cover every supported layout:

    - `cache: false` with an upstream — nodes pull straight from the upstream, no cache is deployed.
    - `cache: true` with an upstream — a pass-through cache, filled from the upstream.
    - `cache: true` without an upstream — air-gap: the cache is the only source of images and is filled with `d8 mirror push`.

    Turning the cache on or off is a safe, idempotent reconfiguration. Removing the upstream while the cache is on is the one transition with a condition: it takes effect only once the cache leader holds the whole expected image set, so nodes are never cut off.

    Default: `false`

  - **settings.storage.garbageCollection**
    object

    When the cache reclaims the disk taken by releases the cluster has moved past.

    Needed because nothing else ever removes anything: every release adds a slice of the repository, so a cluster that lives for years fills its store and then stops being able to pull.

    A collection does not interrupt serving: the replica keeps serving every image it holds. It does not start while the store is being filled or a `d8 mirror push` is in progress, and while it runs the replica stops filling its own store. A `d8 mirror push` started during a collection can fail and has to be retried. Only one replica collects at a time, so the others are unaffected.

    - **settings.storage.garbageCollection.enabled**

boolean

Whether the cache reclaims its disk on its own: on the schedule, once it holds a new image set, and when it refuses writes.

Turning this off leaves the store to grow without bound, which only makes sense with a disk large enough that it never matters. A collection created by hand as a RegistryOperation object still runs.

Default: `true`

- **settings.storage.garbageCollection.schedule**
  string

  A five-field cron expression, in UTC.

  Defaults to a night hour. If the `master` node group has a maintenance window, the start of that window is used instead — that being a time the operator has already declared safe for disruption.

  Pattern: `^\s*\S+\s+\S+\s+\S+\s+\S+\s+\S+\s*$`

  Examples:

  ```
  schedule: 17 3 * * *
  ```

  ```
  schedule: 0 2 * * Sun
  ```

- **settings.storage.size**
  string

  How much the cache may hold on each master: the budget of its store, which the registry enforces on every write.

  Once the store holds this much, it refuses new writes — a fill, a replication, a `d8 mirror push` — and keeps serving everything it holds. It never deletes anything to make room; that is the garbage collection's job.

  Independently of this value, the store never takes the space kept free on its filesystem: on a filesystem shared with the node, the kubelet's soft eviction threshold (10% of the filesystem, at most 40 GiB) plus a margin (10%, at most 20 GiB); on a disk of the store's own, the margin alone. So an unset or too large value cannot fill a master's disk — but it leaves the reserve as the only limit, which the `D8RegistryStoreUnbounded` alert reports.

  The reserve is taken from the full size of the filesystem, while free space does not include the blocks the filesystem keeps for root. On ext4 these are 5% by default, so on a filesystem under 200 GiB the store and everything else on it get about 75% of the disk rather than 80%.

  Size it for three releases of the image set (the deployed one, the previous one kept for a rollback, and the next one) together with the modules the cluster runs and the catalog of modules the module sources offer. A replica copies the next release ahead of the update only while the room it has left, in the budget and on the filesystem above the reserve, is at least a fifth of the budget (or of the filesystem, when `storage.size` is not set); with an upstream this applies to every replica. In an air-gapped cluster the next release arrives on the leader with `d8 mirror push` and needs that room, and the other replicas copy it from the leader under the same rule. The store holds the union of the releases' images: a layer they share is stored once. Make sure the value fits on the disk under the store above the reserve.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

  ```
  size: 50Gi
  ```

- **settings.storage.source**
  object

  The image set the cache is expected to hold.

  Required in an air-gapped cluster: with no upstream to fall back on, completeness must be decidable before the cache can be trusted as the only source.

        - **settings.storage.source.bundleRef**
          string

          The name of the image set, for example the bundle pushed with `d8 mirror push`.

          Example:

          ```
          bundleRef: d8-mirror-bundle
          ```

        - **settings.storage.source.expectedDigests**
          integer

          The number of distinct digests the set contains.

          Allowed values: `0 <= X`

          Example:

          ```
          expectedDigests: 459
          ```

    - **settings.whitelistSourceRanges**
      array of strings

      A list of CIDR-formatted addresses allowed to connect to the registry's publication endpoint, the Ingress that `d8 mirror push` writes through. If not specified, connections from any address are allowed.

      Applied by the Ingress only. The write port of the in-cluster cache behind it (`4283/TCP` on the control-plane nodes) does not filter by source address: it refuses any connection without a client certificate that the module's certificate authority issued to the ingress controller or to the cache's own pods. The cache's read port (`4281/TCP`) does not accept writes at all, so the write port is the only one a push can land on.

      The ingress controller presents its certificate for any Ingress that names the module's ingress client secret. If the controller lets an Ingress use a secret of another namespace (`allow-cross-namespace-resources`, enabled by default in ingress-nginx before 1.12), an Ingress of any namespace can reach the write port this way, outside this list; the write credentials are still checked. See What protects the ports on control-plane nodes.

      Example:

      ```
      whitelistSourceRanges:
      - 10.0.0.0/10
      - 192.168.0.0/16
      ```

        - **Element of the array**
          string

          Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))?$`

RegistryConfig

Short names: rcfg

Scope: Cluster
Version: v1alpha1

Defines the resolved registry configuration of the cluster.

In normal operation the object is rendered by the module from ModuleConfig/registry. It is a contract rather than Deckhouse property: an administrator may edit it directly when the Deckhouse operator is unavailable, and the change is applied on the fly by the registry controller and the storage syncer without a helm re-render.

Only one object named `registry` is used.

- **spec**
  object

  Required value

  - **spec.mode**
    string

    Whether the module manages the image pull path.

    - `Managed` — the module owns the pull path and creates its components.
    - `Unmanaged` — the module owns nothing; no components are created.

    Default: `Managed`

    Allowed values: `Managed`, `Unmanaged`

  - **spec.primary**
    object

    The single authoritative source of Deckhouse component images.

    Additional registries are declared as separate RegistryUpstream objects. More than one primary source is not supported: it would make both “is the cache complete” and “what fills the cache in an air-gapped cluster” ambiguous.

    - **spec.primary.upstream**
      object

      The registry to pull Deckhouse component images from.

      If omitted, the cluster is air-gapped: the in-cluster cache becomes authoritative and is populated out of band with `d8 mirror push`. Omitting it requires `storage.cache: true`.

      - **spec.primary.upstream.auth**
        object

        Credentials for the registry.

        Sensitive. Credentials are stored inline in the object rather than referenced from a Secret, so that the node agent stays self-sufficient while the API server is unreachable. Restrict access to registry resources accordingly.

        - **spec.primary.upstream.auth.auth**
          string

          Pre-encoded `base64("username:password")`.

          Takes precedence over `username` and `password` when set.

          If the caller is not allowed to read the `registryconfigs/sensitive` subresource, the API returns `<omitted>` instead of the value.

        - **spec.primary.upstream.auth.password**
          string

          The password for basic authentication.

          If the caller is not allowed to read the `registryconfigs/sensitive` subresource, the API returns `<omitted>` instead of the value.

        - **spec.primary.upstream.auth.username**

string

The username for basic authentication.

- **spec.primary.upstream.ca**
  string

  A PEM-encoded certificate authority bundle used to verify the registry when `scheme` is `HTTPS`.

  If omitted, the system trust store is used.

- **spec.primary.upstream.host**
  string

  Required value

  The registry host, optionally with a port.

  Example:

  ```
  host: registry.deckhouse.io
  ```

- **spec.primary.upstream.mirrors**
  array of objects

  Additional addresses serving **the same** content as the primary registry, used for failover and load balancing.

  Mirrors are not separate sources. The storage caches one de-duplicated set regardless of which mirror the images were pulled from.

  - **spec.primary.upstream.mirrors.auth**
    object

    Credentials for the mirror.

    Sensitive. See `primary.upstream.auth`.

    - **spec.primary.upstream.mirrors.auth.auth**
      string

      Pre-encoded `base64("username:password")`.

      If the caller is not allowed to read the `registryconfigs/sensitive` subresource, the API returns `<omitted>` instead of the value.

    - **spec.primary.upstream.mirrors.auth.password**
      string

      The password for basic authentication.

      If the caller is not allowed to read the `registryconfigs/sensitive` subresource, the API returns `<omitted>` instead of the value.

    - **spec.primary.upstream.mirrors.auth.username**
      string

      The username for basic authentication.

  - **spec.primary.upstream.mirrors.ca**
    string

    A PEM-encoded certificate authority bundle used to verify the mirror.

  - **spec.primary.upstream.mirrors.host**
    string

    Required value

    The mirror host, optionally with a port.

    Example:

    ```
    host: registry-mirror.example.com
    ```

  - **spec.primary.upstream.mirrors.path**

string

The repository prefix inside the mirror.

- **spec.primary.upstream.mirrors.scheme**
  string

  The protocol used to reach the mirror.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.primary.upstream.path**
  string

  The repository prefix inside the registry.

  Example:

  ```
  path: "/deckhouse/ee"
  ```

- **spec.primary.upstream.scheme**
  string

  The protocol used to reach the registry.

  Use `HTTP` only for insecure, trusted registries.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.storage**
  object

  Configures the in-cluster registry cache.

  - **spec.storage.cache**
    boolean

    Whether pulls go through the in-cluster cache on the master nodes.

    This is the first of the two configuration axes. The second is whether `primary.upstream` is set. Together they replace the former mode state machine:

    - `cache: false` with an upstream — the agent forwards pulls straight to the upstream and no storage is needed.
    - `cache: true` with an upstream — a pass-through cache, filled from the upstream.
    - `cache: true` without an upstream — air-gap: the cache is authoritative and is filled with `d8 mirror push`.

    Default: `false`

  - **spec.storage.garbageCollection**
    object

    When the cache reclaims the disk taken by releases the cluster has moved past.

    Nothing else ever removes anything: every release adds a slice of the repository, so a cluster that lives for years fills its store and then stops being able to pull.

    A collection does not interrupt serving: the replica keeps serving every image it holds. It does not start while the store is being filled or a `d8 mirror push` is in progress, and while it runs the replica stops filling its own store. A `d8 mirror push` started during a collection can fail and has to be retried. Only one replica collects at a time, so the others are unaffected.

    - **spec.storage.garbageCollection.enabled**
      boolean

      Whether the cache reclaims its disk on its own: on the schedule, after a new image set, and when the store refuses writes. A RegistryOperation created by hand runs either way.

    - **spec.storage.garbageCollection.schedule**
      string

A five-field cron expression, in UTC.

Defaults to a night hour, or to the start of the `master` node group's maintenance window when one is set.

- **spec.storage.size**
  string

  The size of the persistent volume backing the cache.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

  ```
  size: 50Gi
  ```

- **spec.storage.source**
  object

  The image set the cache is expected to hold.

  Required in an air-gapped cluster: with no upstream to fall back on, completeness must be decidable before it is safe to serve from the cache alone.

  - **spec.storage.source.bundleRef**
    string

    The name of the image set, for example the bundle pushed with `d8 mirror push`.

    Example:

    ```
    bundleRef: d8-mirror-bundle
    ```

  - **spec.storage.source.expectedDigests**
    integer

    The number of distinct digests the set contains.

    Allowed values: `0 <= X`

    Example:

    ```
    expectedDigests: 459
    ```

- **status**
  object
  - **status.conditions**
    array of objects

    The health summary written by the registry controller.

    - `Valid` — the resolved configuration is coherent.
    - `UpstreamValid` — the result of the preflight probe of the primary upstream: reachable, credentials accepted, sentinel content in place. `False` means the controller is holding the last known good upstream and has **not** switched over, so a broken license or a wrong address cannot take the cluster down.
    - `StorageConverged` — the storage has reached the state the configuration asks for.
    - **status.conditions.lastTransitionTime**
      string

      Required value

      When the condition last changed.

    - **status.conditions.message**
      string

      A human-readable explanation.

    - **status.conditions.observedGeneration**
      integer

      The `spec` generation the condition was set for.

    - **status.conditions.reason**

string

Required value

A machine-readable reason for the condition.

- **status.conditions.status**
  string

  Required value

  The condition status.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  The condition type.

- **status.effectiveUpstream**
  object

  The upstream actually in effect, which is not necessarily the configured one.

  This is the controller’s own record of the last upstream that passed its preflight probe, and it is what makes a bad change survivable: entering credentials that do not work, or switching to a license without access, leaves this field — and the cluster — on the previous working upstream, while the `UpstreamValid` condition reports why.

  It also holds the upstream through the air-gap transition, where the configuration already says “none” but the cache is not complete yet.

  Empty means no upstream is in effect: either the cluster is air-gapped, or nothing has been configured yet.

  - **status.effectiveUpstream.ca**
    string

    A PEM-encoded certificate authority bundle used to verify the registry.

  - **status.effectiveUpstream.host**
    string

    The registry host, optionally with a port.

  - **status.effectiveUpstream.mirrors**
    array of objects

    Additional addresses serving the same content.

    - **status.effectiveUpstream.mirrors.ca**
      string

      A PEM-encoded certificate authority bundle used to verify the mirror.

    - **status.effectiveUpstream.mirrors.host**
      string

      Required value

      The mirror host, optionally with a port.

    - **status.effectiveUpstream.mirrors.path**
      string

      The repository prefix inside the mirror.

    - **status.effectiveUpstream.mirrors.scheme**
      string

      The protocol used to reach the mirror.

      Allowed values: `HTTP`, `HTTPS`

  - **status.effectiveUpstream.path**
    string

The repository prefix inside the registry.

- **status.effectiveUpstream.scheme**
  string

  The protocol used to reach the registry.

  Allowed values: `HTTP`, `HTTPS`

- **status.effectiveUpstreamAuthDigest**
  string

  Identifies the credentials in effect without disclosing them.

  Needed because “has the configuration changed?” has to include the credentials: a rotated license under an unchanged address is exactly the change that must be probed before the cluster is switched onto it. With the credentials no longer recorded here, comparing this against a digest of the configured ones is what keeps that question answerable.

- **status.observedGeneration**
  integer

  The `spec` generation the controller last acted on.

RegistryNode

Short names: rnode

Scope: Cluster
Version: v1alpha1

Defines the complete registry layout of a single node, as compiled for its agent.

One object per node, named after the node, with an `ownerReference` on it. Written by the registry controller; `status` is written by the agent only.

The object is **flat** and, apart from one deliberate reference, self-contained: certificate authority bundles and routes are inlined, and the agent keeps a full copy on disk so it keeps serving images while the API server is unreachable — at which point there is nothing left to dereference. The exception is credentials: they are named rather than held (`auth.secretRef` points at the Secret this module resolves them into), which is what lets every node read this object without also reading every registry credential in the cluster. For the same reason the controller compiles every accepted RegistryUpstream into `spec.additionalRoutes` instead of having the agent watch N objects: consistency across many objects cannot be guaranteed when the API is down.

The object carries **no per-node secrets**. Everything in it is global configuration, identical on every node. This is what makes it safe for the whole `system:nodes` group to read, which is how the agent gets access using the kubelet’s kubeconfig.

- **spec**
  object

  Required value

  - **spec.additionalRoutes**
    array of objects

    The accepted RegistryUpstream objects, compiled by the controller.

    Always transit, never cached: the agent proxies the pull and streams it through without writing to disk.

    - **spec.additionalRoutes.auth**
      object

      Where the credentials for this endpoint are kept.

      Named rather than carried. This resource is cluster-scoped and the node agent’s role is bound to the `system:nodes` group, so a credential written here would be readable through the API by every kubelet in the cluster — including credentials for registries that node never pulls from. The component that reads this resolves the reference once and keeps the result, so it still works when the API server does not.

      - **spec.additionalRoutes.auth.secretRef**
        object

        The Secret holding the credentials, and the key inside it.

        - **spec.additionalRoutes.auth.secretRef.key**
          string

          Required value

          Key inside it. One Secret holds every credential the module resolved, keyed by what it belongs to.

        - **spec.additionalRoutes.auth.secretRef.name**
          string

          Required value

          Name of the Secret in the `d8-system` namespace.

    - **spec.additionalRoutes.ca**
      string

      A PEM-encoded certificate authority bundle used to verify the upstream.

    - **spec.additionalRoutes.host**
      string

      Required value

      The upstream host, optionally with a port.

      Example:

      ```
      host: registry-vendor.example.com
      ```

    - **spec.additionalRoutes.match**
      string

      Required value

      The registry host intercepted on this node.

      Example:

      ```
      match: images.virtualization.example.com
      ```

    - **spec.additionalRoutes.mirrors**
      array of objects

      Additional addresses serving the same content.

        - **spec.additionalRoutes.mirrors.auth**
          object

          Where the credentials for this mirror are kept.

          Named rather than carried, for the same reason as the endpoint above: this resource is readable by every node in the cluster. A mirror can need credentials of its own, so it can name a key of its own.

            - **spec.additionalRoutes.mirrors.auth.secretRef**
              object

              The Secret holding the credentials, and the key inside it.

                - **spec.additionalRoutes.mirrors.auth.secretRef.key**
                  string

                  Required value

                  Key inside it.

                - **spec.additionalRoutes.mirrors.auth.secretRef.name**
                  string

                  Required value

                  Name of the Secret in the `d8-system` namespace.

        - **spec.additionalRoutes.mirrors.ca**
          string

A PEM-encoded certificate authority bundle used to verify the mirror.

- **spec.additionalRoutes.mirrors.host**
  string

  Required value

  The mirror host, optionally with a port.

- **spec.additionalRoutes.mirrors.path**
  string

  The repository prefix inside the mirror.

- **spec.additionalRoutes.mirrors.scheme**
  string

  The protocol used to reach the mirror.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.additionalRoutes.path**
  string

  The repository prefix inside the upstream.

- **spec.additionalRoutes.scheme**
  string

  The protocol used to reach the upstream.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.backends**
  array of objects

  The sources of the **primary** image set, in priority order.

  With the cache on, this is the storage followed by the upstream as a fallback while the cache is still filling; the upstream entry disappears from the layout when the cluster goes air-gap. With the cache off, it is the upstream alone.

  - **spec.backends.auth**
    object

    Where the credentials for this endpoint are kept.

    Named rather than carried. This resource is cluster-scoped and the node agent’s role is bound to the `system:nodes` group, so a credential written here would be readable through the API by every kubelet in the cluster — including credentials for registries that node never pulls from. The component that reads this resolves the reference once and keeps the result, so it still works when the API server does not.

    - **spec.backends.auth.secretRef**
      object

      The Secret holding the credentials, and the key inside it.

      - **spec.backends.auth.secretRef.key**
        string

        Required value

        Key inside it. One Secret holds every credential the module resolved, keyed by what it belongs to.

      - **spec.backends.auth.secretRef.name**
        string

        Required value

        Name of the Secret in the `d8-system` namespace.

  - **spec.backends.ca**
    string

A PEM-encoded certificate authority bundle used to verify the backend.

- **spec.backends.host**
  string

  Required value

  The backend host, optionally with a port.

  Example:

  ```
  host: registry.d8-system.svc:5001
  ```

- **spec.backends.mirrors**
  array of objects

  Other addresses of the same backend. The agent recognises requests that name them, but pulls the primary image set only from the endpoint.

  - **spec.backends.mirrors.auth**
    object

    Where the credentials for this mirror are kept.

    Named rather than carried, for the same reason as the endpoint above: this resource is readable by every node in the cluster. A mirror can need credentials of its own, so it can name a key of its own.

    - **spec.backends.mirrors.auth.secretRef**
      object

      The Secret holding the credentials, and the key inside it.

      - **spec.backends.mirrors.auth.secretRef.key**
        string

        Required value

        Key inside it.

      - **spec.backends.mirrors.auth.secretRef.name**
        string

        Required value

        Name of the Secret in the `d8-system` namespace.

  - **spec.backends.mirrors.ca**
    string

    A PEM-encoded certificate authority bundle used to verify the mirror.

  - **spec.backends.mirrors.host**
    string

    Required value

    The mirror host, optionally with a port.

  - **spec.backends.mirrors.path**
    string

    The repository prefix inside the mirror.

  - **spec.backends.mirrors.scheme**
    string

    The protocol used to reach the mirror.

    Default: `HTTPS`

    Allowed values: `HTTP`, `HTTPS`

- **spec.backends.name**
  string

  Required value

The backend’s role.

- `Storage` — the in-cluster cache.
- `Upstream` — the primary upstream, used either as the only backend or as a fallback while the cache fills.

Allowed values: `Storage`, `Upstream`

- **spec.backends.path**
  string

  The repository prefix inside the backend.

- **spec.backends.scheme**
  string

  The protocol used to reach the backend.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.cache**
  boolean

  The cache axis for this node.

  `true` sends the agent to the in-cluster storage, `false` straight to the primary upstream.

- **status**
  object

  Written by the agent only, reporting containerd-side facts.

  It carries no storage completeness: that is a property of the storage and lives in RegistryStorage `.status.replicas`. Any node can patch any `RegistryNode` status, because RBAC cannot scope `list/watch` by field selector, so nothing here may be load-bearing for the pull path — it is observability.

  - **status.activeBackends**
    array of strings

    The backends the agent is currently able to use.

  - **status.conditions**
    array of objects

    The detailed state reported by the agent.

    - `Reconciled` — whether the spec has been applied. The reason distinguishes a normal reconcile from one applied out of the on-disk copy (`AppliedFromCache`): the agent could not get a usable spec from the API server. Most often the credentials it references could not be read; a read of the spec that failed while the status write after it went through, as on a short API server outage, looks the same. The agent reports the fallback by writing this status, so an agent that cannot write it at all, such as one on a node cut off from the API server, leaves the previous condition in place.
    - **status.conditions.lastTransitionTime**
      string

      Required value

      When the condition last changed.

    - **status.conditions.message**
      string

      A human-readable explanation.

    - **status.conditions.observedGeneration**
      integer

      The `spec` generation the condition was set for.

    - **status.conditions.reason**
      string

      Required value

A machine-readable reason for the condition.

- **status.conditions.status**
  string

  Required value

  The condition status.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  The condition type.

- **status.observedGeneration**
  integer

  The `spec` generation the agent last applied.

- **status.proxyListening**
  boolean

  Whether the agent is serving the registry endpoint.

- **status.reconciled**
  boolean

  Whether the agent has applied the spec it currently sees.

- **status.staleStorageDataBytes**
  integer

  How much of the in-cluster cache’s data is still on this node while no cache is configured.

  The blobs are left behind deliberately when the cache is turned off: turning it back on then refills from what is already there rather than from scratch, and over a slow link that difference is hours. What would not be acceptable is keeping them silently, since nothing else in the module would ever mention the disk they occupy — so the agent measures them and an alert says so.

  To reclaim the space, remove the contents of the cache directory on the node, keeping the directory itself, which the agent has mounted: `/var/lib/deckhouse/registry` on a node of a NodeGroup with `systemType: DeckhouseEngine`, `/opt/deckhouse/registry` on other nodes. Absent while a cache is configured, and on a node that never held one.

RegistryOperation

Short names: rop

Scope: Cluster
Version: v1alpha1

An operation every replica of the registry cache performs on its own store, one replica at a time.

Images keep being served throughout.

There are three operation types:

- `GarbageCollection` removes from the cache what the releases the cluster has moved past left there.
- `Verify` reads blobs of the store and compares each with its digest: every blob, or those of the images named in `spec.verify.digests`. What does not match is recorded in `RegistryStorage.status.replicas[].corruptedBlobs`. Besides, every replica checks its whole store in the background about once an hour, so a `Verify` is for starting a check manually.
- `Repair` checks the images named in `spec.repair.digests` and replaces their broken or missing blobs with whole copies from another replica of the cache or, when the cluster has one, from the upstream. A blob is downloaded beside the store, checked against its digest and only then put in place, so no image is removed and nothing is lost if no whole copy is found. The module creates a `Repair` itself for the broken blobs a replica finds, with the cause `CorruptionDetected`.

`Verify` and `Repair` read from the disk at no more than 32 MiB/s, so a store of 15 GB takes a replica about eight minutes to check. Neither waits for a fill or a `d8 mirror push` to finish.

The module creates garbage collections itself:

- on the schedule set in `storage.garbageCollection` of the module configuration;
- once the cache holds a new image set — after a Deckhouse Platform update, or after a module is enabled or updated;
- when the store refuses writes and so can never take in a new set — once per deployed Deckhouse Platform release.

With `storage.garbageCollection.enabled: false` the module creates no operations. An operation created by hand runs either way.

A garbage collection starts on a replica only when its store is not being written to: while the cache is being filled or an image set is being pushed with `d8 mirror push`, the replica waits. A store that refuses writes — over its budget, or down to the space kept free on its filesystem — is not waited for: a fill cannot go on until something frees room. A replica that has not picked the operation up, or is still held back by its store, an hour after the operation was accepted fails with the reason `DeadlineExceeded`. Once its turn comes, a replica looks at its store again: if a fill or a push has started meanwhile, it gives the turn back and waits for the store to go quiet.

Only one operation runs at a time. An operation created while an older one is not finished fails with the reason `AnotherOperationActive`.

A replica that is gone fails with the reason `ReplicaLost`:

- a replica collecting garbage, when it has not held the Lease `registry-storage-gc` in the `d8-system` namespace for five minutes;
- a replica waiting, when its node has not been `Ready` for ten minutes.

To cancel an operation, set the label `registry.deckhouse.io/cancel: "true"` on it. A replica that has not started does not start, and a replica that is running stops. What it has already removed stays removed. Deleting the RegistryOperation object cancels an operation too, but does not stop a replica whose operation has already started.

A finished operation is deleted a day after it finished.

Examples:

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryOperation
metadata:
  generateName: gc-manual-
spec:
  type: GarbageCollection
  cause: Free space before pushing a new release.
```

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryOperation
metadata:
  generateName: verify-
spec:
  type: Verify
  cause: Check the cache after a disk failure on master-1.
  verify:
    nodes: ["master-1"]
```

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryOperation
metadata:
  generateName: repair-
spec:
  type: Repair
  repair:
    digests:
["sha256:0123456789abcdef0123456789abcdef0123456789abcdef0123456789abcdef"]
```

- **spec**
  object

Required value

Does not change once the operation is created.

- **spec.cause**
  string

  Why the operation was created, for a person reading it.

  The module sets it on the operations it creates itself.

  Maximum length: `1024`

- **spec.repair**
  object

  The `Repair` operation.

  - **spec.repair.digests**
    array of strings

    Required value

    Images, by the digest of their manifest, or single blobs, by their digest. An image is repaired together with every blob it consists of.

    The image digests are listed by `d8 k get registryimages`; the broken blobs, by `RegistryStorage.status.replicas[].corruptedBlobs`.

    - **Element of the array**
      string

      Pattern: `^sha256:[a-f0-9]{64}$`

  - **spec.repair.nodes**
    array of strings

    The replicas where the operation runs, specified by node name. Empty means every replica. An operation that names a node without a replica of the cache fails with the reason `UnknownNode`.

    - **Element of the array**
      string

      Maximum length: `253`

- **spec.type**
  string

  Required value

  What the operation does.

  - `GarbageCollection` — remove from the cache what the releases the cluster has moved past left there. The deployed release, the previous one, anything newer and every tag that is not a version are kept.
  - `Verify` — read blobs of the store and compare each with its digest. What does not match is recorded and repaired by a `Repair` the module creates.
  - `Repair` — check the images named in `spec.repair` and replace their broken or missing blobs with whole copies.

  Allowed values: `GarbageCollection`, `Verify`, `Repair`

- **spec.verify**
  object

  The `Verify` check. Absent means every blob of every replica.

  - **spec.verify.digests**
    array of strings

    Images, by the digest of their manifest, or single blobs, by their digest. An image is checked together with every blob it consists of. Empty means every blob of the store.

    The image digests are listed by `d8 k get registryimages`.

    - **Element of the array**
      string

Pattern: `^sha256:[a-f0-9]{64}$`

- **spec.verify.nodes**
  array of strings

  The nodes where the operation runs. Empty means every node. An operation that names a node without a replica of the cache fails with the reason `UnknownNode`.

  - **Element of the array**
    string

    Maximum length: `253`

- **status**
  object
  - **status.acceptedAt**
    string

    When the operation was accepted.

  - **status.deadline**
    string

    When a replica held back by a store that is being written to gives up.

    An hour after `acceptedAt`.

  - **status.finishedAt**
    string

    When the operation reached a terminal phase.

    The operation is deleted a day later.

  - **status.garbageCollection**
    object

    What a `GarbageCollection` removed, summed over the replicas.

    - **status.garbageCollection.reclaimedBytes**
      integer

      How many bytes the store shrank by: its blobs and uploads in progress, measured before the collection and after.

      Absent when the store could not be measured.

    - **status.garbageCollection.removedBlobs**
      integer

      How many blobs the sweep removed, as the registry counts them.

      A sweep also removes what an earlier one failed to, so these blobs need not belong to the images deleted in this run. Absent when the sweep did not run.

    - **status.garbageCollection.removedManifests**
      integer

      How many images were deleted by digest — the images the fill writes with no tag, where nearly all of a store’s weight is.

    - **status.garbageCollection.removedVersions**
      array of strings

      The Deckhouse Platform releases removed.

  - **status.message**
    string

    A human-readable explanation of the reason.

  - **status.phase**
    string

    Where the operation is.

    - `Pending` — no replica has started yet.
    - `Running` — at least one replica has started, and not every one has finished.
    - `Succeeded` — every replica finished the operation.

- `Failed` — the operation was refused, or a replica did not finish it.
- `Canceled` — the operation was canceled before every replica finished.

Allowed values: `Pending`, `Running`, `Succeeded`, `Failed`, `Canceled`

- **status.reason**
  string

  A machine-readable reason for the phase.

  - `Pending`: `Accepted`.
  - `Running`: `InProgress`.
  - `Succeeded`: `Completed`.
  - `Failed`: `NoCache` (the cache is turned off), `NoReplicas` (no replica of the storage has reported yet), `AnotherOperationActive`, `UnknownNode` (`nodes` names a node without a replica), `ReplicaFailed`.
  - `Canceled`: `Canceled`.
- **status.replicas**
  array of objects

  One entry per replica the operation was handed to.

  Every replica of the storage that had reported when the operation was accepted is included.

  - **status.replicas.finishedAt**
    string

    When the replica finished.

  - **status.replicas.garbageCollection**
    object

    What a `GarbageCollection` removed from the replica’s store.

    - **status.replicas.garbageCollection.reclaimedBytes**
      integer

      How many bytes the store shrank by: its blobs and uploads in progress, measured before the collection and after.

      Absent when the store could not be measured.

    - **status.replicas.garbageCollection.removedBlobs**
      integer

      How many blobs the sweep removed, as the registry counts them.

      A sweep also removes what an earlier one failed to, so these blobs need not belong to the images deleted in this run. Absent when the sweep did not run.

    - **status.replicas.garbageCollection.removedManifests**
      integer

      How many images were deleted by digest — the images the fill writes with no tag, where nearly all of a store’s weight is.

    - **status.replicas.garbageCollection.removedVersions**
      array of strings

      The Deckhouse Platform releases removed.

  - **status.replicas.message**
    string

    A human-readable explanation of the reason.

  - **status.replicas.node**
    string

    Required value

    The node the replica runs on.

  - **status.replicas.phase**
    string

    Required value

Where the replica is.

- `Pending` — the replica has not picked the operation up yet.
- `Waiting` — the replica is held back; `reason` says by what.
- `Running` — the replica is running the operation.
- `Succeeded` — the replica finished the operation.
- `Failed` — the replica did not finish the operation.
- `Skipped` — the replica left the storage before it started.
- `Canceled` — the operation was canceled before the replica finished.

Allowed values: `Pending`, `Waiting`, `Running`, `Succeeded`, `Failed`, `Skipped`, `Canceled`

- **status.replicas.reason**
  string

  A machine-readable reason for the phase.

  - `Waiting`: `Filling` (the cache is being filled), `Pushing` (an image set is being pushed with `d8 mirror push`), `Turn` (another replica is running the operation; or the replica waited a whole window for its turn and waits for the store to go quiet before waiting again).
  - `Failed`: `OperationFailed` (for a `Repair`, also when a digest could not be repaired), `DeadlineExceeded` (by `deadline`, the replica had not picked the operation up, or its store was still being written to), `TimedOut` (the replica did not report a result within 24 hours), `ReplicaLost` (the replica is gone: it stopped holding the collection lease while it collected, or its node was not `Ready` for ten minutes while it waited).
  - `Skipped`: `ReplicaGone`, `NoCache`.
  - `Canceled`: `Canceled`.
- **status.replicas.repair**
  object

  `Repair` results on the replica.

  - **status.replicas.repair.digests**
    array of objects

    One entry per digest of the operation.

    - **status.replicas.repair.digests.digest**
      string

      Required value

      The digest the operation names.

    - **status.replicas.repair.digests.message**
      string

      Why it failed, or where the whole copies came from.

    - **status.replicas.repair.digests.outcome**
      string

      Required value

      Results:

      - `Intact` — every blob matches its digest; nothing was changed.
      - `Repaired` — broken or missing blobs were replaced with whole copies.
      - `NotHeld` — the replica holds neither an image nor a blob by this digest.
      - `Failed` — a blob could not be replaced; `message` says why. The blob stays as it was.

      Allowed values: `Intact`, `Repaired`, `NotHeld`, `Failed`

    - **status.replicas.repair.digests.repairedBlobs**
      integer

      How many blobs were replaced.

- **status.replicas.startedAt**
  string

  When the replica started.

        - **status.replicas.verify**
          object

          `Verify` results on the replica.

          - **status.replicas.verify.checkedBlobs**
            integer

            The number of blobs read and compared with their digests.

          - **status.replicas.verify.checkedBytes**
            integer

            Volume of data read in bytes.

          - **status.replicas.verify.corruptedBlobs**
            array of strings

            The blobs whose content does not match their digest, sorted, at most 50.

          - **status.replicas.verify.corruptedCount**
            integer

            The number of broken blobs found, including those beyond the list limit.

          - **status.replicas.verify.missingDigests**
            array of strings

            The digests asked about that the replica holds neither as an image nor as a blob.

    - **status.startedAt**
      string

      When the first replica started.

RegistryStorage

Short names: rstor

Scope: Cluster
Version: v1alpha1

Defines how the in-cluster registry storage operates, and reports the state it is actually in.

The object is written by the registry controller and read by the syncer sidecar, which reconfigures `distribution` on the fly. This is the path that makes a credential or certificate change take effect while the Deckhouse operator is down: it never goes through a helm re-render.

It carries a real `spec` rather than being a status-only mirror, because `distribution` has to be told what to do, not merely observed.

Only one object named `registry` is used.

- **spec**
  object

  Required value

  - **spec.airGapRequested**
    boolean

    Whether the configuration asked to run without an upstream, whether or not the upstream has been dropped yet.

    This is the transition window: air-gap asked for, the upstream still held so the cluster keeps working, images arriving through `d8 mirror push` that the syncer never sees. It is what decides that completeness must be measured by reading the store rather than by counting what a copy wrote — a distinction that matters because a pass-through cache writes into its own store on every miss, so the same reading on a caching cluster would count images it merely fetched.

  - **spec.auth**
    string

    The bearer token guarding the storage.

    Sensitive. Authentication is never disabled, not even in an air-gapped cluster where the cache only serves reads.

- **spec.garbageCollection**
  object

  When and whether a replica reclaims the disk taken by releases the cluster has moved past.

  Needed because nothing else ever removes anything: every release adds a slice of the repository, so a cluster that lives for years fills its store and then stops being able to pull.

  A collection does not interrupt serving: the replica keeps serving every image it holds. It does not start while the store is being filled or a `d8 mirror push` is in progress, and while it runs the replica stops filling its own store. A `d8 mirror push` started during a collection can fail and has to be retried. Only one replica collects at a time, so the others are unaffected.

  - **spec.garbageCollection.enabled**
    boolean

    Whether the controller creates garbage collections on its own: on the schedule, after a new image set, and when the store refuses writes.

    A RegistryOperation created by hand runs either way.

  - **spec.garbageCollection.schedule**
    string

    A five-field cron expression, in UTC.

    Defaults to a night hour, or to the start of the `master` node group's maintenance window when one is set — that being the time an operator has already declared safe for disruption.

- **spec.needSync**
  boolean

  How the controller hands the syncers a fill or replication task.

  Set while any replica is short of the expected set: the leader filling from the upstream, or a follower that has not caught up with the leader. Cleared once every replica holds the set; nothing is copied until the set changes again.

- **spec.publish**
  boolean

  Whether to expose an authenticated write endpoint (Ingress) for `d8 mirror push`.

  Write credentials are separate from read credentials. The endpoint is a second listener of the same registry, served without the cache in front of the store, so publishing it costs the address the cluster pulls through nothing — one listener cannot both proxy an upstream and accept a push.

- **spec.source**
  object

  The image set that must end up in the storage.

  - **spec.source.bundleRef**
    string

    The name of the image set.

  - **spec.source.expectedDigests**
    integer

    The number of distinct digests the set contains.

    Allowed values: `0 <= X`

- **spec.store**
  object

  Where `distribution` keeps its blobs.

  - **spec.store.path**
    string

    Path on the node. Set by the module, not by the user: `/var/lib/deckhouse/registry` when the master NodeGroup has `systemType: DeckhouseEngine`, `/opt/deckhouse/registry` otherwise.

Example:

```
path: "/opt/deckhouse/registry"
```

- **spec.store.size**
  string

  The budget of each replica’s store, taken from `storage.size` of the ModuleConfig: how much its blobs and uploads in progress may take. Unset means no budget; the reserve kept free on the store’s filesystem (see `status.replicas[].store.reserveBytes`) applies either way.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.upstream**
  object

  The primary upstream, projected here by the controller.

  Set means a pass-through cache. Absent means the cache is authoritative (air-gap).

  The controller removes this field **only after the leader is full**, so nodes are never left without a source of images — even if the upstream has already been removed from the configuration by the user.

  - **spec.upstream.auth**
    object

    Where the credentials for this endpoint are kept.

    Named rather than carried. This resource is cluster-scoped and the node agent’s role is bound to the `system:nodes` group, so a credential written here would be readable through the API by every kubelet in the cluster — including credentials for registries that node never pulls from. The component that reads this resolves the reference once and keeps the result, so it still works when the API server does not.

    - **spec.upstream.auth.secretRef**
      object

      The Secret holding the credentials, and the key inside it.

      - **spec.upstream.auth.secretRef.key**
        string

        Required value

        Key inside it. One Secret holds every credential the module resolved, keyed by what it belongs to.

      - **spec.upstream.auth.secretRef.name**
        string

        Required value

        Name of the Secret in the `d8-system` namespace.

  - **spec.upstream.ca**
    string

    A PEM-encoded certificate authority bundle used to verify the registry.

  - **spec.upstream.host**
    string

    Required value

    The registry host, optionally with a port.

  - **spec.upstream.mirrors**
    array of objects

    Additional addresses serving the same content. The syncer pulls from whichever is reachable and stores one de-duplicated set.

    - **spec.upstream.mirrors.auth**
      object

      Where the credentials for this mirror are kept.

.

Named rather than carried, for the same reason as the endpoint above: this resource is readable by every node in the cluster. A mirror can need credentials of its own, so it can name a key of its own.

- **spec.upstream.mirrors.auth.secretRef**
  object

  The Secret holding the credentials, and the key inside it.

  - **spec.upstream.mirrors.auth.secretRef.key**
    string

    Required value

    Key inside it.

  - **spec.upstream.mirrors.auth.secretRef.name**
    string

    Required value

    Name of the Secret in the `d8-system` namespace.

- **spec.upstream.mirrors.ca**
  string

  A PEM-encoded certificate authority bundle used to verify the mirror.

- **spec.upstream.mirrors.host**
  string

  Required value

  The mirror host, optionally with a port.

- **spec.upstream.mirrors.path**
  string

  The repository prefix inside the mirror.

- **spec.upstream.mirrors.scheme**
  string

  The protocol used to reach the mirror.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.upstream.path**
  string

  The repository prefix inside the registry.

- **spec.upstream.scheme**
  string

  The protocol used to reach the registry.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **status**
  object
  - **status.allReplicasFull**
    boolean

    Whether every replica holds the expected set, so losing the leader costs nothing.

  - **status.authoritative**
    boolean

    Whether the upstream has been dropped and the cache is now the only source of images.

  - **status.conditions**
    array of objects

    The detailed state of the storage

The detailed state of the storage.

- **status.conditions.lastTransitionTime**
  string

  Required value

  When the condition last changed.

- **status.conditions.message**
  string

  A human-readable explanation.

- **status.conditions.observedGeneration**
  integer

  The `spec` generation the condition was set for.

- **status.conditions.reason**
  string

  Required value

  A machine-readable reason for the condition.

- **status.conditions.status**
  string

  Required value

  The condition status.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  The condition type.

- **status.fill**
  object

  Progress of the current fill task.

  - **status.fill.filled**
    integer

    The number of digests written so far.

  - **status.fill.total**
    integer

    The number of digests expected.

- **status.leader**
  string

  The node currently holding the storage leader lease.

  Not a plain election. Leadership is not a symmetric role — the leader is the replication source every follower copies from, and the one whose completeness gates going air-gap. Once some replica holds the whole expected set, a leader that cannot complete the set by itself steps aside for it: one with no upstream, one whose last pass failed, one whose store refuses writes, or one that has stopped renewing the lease. A leader still completing the set from the upstream keeps the lease even if a follower finishes first. While no replica is full, which is where every cluster starts, the lease does not move; with no leader at all, it goes to the replica holding the most verified images.

  Without that rule an air-gapped cluster can stall. `d8 mirror push` arrives through the publication endpoint and always lands on the leader; an incomplete leader beside a full follower (for example, one whose store was lost) has no upstream to fill itself from, the followers replicate its gaps, and the replica holding the images sits idle.

- **status.observedGeneration**
  integer

  The `spec` generation the controller last acted on.

The `spec` generation the controller last acted on.

- **status.phase**
  string

  A coarse summary of the fill state.

  - `Idle` — no fill or verification task is running.
  - `Filling` — the leader is being populated.
  - `Verifying` — the contents are being checked against `spec.source`.
  - `Ready` — the leader holds the expected set.
  - `Failed` — a fill or verification task failed. The upstream is **not** dropped in this state.

  Allowed values: `Idle`, `Filling`, `Verifying`, `Ready`, `Failed`

- **status.replicas**
  array of objects

  The per-replica fill state.

  This is the **only** place storage completeness is reported. RegistryNode deliberately carries none of it, since completeness is a property of the storage and not of a node.

  - **status.replicas.address**
    string

    Where this replica answers, as `host:port`.

    Reported by the replica itself so that a follower can replicate from the leader without resolving a node name into an address.

  - **status.replicas.aheadSet**
    string

    The parts of what is ahead of the set that this replica holds as well — the platform version the cluster updates to next, and each module update it is about to apply — as their keys, sorted and comma-separated.

    A part is reported once a copy ahead left it whole. Separate from `verifiedSet` because it is copied separately — after the set, in the background, best-effort — and by part, so that one module that never arrives does not keep the rest from counting. A follower copies the parts its leader holds and it does not, so an update brought to the leader alone, such as one pushed with `d8 mirror push`, reaches the other replicas. Empty when nothing is pending or nothing pending has been copied.

  - **status.replicas.collectedAt**
    string

    When this replica last reclaimed its disk.

    Absent until it has. Reported per replica because each collects its own store, one at a time: a cluster where one replica has not collected for a month while the others have is a different problem from one where none has.

  - **status.replicas.collectionError**
    string

    Why the last attempt to reclaim did not finish, empty when it did.

    Separate from `error`, which is about filling. A store that cannot be reclaimed still serves every image it holds, so the two say different things about how worried to be.

  - **status.replicas.corruptedBlobs**
    array of strings

    The blobs of this replica’s store whose content does not match their digest, sorted, at most 100. Usually empty.

    They are found during the background check, which reads the whole store once an hour, and by a RegistryOperation of type `Verify` or `Repair` that could not finish the repair. An image that references such a blob is not counted as held: while an image of the set does, the replica is not `full`, and a leader hands the lease to a replica that holds the set whole.

    The module creates a `RegistryOperation` of type `Repair` for these blobs as soon as no other operation runs, and again four hours after a repair that did not fix them.

  - **status.replicas.declaredDigests**

integer

How big the set **is** — the number `verifiedDigests` is out of.

Reported by the replica because only the replica computing the set knows its size, and nothing is decided from it. Before it existed the only denominator the status could use was `spec.source.expectedDigests`, which an operator states when declaring air-gap and nobody states otherwise — so a cluster with an upstream showed `filled: 0, total: 0` throughout its longest phase while gigabytes were being copied. Completeness is still `full`, and the air-gap transition is still decided from `spec.source.expectedDigests`: a declaration by an operator is not replaced by a number the cluster computes about itself.

- **status.replicas.error**
  string

  Why the last fill or verification task failed, as reported by this replica's syncer. Empty when the last task succeeded.

  While the last task did not fail, it also carries what `healthError` reports.

  Safety does not depend on this field: a failed replica is simply not `full`, and the upstream is only ever dropped once the leader **is** full. It exists so that an operator can tell "still filling" from "broken", which the fill counters alone cannot express.

- **status.replicas.full**
  boolean

  Whether this replica holds the expected set.

  Derived from what the syncer actually **wrote**, never from probing the serve path: on a miss a pass-through cache would fetch the image from the upstream and report success on an empty store. In an air-gapped cluster self-filling is impossible, so reading the catalogue and comparing against `spec.source.expectedDigests` is honest there.

- **status.replicas.healthError**
  string

  Why this replica cannot serve what it holds: its registry has not answered for five minutes, or its store has refused writes for two. Empty while both work.

  The syncer checks both every half a minute on its own, whatever the fill is doing, and clears the error once the registry answers and the store accepts writes again; `full` is left as it was and counts again from then on. A leader reporting it hands the lease over to a replica that holds the whole expected set, if there is one; otherwise it keeps the lease and only reports the error.

  While no replica holds the whole set and none leads, the replicas' syncers choose among themselves which one leads and begins filling: the one that holds the most. They skip a replica reporting this error. They also skip one whose store is at its budget or at the node's reserve (`store.writable` is `false`), unless every replica's store is. An `error` alone, such as a failed copy from a leader that is gone, does not keep a replica from being chosen.

- **status.replicas.images**
  object

  The number of images held by this replica, by state. The images themselves are listed by `d8 k get registryimages`.

  - **status.replicas.images.corrupted**
    integer

    Images, of the set or not, that reference a broken blob.

  - **status.replicas.images.incomplete**
    integer

    Images of the set the replica holds without some of their blobs.

  - **status.replicas.images.missing**
    integer

    Images of the set the replica does not hold at all.

  - **status.replicas.images.outOfSet**
    integer

Images the replica holds that no release or module of the cluster declares — pulled through the cache on request, or left by an older release.

- **status.replicas.images.present**
  integer

  Images of the set the replica holds whole.

- **status.replicas.node**
  string

  Required value

  The node the replica runs on.

- **status.replicas.role**
  string

  The replica’s role in replication.

  - `Leader` — filled from the upstream, or by `d8 mirror push` in an air-gapped cluster, and hands out replication tasks.
  - `Follower` — filled from the leader, ahead of time, so a leader loss does not mean filling from scratch.

  Allowed values: `Leader`, `Follower`

- **status.replicas.scrubbedAt**
  string

  When the background check last finished reading the whole store and comparing every blob with its digest.

- **status.replicas.source**
  string

  The replica this one is filled from. Empty for the leader.

- **status.replicas.store**
  object

  How much of its node’s disk this replica’s store takes, and whether it still accepts writes. Absent until the replica has measured it.

  The registry enforces both limits itself, on every write; this is the syncer’s account of the same figures, for the status and the alerts. Sizes are rounded to 16 MiB — used up, free and capacity down — so that a filesystem shared with the rest of the node does not rewrite the status on every pass.

  - **status.replicas.store.budgetBytes**
    integer

    `storage.size` of the module configuration. Absent when none is set, and then only the reserve applies.

  - **status.replicas.store.dedicatedFilesystem**
    boolean

    True when the store has a filesystem of its own: a disk mounted at the store’s directory or at the store path above it, holding neither the kubelet’s nor containerd’s directory. The replica finds this from its mounts when it starts. Absent when the store shares a filesystem with the node, or when that could not be told: such a filesystem is treated as shared.

  - **status.replicas.store.filesystemCapacityBytes**
    integer

    Required value

    Size of the filesystem the store is on, as measured now: a filesystem grown under a running store shows its new size, and the reserve follows it.

  - **status.replicas.store.filesystemFreeBytes**
    integer

    Required value

    Free space on the filesystem the store is on. On a node without a dedicated disk it

is the filesystem the kubelet and containerd use too.

- **status.replicas.store.reason**
  string

  What writes are refused on, when they are.

  - `BudgetExhausted` — the store holds as much as `storage.size` allows;
  - `ReserveExhausted` — the filesystem under the store is down to the space kept free on it, see `reserveBytes`;
  - `NotWritable` — the registry cannot create files in its tree in the store: `docker/registry/v2` and the directories under it, or the store's directory while that tree does not exist yet. Their owner or mode, the immutable attribute, a read-only mount or a security module stands in the way. No limit is involved, and neither a garbage collection nor a larger `storage.size` helps. The replica's `error` names the directory and the command that fixes it. Takes precedence over either limit.

  Allowed values: `BudgetExhausted`, `ReserveExhausted`, `NotWritable`

- **status.replicas.store.reserveBytes**
  integer

  Required value

  How much of the filesystem the store leaves free, taken of the filesystem's current size rounded up to a whole GiB. On a filesystem shared with the node it is the kubelet's soft eviction threshold (10%, at most 40 GiB) plus a margin for other writers (10%, at most 20 GiB). On a filesystem of the store's own (see `dedicatedFilesystem`) only the margin is kept.

- **status.replicas.store.usedBytes**
  integer

  Required value

  What the store's blobs and uploads in progress take.

- **status.replicas.store.writable**
  boolean

  Required value

  False while the store refuses new writes. Reads are never refused: a full store serves everything it holds, and a pull it cannot keep is streamed from the upstream. The exception is `reason: NotWritable`, where the registry fails such a pull: its directories refuse it before any limit is checked.

- **status.replicas.syncerStartedAt**
  string

  When the syncer process that wrote this entry started, to the second. Set only once that process has itself counted, copied into or rechecked its store; absent before.

  An entry outlives the process that wrote it. A leader whose pod is recreated on the same node takes the lease back at once, and until the new process reads its store, its entry still says what the previous process found, `full` included, even if the store was wiped with the pod. So the upstream is dropped only on a lease holder's entry stamped no earlier than the start of the `syncer` container running in its Ready pod. Both times come from the clock of that node.

- **status.replicas.totalDigests**
  integer

  How many distinct digests this replica holds **altogether**.

  A different population from `verifiedDigests`, and nothing is decided from it. It is here so that a store holding more than this cluster needs — a bundle pushed with other modules, other editions, attestations — looks like what it is rather than like a shortfall against `spec.source.expectedDigests`.

- **status.replicas.verifiedDigests**
  integer

  How many digests **of the set** were confirmed present.

  The set is what the cluster's releases and the modules it keeps declare — the digests

deckhouse-controller knows about — so this number is directly comparable with `full` and is what the air-gap transition is decided from. Anything else the store happens to hold is counted in `totalDigests`.

- **status.replicas.verifiedSet**
  string

  A fingerprint of the set this replica was last found `full` against: the platform's versions and the modules the cluster keeps, each with its version and source.

  `full` is only as good as the set it was measured against, and the set moves — a module is installed, the platform is updated. Every replica reports it with its `full`. The leader compares its own with the set the cluster needs now; when they differ it takes `full` back and verifies before an air-gap transition may rely on it. A `full` for another set counts for nothing when the replicas decide who may lead. Empty when `full` is not set.

- **status.safeToDropUpstream**
  boolean

  Whether the **leader** holds the expected set and nothing on the platform still names the upstream, which together are the gate for going air-gap.

  Deliberately the leader alone and not every replica: followers are filled ahead of time and in parallel, so waiting for all of them would delay the transition without adding safety.

  A full cache does not make up for a remaining reference: an image reference that names the upstream by its own name is not answered by the cache once the upstream is gone. For details, see `upstreamReferences`.

  The leader's `full` counts only when the syncer running on its node now wrote it, after reading its own store (see `replicas[].syncerStartedAt`). After the leader's syncer restarts, this stays `false` until its first pass, normally within two minutes.

- **status.upstreamReferences**
  integer

  Number of objects in platform namespaces whose images still reference the upstream the storage is holding.

  Each object is counted separately: Deployment, DaemonSet, StatefulSet and CronJob templates, pods not started yet, pods that would pull again on their next start, and replicas of the storage itself, which cannot pull their own image from the storage once the upstream is gone. A Deployment in the middle of a rollout adds one for its template and one for each such pod.

  Only the `kube-system` and `d8-*` namespaces are counted. Workloads in other namespaces whose images reference the upstream address do not hold the transition, and once the upstream is removed they have nowhere to pull from. Move them onto the in-cluster address before removing the upstream.

  Counted while the leader is full and the upstream is still held. If the field is absent, the count was not taken, and `safeToDropUpstream` is `false`, as with a nonzero count.

RegistryUpstream

Short names: rup

Scope: Cluster
Version: v1alpha1

Declares an additional registry the cluster routes to, on top of the primary one.

This is the supported way for a module, an administrator or a user to bring their own registry. A module creates the object with an `ownerReference` on itself, so the object is garbage-collected together with the module; a GitOps tool owning ModuleConfig never competes for field ownership, because every upstream is a separate object.

Traffic through these upstreams is **always transit**: the agent proxies the pull, substituting credentials and the certificate authority, and streams it through without writing to disk or to the cache. Cache space is finite and reserved for Deckhouse components, all the more so in an air-gapped cluster where the cache is the only source of images.

A `match` already claimed by another object, or one that would shadow the primary path, is rejected rather than silently merged. See `status.conflict`.

Objects are accepted in creation order, starting with the earliest created object. Settings from no more than 256 objects are applied at a time. The combined size of their `spec` fields in JSON format must not exceed 256 KiB. If adding the next object exceeds either limit, its settings are not applied. Creating a new object does not displace a previously accepted object from the node configuration.

With the module disabled or in `Unmanaged` mode, there is no agent on the nodes. The objects are then arbitrated by the same rules by `node-manager`, which writes `status` and hands the accepted ones to the nodes. The nodes apply them directly to the container runtime configuration: the runtime pulls from the upstream and its mirrors without a proxy. A `match` equal to the registry of a `ModuleSource` is accepted: on Immutable nodes the object takes over that registry together with its certificate authority, while nodes configured by bashible, apart from those with containerd v1 described below, keep the registry as the `ModuleSource` configures it. While the module configures no node — it is disabled or in `Unmanaged` mode — nodes with containerd v1 (`Containerd`) do not apply an upstream with `path`, or one whose registry is already configured on the node or named twice in the object. Such an object stays accepted, and the message of its `Accepted` condition names the node groups that do not apply it and why.

- **spec**
  object

  Required value

  - **spec.match**
    string

    Required value

    The registry host intercepted on the nodes.

    Pattern: `^[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?(\.[a-zA-Z0-9]([-a-zA-Z0-9]*[a-zA-Z0-9])?)*(:[0-9]{1,5})?$`

    Length: `1..255`

    Example:

    ```
    match: images.virtualization.example.com
    ```

  - **spec.upstream**
    object

    Required value

    Where the intercepted pulls are actually sent.

    - **spec.upstream.auth**
      object

      Credentials for the registry.

      Sensitive. Credentials are stored inline in the object rather than referenced from a Secret, so that the node agent stays self-sufficient while the API server is unreachable.

      - **spec.upstream.auth.auth**
        string

        Pre-encoded `base64("username:password")`.

        Takes precedence over `username` and `password` when set. When both forms are set, they must name the same credentials.

        If the caller is not allowed to read the `registryupstreams/sensitive` subresource, the API returns `<omitted>` instead of the value.

        Maximum length: `4096`

      - **spec.upstream.auth.password**
        string

        The password for basic authentication.

        If the caller is not allowed to read the `registryupstreams/sensitive` subresource, the API returns `<omitted>` instead of the value.

        Maximum length: `4096`

      - **spec.upstream.auth.username**

string

The username for basic authentication.

Maximum length: `1024`

- **spec.upstream.ca**
  string

  A PEM-encoded certificate authority bundle used to verify the registry when `scheme` is `HTTPS`.

  Only `CERTIFICATE` blocks are accepted, and each of them must parse.

  Maximum length: `65536`

- **spec.upstream.host**
  string

  Required value

  Registry URL, optionally with a port.

  An IPv6 address is written in brackets, followed by a port.

  Length: `1..255`

  Example:

  ```
  host: registry-vendor.example.com
  ```

- **spec.upstream.mirrors**
  array of objects

  Additional addresses serving **the same** content as the registry, used for failover.

  - **spec.upstream.mirrors.auth**
    object

    Credentials for the mirror.

    Sensitive. See `upstream.auth`.

    - **spec.upstream.mirrors.auth.auth**
      string

      Pre-encoded `base64("username:password")`.

      If the caller is not allowed to read the `registryupstreams/sensitive` subresource, the API returns `<omitted>` instead of the value.

      Maximum length: `4096`

    - **spec.upstream.mirrors.auth.password**
      string

      The password for basic authentication.

      If the caller is not allowed to read the `registryupstreams/sensitive` subresource, the API returns `<omitted>` instead of the value.

      Maximum length: `4096`

    - **spec.upstream.mirrors.auth.username**
      string

      The username for basic authentication.

      Maximum length: `1024`

  - **spec.upstream.mirrors.ca**
    string

    A PEM-encoded certificate authority bundle used to verify the mirror.

    Maximum length: `65536`

  - **spec.upstream.mirrors.host**

string

Required value

Mirror URL, optionally with a port.

An IPv6 address is written in brackets, followed by a port.

Length: `1..255`

- **spec.upstream.mirrors.path**
  string

  The repository prefix inside the mirror.

  Maximum length: `1024`

- **spec.upstream.mirrors.scheme**
  string

  The protocol used to reach the mirror.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **spec.upstream.path**
  string

  The repository prefix inside the registry.

  Maximum length: `1024`

  Example:

  ```
  path: "/virt"
  ```

- **spec.upstream.scheme**
  string

  The protocol used to reach the registry.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

- **status**
  object
  - **status.accepted**
    boolean

    Whether the controller compiled this upstream into the per-node layout.

  - **status.conditions**
    array of objects

    The arbitration result with a machine-readable reason.

    - `Accepted` — whether the upstream is part of the per-node layout.
    - **status.conditions.lastTransitionTime**
      string

      Required value

      When the condition last changed.

    - **status.conditions.message**
      string

      A human-readable explanation.

    - **status.conditions.observedGeneration**
      integer

      The `spec` generation the condition was set for.

    - **status.conditions.reason**
      string

Required value

A machine-readable reason for the condition.

- **status.conditions.status**
  string

  Required value

  The condition status.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  The condition type.

- **status.conflict**
  string

  Reason for rejecting the object: the `match` value is already used by another object, `match` intercepts requests to the primary image registry (Primary), a field in `spec` is invalid, or adding the object exceeds the limit on the number of accepted objects or the combined size of their `spec` fields.

  Empty when the object is accepted.

- **status.observedGeneration**
  integer

  The `spec` generation the controller last acted on.

FAQ

> ⚠ The module lifecycle stage: Preview

How does the migration to the registry module work?

There are two ways a Deckhouse Platform (DP) cluster's image pull path can be managed:

- **the v1 implementation** (DP up to and including 1.77) — the `registry` section of the `deckhouse` ModuleConfig, with the modes `Unmanaged`, `Direct`, `Proxy`, and `Local`;
- **the current implementation** — this module, configured through the `registry` ModuleConfig.

The migration is the handover of the pull path from the v1 implementation to the module. It is not started by hand and has no command of its own: the module takes over automatically after the cluster is upgraded to DP 1.78. The only condition is that by then the v1 implementation must have released the pull path. Both implementations configure the same thing on every node — which registry the container runtime pulls from and with which credentials — so they never manage a cluster at the same time.

What has to be done for the handover, and when, depends on the mode the v1 implementation is running in. The mode is set in the `settings.registry.mode` parameter of the `deckhouse` ModuleConfig:

```
d8 k get mc deckhouse -o jsonpath='{.spec.settings.registry.mode}'
```

Empty output means `Unmanaged` mode: the registry settings of this cluster have never been touched. Such a cluster — like any other cluster in `Unmanaged` — needs no action for the migration: the handover happens on its own.

Mode	What to do	When
`Unmanaged`	Nothing — the handover happens on its own	—
`Direct`	Configure the module: `mode: Managed` with `primary.upstream`	Before the upgrade
`Proxy`	Switch the cluster to `Unmanaged`	Before the upgrade
`Local`	Follow the procedure for air-gapped clusters	Before the upgrade

✖ Prepare the cluster **before** the upgrade: upgrading to DP 1.78 is blocked while the cluster is running in `Proxy` or `Local` mode, or in `Direct` mode without a configured `registry` ModuleConfig. DP 1.78 contains neither the components of the v1 implementation nor the code that switches its modes, so all preparation happens on DP 1.77.

`Direct` mode needs no mode switch. The module's settings are deliberately accepted already in DP 1.77: written before the upgrade, they are stored without effect and take effect on the module's first reconciliation after it.

On nodes with containerd v1, a migration from or through `Unmanaged` restarts containerd. See Does the migration restart containerd?.

The cluster records which implementation is actually running (see the next question). While the handover is impossible, the upgrade to DP 1.78 is blocked, and the error message says what to do.

Which implementation is my cluster running?

When the module takes over the pull path, it records that in the `registry-v2-switch` secret. Check whether the secret exists:

```
d8 k -n d8-system get secret registry-v2-switch >/dev/null 2>&1 \
  && echo "current implementation" || echo "v1 implementation"
```

If the cluster is still on the v1 implementation, the module reports the reason on every reconciliation and fires the `D8RegistryMigrationPending` alert. To see what it is waiting for:

```
d8 k -n d8-system get secret registry-state -o jsonpath='{.data.state}' | base64 -d | head
```

On DP 1.78 the update deletes the `registry-state` secret. The mode is then still shown by the node configuration the v1 implementation left in the `registry-bashible-config` secret. This command prints only the mode and the proxy endpoints, without credentials:

```
d8 k -n d8-system get secret registry-bashible-config -o jsonpath='{.data.config}' | base64 -d \
  | awk '/^(agent|mode):/ {print; next} /^proxyEndpoints:/ {p=1; print; next} p && /^
*- / {print; next} {p=0}'
```

An `agent:` line in the output, or the `registry.deckhouse.io/installer-config-sha256` annotation on the secret, means the configuration was written by the current implementation or by the installer of DP 1.78 or later, not by the v1 implementation. The annotation counts only while the configuration is unchanged since the installer wrote it.

How do I migrate from Unmanaged mode?

In `Unmanaged` mode the v1 implementation does not manage the pull path, so there is nothing to prepare: the handover happens on its own.

1. If the cluster is switching to `Unmanaged` from another mode, wait for the transition to complete. The status must show `mode: Unmanaged` with no pending target mode:

   ```
   d8 k -n d8-system get secret registry-state -o jsonpath='{.data.state}' | base64 -d | head
   ```

2. Upgrade the cluster to DP 1.78 (or, if it is already on it, just wait for the next reconciliation). The

module takes over automatically, and the pull source does not change: the module's default mode is also `Unmanaged`, so the cluster keeps pulling from the same registry as before. On containerd v1 nodes, however, the takeover restarts containerd node by node if the v1 implementation left a node registry configuration, and enabling `mode: Managed` in the next step restarts it (a second time, if the takeover already did; see Does the migration restart containerd?).

3. To have the module manage the pull path, set `mode: Managed` in the `registry` ModuleConfig and specify the registry to pull from. A ready-made configuration for your cluster is published in the `registry-suggested-config` secret — see enabling the module.

How do I migrate from Direct mode?

In `Direct` mode the nodes pull images through an in-cluster address served by the v1 implementation's proxy. The module serves the same address, so the migration is a direct handover of that address: no switch through `Unmanaged` is needed, and no components restart.

1. Configure the module before the upgrade — without this configuration the upgrade is blocked. Take the values from the `registry.direct` section of the `deckhouse` ModuleConfig: `imagesRepo` splits into `host` and `path`, the credentials are the same `license` (or `username`/`password`), plus `ca` if the registry requires one:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: registry
   spec:
     enabled: true
     version: 1
     settings:
       mode: Managed
       primary:
         upstream:
           scheme: HTTPS
           host: registry.deckhouse.io
           path: /deckhouse/ee
           auth:
             license: <LICENSE_KEY>
   ```

   DP 1.77 stores these settings without acting on them, so nothing changes in the cluster until the upgrade.

2. Upgrade the cluster. The handover happens on the module's next reconciliation, and pulls keep working throughout: the Service and the proxy of the v1 implementation keep serving the in-cluster address until the module's agent has taken it over on every node, and only then does the controller remove them.

3. Track the progress:

   ```
   d8 k -n d8-system get secret registry-v2-switch >/dev/null 2>&1 && echo "handed over"
   d8 k get registrynode -o custom-columns='NODE:.metadata.name,READY:.status.reconciled,SERVING:.status.proxyListening'
   ```

   For reference, the order and rough scale to expect: the handover is recorded a couple of minutes after the new version starts, the node agent appears on the nodes several minutes later, and the objects of the v1 implementation are removed shortly after that. Pulls keep working at every point in between.

How do I migrate from Proxy mode?

`Proxy` mode keeps a proxy of its own, with its own certificates, on every node — state the module cannot adopt. So the cluster must first be switched to `Unmanaged`, and this can only be done before the upgrade.

1. In the `deckhouse` ModuleConfig, set `registry.mode: Unmanaged`, keeping the same registry address and credentials — see the mode switching examples. All nodes are reconfigured to pull directly from the external registry, so the caching `Proxy` provided is lost until you bring it back in

step 4.

2. Wait for the transition to complete — `mode: Unmanaged` with no pending target mode. A cluster caught mid-transition cannot be migrated, and the status shows which mode it is still heading to:

   ```
   d8 k -n d8-system get secret registry-state -o jsonpath='{.data.state}' | base64 -d | head
   ```

3. Upgrade the cluster. The handover happens on the module's next reconciliation, and the pull source does not change: in `Unmanaged` mode the module does not manage the pull path either. On containerd v1 nodes, however, the takeover restarts containerd node by node, and enabling `mode: Managed` in the next step restarts it again (see Does the migration restart containerd?).

4. To get in-cluster caching back, set `mode: Managed` with `storage.cache: true` and the same upstream registry. Note that the module's cache is built differently from `Proxy`: a single store with replicas on the master nodes instead of a proxy on every node. Before enabling it on a cluster with little free disk space on the control-plane nodes, read how the cache is filled and cleaned up.

How do I migrate an air-gapped cluster from Local mode?

In `Local` mode the cluster's registry lives inside the cluster itself, and there is no external one. The standard procedure does not apply here: it goes through `Unmanaged`, where every node pulls directly from an external registry — and this cluster has none.

The way through is to give the cluster an external registry temporarily: run it in the same cluster, but outside the DP namespaces; switch the cluster to it; upgrade; let the module's storage fill up; then remove it. The procedure has been verified end to end on a test cluster.

Disk requirements

Before starting, make sure the control-plane nodes have free space for **four image sets**. Three copies exist at the peak — the `Local` store, the temporary registry, and the module's storage being filled — and the fourth set is headroom the node must not run out of.

To get a sense of the scale, take an image set on the order of 13 GB (platform with modules): it occupies about 21 GB in the temporary registry (two releases — the one the cluster runs and the one it moves to) and grows the store from 13 to 21 GB, on top of the node's own image cache and the system. A 100 GB control-plane node peaks at around 38 GB that way, while a 50 GB node runs into pod eviction.

The headroom is critical. When free disk space on a control-plane node runs low, kubelet starts evicting pods and deleting images it considers unused — and in a cluster whose registry runs inside it, the deleted image can be the registry's own. The store is then left with no process to serve it, and the node with nowhere to pull that image from. In the test this deadlock lasted 99 minutes and was resolved only by loading images onto the node manually. Plan the disk space in advance and monitor it while the migration runs.

The images already on the control-plane disks are adopted by the module's storage — verified in place rather than downloaded again (see step 6). What adoption cannot do is merge two different releases into one set: the store ends up holding both the release the old cluster ran and the one the new cluster runs, which is where the peak size comes from.

Procedure

Steps 1–4 are performed before the upgrade, on DP 1.77, which still contains the v1 implementation.

1. Run a temporary OCI registry in a namespace of your own. Any registry implementation will do, but it must serve TLS with a certificate the cluster can verify. DP must not manage it: whatever happens to the module's own objects, the temporary registry must keep working.

   The registry must be reachable **at one address from two places**: in step 3 the nodes pull from it, and in step 6 the module's syncer reads it from inside a pod. The certificate must cover the chosen address. Options tested on one cluster:

Address	From a node	From a pod
`hostNetwork` port at the node's own IP (`<NODE_IP>:5000`)	works	works
Service name (`<SERVICE>.<NAMESPACE>.svc:<PORT>`)	does not resolve	works

Address	From a node	From a pod
NodePort at a node’s IP	works	fails: `operation not permitted`

Use the first option: run the registry with `hostNetwork: true` on one node, address it by that node’s IP, and include the IP in the certificate’s SAN. The whole migration then stays on a single address. A Service name looks tidier but breaks in step 3: the container runtime on a node does not resolve cluster DNS.

2. Load the image set into the temporary registry: run `d8 mirror pull` on a machine with access to the DP registry, then `d8 mirror push` into the temporary one. This is the copy the disk budget above accounts for.

3. Point the v1 implementation at the temporary registry and switch it to `Unmanaged`: in the `deckhouse` ModuleConfig, set `registry.mode: Unmanaged` together with the address, the CA certificate, and the credentials of the temporary registry. The nodes start pulling from it. The `Local` store leaves the pull path, but its data stays where it is — under `/opt/deckhouse/registry` on the control-plane nodes.

4. Make sure the transition is complete and images really are pulled from the temporary registry — the rest of the migration rests on this step. The checks are the same as for any `Unmanaged` cluster:

   ```
   d8 k -n d8-system get secret registry-state -o jsonpath='{.data.state}' | base64 -d | head
   ```

5. Upgrade the cluster to DP 1.78. The handover happens on the module’s next reconciliation; the cluster keeps pulling from the temporary registry throughout. On containerd v1 nodes the takeover restarts containerd node by node, and enabling `mode: Managed` in the next step restarts it again (see Does the migration restart containerd?).

6. Enable the module: `mode: Managed` with `storage.cache: true`, the temporary registry as `primary.upstream` — **and `storage.source` in the same edit**. The module’s storage starts on the same host path the `Local` store used, so the images already on the disks are adopted: the fill verifies them and downloads only what is missing.

   Do not postpone specifying `storage.source`: without it, the upstream cannot be removed in the next step. A `Managed` configuration without `primary.upstream` is only accepted when `storage.source` is set, so the next step would be rejected with `'storage.source' is required when 'primary.upstream' is not set`.

   In `storage.source`, `bundleRef` is a name for the image set, and `expectedDigests` is the number of distinct digests in it. Count them in the bundle you pushed:

   ```
   for tar in <BUNDLE_DIR>/*.tar; do tar -xOf "$tar" --wildcards '*index.json'; done |
     jq -r '.manifests[]?.digest' | sort -u | wc -l
   ```

   Setting `storage.source` does not restart the storage: it is not part of the registry process’s configuration. The registry restarts in the next step, when the upstream is removed.

7. Wait until the storage reports that it holds the whole set — `phase: Ready` with `safeToDropUpstream: true` — and remove `primary.upstream` from the `registry` ModuleConfig. The cluster is air-gapped again, now on the module. After a storage replica restarts, `safeToDropUpstream` can stay `false` until the leader’s syncer has read its store, normally within two minutes, or about ten minutes if that first reading fails:

   ```
   d8 k get registrystorage registry -o jsonpath='{.status.phase}
   {.status.safeToDropUpstream}{"\n"}'
   ```

   Removing the upstream restarts the registry process. If the restarted registry spends more than a few tens of seconds reading its store, the RegistryStorage resource reports `Failed` with an error about reading the image set. This is expected; wait for it to return to `Ready`.

8. Delete the temporary registry and reclaim its disk space.

Does the migration restart containerd?

On nodes with containerd v1 (`cri.type: Containerd`), it does. Nodes with containerd v2 always take their registry settings from the `/etc/containerd/registry.d` directory, and containerd is not restarted on them.

On a containerd v1 node, `/etc/containerd/config.toml` points containerd at `/etc/containerd/registry.d` only while the cluster has a node registry configuration, the `registry-bashible-config` secret. Without that secret, the file describes the registry with its own `mirrors` and `configs` blocks. In `Unmanaged` mode the module removes the secret, including the one the v1 implementation left behind. A change of `config.toml` restarts containerd, and kubelet after it. Therefore, on containerd v1:

- every switch between `Unmanaged` and `Managed`, in either direction, restarts containerd once. From `Managed` to `Unmanaged`, the restart comes when the module stops serving, that is once no workload names the in-cluster address `registry.d8-system.svc:5001` any more, not when the ModuleConfig is changed;
- a cluster where the v1 implementation left the secret restarts it twice on the way through `Unmanaged`: when the module takes over after the upgrade, and again when `mode: Managed` is enabled. That is a cluster switched from `Proxy` or `Local` to `Unmanaged` with a registry address before the upgrade, and any other `Unmanaged` cluster with a registry address;
- a migration from `Direct` does not restart it: the node configuration is kept throughout.

To check whether the secret is there, run `d8 k -n d8-system get secret registry-bashible-config`.

containerd is not restarted on all nodes at once. The change reaches them as a regular node update, which waits for approval, and approval is granted one node at a time in each NodeGroup by default (see `update.maxConcurrent`). Running containers survive the restart. On the node being updated, image pulls in progress fail and kubelet retries them, and open `exec`, `attach`, `port-forward` and `logs -f` sessions are cut.

What do the registry alerts mean?

Apart from the two about the node agent, `D8RegistryStorageLeaderAbsent` in an air-gapped cluster and `D8RegistryMigrationPending`, none of these alerts mean that the cluster has stopped pulling images. Most of them report a state where everything works, but not the way the configuration asks — a state that is easy to miss otherwise.

`D8RegistryMigrationPending`
: The module has not taken over from the v1 implementation, used up to and including DP 1.77, and the alert's reason says why. If the reason names the `Direct` mode, configure the module as described in migrating from Direct mode: the module then takes over on its own. Any other reason (the `Proxy` or `Local` mode, a transition, no recorded mode, or a state that cannot be read) means a state that is not supported. A cluster gets there only through an update that bypassed the `registryImplementation` release requirement: a forced release, an edited image, or a jump from a release older than DP 1.77.1. DP 1.78 does not deploy the v1 implementation, and the update removed the components that managed its node services on the masters, so those services were stopped or keep running with nothing to manage them. Images already on a node keep working; pulling any other image may fail. Do not change the `registry` or `deckhouse` ModuleConfigs and do not delete the `registry-*` secrets in `d8-system`: those secrets keep the current implementation from being deployed next to what the v1 implementation left. Contact Deckhouse Platform technical support. See also which implementation the cluster is running.

`D8RegistryConfigInvalid`
: The configuration was rejected; the cluster keeps working with the previous one. The reason is in `.status.conditions` of the `registryconfig/registry` resource.

`D8RegistryNodeNotConverged`
: The agent on some nodes has not applied the configuration it was given. Those nodes keep pulling with their old configuration, and further changes will not reach them either.

`D8RegistryNodeRunningFromDisk`
: The agent on some nodes could not get a usable configuration from the API server and routes pulls using the copy stored on disk. Most often the credentials the configuration references cannot be read; a read of the configuration that failed while the status write after it went through, as on a short API server outage, looks the same. This fallback works as designed: pulls on those nodes succeed, so nothing else would report the problem — meanwhile their configuration can lag arbitrarily far behind the cluster's. The agent reports the fallback through the API server, so the alert does not cover an agent that cannot write there: a node cut off from the API server shows as `NotReady` instead, and an agent refused access on a `Ready` node is not reported at all.

`D8RegistryAgentNotReady`
: The agent on a node has not been ready for 15 minutes: it fails on start, does not answer, or is not running on the node at all. Until it is back, containerd on that node pulls without it: platform images and images from registries that need the cluster's credentials or CA fail, other images bypass the cache. See where to look.

`D8RegistryAgentRestartingTooOften`
: The agent on a node has restarted five times or more in an hour. Each restart drops the pulls in progress on the node. The container's last state and the log of the previous run say whether it exited on its own or was restarted for not answering.

`D8RegistryStorageIncomplete`
: Some cache replicas do not hold the whole expected image set. While an upstream is configured

this does not affect pulls, but the cluster would not survive losing the upstream — and this is what blocks a transition to air-gap. A replica whose store the registry cannot write to (`NotWritable`) is reported by `D8RegistryStoreWritesRefused` instead.

`D8RegistryAirGapTransitionHeld`
: The upstream was removed from the configuration, but the module keeps using it: either the cache cannot serve the cluster alone yet, or the cache leader's report was not written by the `syncer` running on its node now (`syncerStartedAt` in the RegistryStorage status), or workloads in the `kube-system` and `d8-*` namespaces still reference the upstream (`upstreamReferences`). This is the safe outcome: dropping the upstream at that point would leave the nodes with nowhere to pull from. The alert does not resolve on its own if the cache has stopped filling, a rollout onto the in-cluster address is stuck, the leader's storage pod is not Ready, or that pod runs a `syncer` from before `syncerStartedAt` existed (during a module update).

`D8RegistryUpstreamProbeFailing`
: A change to the primary upstream was rejected, and the cluster keeps using the last working one. The `outcome` label tells the problems apart: `unreachable` — network or the registry itself; `auth` — usually an expired license key; `sentinel` — the registry responded and accepted the credentials, but does not contain the DP images (usually a wrong repository path).

`D8RegistryUpstreamRejected`
: A RegistryUpstream resource was not accepted, so pulls for the registry it names are not intercepted. The `reason` label says whether it conflicts with the primary registry or with another resource claiming the same name.

`D8RegistryStorageNotReclaimed`
: No replica has run garbage collection for a week. Collection is the only thing that removes data from the store, so if it has stopped, the disk will eventually fill up. See what cleans the cache up.

`D8RegistryStoreCorrupted`
: A replica holds blobs whose content does not match their digest, and the repair the module started on its own has not fixed them for two hours. Pulls of the affected images from that replica fail. See how to check and repair the images.

`D8RegistryStaleCacheData`
: A node holds cache data that nothing uses. See how to remove it.

`D8RegistryStoreWritesRefused`
: The cache on a master has stopped accepting writes: its store reached `storage.size` (`BudgetExhausted`) or the space kept free on its filesystem (`ReserveExhausted`). The node is safe and the cache keeps serving what it holds; what stops is filling it. See what happens when the store is full. `NotWritable` means something else: the registry cannot create files in its tree in the store (`docker/registry/v2` and below, or the store's directory while that tree does not exist yet), because of their owner or mode, an attribute, a read-only mount or a security module. Neither garbage collection nor a larger `storage.size` helps. The replica's `error` in the RegistryStorage status names the directory and the command that fixes it.

`D8RegistryStoreNearlyFull`
: The store on a master holds over 85% of `storage.size`. The next release may not fit.

`D8RegistryStoreUnbounded`
: The cache is on and `storage.size` is not set, so the only limit is the space kept free on the store's filesystem.

`D8RegistryControllerDown`
: No replica of `registry-controller` is ready and answering Prometheus. Pulls are not affected, but no configuration change reaches the nodes, and most other alerts of the module are silent while this one fires: they read what the controller exports. `D8RegistryStorageLeaderAbsent` and the migration and drain alerts do not depend on the controller and keep working.

`D8RegistryStorageLeaderAbsent`
: No ready cache replica reports holding the leader lease. Nothing fills the cache, the other replicas have nobody to replicate from, and `d8 mirror push` has nowhere to go. The nodes still route pulls to the replica named as leader: with an upstream configured pulls are slower, in an air-gapped cluster images the nodes do not already hold cannot be pulled. If the Lease `registry-storage` in `d8-system` keeps being renewed, the leader is alive but its report is not scraped: either its pod is not ready, then find out which of its containers is not ready, or the scrape of that pod fails, then look at the log of its `kube-rbac-proxy` container. If the master that held the lease is lost and is not coming back, delete its Node object; otherwise look at the `error` the replicas report in the RegistryStorage status and at their `syncer` logs. A cache replica that is merely not ready is reported by `KubernetesStatefulSetReplicasUnavailable` of the `extended-monitoring` module, if it is enabled.

`D8RegistryStorageUpdateBlocked`
: The cache has a new revision, but for an hour the controller has been unable to replace the next replica. Existing replicas remain running, but the cache update cannot proceed. The `reason` label says what the controller is waiting for and whether anything needs doing. See how the cache is updated.

How do I remove leftover cache data from a node?

When the cache is turned off, the data in the cache directory is intentionally kept: if the cache is turned back on, it refills from what is already on disk instead of downloading everything again — over a slow link that saves hours. Deleting the data automatically would make turning the cache off irreversible, so

the module leaves the decision to you: the agent measures the leftover data and fires `D8RegistryStaleCacheData`.

Check how much space the data takes:

```
d8 k get registrynodes -o custom-columns=\
NODE:.metadata.name,STALE:.status.staleStorageDataBytes
```

If you are not going to turn the cache back on, remove the contents of the cache directory on the node: `/var/lib/deckhouse/registry` on a node of a NodeGroup with `systemType: DeckhouseEngine`, `/opt/deckhouse/registry` on other nodes. Keep the directory itself: the agent has it mounted, and once it is removed the agent no longer sees the node's directory, so data a cache leaves there later goes unreported until the agent restarts. To do this, follow these steps:

1. Open a root shell on the node over SSH. A node of a NodeGroup with `systemType: DeckhouseEngine` has no SSH: start a debug pod on it and switch to the node's root filesystem:

   ```
   d8 k debug node/<NODE> -it --image=<IMAGE>
   chroot /host
   ```

2. Remove the data. The command checks both directories and keeps the directories themselves:

   ```
   for dir in /opt/deckhouse/registry /var/lib/deckhouse/registry; do
     [ -d "$dir" ] && du -sh "$dir" && find "$dir" -mindepth 1 -delete
   done
   ```

The cache keeps growing. What reclaims it?

Garbage collection, which every storage replica runs on its own store. The module starts it on a schedule, once the cache holds a new image set, and when the store refuses writes; it can also be started by hand.

It is the only mechanism that removes anything from the store. Every DP release adds new images, so without collection the store of a long-lived cluster eventually fills up and stops accepting writes — and an air-gapped cluster with a full store cannot be updated.

Collection removes the images of the releases the cluster has moved past. It keeps:

- the deployed release and the previous one, so that a rollback does not have to re-download anything;
- everything newer than the deployed release — an update in progress or, in an air-gapped cluster, a release pushed on purpose;
- every tag that is not a version: release channel names such as `stable`, floating tags, anything pushed by hand. The collector cannot know what these mean, so it does not touch them.

It also removes blobs that no image references, such as those left by an interrupted fill or by a collection whose cleanup failed. A collection removes them even when there are no images to delete.

The collector is deliberately cautious. In an air-gapped cluster, deleting a blob that is still needed is unrecoverable without another `d8 mirror push`, while keeping an unneeded one merely costs disk space. So a run that cannot determine what to keep — for example, when no deployed release is found — does nothing at all.

To check the collection status and schedule, use these commands:

List the recent collections — what started them, how they went, and how much they freed. A finished collection is kept for a day:

```
d8 k get registryoperation -o wide
```

Check the last collection time on each replica, and any errors:

```
d8 k get registrystorage registry -o jsonpath='{.status.replicas}' | jq \
  'map({node, collectedAt, collectionError})'
```

Check the current collection schedule:

```
d8 k get registrystorage registry -o jsonpath='{.spec.garbageCollection}' | jq
```

When it runs, and what happens during a run?

The registry's collector first computes the set of reachable blobs and then deletes the rest, so a blob written between those two steps and not yet referenced by a manifest would be deleted. A replica therefore collects only when its store is not being written to:

- a collection does not start while the cache is being filled or replicated, or while a `d8 mirror push` is in progress — it waits until the writing is over;
- the replica looks at its store again when its turn comes: if a fill or a push started while it waited, it gives the turn back and waits again;
- it looks once more right before removing blobs: if a push has started by then, the blobs are left for the next collection;
- while it collects, the replica stops filling and replicating its own store.

The replica keeps serving all the images it holds and fetching cache misses from the upstream. Do not run `d8 mirror push` while a collection is running: check `d8 k get registryoperation` first. A push that starts during the removal of blobs can fail with a visible error, and it can also report success and leave an image incomplete: a layer the store already held is not uploaded again, and the collection can remove it. Such an image fails to pull later with a missing blob. If a push overlapped a collection, run it again after the collection finishes.

Only one replica collects at a time; the others work normally.

The schedule is in UTC. By default, collection is scheduled at a night hour — or, if the `master` node group has a maintenance window, at its start, since that hour is already declared safe for disruption. To set your own schedule, use the `storage.garbageCollection` parameter:

```
spec:
  settings:
    storage:
      garbageCollection:
        schedule: "0 2 * * Sun"
```

A cron expression that cannot be parsed is rejected rather than guessed at: collecting at an unexpected hour is worse than not collecting. For the same reason a changed schedule counts from the moment it changed: a firing of the new schedule that has already passed is not made up for. The same applies after collection is turned back on.

Collection also starts once every replica holds a new image set: after a Deckhouse Platform update, or after a module is enabled or updated. That is the moment the images only the previous set needed become garbage. Disabling a module does not change the set: its images are kept for when it is enabled again.

A store that refuses writes — over its budget, or down to the space kept free on its filesystem — can never take in a new set, so it is collected without waiting for one: once per deployed Deckhouse Platform release, and again after an update or after the store has accepted writes in between. If that collection fails, it is tried again four hours after it ended.

Every collection is a RegistryOperation object of type `GarbageCollection`, whoever started it. Only one runs at a time: a firing of the schedule that comes while another collection is running is skipped, and a collection for a new image set waits for the running one to finish.

Is a collection worth running now?

Each storage replica estimates how much a collection of its store would free and exports the estimate to Prometheus metrics:

- `d8_registry_storage_reclaimable_bytes`: how many bytes a collection would free now. Zero means a collection would free nothing.
- `d8_registry_storage_reclaimable_estimated_timestamp_seconds`: when the estimate was made.

Both carry the `node` label of the replica. Neither is exported before the replica's first estimate.

A replica makes the estimate:

- when the image set the cluster needs changes;
- after a collection on that replica;

- every 30 minutes otherwise, and not more often than once in 5 minutes.

Estimate is not performed:

- during the filling of the cache;
- while uploading images to the storage (‘d8 mirror push’);
- during garbage collection.

Therefore, when viewing an estimate, pay attention to its time. Storage that refuses to write is evaluated as usual: this is when garbage collection is most needed.

To see the estimate for every replica, run the following query in Prometheus:

```
d8_registry_storage_reclaimable_bytes
```

How to run garbage collection manually?

To run garbage collection manually, create a RegistryOperation object of type `GarbageCollection`:

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1alpha1
kind: RegistryOperation
metadata:
  generateName: gc-manual-
spec:
  type: GarbageCollection
  cause: Free space before pushing a new release.
EOF
```

It runs even when automatic collection is turned off. Replicas collect one at a time, exactly as on schedule. A replica starts only when its store is not being written to: while the cache is being filled or a `d8 mirror push` is in progress, the replica waits, and the reason is shown in `status.replicas[].reason`. A store that refuses writes is not waited for: a fill cannot go on until the collection frees room. A replica still held back an hour after the operation was accepted fails with the reason `DeadlineExceeded`. An operation created while another one is running fails with the reason `AnotherOperationActive`.

Follow the operation and see what it removed:

```
d8 k get registryoperation <NAME> -o jsonpath='{.status}' | jq \
  '{phase, reason, message, garbageCollection}'
```

To cancel an operation, including one a replica is already running, set the cancel label on it:

```
d8 k label registryoperation <NAME> registry.deckhouse.io/cancel=true
```

What was deleted before the cancellation stays deleted.

If a replica’s `syncer` container stops answering while the replica collects or waits for its turn, for example because its master went `NotReady`, the replica fails with the reason `ReplicaLost`, so that the operation does not hold every collection after it for a day:

- a replica that was collecting, once it has not held the Lease `registry-storage-gc` in the `d8-system` namespace for five minutes;
- a replica that was waiting, once its node has not been `Ready` for ten minutes. A master that is back sooner keeps its replica’s turn.

A replica that waits on a node that stays `Ready` while its `syncer` does not answer is released by the cancel label, by the 24-hour timeout (the reason `TimedOut`), or by deleting the operation:

```
d8 k delete registryoperation <NAME>
```

Turning it off

To disable automatic garbage collection, set the value to `false` for the `storage.garbageCollection` parameter:

```
spec:
  settings:
    storage:
      garbageCollection:
        enabled: false
```

This only makes sense with a disk large enough that unbounded growth of the store never becomes a problem. Note that `D8RegistryStorageNotReclaimed` still fires a week after the last collection: from the outside, “turned off” and “silently stopped” look the same.

Garbage collection created [manually] (#how-to-run-garbage-collection-manually) is performed even if automatic is disabled.

What happens when the cache’s store is full?

Each master’s store has two limits, and the registry checks both on every write:

- the budget, `storage.size` in the `registry` ModuleConfig — how much the store may hold;
- the reserve — how much of the filesystem under the store must stay free. On a filesystem shared with the node it is the kubelet’s soft eviction threshold (10% of the filesystem, at most 40 GiB) plus a margin (10%, at most 20 GiB). On a disk of the store’s own (`dedicatedFilesystem: true` in the replica’s `store`) it is the margin alone. Both are taken of the filesystem’s current size, so a disk grown under a running store moves the reserve without a restart. The reserve applies whatever `storage.size` says, including when it is not set.

The reserve is taken from the full size of the filesystem, while free space is counted the way the kubelet counts it: without the blocks the filesystem keeps for root. On ext4 these are 5% by default, so on a filesystem under 200 GiB the store and everything else on it get about 75% of the disk rather than 80%. On a filesystem dedicated to the store, the root reservation can be lowered with `tune2fs -m`.

When either limit is reached, the store refuses new writes and keeps serving everything it holds:

- a fill or a replication stops. Why the store refuses is in the replica’s `store` field (`writable: false` and `reason`, see below), and `.status.replicas[].error` holds the error of the fill or replication that stopped;
- `d8 mirror push` gets `507 Insufficient Storage` with the reason and the way out, before the upload’s data is sent. A blob larger than the space left can still be refused in the middle of its upload, with `500`; push again once there is room;
- a cache miss is served from the upstream while there is one, so the nodes do not notice: the layers the store cannot keep are streamed through without being stored, and a manifest the store cannot write fails at the store, so the agent takes the image from the upstream. In an air-gapped cluster a release that is not in the store cannot be installed.

The store keeps the deployed release and the previous one, for a rollback, together with the modules the cluster runs and the catalog of modules the module sources offer. It also needs room for the next release:

- a replica copies the next release ahead of the update only while the room it has left in the budget, and on the filesystem above the reserve, is at least a fifth of the budget (or of the filesystem, when `storage.size` is not set); otherwise the copy ahead is skipped, and the release is filled once it is deployed. With an upstream, this applies to every replica;
- in an air-gapped cluster, the next release arrives with `d8 mirror push` on the leader, and the garbage collection does not delete the deployed or the previous release to make room for it. The followers copy it from the leader under the same rule, so a follower short of room gets the release only once it is deployed.

So size `storage.size` for three releases together with the modules and the catalog. The store holds the union of their images: a layer the releases share is stored once.

Nothing is deleted to make room. Space is freed by the garbage collection, or made by raising `storage.size` or giving the store more disk.

To see where each replica stands:

```
d8 k get registrystorage registry -o json | jq '.status.replicas[] | {node, store}'
```

`writable: false` with `reason: BudgetExhausted` means `storage.size` is reached: raise it if the disk has room, or let the collection reclaim what no deployed release needs. `reason: ReserveExhausted` means the disk is. On a filesystem shared with the node, free space on the node or move the store to a disk of its own. On a disk of its own, grow the disk or let the collection reclaim space. `reason: NotWritable` is not a limit: the registry cannot create files in the store, and

`.status.replicas[].error` names the directory and the command that fixes it.

The store's disk did not mount. What happens?

If the store was on a disk of its own (`dedicatedFilesystem: true`) last time and that disk is not mounted now, for example after a reboot, the store starts on the node's own filesystem and fills there. The replica reports this in `.status.replicas[].error` for as long as the disk is missing, and keeps reporting it after the store has filled. A replica with an error does not count as full:

- it does not stay the leader while another replica is full: that replica takes over;
- if it is the leader and no other replica is full, for example on a single master, the RegistryStorage phase is `Failed` and a transition to air-gap waits;
- after two hours `D8RegistryStorageIncomplete` fires.

To fix it, mount the disk before the kubelet starts (in `/etc/fstab` without `nofail`) and delete the replica's pod on that node. To keep the store on the node's filesystem on purpose, delete the `.filesystem-before` file in the store's directory on the node, then the replica's pod:

```
d8 k -n d8-system delete pod -l app=registry-storage --field-selector spec.nodeName=<NODE>
```

A pull is failing on a node. Where do I look?

Start with the agent: it is on the path of every pull on the node. It is deployed as a static pod, so it is available even when the cluster is not.

The kubelet probes the agent on the address the container runtime uses, `127.0.0.1:5001`, and restarts it after a minute without an answer. An agent that stays not ready raises `D8RegistryAgentNotReady`, and one that keeps restarting raises `D8RegistryAgentRestartingTooOften`. Neither alert covers an agent that answers but cannot reach the API server: that one is ready.

To check the agent's logs, use the command:

```
d8 k -n kube-system logs -l component=registry-agent --tail=100
```

To check the configuration the agent has, and whether it agrees with the cluster, use the command:

```
d8 k get registrynode <NODE> -o jsonpath='{.status}' | jq
```

The agent's metrics — its own view of the pulls passing through it. Prometheus collects them through the node exporter of the `monitoring-kubernetes` module: every 30 seconds the agent writes them to the node exporter's textfile directory, `/var/run/node-exporter-textfile/registry-agent.prom`. The `d8_registry_agent_*` series therefore come with `job="node-exporter"` and the node's name in the `node` label, for example:

```
sum by (node, kind, result) (rate(d8_registry_agent_requests_total[5m]))
```

Nothing scrapes the agent directly: it is a static pod precisely because it has to work when the API server does not, and a `kube-rbac-proxy` beside it would authenticate against that same API server. Without `monitoring-kubernetes` the series are not collected. On the node itself the same metrics, together with the agent's Go runtime metrics, are served on the loopback address:

```
ssh <NODE> 'curl -s http://127.0.0.1:4286/metrics | grep d8_registry_agent'
```

The configuration given to the container runtime. It is a single file, regardless of how many registries are configured:

```
ssh <NODE> 'cat /etc/containerd/registry.d/_default/hosts.toml'
```

If this file is missing, the agent has not applied a configuration yet: nothing on the node can pull, and the reason is in the agent's log. If the file is present and pulls still fail, the failure is beyond the agent — the metrics above name the target that failed and the error.

containerd can also pull past the agent, and this is by design. `_default/hosts.toml` sets no `server`, so containerd keeps the original registry as the last host and goes there directly when the agent does not answer, or answers `404` or another error status. This way images from public registries can still be pulled while the agent is down, but the direct attempt gets nothing the agent adds:

- no cluster credentials, only the pod's own pull secret, if it has one;
- no RegistryUpstream routes or mirrors, and no cache;
- no certificate authority of a private registry, so such a registry usually fails with `x509`;
- no in-cluster address: `registry.d8-system.svc:5001` does not resolve on the node, so platform images cannot be pulled this way at all.

Which error containerd reports when a pull fails depends on the step that failed and on the containerd version. While resolving the image reference, a tag or a digest:

- containerd 1.7 (`Containerd`) reports the first error it got other than `404`. If the agent did not answer or answered with an error status, that is the agent's error, even though the direct attempt was made after it: a refused connection or a TLS handshake timeout to the agent's address, or an error status such as `502 Bad Gateway`. The error of the direct attempt (`no such host`, `401`, `x509`) is reported only when the agent answered `404`, and then it hides that the agent did not find the image.
- containerd 2.2 (`ContainerdV2`) reports an error status other than `404` ahead of a `404`, and a `404` ahead of a failed connection; of two errors of the same kind, it reports the agent's. So an error status from the agent, such as `502 Bad Gateway`, is always what shows. A failed connection to the agent shows only when the direct attempt failed to connect too, and a failed connection of the direct attempt (`no such host`, `x509`) never shows. Otherwise the answer to the direct attempt shows: its error status, such as `403`, or `not found` for its `404`. An agent's `404` is reported as `not found` unless the registry answered the direct attempt with an error status.

Either way, check the agent's log and metrics first. When the direct attempt answers `404` too, as for a tag missing from a public registry, the pull is reported as `not found`. While fetching the manifest by digest, the image config and the layers, both versions report the agent's error whatever it was, `404` included: a layer the agent does not have is reported as `not found` even when the direct attempt then failed with another error.

While the agent does not answer, pulls are also slow to fail or succeed: on a test cluster with the agent frozen, pulls of platform images failed after about 20 seconds (a TLS handshake timeout to the agent), and images from public registries arrived over the direct path after about 50 seconds.

Modules from other ModuleSources: what the cache holds and what to do before air-gap

The cache holds every module the cluster runs, whichever ModuleSource it was installed from, and counts it towards completeness: a cluster does not go air-gap while a module it runs is missing from the store.

- A module whose ModuleSource is on the upstream's registry is filled from the upstream, like the platform itself.
- A module whose ModuleSource is on a registry of its own is filled from that registry, with the credentials and certificate authority the ModuleSource carries.

The platform's own modules — ModuleSource `deckhouse` — are stored under `system/deckhouse/modules`. Every other ModuleSource has a path of its own in the in-cluster registry, `system/deckhouse/module-sources/<ModuleSource>`: its modules under `<path>/<module>`, and its list of modules as the tags of `<path>`. A path apart, because the platform's is the upstream's as long as an upstream is configured, and a module another source ships under a name the platform also has would be replaced there by the upstream's build.

That path is the only place a node can pull the source's modules from once the upstream is gone, but the module's pods keep referring to their ModuleSource's registry until the source is changed. So before removing the upstream, point every such ModuleSource at its path, with the registry settings the platform's own source uses:

```
NAME=<ModuleSource>
REGISTRY=$(d8 k get modulesource deckhouse -o json | jq -c --arg name "$NAME" \
  '.spec.registry | .repo = "registry.d8-system.svc:5001/system/deckhouse/module-
sources/" + $name')
d8 k patch modulesource "$NAME" --type merge -p "{\"spec\":{\"registry\":$REGISTRY}}"
```

After that the module's images are rendered with the in-cluster address and are served from the cache.

What does destroying an air-gapped cloud cluster need from the store?

`dhctl destroy` of a cloud cluster whose provider is not built into the installer, such as Deckhouse Virtualization Platform, needs that provider's bundle: its schemas, OpenTofu modules and plugins. dhctl takes the bundle from its download directory (`--download-dir`, `/tmp/dhctl` by default) when it is there, and pulls it from the registry the cluster names otherwise. An air-gapped cluster names no

upstream, so the bundle is pulled from the cluster's own store, through dhctl's SSH connection to a master. With the store empty or missing that image, destroy stops at `Get cluster configuration` with `MANIFEST_UNKNOWN`. The simplest way out is to run dhctl in a container that already has this bundle downloaded, such as the one a previous operation on this cluster ran in. Otherwise keep the store until the cluster is destroyed, or bring the bundle yourself: on a machine with access to the public registry, pull the digest the error names from the platform's image repository there, the one the cluster was installed from (for example, `registry.deckhouse.io/deckhouse/<edition>`; `system/deckhouse` in the error's address is only the store's name for that repository). A `d8 mirror` bundle of the release holds the image too. Unpack the image into the directory the error names.

How do I push a new Deckhouse Platform release or a new module version into an air-gapped cluster?

Once the upstream is removed from the configuration and the cluster has no internet access, `d8 mirror push` is the only way new images get into the in-cluster cache. The cache leader accepts the push, and the other replicas copy the images from it. As soon as a release is in the cache, the cluster sees it the same way it would see it in the upstream and updates by the usual rules: the release channel, the update windows, and manual approval if it is enabled.

You don't need to bring the upstream back for this, and you don't need to change `storage.source` either. The cache's completeness is checked against the image set the cluster needs, not against `expectedDigests`. Garbage collection keeps releases newer than the deployed one, so a pushed release stays in the store until it is deployed.

Step 1. Pull the images on a machine with internet access

Get the Deckhouse Platform edition and version running in the cluster:

```
d8 k -n d8-system get deployment deckhouse -o json | jq -r '.metadata.annotations |
{"core.deckhouse.io/edition","core.deckhouse.io/version"}'
```

Pull the Deckhouse Platform releases starting from the cluster's minor version. Minor versions are installed one after another, so the bundle has to contain every one in between, and `--since-version` pulls them:

```
d8 mirror pull --source='registry.deckhouse.io/deckhouse/<EDITION>' --
license='<LICENSE_KEY>' \
  --since-version='<X.Y>' ./d8-bundle
```

To update only a module without pulling the platform, give its current version. The command pulls that version, the newer ones, and the versions on the release channels:

```
d8 mirror pull --source='registry.deckhouse.io/deckhouse/<EDITION>' --
license='<LICENSE_KEY>' \
  --no-platform --include-module='<MODULE>@<VERSION>' ./d8-bundle
```

The Updating DP in air-gapped environment guide explains how to make the bundle smaller and how to build the list of modules.

Move the bundle to the machine you will run `d8 mirror push` from. Make sure the cache's store has room for it: a push into a full store gets `507 Insufficient Storage` (see What happens when the cache's store is full?).

Step 2. Check the publication endpoint

Images get into the cache only through the publication endpoint: the `registry-push` Ingress in the `d8-system` namespace, which passes the push on to the cache leader. A push sent straight to a master node, around the Ingress, is refused: the port that accepts writes there takes them only from the ingress controller and from the cache itself (see What protects the ports on control-plane nodes).

Check whether the cluster has the `registry-push` Ingress and whether an ingress controller serves it:

```
d8 k -n d8-system get ingress registry-push -o jsonpath='{.spec.ingressClassName}{"\t"}
{.spec.rules[0].host}{"\n"}'
d8 k get ingressclass
```

- The Ingress exists and its class is among the IngressClasses: go on to step 3.
- The Ingress exists, but its class is not among the IngressClasses: set the `ingressClass` parameter of the `registry` ModuleConfig to the class of an existing controller, then go on to step 3.
- There is no Ingress: it is created only when `publicDomainTemplate` is set and the `cert-manager` module is enabled. Set the parameter and enable the module: the Ingress appears on the next run of the `registry` module. If the cluster cannot have the Ingress, set `primary.upstream` to a registry the cluster can reach that holds the images, let the cache fill from it, and remove the upstream again.

Run the `d8 k` commands in the next steps where you have access to the cluster's API. If the bundle is on another machine, carry the values over to it.

Step 3. Push the images

```
HOST=$(d8 k -n d8-system get ingress registry-push -o jsonpath='{.spec.rules[0].host}')
PUSH_SECRET=$(d8 k -n d8-system get secret registry-storage-push -o json)
d8 mirror push ./d8-bundle "$HOST/system/deckhouse" \
  --registry-login="$(echo "$PUSH_SECRET" | jq -r .data.username | base64 -d)" \
  --registry-password="$(echo "$PUSH_SECRET" | jq -r .data.password | base64 -d)"
```

What the push needs:

- The name in `$HOST` resolves to the ingress controller's address on the machine you push from.
- If `whitelistSourceRanges` is set, that machine's address is in the list.
- The machine trusts the Ingress certificate. Let's Encrypt can't issue one for an air-gapped cluster, so such clusters usually use their own ClusterIssuer or the `CustomCertificate` mode (the `https` parameter). If the machine doesn't trust the certificate authority, pass its certificate in the `SSL_CERT_FILE` environment variable.
- The cache has a leader. While there is none, the push is refused; look at the replicas in the RegistryStorage status (see How do I check the state of the in-cluster cache?). If the leader changed during the push, for example because a master node rebooted, run the command again.

Do not push while a garbage collection is running: check `d8 k get registryoperation` first. A push that overlaps a collection can fail, and it can also report success and leave an image incomplete. If a push overlapped a collection, run it again after the collection finishes (see When it runs, and what happens during a run?).

Step 4. Check that the release has reached the cluster

Check the state of the cache. The other replicas copy the new release from the leader before it is deployed:

```
d8 k get registrystorage registry -o jsonpath='{.status}' | jq
'{phase,fill,leader,allReplicasFull}'
```

Check that the cluster sees the new Deckhouse Platform release or module release:

```
d8 k get deckhousereleases
d8 k get modulereleases
```

From here on the release is deployed according to the Deckhouse Platform update settings and the module update settings.

Image availability alerts from `extended-monitoring` for the in-cluster registry

With the module in charge, every image reference in the cluster names `registry.d8-system.svc:5001`. Nodes pull by that address through the node agent on the loopback, not through cluster DNS. The image availability exporter of the `extended-monitoring` module checks images from a pod, where the name is looked up in cluster DNS instead, so it reports every such image as `…ImageAvailabilityUnknownError`:

- without the in-cluster cache, or while no storage replica is ready, the name does not resolve from a pod: `no such host`;
- with the cache, the name is a headless Service that resolves to the master nodes running ready storage replicas. The storage answers there with a certificate issued by the module's own certificate authority, which the exporter does not trust: `x509: certificate signed by unknown authority`.

Nothing is wrong with the images: what the exporter would detect is covered by this module's own alerts — `D8RegistryStorageIncomplete`, `D8RegistryUpstreamProbeFailing`, `D8RegistryNodeNotConverged`. Exclude the in-cluster address from the exporter's checks:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: extended-monitoring
spec:
  version: 2
  settings:
    imageAvailability:
      ignoredImages:
      - 'registry\.d8-system\.svc:5001/.*'
```

Each entry is a regular expression. Images from other registries are still checked.

How do I check the state of the in-cluster cache?

The state of the cache is published in the status of the RegistryStorage resource. To view it, use the command:

```
d8 k get registrystorage registry -o jsonpath='{.status}' | jq
```

Description of the response fields:

- `replicas` is the only place where completeness information is reported, and each entry is the replica's own account of itself. A replica reporting `full: true` alongside an `error` is not complete: `full` says what it holds, and the error says whether its last pass finished, or whether its registry or disk has stopped working (see `leader`). `syncerStartedAt` is when the syncer that wrote the entry started, set once that syncer has read its own store; the upstream is dropped only when the leader's entry carries the start of the syncer running in its pod now.
- `leader` is the replica that fills from the upstream and serves as the replication source for the others. The election is deliberately not symmetric: once a replica holds the whole expected set, a leader that cannot complete it by itself steps aside for that replica. A leader cannot complete the set by itself when there is no upstream, when its last pass failed, when its store refuses writes, or when it no longer renews its lease. This is what keeps an air-gapped cluster from deadlocking with an empty leader and a full follower. A leader that is still completing the set from the upstream keeps leading: a follower copies from it and may finish first, and moving the lease then would gain nothing. A replica on a node unreachable for about two minutes is not counted in the election, and a replica whose registry stops answering or whose disk stops accepting writes reports it in `healthError` and `error` and steps aside for a full replica, if there is one. A leader whose store has lost the set (the deployed release or most of a sample of the set is missing on its disk, or `totalDigests` is at most half of its `verifiedDigests`) steps aside for a replica full for the current set, reporting `full: false` and `verifiedDigests: 0`, and copies the set from it. With no such replica it keeps leading, reports `full: false` and `verifiedDigests: 0` all the same, and fills the set again from the upstream (in an air-gapped cluster, it counts its store again, and the set comes back only with a new `d8 mirror push`).

Which images are in the cache?

Every image of the cache, by the digest of its manifest, is listed by the RegistryImage resource of the `registry.deckhouse.io` group. It is not stored anywhere: each request asks every replica of the cache, and each replica answers from an index it keeps in memory and rebuilds by reading its store every two minutes and after every operation. The answer is always up to date, and building it puts no load on the disks of the master nodes.

Request examples:

```
d8 k get registryimages
d8 k get registryimages -o wide
d8 k get registryimages -l registry.deckhouse.io/module=prometheus
d8 k get registryimages -l registry.deckhouse.io/state=Corrupted
d8 k get registryimages -l registry.deckhouse.io/in-set=false
d8 k get registryimage sha256-<digest> -o yaml
d8 k explain registryimages
```

Image fields in the response:

- `owners` — every place the image is used: the module and the image name from `images_digests.json`, and the Deckhouse Platform releases or module versions that declare it. One digest can be used by several modules; all of them are listed.
- `inSet` — the cluster release or module that uses the image. An image outside the set or left by an older release may be listed and is later removed by the garbage collection. Such images cannot be removed by hand.
- `state` and `replicas[].state` — where the image is on each replica:
  - `Present` — the replica holds the manifest and every blob of the image;
  - `Missing` — an image of the set the replica does not hold at all;
  - `Incomplete` — the replica holds the manifest without some of its blobs, which can happen when a pull-through cache served only the manifest;
  - `Corrupted` — one of the image's blobs does not match its digest;
  - `Unknown` — the replica did not answer, or has not read its store since it started. When no replica can answer, the request fails with `ServiceUnavailable` and names each replica's reason.
- `size` — the full size of the image: its manifest and every layer, each counted once.
- `reclaimableSize` — the amount of space freed on a replica if only this image is removed.

An image is made of layers, and a layer that several images share is stored once. So the sizes of all images add up to more than the cache takes on disk, and removing one image frees only the layers no other image uses: `reclaimableSize`. The images of the platform share few layers, so `reclaimableSize` and `size` are usually close.

The counts by state are in the RegistryStorage status, under `replicas[].images`, and stay there while registry-controller is not running. During this time, the `registry.deckhouse.io` group is not served: `kubectl api-resources` reports an error for it, and namespaces being deleted stay `Terminating` with the `NamespaceDeletionDiscoveryFailure` condition until a replica of the controller answers again. The `D8RegistryControllerDown` alert fires at the same time.

Reading RegistryImage requires the `get` and `list` permissions on `registryimages` of the `registry.deckhouse.io` group. The user must have the `registry.view` RBACv2 capability.

Which images take the most space?

Sort the list by `size` or `reclaimableSize`. kubectl sorts in ascending order, so the largest images are at the end of the output, and images without a size, such as `Missing` ones, are at the start. Sorting works together with any label selector.

```
# The 20 largest images.
d8 k get registryimages --sort-by=.size | tail -n 20
# The 20 images that take the most space on their own: layers no other image uses.
# With -o wide both sizes are shown.
d8 k get registryimages --sort-by=.reclaimableSize -o wide | tail -n 20
# The largest images outside the set, which the garbage collection removes.
d8 k get registryimages -l registry.deckhouse.io/in-set=false --sort-by=.reclaimableSize -o wide |
tail -n 20
# The images of one module by size.
d8 k get registryimages -l registry.deckhouse.io/module=prometheus --sort-by=.size
```

How do I check and repair images in the cache?

Every replica reads its store once an hour in the background and compares every blob with its digest. The read speed is about 4 MiB/s on a store of 15 GB, with a maximum of 16 MiB/s. The kernel drops what it read from the page cache so that etcd and the API server on the same master do not react to the load. Pulls are not blocked. The time when the last full pass finished is in `RegistryStorage.status.replicas[].scrubbedAt`.

A blob that does not match its digest is recorded in `RegistryStorage.status.replicas[].corruptedBlobs`, and the images that use it are marked `Corrupted`. The following happens automatically:

- While an image of the set uses the broken blob, the replica is not `full`. A leader then hands the lease to a replica whose set has no broken blobs, and the nodes pull from it.
- The module creates a RegistryOperation of type `Repair` for the broken blobs as soon as no other operation runs. `Repair` downloads a whole copy of each broken blob from another replica or from the upstream (if available), checks it against its digest and only then replaces the broken copy. A blob for which no whole copy is found stays as it was.
- One `Repair` takes up to 50 blobs. If it did not fix everything, `Repair` is repeated four hours later;

if there are more than 50 broken blobs, it starts with the next batch. After two hours the `D8RegistryStoreCorrupted` alert fires.

To check the store manually, create a RegistryOperation with the `Verify` operation type:

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryOperation
metadata:
  generateName: verify-
spec:
  type: Verify
  # Optional: only these images or blobs, and only these replicas.
  verify:
    digests: ["sha256:<digest>"]
    nodes: ["<master-node>"]
```

The read speed reaches 32 MiB/s. A store of 15 GB is checked in about eight minutes per replica, one replica at a time.

To repair images manually, for example after pushing a release again with `d8 mirror push`, create a RegistryOperation with the `Repair` operation type with their digests (up to 50):

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryOperation
metadata:
  generateName: repair-
spec:
  type: Repair
  repair:
    digests: ["sha256:<digest>"]
```

`Repair` of a whole image reports `Intact` when every blob matches its digest. The outcome for each digest is in `status.replicas[].repair.digests` of the operation. Only one operation runs at a time. If an operation was created while a garbage collection runs, it fails with `AnotherOperationActive` and has to be created again.

Creating operations needs the RBACv2 capability `registry.edit`.

How is the cache updated?

A new Deckhouse Platform release can change the images of the cache itself, the `registry-storage` StatefulSet in `d8-system`. The StatefulSet uses the `OnDelete` update strategy, and its replicas are replaced by `registry-controller`: one at a time, followers first and the leader last, and only while every other replica is ready. A replica on the old revision that has never started or is in `CrashLoopBackOff` is replaced at once.

A replaced replica pulls its new images after it is deleted, from the cache it was part of. So the controller replaces a replica only while something else can serve them:

- a follower: the leader keeps serving;
- the leader: once a follower holds the whole image set. The lease then goes to whichever replica holding the whole set takes it first: a follower holding it or the leader’s own replacement, which comes back on the same node over the same store;
- any replica: the upstream registry, if the cluster has one.

One master node in an air-gapped cluster

With a single replica and no upstream, nothing else can serve the images. The new images therefore have to be on the master before the replica is replaced. The module keeps them there with the `registry-storage-image-holder` DaemonSet: on every master it runs each image of the cache’s pod as `/pause`. When the images change, the holder pulls the new ones from the running cache, and as long as it runs them the kubelet does not delete them from the node. Once the holder on the master runs every new image, the controller replaces the replica, and the new pod starts from the images already on the node.

While the only replica of the cache restarts, the nodes cannot pull images from it. How long this takes depends on stopping the old replica and starting the new one. The kubelet retries failed pulls with a back-off of up to 5 minutes, so some pods may start with an extra delay after the cache is back.

The holder requests 10m CPU and 10Mi of memory per image on each master, 40m and 40Mi in total. It holds the images on every master, but the controller only uses it when the cache has one replica and no upstream.

Several master nodes in an air-gapped cluster

The leader is replaced last, and only once a follower holds the whole image set. Otherwise the lease would move to a follower with images missing, and the images only the old leader had would be gone from the cluster. The image holder does not replace that check. A follower counts only if it was found full against the same set as the leader: after an update that changes the Deckhouse Platform release or the modules, a replaced follower still reports the set it held before until it has copied the new one. Normally this means waiting while a follower copies the set from the leader. If the leader itself does not hold the whole set, the followers cannot complete it either: they copy from the leader. Then the update continues only once the Deckhouse Platform release and the modules the cluster uses are pushed into the cache.

What the UpdateBlocked event means

While the controller waits, it writes an `UpdateBlocked` event to the StatefulSet with the replica, the reason and what ends the wait. It writes the event again when what the wait depends on changes, and otherwise every five minutes while the wait lasts:

```
d8 k -n d8-system get events --field-selector involvedObject.name=registry-
storage,reason=UpdateBlocked
```

The same reason is the `reason` label of the `d8_registry_storage_update_blocked` metric, and the `D8RegistryStorageUpdateBlocked` alert fires if the wait lasts longer than an hour:

- `HolderNotReady` — one replica, and the holder on its master does not run every new image yet. If its pod is in `ImagePullBackOff`, the cache does not hold an image: push the Deckhouse Platform release the cluster is updating to with `d8 mirror push`, and the holder pulls it on its next retry. If its pod is in `CrashLoopBackOff` or `CreateContainerError`, the holder has the image but cannot run it, and a push does not help: the cause is in the events of the pod. Otherwise the holder is still rolling or pulling, and nothing needs to be done.
- `SingleReplicaWithoutHolder` — one replica, and the holder DaemonSet has no pod on its master. For a moment this is normal while the DaemonSet creates its pod on the node. If it lasts, find out why the DaemonSet does not schedule a pod there: `d8 k -n d8-system describe daemonset registry-storage-image-holder`.
- `LeaderWithoutFullFollower` — only the leader remains to be replaced, but no follower holds the whole set. If the leader holds it, wait for a follower to finish copying. If the leader reports that it does not hold it, pull the Deckhouse Platform release and the modules the cluster uses with `d8 mirror pull`, as described in the air-gapped update guide, and push them into the cache with `d8 mirror push`, as in step 2 of Going air-gapped. If the leader has not reported yet, reports an error or cannot tell which set the cluster needs, a push does not help, and the update continues only after a pass of the leader succeeds: look at the log of the `syncer` container of the leader's pod.
- `LeaderNotServing` — the storage lease names a master without a serving replica. It moves on its own once the lease expires.
- `StorageUnknown` — the `RegistryStorage` resource does not exist yet. The controller creates it. If it does not appear, check the log of `registry-controller`.

To see what the holders and the replicas are doing:

```
d8 k -n d8-system get pods -l app=registry-storage-image-holder -o wide
d8 k get registrystorage registry -o jsonpath='{.status.replicas}' | jq
```

Who can read from and write to the in-cluster cache?

The cache's registry accepts three accounts. Each of them is limited to the platform's path, `system/deckhouse`, and everything under it: that is where the cache keeps the platform, its modules, and the modules of other ModuleSources. A request for any other repository is refused, whatever the account.

Account	Who uses it	What it may do
`registry-ro`	the node agent on every node	pull; list the store's repositories

Account	Who uses it	What it may do
`registry-sync`	the cache's own pods only	pull, push and delete: filling from the upstream, replication, garbage collection
`registry-rw`	`d8 mirror push`, through the publication endpoint	pull and push

- The read account is held by every node, so it can change nothing the nodes pull.
- The sync account is the one that writes into the store from inside the cluster. Its password is used only by the cache's pods: the registry controller and `registry-packages-proxy` read the Secret `registry-storage-client`, which carries the certificate authority, the read account and the replicas' addresses and nothing else.
- The publication account is for the platform administrator. It is how a new release reaches an air-gapped cluster, so it can replace the platform's images by design: whoever can read the Secret `registry-storage-push` in `d8-system` can replace what every node pulls. Grant read access to that Secret only to those who publish the platform. The account can neither delete images nor list the store's repositories: images are removed by the garbage collection.

Push to the platform's path, `<publication endpoint>/system/deckhouse`, as in the air-gap example; a push to any other path is refused.

The v1 implementation

The information below applies to a cluster still running the v1 implementation of the module (DP up to and including 1.77), configured through the `deckhouse` ModuleConfig.

How to Migrate to the registry module?

This procedure moves a cluster from the deprecated format (without the `registry` module) to the v1 implementation. It is not a step of the migration to the current implementation: a cluster in the deprecated format needs no preparation for the upgrade to DP 1.78. See how the migration works.

During the migration, Containerd v1 will switch to the new registry configuration format. Containerd v2 uses the new format by default. For more details, see the section with a description of configuration methods.

For containerd v2

1. Switch to using the `registry` module. To do this, specify the `Unmanaged` mode parameters in the ModuleConfig `deckhouse`. If you are using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for proper configuration.

   You can view the current registry settings using the following command:

   ```
   d8 k -n d8-system exec -it svc/deckhouse-leader -c deckhouse -- deckhouse-controller global values | yq e '.modulesImages.registry' -
   ```

   Specify this configuration when setting up the `Unmanaged` mode:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: deckhouse
   spec:
     version: 1
     enabled: true
     settings:
       registry:
         mode: Unmanaged
         unmanaged:
           imagesRepo: registry.deckhouse.io/deckhouse/ee
           scheme: HTTPS
           license: <LICENSE_KEY> # Replace with your license key
   ```

2. Wait for the switch to complete. Example status output:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

For Containerd v1

- During the switch, containerd v1 will be restarted.
- During the switch, containerd v1 will be migrated to the new registry configuration scheme.
- During the switch, custom registry configurations for containerd v1 will be temporarily unavailable.

1. Make sure that nodes with containerd v1 do not have any custom registry configurations located in the `/etc/containerd/conf.d` directory.
2. If configurations are present, you need to migrate to the new registry configuration format in containerd. To do this, add new configuration files to the `/etc/containerd/registry.d` directory. These configurations will take effect after switching to the `registry` module. To add configurations, prepare a NodeGroupConfiguration. For more details, see the section with a description of configuration methods. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not
required
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - <<
EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        [host."https://${REGISTRY_URL}".auth]
          username = "username"
          password = "password"
    EOF
```

3. Apply the NodeGroupConfiguration. Wait until the configuration files appear in the `/etc/containerd/registry.d` directory on all nodes.
4. Verify that the configurations are working correctly. To do this, use the following command:

```
# For HTTPS:
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/
private.registry.example/registry/path:tag

# For HTTP:
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/ --plain-http
private.registry.example/registry/path:tag
```

5. Switch to using the `registry` module. To do this, specify the `Unmanaged` mode parameters in the ModuleConfig `deckhouse`. If you are using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for proper configuration.

   You can view the current registry settings using the following command:

   ```
   d8 k -n d8-system exec -it svc/deckhouse-leader -c deckhouse -- deckhouse-controller global
   values | yq e '.modulesImages.registry' -
   ```

   Specify this configuration when setting up the `Unmanaged` mode:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Unmanaged
      unmanaged:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY> # Replace with your license key
```

6. After applying, wait for the following message to appear in the switch status:

   Example output:

   ```
   conditions:
   # ...
   - lastTransitionTime: "2025-08-13T15:22:34Z"
     message: |
       Check current nodes configuration
       2/2 node(s) Unready:
       - master-0: has custom toml merge containerd configuration
       - worker-5e389be0-578df-s5sm5: has custom toml merge containerd
   configuration
     reason: Processing
     status: "False"
     type: ContainerdConfigPreflightReady
   ```

   This message means that there are old registry configurations on the nodes located in the `/etc/containerd/conf.d` directory. The switch to the new containerd configuration is currently blocked. To allow the switch, you need to remove the old configuration files.

7. Remove the old configuration files to allow switching to the `registry` module. To do this, create a NodeGroupConfiguration. Example of a NodeGroupConfiguration manifest:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth-delete.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    file="/etc/containerd/conf.d/old-config.toml"

    [ -f "$file" ] && rm -f "$file"
```

8. After removing the old configurations, make sure that the switch has resumed. Example of the switch status:

```
conditions:
# ...
- lastTransitionTime: "2025-08-13T16:42:09Z"
  message: ""
  reason: ""
  status: "True"
  type: ContainerdConfigPreflightReady
```

9. Wait for the switch to complete. Example of the switch status:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

10. Delete the NodeGroupConfiguration created in the step for deleting old configuration files:

```
d8 k delete nodegroupconfiguration containerd-additional-config-auth-delete.sh
```

To verify that NodeGroupConfiguration has been deleted, use the command:

```
d8 k get nodegroupconfiguration
```

The list should not contain the NodeGroupConfiguration to be deleted (for this example, `containerd-additional-config-auth-delete.sh`).

How to Migrate Back from the Registry Module?

✖
- This is a deprecated registry management format.
- During the switch, containerd v1 will be restarted.
- During the switch, containerd v1 will be migrated to the legacy registry configuration scheme.
- During the switch, custom registry configurations for containerd v1 will be temporarily unavailable.

1. Switch the registry to `Unmanaged` mode. If you are using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for proper configuration.

   Example configuration:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: deckhouse
   spec:
     version: 1
     enabled: true
     settings:
       registry:
         mode: Unmanaged
         unmanaged:
           imagesRepo: registry.deckhouse.io/deckhouse/ee
           scheme: HTTPS
           license: <LICENSE_KEY>
   ```

2. Check the switch status using the instruction. Example output:

   ```
   conditions:
   # ...
   - lastTransitionTime: "..."
     message: ""
     reason: ""
     status: "True"
     type: Ready
   hash: ..
   mode: Unmanaged
   target_mode: Unmanaged
   ```

3. Switch the registry to the non-configurable `Unmanaged` mode. Example configuration:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: deckhouse
   spec:
     version: 1
     enabled: true
     settings:
       registry:
         mode: Unmanaged
   ```

4. Check the switch status using the instruction. Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: ""
  reason: ""
  status: "True"
  type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

5. If containerd v1 is used and custom registry configurations are applied in the cluster, they must be replaced with the old format. To do this, prepare the registry configurations in the old format. These configurations do not need to be applied at this stage. Example configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]

[plugins."io.containerd.grpc.v1.cri".registry.mirrors."${REGISTRY_URL}"]
            endpoint = ["https://${REGISTRY_URL}"]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]

[plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".auth]
            username = "username"
            password = "password"
            # OR
            auth = "dXNlcm5hbWU6cGFzc3dvcmQ="
    EOF
```

6. Delete the `registry-bashible-config` secret. This will trigger containerd v1 to switch back to

the legacy registry format:

```
d8 k -n d8-system delete secret registry-bashible-config
```

7. After deletion, wait for the switch to complete. Use the instruction to track the progress. Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: ""
  reason: ""
  status: "True"
  type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

8. If containerd v1 is used, apply the previously prepared NodeGroupConfiguration with custom registry configurations.
9. Disable the `registry` module. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry
spec:
  enabled: false
  settings: {}
  version: 1
```

How to check the registry mode switch status?

The status of the registry mode switch can be retrieved using the following command:

```
d8 k -n d8-system -o yaml get secret registry-state | yq -C -P '.data | del .state |
map_values(@base64d) | .conditions = (.conditions | from_yaml)'
```

Example output:

```
conditions:
  - lastTransitionTime: "2025-07-15T12:52:46Z"
    message: 'registry.deckhouse.io: all 157 items are checked'
    reason: Ready
    status: "True"
    type: RegistryContainsRequiredImages
  - lastTransitionTime: "2025-07-11T11:59:03Z"
    message: ""
    reason: ""
    status: "True"
    type: ContainerdConfigPreflightReady
  - lastTransitionTime: "2025-07-15T12:47:47Z"
    message: ""
    reason: ""
    status: "True"
    type: TransitionContainerdConfigReady
  - lastTransitionTime: "2025-07-15T12:52:48Z"
    message: ""
    reason: ""
    status: "True"
    type: InClusterProxyReady
  - lastTransitionTime: "2025-07-15T12:54:53Z"
    message: ""
    reason: ""
    status: "True"
    type: DeckhouseRegistrySwitchReady
  - lastTransitionTime: "2025-07-15T12:55:48Z"
    message: ""
    reason: ""
    status: "True"
    type: FinalContainerdConfigReady
  - lastTransitionTime: "2025-07-15T12:55:48Z"
    message: ""
    reason: ""
    status: "True"
    type: Ready
mode: Direct
target_mode: Direct
```

The output displays the status of the switch process. Each condition can have a status of `True` or `False`, and may contain a `message` field with additional details.

Description of conditions:

Condition	Description
`ContainerdConfigPreflightReady`	State of the containerd configuration preflight check. Verifies there are no custom containerd auth configurations on the nodes.
`TransitionContainerdConfigReady`	State of preparing the containerd configuration for the new mode. Verifies that the configuration contains both the old and new mode settings.
`FinalContainerdConfigReady`	State of finalizing the switch to the new containerd mode. Verifies that the containerd configuration has been successfully applied and contains only the new mode settings.
`DeckhouseRegistrySwitchReady`	State of switching Deckhouse and its components to use the new registry. `True` means Deckhouse successfully switched and is ready to operate.

Condition	Description
`InClusterProxyReady`	State of In-Cluster Proxy readiness. Checks that the In-Cluster Proxy has started successfully and is running.
`CleanupInClusterProxy`	State of cleaning up the In-Cluster Proxy if it is not needed in the selected mode. Verifies that all related resources have been removed.
`NodeServicesReady`	State of Node Services Manager and Static-Pod registry readiness. Verifies that the Node Services Manager is successfully launched and operational, and that the Static-Pod registry has been successfully deployed by it.
`CleanupNodeServices`	State of cleaning up the Node Services Manager and Static-Pod registry if they are not needed in the selected mode. Verifies that all related resources have been removed.
`RegistryContainsRequiredImages`	State of checking the registry for the presence of required images.
`Ready`	Overall state of registry readiness in the selected mode. Indicates that all other conditions are met and the `module` is ready to operate.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Module registry: usage examples

⚠ The module lifecycle stage: Preview

⚠ If, during the switching process, the image of a module did not reload and the module did not reinstall, use the instructions to resolve the issue.

Enabling the module

To have the module manage how the cluster pulls images, set `mode: Managed` and specify the registry to pull from:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry
spec:
  version: 1
  enabled: true
  settings:
    mode: Managed
    primary:
      upstream:
        host: registry.deckhouse.io
        path: /deckhouse/ee
        scheme: HTTPS
        auth:
          license: <LICENSE_KEY>
```

The module publishes a ready-made version of this for your cluster, with the address, path, scheme, certificate authority and credentials of the registry it is already pulling from:

```
d8 k -n d8-system get secret registry-suggested-config -o jsonpath='{.data.registry-mc\.yaml}'
| base64 -d
```

Review it, then apply it. It saves a transcription rather than typing: those values are spread across a secret and a docker configuration blob, and retyping them by hand is where a truncated path or the wrong authority comes from — on the one setting that decides whether the cluster can pull at all.

To see the change take effect, use the following commands:

```
d8 k get registryconfig registry -o jsonpath='{.status}' | jq
d8 k get registrynodes -o custom-columns=\
NODE:.metadata.name,APPLIED:.status.observedGeneration,OK:.status.reconciled,BACKENDS:.status.activeBackends
```

Turning the in-cluster cache on

To turn on the in-cluster cache, add the module's `storage.cache` ModuleConfig setting and specify a size for the store:

```
spec:
  settings:
    mode: Managed
    primary:
      upstream:
        host: registry.deckhouse.io
        path: /deckhouse/ee
        auth:
          license: <LICENSE_KEY>
    storage:
      cache: true
      size: 50Gi
```

Nothing on any node is reconfigured. The container runtime already asks the node agent about every registry, and the agent starts preferring the cache with the upstream as a fallback — so a cache miss is a slower pull rather than a failed one, from the first moment.

To check how full the in-cluster cache is, use the following command:

```
d8 k get registrystorage registry -o jsonpath='{.status}' | jq
'{phase,fill,leader,allReplicasFull}'
```

Turning the in-cluster cache off again is the same change in reverse, and just as safe. The blobs on disk

are left alone, so turning it on again refills from what is already there rather than from scratch — see how to reclaim that space if you do not intend to.

Going air-gapped

An air-gapped cluster has no upstream (not set in the `primary.upstream` parameter). For such a cluster, the cache is the only source of images, and `d8 mirror push` is the way in. Because completeness has to be decidable before the cache can be trusted alone, `storage.source` must describe the expected image set.

To move a cluster to air-gap, follow these steps:

1. Pull the images on a machine that has internet access:

   ```
   d8 mirror pull --license <LICENSE_KEY> ./d8-bundle
   ```

2. Push them into the cluster, through the publication endpoint:

   ```
   PUSH_SECRET=$(d8 k -n d8-system get secret registry-storage-push -o json)
   d8 mirror push ./d8-bundle registry.example.com/system/deckhouse \
     --registry-login "$(echo "$PUSH_SECRET" | jq -r .data.username | base64 -d)" \
     --registry-password "$(echo "$PUSH_SECRET" | jq -r .data.password | base64 -d)"
   ```

   The publication endpoint exists only while the cache is enabled, `publicDomainTemplate` is set and the `cert-manager` module is enabled; see Air-gapped clusters.

3. Describe the expected set of images in the cache, and remove the upstream:

   ```
   spec:
     settings:
       mode: Managed
       storage:
         cache: true
         size: 50Gi
         source:
           bundleRef: d8-mirror-bundle
           expectedDigests: 459
   ```

The upstream is not removed from the nodes the moment you remove it from the configuration. It is removed once the cache leader holds the whole expected set and nothing in the platform namespaces (`kube-system` and `d8-*`) still references the upstream — this is the one transition that could otherwise leave every node with nowhere to pull from, so it waits, and says so. When the upstream is removed, the registry restarts, and the RegistryStorage resource may briefly report `Failed`: this is expected, wait for it to return to `Ready`.

> ⚠ Workloads in other namespaces are not counted. If the images of your own workloads reference the upstream address, move them onto the in-cluster address before removing the upstream: once it is removed, they have nowhere to pull from.

To check the status of the transition, use the following commands:

Check whether the cache leader holds the whole expected set of images, and how many platform workloads still name the upstream (`upstreamReferences`):

```
d8 k get registrystorage registry -o jsonpath='{.status}' | jq
'{safeToDropUpstream,fill,upstreamReferences}'
```

A nonzero `upstreamReferences` means that a rollout of platform workloads onto the in-cluster address has not finished. The `registry-controller` log names up to five of the referencing objects each time the count changes. To see the last such line, run:

```
d8 k -n d8-system logs -l app=registry-controller -c registry-controller --prefix --tail=-1 | grep
'still names the upstream' | tail -1
```

Get the value of `effectiveUpstream`:

```
d8 k get registryconfig registry -o jsonpath='{.status.effectiveUpstream}' | jq
```

While `effectiveUpstream` is still set, the cluster is using it. When it becomes empty, the cluster is air-gapped.

If the transition does not finish, find what holds it:

- The cache is not complete (`safeToDropUpstream: false` with the leader not `full`): wait for the fill, or check the `error` of the leader in `.status.replicas`.
- `upstreamReferences` stays above zero: finish or fix the rollout of the objects named in the `registry-controller` log.
- The leader is `full` and `upstreamReferences` is `0`: the upstream is held until the `syncer` running on the leader's node has read its store and stamped its report with `syncerStartedAt`, normally within two minutes of its start. This does not end while the leader's storage pod is not Ready, or while that pod runs a `syncer` from before this field existed (during a module update). Deleting the leader's storage pod is safe while the upstream is held: the new `syncer` reads its store and stamps its report, normally within two minutes. To see the leader's report and the reason the controller gives:

  ```
  d8 k get registrystorage registry -o json | jq '.status as $s | $s.replicas[] |
  select(.node == $s.leader) | {node,full,error,syncerStartedAt}'
  d8 k -n d8-system logs -l app=registry-controller -c registry-controller --prefix --tail=-1 |
  grep 'the upstream is held' | tail -1
  ```

To stay on the upstream instead, put the same `primary.upstream` back into the ModuleConfig: the cluster has been using it all along and keeps doing so.

Adding another registry

A registry that is not the source of DP component images is declared as its own resource — RegistryUpstream — rather than another field in the ModuleConfig. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: RegistryUpstream
metadata:
  name: virtualization-images
spec:
  match: images.virtualization.example.com
  upstream:
    host: vendor.example.com
    path: /virtualization
    scheme: HTTPS
    auth:
      username: robot
      password: <PASSWORD>
```

Pulls naming `images.virtualization.example.com` are then routed to `vendor.example.com/virtualization` by the agent on every node, with the credentials and certificate authority held by the cluster rather than by each workload. Nothing on any node is reconfigured for this.

After creating the RegistryUpstream, check that it has been accepted. The object is rejected in the following cases:

- It conflicts with the primary registry or another object claiming the same `match` value. The object is rejected rather than merged.
- It contains an invalid field, such as a `ca` that is not a PEM certificate.
- Adding the object exceeds either of the following limits:
  - Settings from no more than 256 RegistryUpstream objects can be applied at a time.
  - The combined size of the accepted objects' `spec` fields in JSON format must not exceed 256 KiB.

To check whether the object has been accepted, run the following command:

```
d8 k get registryupstreams -o custom-columns=\
NAME:.metadata.name,MATCH:.spec.match,ACCEPTED:.status.conditions[0].status,REASON:.status.conditions[0].rea
son
```

Pulling from a private registry without declaring it

Nothing needs to be declared to pull from a registry the module does not know about. When the module manages how images are pulled, the node agent is what the container runtime turns to for any registry, including ones the module has no information about. An unconfigured registry is proxied untouched, along with whatever credentials the pull request already carried.

So an ordinary `imagePullSecret` behaves exactly as it would on a cluster where this module was never enabled.

To create a secret with the credentials of the private registry, run:

```
d8 k create secret docker-registry my-private-registry \
  --docker-server=private.example.com \
  --docker-username=robot \
  --docker-password=<PASSWORD>
```

To use this secret when pulling images, add it to the pod's `imagePullSecrets`:

```
apiVersion: v1
kind: Pod
metadata:
  name: example
spec:
  imagePullSecrets:
  - name: my-private-registry
  containers:
  - name: app
    image: private.example.com/team/app:v1
```

It is worth creating a `RegistryUpstream` only if you want the cluster to hold the credentials instead of every workload doing so individually, or if the registry needs a certificate authority the nodes do not have.

Turning the module off again

To have the module stop managing how images are pulled, set the `mode` parameter to `Unmanaged`:

```
spec:
  settings:
    mode: Unmanaged
```

The module then manages nothing: its components are removed, the node configuration it wrote is withdrawn, and the cluster goes back to pulling from the registry recorded in the `deckhouse-registry` secret — which is where it was pulling from before the module was ever enabled.

Cache data on the control-plane nodes is deliberately left behind: turning the cache on again fills in only the missing images from the registry, rather than starting from scratch. If you do not plan to use the cache again, see how to reclaim that space.

Examples for the v1 implementation

Everything below applies to a cluster still running the v1 implementation (DP up to and including 1.77), configured through the `deckhouse` ModuleConfig. See how the migration works.

Switching to the `Unmanaged` Mode

To switch an already running cluster to `Unmanaged` mode, follow these steps:

✖ Changing the registry in `Unmanaged` mode will result in a full restart of all DP components.

1. Make sure the `registry` module is enabled and running. To do this, execute the following command:

   ```
   d8 k get module registry -o wide
   ```

   Example output:

   ```
   NAME       WEIGHT ...  PHASE   ENABLED   DISABLED MESSAGE   READY
   registry   38     ...  Ready   True                         True
   ```

2. Ensure the Deckhouse job queue is empty and contains no errors:

   ```
   d8 system queue list
   ```

   Example output:

   ```
   Summary:
   - 'main' queue: empty.
   - 107 other queues (0 active, 107 empty): 0 tasks.
   - no tasks to handle.
   ```

3. Set the `Unmanaged` mode configuration in the ModuleConfig `deckhouse`. If you're using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for correct configuration.

   Configuration example:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: deckhouse
   spec:
     version: 1
     enabled: true
     settings:
       registry:
         mode: Unmanaged
         unmanaged:
           imagesRepo: registry.deckhouse.io/deckhouse/ee
           scheme: HTTPS
           license: <LICENSE_KEY> # Replace with your license key.
   ```

4. Check the registry switch status in the `registry-state` secret using this guide.

   Example output:

   ```
   conditions:
   # ...
     - lastTransitionTime: "..."
       message: ""
       reason: ""
       status: "True"
       type: Ready
   hash: ..
   mode: Unmanaged
   target_mode: Unmanaged
   ```

5. If you need to switch back to the old registry management method, refer to the instruction.

⚠ This is a deprecated format for registry management.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The registry-packages-proxy module

Included in extensions: **Advanced Infrastructure Security**

The module lifecycle stage: General Availability

The `registry-packages-proxy` module provides an in-cluster HTTP proxy service for accessing packages from container registries. It acts as an intermediary between cluster components and external or internal registries, offering caching capabilities to optimize bandwidth usage and improve package retrieval performance.

This module is a critical infrastructure component that runs on master nodes and is used during cluster bootstrap and runtime operations to fetch packages from container registries.

The module deploys a highly-available proxy service that:

- Runs as a deployment on master nodes with `hostNetwork` enabled to ensure availability during bootstrap when CNI is not yet available.
- Listens on port `4219` (HTTPS) on each master node's IP address.
- Provides a `/package` endpoint for retrieving registry packages by digest.
- Implements local caching of retrieved packages (up to 1 GB) to reduce network traffic and improve performance.
- Watches ModuleSource custom resources to obtain registry credentials for different repositories.
- Uses `kube-rbac-proxy` to secure access to the proxy and metrics endpoints.
- Exposes a public HTTPS API (via Ingress) for Deckhouse CLI binaries.
- Exposes an in-cluster HTTPS API for package icons (no public Ingress).

Architecture

The proxy service consists of two containers:

1. **registry-packages-proxy**: The main proxy application that:
   - Fetches packages from remote registries using digests.
   - Caches packages locally in an ephemeral volume (1 GB max).
   - Supports authentication to registries via credentials from ModuleSource resources.
   - Provides health checks and Prometheus metrics.
   - Listens on `127.0.0.1:5080` (HTTP, internal).
2. **kube-rbac-proxy**: Provides RBAC-based access control:
   - Exposes the service on port `4219` (HTTPS).
   - Secures `/metrics` endpoint with Kubernetes RBAC authorization.
   - Secures `/package` endpoint requiring appropriate permissions.
   - Secures `/v1/images/*` (Deckhouse CLI downloads) with Kubernetes RBAC authorization.
   - Allows unauthenticated access to `/healthz`.

HTTP API

After the cluster is bootstrapped and the DNS name template is configured in the publicDomainTemplate parameter, the module creates an Ingress for `registry-packages-proxy` using that template (for example, `registry-packages-proxy.company.my` for `publicDomainTemplate: "%s.company.my"`).

The endpoints listed below are reachable in two ways:

- **Public** (via the Ingress on the `registry-packages-proxy` public host): only `/v1/images/*`.
- **In-cluster only** (via the `registry-packages-proxy.d8-cloud-instance-manager.svc` Service

on port `443`, or `:4219` on each master node for bootstrap): all routes, including `/v1/packages/*`.

Package icons (`/v1/packages/`) — in-cluster only

Package icons are served **without authentication** (`kube-rbac-proxy` excludes these paths from RBAC) but are **only reachable from inside the cluster**. They are intentionally **not** routed through the public Ingress, so the public domain `registry-packages-proxy.<publicDomain>` will not serve them.

Method	Path	Description
`GET`, `HEAD`	`/v1/packages/<PACKAGE-REPOSITORY>/<PACKAGE-NAME>/metadata/icon/`	Icon of the latest semver tag
`GET`, `HEAD`	`/v1/packages/<PACKAGE-REPOSITORY>/<PACKAGE-NAME>/metadata/icon`	Same as above
`GET`, `HEAD`	`/v1/packages/<PACKAGE-REPOSITORY>/<PACKAGE-NAME>/metadata/icon/<VERSION>`	Icon of a specific version (`<VERSION>` is a semantic version, e.g. `v1.0.1`)

`<PACKAGE-REPOSITORY>` is the `metadata.name` of a PackageRepository custom resource; its `spec.registry.repo` field tells the proxy which registry path to pull the icon from. The proxy reads the icon from the OCI image `<spec.registry.repo>/<PACKAGE-NAME>:<TAG>`.

The proxy looks for the following files inside the package image, in this priority order, and returns the first one it finds:

Path	Content-Type
`docs/icon.svg`	`image/svg+xml`
`docs/icon.png`	`image/png`
`docs/icon.jpg`	`image/jpeg`
`docs/icon.jpeg`	`image/jpeg`

If none of these are present (or the file is larger than 4 MiB), the proxy returns `404 Not Found`; callers should fall back to a default icon. SVG is preferred because it is resolution-independent.

Example request from a pod in the cluster:

```
curl -fsSk "https://registry-packages-proxy.d8-cloud-instance-manager.svc/v1/packages/my-repo/my-module/metadata/icon/"
```

Example response headers (when the image ships `docs/icon.svg`):

```
Content-Type: image/svg+xml
Content-Disposition: attachment; filename="<PACKAGE-NAME>.svg"
```

Deckhouse CLI downloads (`/v1/images/`) — public

These endpoints are reachable through the public Ingress (`registry-packages-proxy.<PUBLIC_DOMAIN>`) and require a valid Kubernetes token or a client certificate accepted by `kube-rbac-proxy`. The account must have a RBAC permission to `get` the `deployments/cli-binary` subresource `registry-packages-proxy` in the namespace `d8-cloud-instance-manager`.

To grant the required permission, use the ClusterRole `d8:registry-packages-proxy:cli-download`. For details, refer to “Granting access to Deckhouse CLI downloads”.

The same permission is used to download the Deckhouse CLI plugins. The plugins are available at `deckhouse-cli/plugins/<PLUGIN>` through the same `/v1/images/` endpoints.

Method	Path	Description
`GET`	`/v1/images/<IMAGE>/tags`	Returns a list of tags in JSON format

Method	Path	Description
`GET`, `HEAD`	`/v1/images/<IMAGE>/images/<VERSION>`	Returns an OCI image in the `application/x-gzip` format (with flattened layers)
`GET`	`/v1/images/<IMAGE>/manifests/<REFERENCE>`	Returns an image manifest

Allowed `<IMAGE>` values:

- `deckhouse-cli`
- `deckhouse-cli/plugins/<PLUGIN>`, where `<PLUGIN>` is a single path segment

Deckhouse CLI artifacts can live at one of two places. The official registry publishes them once for all editions, at the registry root one level above the cluster's edition repository. A registry filled by `d8 mirror push` keeps them right under the cluster repository, exactly as pushed.

The proxy takes the repository from the `d8-system/deckhouse-registry` secret and probes the candidate roots in order: first the repository as is, then the repository without the trailing edition segment (`ce`, `be`, `se`, `se-plus`, `ee`, `fe`). The root that answers is remembered and tried first afterwards; a 404 on the remembered root or a repository change in the secret triggers a re-probe. For example, a cluster with the `registry.deckhouse.io/deckhouse/ee` repository reads the images from `registry.deckhouse.io/deckhouse/deckhouse-cli` and `registry.deckhouse.io/deckhouse/deckhouse-cli/plugins/<PLUGIN>`, while a cluster mirrored to `registry.local/dest/ee` reads them from `registry.local/dest/ee/deckhouse-cli/plugins/<PLUGIN>`. A repository without an edition segment is used as is. The credentials come from the same secret in all cases.

The `/v1/images/<IMAGE>/images/<VERSION>` endpoint accepts an optional `platform=<OS>-<ARCH>` query parameter and picks the matching child manifest from a multi-platform index. If the parameter isn't set, the `linux/amd64` platform is used.

The following is an example of a query for a list of Deckhouse CLI tags:

```
curl -fsS \
  -H "Authorization: Bearer ${TOKEN}" \
  "https://registry-packages-proxy.example.com/v1/images/deckhouse-cli/tags"
```

Internal `/package` endpoint

The legacy `/package?digest=...` endpoint (used during bootstrap and by internal components) remains protected by RBAC (`deployments/http` subresource). It is not exposed through the public Ingress.

Package retrieval flow

When a component requests a package:

1. The request includes a `digest` parameter (required) and optional `repository` and `path` parameters.
2. The proxy checks its local cache for the requested digest.
3. If cached, the package is served directly from cache.
4. If not cached:
   - The proxy fetches credentials for the specified registry from watched ModuleSource resources.
   - The package is retrieved from the remote registry.
   - The package is streamed to the client while simultaneously being cached for future requests.
5. Responses include appropriate HTTP headers for caching (`Cache-Control`, `ETag`, `Content-Length`).

High availability

The module ensures high availability through:

- Running multiple replicas on master nodes (in HA configurations).
- Pod anti-affinity rules to distribute pods across different masters.
- PodDisruptionBudget to prevent simultaneous disruption of all replicas.
- Vertical Pod Autoscaler support for automatic resource adjustments.

RBAC roles provided by the module

ClusterRole	Purpose
`d8:registry-packages-proxy:cli-download`	Access to `/v1/images/*`: the `deckhouse-cli` binary and its plugins
`d8:registry-packages-proxy:packages-download`	Reserved for future authenticated `/v1/packages/*` routes (icons are served anonymously, in-cluster only)

Neither role is bound to anyone out of the box.

Granting access to Deckhouse CLI downloads

For Deckhouse CLI to work, a user requires permissions to download binaries and obtain the proxy public address.

⚠ To be able to create ClusterRoleBinding or RoleBinding, the account must have permissions to assign a respective role. Use the account with the corresponding permissions if necessary, such as `/etc/kubernetes/super-admin.conf`.

1. Grant access to download binaries. To do that, use the ClusterRole `d8:registry-packages-proxy:cli-download`. This role grants permissions required to self-update Deckhouse CLI (`d8 cli`) and download plugins (`d8 plugins`):

   Create a ClusterRoleBinding:

   ```
   d8 k create clusterrolebinding d8-cli-download \
     --clusterrole=d8:registry-packages-proxy:cli-download \
     --group=<GROUP>
   ```

   Instead of `--group=<GROUP>`, you can grant permissions to a specific user (`--user=<EMAIL>`) or service account (`--serviceaccount=<NAMESPACE>:<NAME>`).

2. Grant access to obtain public address of the proxy. Deckhouse CLI obtains public address from the `registry-packages-proxy` Ingress.

   - Create the `d8-cli-ingress` Role, which grants the `get` permission for that Ingress:

     ```
     d8 k -n d8-cloud-instance-manager create role d8-cli-ingress \
       --verb=get \
       --resource=ingresses \
       --resource-name=registry-packages-proxy
     ```

   - Create a RoleBinding for assigning the created role to a target group:

     ```
     d8 k -n d8-cloud-instance-manager create rolebinding d8-cli-ingress \
       --role=d8-cli-ingress \
       --group=<GROUP>
     ```

   Without granted access, the proxy address needs to be specified manually:

   ```
   d8 cli check --rpp-endpoint https://registry-packages-proxy.<PUBLIC_DOMAIN>
   ```

3. Check the granted permissions without logging in as the user. The permissions are limited by `resourceNames`, therefore make sure to specify the resource name.

   - Ensure the access to download binaries has been granted:

     ```
     d8 k auth can-i get deployments/registry-packages-proxy \
       -n d8-cloud-instance-manager \
       --subresource=cli-binary \
       --as=<EMAIL_OR_SERVICE_ACCOUNT>
     ```

   - Ensure the access to obtain Ingress `registry-packages-proxy` has been granted:

```
d8 k auth can-i get ingresses/registry-packages-proxy \
  -n d8-cloud-instance-manager \
  --as=<EMAIL_OR_SERVICE_ACCOUNT>
```

`Kube-rbac-proxy` caches authorization decisions: a denial for 30 seconds, an approval for 5 minutes. Consider that while checking the granted permissions: once the permission has been granted, a `403` response clears in half a minute, and after a permission has been revoked, the access is still granted for up to 5 minutes.

Limitations

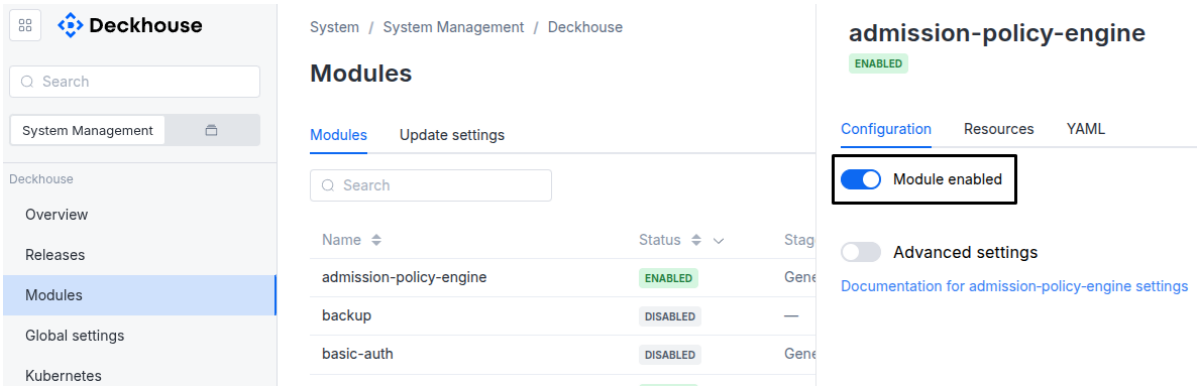
- The module runs exclusively on master nodes.
- It requires `hostNetwork: true` to function during bootstrap phase.
- Cache size is limited to 1 GB per pod.
- Most HTTP endpoints require Kubernetes RBAC; only health checks (healthz) and package icons are anonymous. Package icons are additionally limited to in-cluster access (no public Ingress route).
- Package icons are read from fixed paths inside the package image (`docs/icon.svg`, `docs/icon.png`, `docs/icon.jpg`, `docs/icon.jpeg`) with SVG preferred. Maximum icon size is 4 MiB.

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The registry-packages-proxy: configuration

Included in extensions: **Advanced Infrastructure Security**



The module lifecycle stage: General Availability

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry-packages-proxy` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

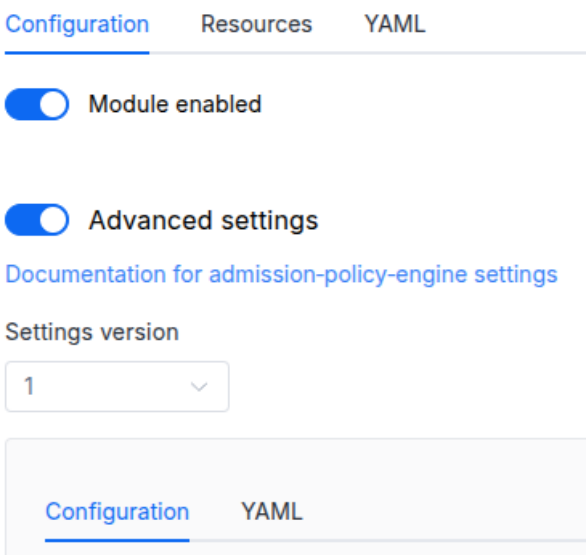
```
d8 system module enable registry-packages-proxy
```

- **Using ModuleConfig `registry-packages-proxy`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `registry-packages-proxy` (create it if necessary);

  Example of a manifest to enable module `registry-packages-proxy`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry-packages-proxy
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry-packages-proxy` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `registry-packages-proxy` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `registry-packages-proxy`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `registry-packages-proxy` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc registry-packages-proxy
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

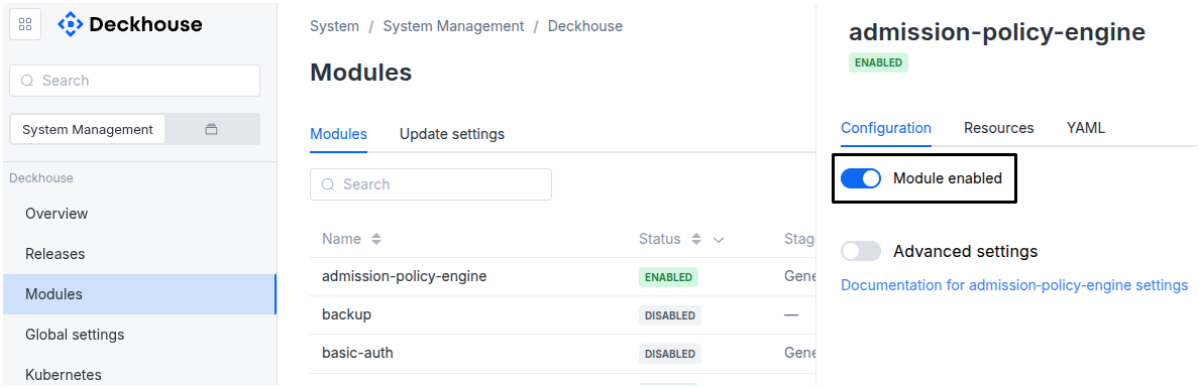
  You can also create a file with manifest for ModuleConfig `registry-packages-proxy` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `registry-packages-proxy`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry-packages-proxy
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```



The module does not have any mandatory parameters.

The module is **enabled** by default in the `Default`, `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`, `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry-packages-proxy` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

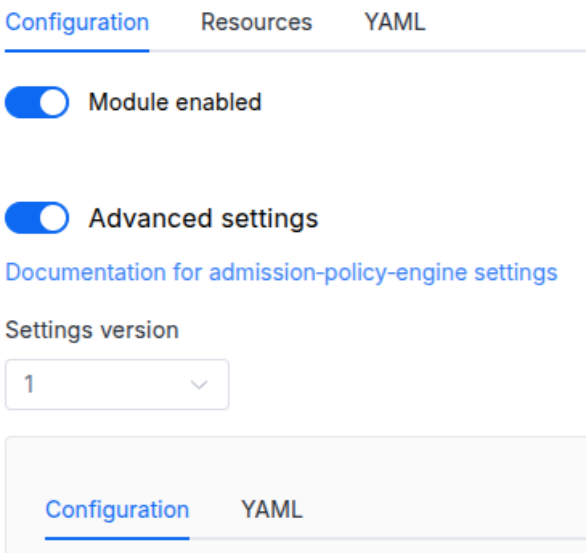
```
d8 system module enable registry-packages-proxy
```

- **Using ModuleConfig `registry-packages-proxy`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `registry-packages-proxy` (create it if necessary);

  Example of a manifest to enable module `registry-packages-proxy`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry-packages-proxy
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry-packages-proxy` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `registry-packages-proxy` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `registry-packages-proxy`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `registry-packages-proxy` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc registry-packages-proxy
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `registry-packages-proxy` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `registry-packages-proxy`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: registry-packages-proxy
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.highAvailability**
    boolean

Manually enable the high availability mode.

By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

Example:

```
highAvailability: true
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The secret-copier module

> The module lifecycle stage: General Availability

This module copies Secrets to all namespaces.

It facilitates the copying of Secrets required to pull images and to provision Ceph's RBDs as part of the CI process.

> ⚠ The `secret-copier` module cannot be used together with `multitenancy-manager`.
>
> `multitenancy-manager` creates isolated environments for users within their projects, while `secret-copier` automatically distributes secrets across all namespaces. This may lead to sensitive data leaks if important secrets end up in a user's isolated environment, violating the security model.
>
> If you need to provide a shared certificate (e.g., a WC certificate for an internal environment) or a shared registry access token, do not use `secret-copier`. Instead, place such secrets in the project template in `multitenancy-manager` — the cluster administrator should define them in the project configuration.

How does it work?

This module monitors the Secrets (with the `secret-copier.deckhouse.io/enabled: ""` label) in the `default` namespace for changes.

- The module copies such a Secret to all namespaces after it is created.
- When a Secret is changed, its new contents are also propagated to all namespaces.
- When a Secret is deleted, its copies are deleted from all namespaces.
- The module restores the original content of a copy of a Secret in the application namespace if it gets modified.
- The module copies all the Secrets (that have the `secret-copier.deckhouse.io/enabled: ""` label) of the `default` namespace to any newly created namespace.
- The module never creates, updates or deletes the Secret `d8-system/cluster-key`, which holds the cluster key of Deckhouse Platform licensing.
- The module does not copy Secrets of the `bootstrap.kubernetes.io/token` type. The copies of such Secrets that earlier versions of the module made are deleted.
- The module updates and deletes only its own copies. If a namespace already has a Secret with the same name that the module did not create, the module leaves it as is and does not copy the Secret into that namespace.

Additionally, it synchronizes the Secrets every night, ensuring they are identical to those in the `default` namespace.

What do I need to configure?

All you need to do is to create a Secret with the `secret-copier.deckhouse.io/enabled: ""` label in the `default` namespace.

> **Note!** The working namespace for the module is `default`, Secrets will be copied only from it. Secrets with the secret-copier.deckhouse.io/enabled: “” label created in other namespaces will be automatically deleted when the module is enabled.

How to synchronize Secret to some selected namespaces instead of all namespaces?

Specify namespace label-selector in the value of the `secret-copier.deckhouse.io/target-namespace-selector` annotation. For example: `secret-copier.deckhouse.io/target-namespace-selector: "app=custom"`. The module will create a copy of that Secret in all namespaces that matches the label-selector.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The terraform-manager module

> The module lifecycle stage: General Availability

The module is responsible for monitoring and synchronizing the state of the underlying infrastructure and persistent nodes in the cloud environment. The implementation is based on Terraform and is used in the Deckhouse Platform for interaction with supported cloud providers.

- The module consists of 2 parts:
  - `terraform-auto-converger` — checks the Terraform state and applies non-destructive changes;
  - `terraform-state-exporter` — checks the Terraform state and exports cluster metrics.
- The module is enabled by default if the following secrets are present in the cluster:
  - `kube-system/d8-provider-cluster-configuration`;
  - `d8-system/d8-cluster-terraform-state`.

Third-party components

List of third-party software used in the `terraform-manager` module:

- Terraform

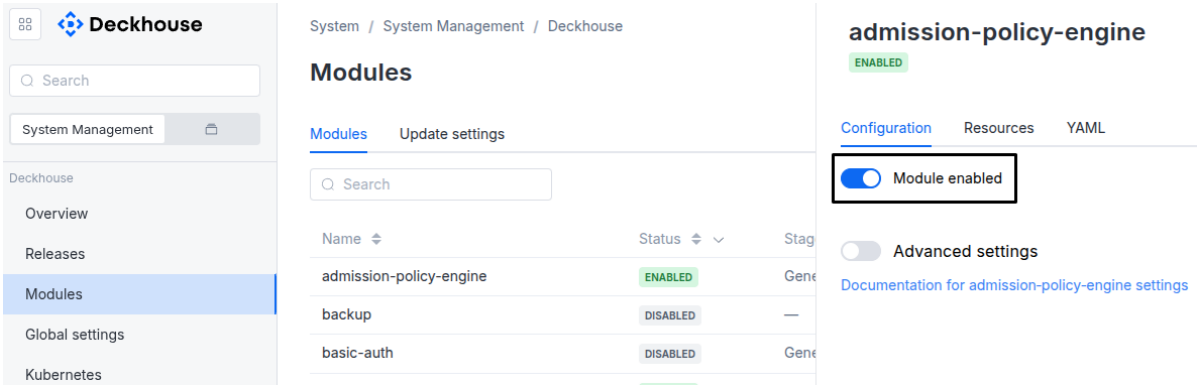
  License: Mozilla Public License 2.0

  A tool for building, changing, and versioning infrastructure safely and efficiently.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

> The module lifecycle stage: General Availability



The module has 10 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `terraform-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

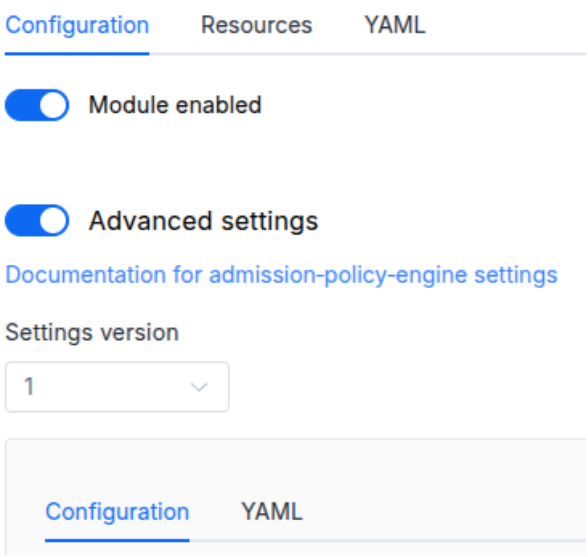
```
d8 system module enable terraform-manager
```

- **Using ModuleConfig `terraform-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `terraform-manager` (create it if necessary);

  Example of a manifest to enable module `terraform-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: terraform-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `terraform-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `terraform-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `terraform-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `terraform-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc terraform-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `terraform-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `terraform-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: terraform-manager
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.autoConvergerEnabled**
    boolean

    Enables periodic checking of Terraform state and applying non-destructive changes.

    The frequency of the check is set by the autoConvergerPeriod parameter.

    Default: `true`

- **settings.autoConvergerPeriod**
  string

  The time interval after which the state of Terraform is checked and applied.

  It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

  Default: `1h`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.nodeSelector**
  object

  The same as in the Pod's `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Module user-authn

> **i** Included in extensions: **Billing**

> **i** The module lifecycle stage: General Availability

The module sets up a unified authentication system integrated with Kubernetes and Web interfaces used in other modules (Grafana, Dashboard, etc.).

Main features

The module provides the following features:

- Single sign-on to the web interfaces of Deckhouse Platform (DP) modules and to the Kubernetes API through Dex
- Sign-in through external providers: GitHub, GitLab, Bitbucket Cloud, Atlassian Crowd, LDAP (with Kerberos SSO), OIDC and SAML 2.0
- Static users and groups with a password policy, account lockout and two-factor authentication
- Authentication for any web application in the cluster with DexAuthenticator, and OAuth2 clients for applications that support OIDC (DexClient)
- Kubeconfig generation in the Deckhouse web UI for access with `kubectl` and OIDC tokens
- Basic authentication to the Kubernetes API through one Crowd, OIDC or LDAP provider

Components

The module consists of the following components:

- dex — is a federated OpenID Connect provider that acts as an identity service for static users and can be linked to one or more ID providers (e.g., SAML providers, GitHub, and GitLab);
- `dex-authenticator` (based on oauth2-proxy) authenticates requests to an application published through an Ingress or, with the `alb` module, through Gateway API.

Management of static users is performed using the User and Group resources:

- The User object stores user information, including the email address and a password hash (the plain-text password is not stored);
- The Group object defines a list of users grouped together for easier access management.

User management operations — creating and deleting users, managing groups, resetting passwords, resetting 2FA, and locking/unlocking — can be performed via the CLI using the `d8 iam` command group or via the UserOperation resource. The `UserOperation` resource is single-use and is automatically deleted after `retention.userOperations` (24 hours by default).

The following external authentication protocols/providers are supported:

- GitHub;
- GitLab;
- BitBucket Cloud;
- Crowd;
- LDAP;
- OIDC;
- SAML 2.0.

You can use several external authentication providers simultaneously.

Integration features

OIDC authentication in `kube-apiserver` is configured automatically by the `control-plane-manager` module. For details, see Configuring kube-apiserver.

⚠ When the module is enabled, the web interfaces of DP modules authenticate users through Dex instead of HTTP Basic Auth.

Basic authentication for the Kubernetes API requests

Basic authentication for Kubernetes API requests is available for the Crowd, OIDC and LDAP providers (the `enableBasicAuth` parameter in the crowd, oidc or ldap section). It can be enabled for only one provider in the cluster. For a Crowd or OIDC provider, Basic Authentication bypasses the identity limits of the provider, so only a SuperAdmin can enable it.

i You can also connect to the Kubernetes API via other supported external providers.

Application integration

To add authentication to any web application in the cluster, create a DexAuthenticator in the namespace of the application and add the authentication annotations to its Ingress or HTTPRoute. DexAuthenticator can limit the groups and emails that are allowed to sign in and the networks from which users can authenticate.

If the application supports OIDC itself, create a DexClient in its namespace instead. The module registers an OAuth2 client in Dex and creates the `dex-client-<NAME>` Secret with the client secret in the same namespace. DexClient can limit the groups and emails that are allowed to sign in and list the clients whose tokens the application trusts (`trustedPeers`).

Generating kubeconfig files

After signing in, a user can generate a kubeconfig for kubectl and other Kubernetes tools in the Deckhouse web UI. The kubeconfig uses an OIDC token. If the authentication provider supports session extension, the kubeconfig also contains a refresh token, and the session is extended automatically. If the provider reports during the extension that the user no longer exists or has lost access, Dex refuses the refresh token with the `invalid_grant` error, and the user has to sign in again.

The `kubeconfigGenerator` parameter adds other ways to reach the API server, each with its own

address and CA certificate, for example, for access through a bastion host or a VPN.

Additional Dex capabilities

The module ships Dex with additional capabilities:

- Groups for static users (the Group object)
- Two-factor authentication (2FA) for local users and the users of LDAP and Crowd providers (the `twoFactor` parameter)
- A password policy for static users: complexity, password history, rotation and lockout after failed sign-in attempts (the `passwordPolicy` parameter)
- A forced password change at the next sign-in after an administrator resets the password
- Lockout after failed sign-in attempts for LDAP and Atlassian Crowd users (the `passwordPolicy.lockout.applyToConnectors` parameter)
- Per-IP rate limiting of failed sign-in attempts (the `rateLimit` parameter)
- Locking and unlocking users of any provider with the UserOperation object, also without a password policy
- Lists of allowed users and groups in DexClient and DexAuthenticator that Dex checks at sign-in and at every refresh-token request
- Limits on the identities a provider may assert (the `spec.allowedIdentities` parameter of DexProvider)
- Kerberos (SPNEGO) sign-in through the LDAP provider without the password form, with tickets from the `Authorization: Negotiate` header validated by the service keytab
- Refresh tokens for the SAML provider
- A custom CA certificate for the GitLab provider (the `gitlab.rootCAData` parameter)

High availability mode

In high availability mode (`highAvailability`), Dex and the other module components run in several replicas, so sign-in keeps working if one pod fails. DexAuthenticator follows the same setting unless its own `spec.highAvailability` is set.

Third-party components

List of third-party software used in the `user-authn` module:

- Dex 2.46.0

  License: Apache License 2.0

  A Federated OpenID Connect Provider with pluggable connectors.

- OAuth2 Proxy 7.15.5

  License: MIT License

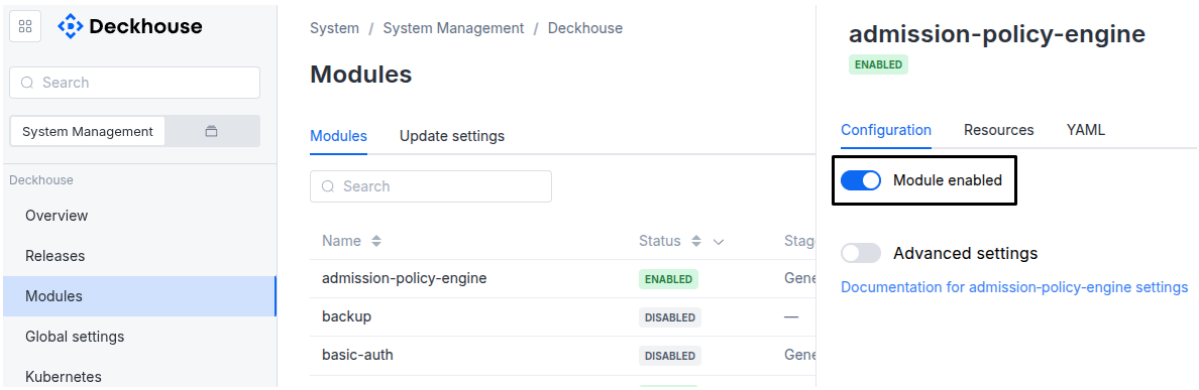
  A reverse proxy and static file server that provides authentication using Providers (Google, GitHub, and others) to validate accounts by email, domain or group.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The user-authn module: configuration

> **i** Included in extensions: **Billing**

> **i** The module lifecycle stage: General Availability



The module has 15 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `user-authn` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

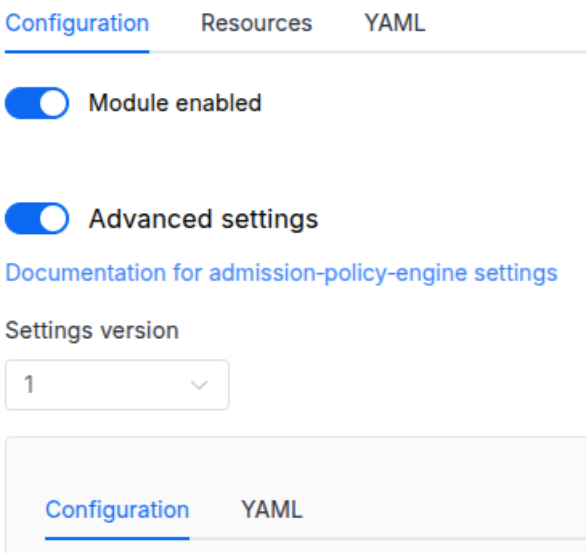
```
d8 system module enable user-authn
```

- **Using ModuleConfig `user-authn`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `user-authn` (create it if necessary);

  Example of a manifest to enable module `user-authn`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `user-authn` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `user-authn` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `user-authn`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `user-authn` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc user-authn
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `user-authn` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `user-authn`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: user-authn
  spec:
    version: 4
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Replace `publishAPI.enable` with `publishAPI.enabled`.

- Updates from version **2** to **3**:

  An `idTokenTTL` of 6 hours or more is replaced with `5h59m`: Dex rotates its signing keys every 6 hours.

- Updates from version **3** to **4**:

  The `staticUsers2FA` parameter is renamed `twoFactor`. The second factor can now be turned on for more than the local users.

Parameters

Schema version: 4

- **settings**
  object
  - **settings.controlPlaneConfigurator**
    object

    Parameters of the `control-plane-manager` module for automatic configuration of `kube-apiserver`.

    - **settings.controlPlaneConfigurator.dexCAMode**
      string

      How to determine the CA that will be used when configuring `kube-apiserver`.

      - `Custom` — use the CA explicitly set via the `dexCustomCA` parameter (see below). This option comes in handy if you use an external HTTPS load balancer in front of Ingresses, and this load balancer relies on a self-signed certificate.
      - `DoNotNeed` — a CA is not required (e.g., when using a public LE or other TLS providers).
      - `FromIngressSecret` — extract the CA of certificate from the Secret that is used in the Ingress. This option comes in handy if you use self-signed certificates with Ingresses.

      Default: `DoNotNeed`

      Allowed values: `Custom`, `DoNotNeed`, `FromIngressSecret`

    - **settings.controlPlaneConfigurator.dexCustomCA**
      string

      The CA to use if `dexCAMode` is `Custom`. Plain text (no base64).

    - **settings.controlPlaneConfigurator.enabled**
      boolean

      Defines if the `control-plane-manager` module should be used to configure OIDC for the `kube-apiserver`.

      Default: `true`

  - **settings.devices**
    object

    Devices of a user: the browsers and the other clients (kubeconfig, `d8 login`) the user signed in from.

    - **settings.devices.maxPerApplication**
      integer

      The maximum number of devices on which a user can be simultaneously logged in to a single application (DexAuthenticator, DexClient, kubeconfig).

      A device is a browser with a Dex session together with all application domains it has logged in to, or a refresh token without a browser session, e.g. a kubeconfig file.

      If a user logs in from a new device and the limit specified in the parameter has been reached, the device that has been unused the longest is logged out of the application. Non-trusted devices are logged out first (for details, see the description of the `trustedAfter` parameter).

      Default: `10`

      Allowed values: `1 <= X <= 1000`

      Examples:

      ```
      maxPerApplication: 10
      ```

```
maxPerApplication: 3
```

- **settings.devices.rememberedBrowsers**
  integer

  How many browsers of a user Dex remembers with their first sign-in.

  A remembered browser that signs in again keeps its age: the time until it is trusted (`trustedAfter`) counts from its first sign-in. Past the limit, the browser seen longest ago is forgotten and counts as new at its next sign-in.

  `0` remembers no browser: every sign-in is a new device.

  Default: `20`

  Allowed values: `0 <= X <= 1000`

  Examples:

  ```
  rememberedBrowsers: 20
  ```

  ```
  rememberedBrowsers: 0
  ```

- **settings.devices.trustedAfter**
  string

  Time after which a device of the user is trusted, counted from the first sign-in from its browser (from the sign-in for a device without a browser).

  Only a trusted device lets the user sign out of all devices, of the other devices or of another device, and request a password change on their own. A device signed in more recently can sign the user out only of itself. Someone who has just signed in with a stolen password therefore can neither sign the owner out nor change the password, while the owner sees the new device on a trusted one and signs it out. A stolen session is not covered: a copied cookie of Dex or of the web interface has the age of the owner’s device. The operations of an administrator are not limited.

  When an application reaches the limit of devices of a user, the devices that are not trusted yet are signed out of it first.

  `0s` trusts every device at once: any device can sign out the others and request a password change.

  Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `2h30m`, `24h`.

  Default: `24h`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

  Examples:

  ```
  trustedAfter: 24h
  ```

  ```
  trustedAfter: 1h
  ```

  ```
  trustedAfter: 0s
  ```

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Learn more about the high availability mode for modules.

  Examples:

  ```
  highAvailability: true
  ```

```
highAvailability: false
```

- **settings.https**
  object

  What certificate type to use with Dex.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object

    Settings of the `CertManager` mode.

    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for Dex.

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.https.customCertificate**
    object

    Settings of the `CustomCertificate` mode.

    - **settings.https.customCertificate.secretName**
      string

      The name of the Secret in the `d8-system` namespace to use with Dex.

      This Secret must have the kubernetes.io/tls format.

      Default: `false`

  - **settings.https.mode**
    string

    The HTTPS usage mode:

    - `CertManager`: Dex uses HTTPS and gets a certificate from the ClusterIssuer set in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate`: Dex uses HTTPS with the certificate from the `d8-system` namespace.
    - `Disabled`: The module is turned off, because it works only with HTTPS.
    - `OnlyInURI`: Dex works over HTTP behind an external load balancer that terminates HTTPS. All `user-authn` links use the HTTPS scheme. The load balancer must redirect HTTP to HTTPS.

    If you set the `https` section without `mode`, `Disabled` applies and the module is turned off.

    Default: `Disabled`

    Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.idTokenTTL**
  string

  TTL of the ID token

TTL of the ID token.

Set as a string specifying hours, minutes, or seconds: `30m`, `20s`, `2h30m10s`, `5h`.

Must be greater than zero and strictly less than 6 hours (Dex signing keys rotate every 6 hours). A ModuleConfig of an earlier settings version (`spec.version` 1 or 2) with a value of 6 hours or more is still accepted: its value is converted to `5h59m`.

Defines the minimum possible user session lifetime (via `keepUsersLoggedInFor` in the DexAuthenticator resource and parameters like `auth.sessionTTL`, for example, in the `console` module).

If the session TTL is less than or equal to `idTokenTTL`, the effective logout time is `idTokenTTL + 1s`.

To force logout sooner than the default `idTokenTTL`, decrease this parameter value as well.

Default: `10m`

Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.ingressClass**
  string

  The class of the Ingress controller that will be used for Dex.

  An optional parameter; by default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.kubeconfigGenerator**
  array of objects

  An array in which additional possible methods for accessing the API server are specified.

  This option comes in handy if you prefer not to grant access to the cluster's API via Ingress but rather do it by other means (e.g., using a bastion host or over OpenVPN).

  - **settings.kubeconfigGenerator.description**
    string

    A couple of words how this authentication method differs from others.

  - **settings.kubeconfigGenerator.id**
    string

    Required value

    The name of the method for accessing the API server (no spaces, lowercase letters).

    Pattern: `^[\@\.\:0-9a-z._-]+$`

  - **settings.kubeconfigGenerator.masterCA**
    string

    A CA for accessing the API:

    - If the parameter is not set, Kubernetes CA is used.
    - We recommend using a self-signed certificate (and specify it as masterCA) if an HTTP proxy (that terminates HTTPS traffic) is used for exposing.

  - **settings.kubeconfigGenerator.masterURI**
    string

    Required value

    API server address that kubeconfig files generated for this access method point to, for example `https://192.168.0.15:6443`.

    If clients reach the API server through a TCP proxy or a load balancer, add its address to the `apiserver.certSANs` parameter of the `control-plane-manager` module.

- **settings.nodeSelector**
  object

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted, it is determined automatically.

- **settings.passwordPolicy**

object

Password policy for local users.

Default:

- **settings.passwordPolicy.complexityLevel**
  string

  Password complexity level.

  Depending on the complexity level, a password must meet the following minimum requirements:

  - `None`: 1 character.
  - `Low`: 8 characters.
  - `Fair`: 8 characters, 1 uppercase letter (`A-Z`), 1 lowercase letter (`a-z`), 1 digit.
  - `Good`: 8 characters, 1 uppercase letter (`A-Z`), 1 lowercase letter (`a-z`), 1 digit, 1 special character (`!@#$%^&*`).
  - `Excellent`: 8 characters, 1 uppercase letter (`A-Z`), 1 lowercase letter (`a-z`), 1 digit, 1 special character (`!@#$%^&*`), no more than 2 identical characters in a row.
  - `Custom`: requirements are defined by the `custom` field.

  Default: `Fair`

  Allowed values: `None`, `Low`, `Fair`, `Good`, `Excellent`, `Custom`

- **settings.passwordPolicy.custom**
  object

  Custom password complexity rules.

  Applied only when `complexityLevel` is set to `Custom`. Any combination of the rules below can be enabled independently.

  - **settings.passwordPolicy.custom.capitalized**
    boolean

    If `true`, a password must contain at least one uppercase letter (`A-Z`).

    Default: `false`

  - **settings.passwordPolicy.custom.minLength**
    integer

    Minimum number of characters in a password.

    Default: `8`

    Allowed values: `1 <= X`

  - **settings.passwordPolicy.custom.numbers**
    boolean

    If `true`, a password must contain at least one digit.

    Default: `false`

  - **settings.passwordPolicy.custom.repeatedChars**
    boolean

    If `true`, a password must not contain more than 2 identical characters in a row (the same rule the `Excellent` level applies).

    Default: `false`

  - **settings.passwordPolicy.custom.specialCharacters**
    boolean

    If `true`, a password must contain at least one special character (anything that is neither a letter nor a digit).

    Default: `false`

- **settings.passwordPolicy.lockout**
  object

  Automatic temporary lockout after consecutive failed login attempts.

This section only controls lockout after a failed password. An administrator lock via UserOperation (`d8 iam user lock`) works independently and does not require `passwordPolicy` or this `lockout` block.

- **settings.passwordPolicy.lockout.applyToConnectors**
  array of strings

  External (non-local) connector types the lockout additionally applies to.

  The built-in `Local` connector is always covered by the lockout policy when this section is configured and does not need to be listed here.

  For the listed connector types, Dex counts failed attempts and locks each pair of a provider and a user separately. The UserAccount object of the user shows the counter and the lock.

  Manually unlocking a user is supported for every provider type via a UserOperation.

  - **Element of the array**
    string

    Allowed values: `LDAP`, `Crowd`

- **settings.passwordPolicy.lockout.lockDuration**
  string

  Required value

  Temporary lockout duration. Can be set in seconds, minutes, hours, or days: `10s`, `5m`, `1h`, `3d`.

  Pattern: `^(?:(?:[1-9]|[1-9][0-9]+)d)?(?:(?:[1-9]|[1-9][0-9]+)h)?(?:(?:[1-9]|[1-9][0-9]+)m)?(?:(?:[1-9]|[1-9][0-9]+)s)?$`

- **settings.passwordPolicy.lockout.maxAttempts**
  integer

  Required value

  Number of consecutive failed login attempts after which the user will be temporarily locked out.

- **settings.passwordPolicy.passwordHistoryLimit**
  integer

  Number of the user’s previous passwords stored in history to prevent their reuse.

  Default: `5`

  Allowed values: `0 <= X`

- **settings.passwordPolicy.rotation**
  object

  Password rotation settings.

  - **settings.passwordPolicy.rotation.interval**
    string

    Required value

    Time interval after which the password must be changed. Can be set in seconds, minutes, hours or days: `10s`, `5m`, `1h`, `3d`.

    Pattern: `^(?:(?:[1-9]|[1-9][0-9]+)d)?(?:(?:[1-9]|[1-9][0-9]+)h)?(?:(?:[1-9]|[1-9][0-9]+)m)?(?:(?:[1-9]|[1-9][0-9]+)s)?$`

- **settings.publishAPI**
  Deprecated
  object

  Obsolete. The module does not publish the Kubernetes API. The API is published with the `apiserver.publishAPI` parameter of the `control-plane-manager` module. Move existing settings there.

  For more information on how to expose the Kubernetes API, see the `control-plane-manager` module documentation.

- **settings.publishAPI.addKubeconfigGeneratorEntry**
  boolean

  Obsolete. Use the `apiserver.publishAPI.ingress.addKubeconfigGeneratorEntry` parameter of the `control-plane-manager` module.

  Default: `true`

- **settings.publishAPI.enabled**
  boolean

  Obsolete. Does not create an Ingress.

  Default: `false`

- **settings.publishAPI.https**
  object

  The HTTPS mode for the API server Ingress.

  Examples:

  ```
  https:
    mode: SelfSigned
  ```

  ```
  https:
    mode: Global
    global:
      kubeconfigGeneratorMasterCA: plainstring
  ```

  - **settings.publishAPI.https.global**
    object

    An additional parameter for the `Global` mode.

    - **settings.publishAPI.https.global.kubeconfigGeneratorMasterCA**
      string

      If there is an external load balancer in front of the Ingress that terminates HTTPS traffic using non-public CA, then you need to specify the CA so it will be included in kubectl-config.

      If you are using certificates issued by the `cert-manager` module and Let's Encrypt in your cluster, you should set an empty string `""` as the value.

      Also, you can set the external LB's certificate itself as a CA if you can't get the CA that signed it for some reason. Note that after the certificate is updated on the LB, all the previously generated kubeconfigs will stop working.

  - **settings.publishAPI.https.mode**
    string

    The mode of issuing certificates for the Ingress resource.

    In the `SelfSigned` mode, a CA-signed certificate will be issued for the Ingress resource.

    In the `Global` mode, the policies specified in the `global.modules.https.mode` global parameter will be applied. Thus, if the global parameter has the `CertManager` mode set (with `letsencrypt` as the ClusterIssuer), then the Let's Encrypt certificate will be issued for the Ingress resource.

    Default: `SelfSigned`

    Allowed values: `SelfSigned`, `Global`

- **settings.publishAPI.ingressClass**
  string

  The Ingress class that will be used to expose the Kubernetes API via Ingress.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.publishAPI.whitelistSourceRanges**

array of strings

An array of CIDRs that are allowed to connect to the API server.

- **Element of the array**
  string

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))?$`

- **settings.rateLimit**
  object

  Brute-force protection for the password endpoints of Dex.

  When enabled, Dex limits the failed requests from each client IP address to the following endpoints:

  - `/token`: Token endpoint: client authentication and the password grant. Other requests of an authenticated client, such as refresh-token requests, do not count.
  - `/auth/{connector}/login`: Sign-in form of the local, LDAP and Crowd providers.
  - `/password/change`: Password change page.
  - `/mfa` and the paths under it: Steps of two-factor authentication (2FA).

  The client IP address is taken from the `X-Real-IP` header that the platform Ingress controller sets. Dex trusts the header only from the proxies of the platform. The Ingress controller proves itself with its client certificate, which the platform CA issued for the `ingress-nginx:auth` organization. The controller presents it to any backend an Ingress asks it to, so whoever can create an Ingress with configuration snippets on that controller can set the address too. The Gateway sends a secret stored in the HTTPRoute object of the module in `d8-user-authn`: whoever can read it can set the address too. For any other request, for example from a pod that calls the Dex Service directly, Dex counts the address of the connection. Through the Gateway API (the `alb` module) Dex counts the last address of `X-Forwarded-For`: the address the ALB saw, or the one a balancer passed when the ALB instance trusts it in `originalIPDetection.setRealIPFrom`. Behind a balancer the ALB instance does not trust, every client is counted by the address of the balancer. Basic Authentication to the Kubernetes API through an LDAP provider is counted per address of the client that the platform Ingress controller or Gateway saw: basic-auth-proxy passes on the last hop of `X-Forwarded-For`. The Ingress controller has to see the address of the client itself: behind a balancer that replaces it, all users are counted together (see Which client address does Dex see?).

  The limit applies to **failed authentication attempts only**. Each request takes a token from the bucket of its IP address, and a successful response (HTTP `2xx` or `3xx`) returns the token. Successful logins and refresh-token exchanges do not consume the per-IP budget. When the bucket is empty, Dex answers with the `429` status code and the `Retry-After` header.

  Limits are tracked in memory in each Dex replica. In HA setups, the effective per-IP rate is multiplied by the number of replicas. Account lockout complements this limit.

  - **settings.rateLimit.enabled**
    boolean

    Enable per-IP rate limiting on Dex password endpoints.

    Default: `false`

  - **settings.rateLimit.perIP**
    object

    Per-source-IP token-bucket configuration.

    Both `requestsPerMinute` and `burst` parameters count failed authentication attempts only.

    - **settings.rateLimit.perIP.burst**
      integer

      Maximum bucket size defining the allowed number of failed authentication attempts from a single IP address before the throttling activates.

      Default: `10`

      Allowed values: `1 <= X`

    - **settings.rateLimit.perIP.requestsPerMinute**

integer

Maximum rate of failed authentication attempts tolerated per IP address (in attempts per minute).

Successful logins and refresh-token exchanges do not consume the budget.

Default: `10`

Allowed values: `1 <= X`

- **settings.refreshTokenAbsoluteLifetime**
  string

  Maximum lifetime of refresh tokens (maps to Dex `expiry.refreshTokens.absoluteLifetime`).

  This setting controls how long user sessions can persist. After this period expires, users will need to re-authenticate, even if they have active refresh tokens.

  A refresh token that is not used for `refreshTokenValidIfNotUsedFor` expires earlier.

  The value must not be shorter than `idTokenTTL`.

  It is specified as a string containing the time unit in hours, minutes and seconds: 30m, 20s, 2h30m10s, 24h.

  Default: `4380h`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.refreshTokenValidIfNotUsedFor**
  string

  Time after which a refresh token that is not used expires (maps to Dex `expiry.refreshTokens.validIfNotUsedFor`).

  A kubeconfig file or an application that has not refreshed its tokens for this time signs in again. By default, about 3 months.

  The value must be greater than zero and not longer than `refreshTokenAbsoluteLifetime`.

  It is specified as a string containing the time unit in hours, minutes and seconds: 30m, 20s, 2h30m10s, 24h.

  Default: `2190h`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

  Examples:

  ```
  refreshTokenValidIfNotUsedFor: 2190h
  ```

  ```
  refreshTokenValidIfNotUsedFor: 720h
  ```

- **settings.retention**
  object

  How long the records of the module are kept.

  - **settings.retention.revocations**
    string

    How long a record of a revocation (the end of the sessions and tokens of a user by an operation or a sign-out) is kept for the components that end the sessions of the user from it: DexAuthenticator objects, Basic Authentication to the Kubernetes API, the authorization webhook.

    By default, and at least, `idTokenTTL` and an hour, but not less than 70 minutes: until every token issued before the revocation expired. A shorter value is raised to this minimum.

    Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `2h30m`, `24h`.

    Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

    Example:

```
revocations: 24h
```

- **settings.retention.userOperations**
  string

  How long a UserOperation object is kept after its creation. Then it is deleted, and the history of operations of the web interface no longer shows it.

  Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `2h30m`, `24h`.

  Default: `24h`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

  Examples:

  ```
  userOperations: 24h
  ```

  ```
  userOperations: 720h
  ```

- **settings.sessions**
  object

  Browser sessions of Dex.

  With sessions on, Dex remembers the user signed in to a browser:

  - The web interfaces of Deckhouse (the DexAuthenticator objects of the platform modules, such as the console or Grafana) share the sign-in: the user enters the password and the second factor once and opens the others without them (see `sso`). For a user of an external provider, this lasts while the stored user data is fresh (see `identityRefresh`).
  - The sign-in form shows the “Remember me” checkbox. With it, the session survives closing the browser.
  - Signing out of an application of a DexAuthenticator object ends the session: the browser is signed out of all the applications of DexAuthenticator objects it signed in to through this session within seconds.

  What does not change:

  - Access tokens for `kubectl` (kubeconfig, `d8 login`) and applications of the DexClient objects that request offline access are issued only after an interactive sign-in, never from a session of the browser. A DexClient with `refreshTokenLifetime: Session` is the exception.
  - An application signed in through a DexAuthenticator stays signed in for `keepUsersLoggedInFor`, even after the session of Dex expires. The session limits only signing in without a password.
  - Signing out of Dex does not sign the user out of an external OIDC provider unless the provider has `upstreamLogout` enabled.
  - **settings.sessions.absoluteLifetime**
    string

    Maximum lifetime of a session, counted from the sign-in.

    However much the browser is used, the session ends after this time, and the next application asks for the password and the second factor again. By default, a user who works every day enters them once a week.

    Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `2h30m`, `24h`.

    Default: `168h`

    Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

  - **settings.sessions.enabled**
    boolean

    Turns the browser sessions of Dex on.

    Default: `false`

  - **settings.sessions.identityRefresh**
    object

    Freshness of the user data that Dex stores at the sign-in, such as the groups of the user.

Dex serves the stored data until it is older than `maxAge`, and then reads it from the provider again. This holds with sessions on or off: a refresh of the tokens of an application reaches the provider only when the stored data is older than `maxAge`. A user disabled at the provider therefore keeps refreshing the tokens until then. If the provider answers that the user no longer exists or is no longer allowed in, Dex ends all the sessions and tokens of the user of this provider. The data of local users is read again every time.

A provider that answers with a server error (HTTP 5xx) looks to Dex like a provider that is down. Once the stored data is older than `maxAge`, Dex answers the refresh of the tokens with 503 and keeps the tokens, and DexAuthenticator sends the user to the sign-in `idTokenTTL` after the first such error. Dex of the upstream project (dexidp/dex) and Deckhouse Dex before version 1.78 may answer the refresh of a deleted local or LDAP user this way. Behind such a provider, a deleted user sees an error page for about `idTokenTTL` and then the sign-in page.

A sign-in from a session needs fresh data too. Dex keeps no credentials of a user of an external provider to read the data in the background, so once the data is older than `maxAge`, such a user signs in to the next application with the password again. Every sign-in and every refresh of the tokens of an application that reads the provider renews the data: a user who keeps working in an application of a DexAuthenticator keeps the single sign-on. To keep it through longer breaks, raise `maxAge`.

- **settings.sessions.identityRefresh.gracePeriod**
  string

  How much longer than `maxAge` Dex serves the stored data when the provider does not answer.

  After this period, Dex refuses to refresh the tokens of the user until the provider answers.

  Set as a string of whole hours, minutes, and seconds, in this order: `30s`, `5m`, `1h`.

  Default: `0s`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.sessions.identityRefresh.maxAge**
  string

  Age of the stored data after which Dex reads it from the provider again.

  Defaults to `idTokenTTL`.

  Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `2h30m`, `24h`.

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.sessions.rememberMeCheckedByDefault**
  boolean

  Whether the “Remember me” checkbox of the sign-in form is selected by default.

  Without “Remember me”, the session ends when the browser is closed.

  Default: `false`

- **settings.sessions.sso**
  string

  Sharing of the sign-in between applications.

  - `Platform`: The web interfaces of Deckhouse share the sign-in. These are the applications of the DexAuthenticator objects in the `d8-*` namespaces. User DexAuthenticator and DexClient objects do not share it.
  - `None`: Every application asks for the sign-in. A session only spares the password when the user signs in to the same application again.

  Default: `Platform`

  Allowed values: `Platform`, `None`

- **settings.sessions.validIfNotUsedFor**
  string

Time after which an unused session ends.

A session is used when the browser signs in to an application through it, and when an application signed in through it refreshes its tokens: an application of a DexAuthenticator object or of a DexClient with `refreshTokenLifetime: Session`. Such an application refreshes its tokens while it is open and sends requests; an application closed, or open in a browser of a sleeping computer, does not use the session. While the browser uses the session, it lasts up to `absoluteLifetime`.

With the default of a day, a session survives a night but not a weekend. For stricter requirements, set a shorter time, for example `1h`: the user then enters the password again after each break of an hour.

Must not be longer than `absoluteLifetime`. When only `absoluteLifetime` is set and is shorter than a day, an unused session ends after `absoluteLifetime`.

Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `2h30m`, `24h`.

Default: `24h`

Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes.

  If the parameter is omitted, it is determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string
- **settings.twoFactor**
  object

  Two-factor authentication (2FA) with a one-time code (TOTP) from an authenticator application, with a security key (WebAuthn), or with both, as `methods` and `require` set.

  The parameter replaces `staticUsers2FA` of the earlier versions of the settings, which covered local users only. The module converts `staticUsers2FA` to this parameter.

  - **settings.twoFactor.enabled**
    boolean

    Required value

    If set to `true`, the users of the providers listed in `providerTypes` will be required to use two-factor authentication (2FA) when logging in.

    Default: `false`

  - **settings.twoFactor.issuerName**
    string

    The issuer name for the two-factor authentication (2FA) tokens. This name is visible to users in the 2FA application (e.g., Google Authenticator) and in the dialog of the browser that registers a security key.

    Default: `Deckhouse`

- **settings.twoFactor.methods**
  array of strings

  Second factors of the users of the types in `providerTypes`, unless `providerTypeOverrides` sets others for a type:

  - `TOTP`: A one-time code from an authenticator application (for example, Google Authenticator).
  - `WebAuthn`: A security key (for example, YubiKey), or the Touch ID or Windows Hello of the device. The key confirms a sign-in only for the domain it is bound to, so a fake sign-in page on another domain gets no response it can reuse.

  With two methods, `require` sets how they combine.

  A user registers a method at the first sign-in that asks for it (and until then anyone who knows the password can register their own device). The secret or the keys the user had for a method that is no longer asked for stay until a `Reset2FA` operation, so asking for the method again brings them back.

  Default: `["TOTP"]`

  - **Element of the array**
    string

    Allowed values: `TOTP`, `WebAuthn`

- **settings.twoFactor.providerTypeOverrides**
  array of objects

  Second factors of the users of one type of provider, instead of `methods` and `require`. The type must be listed in `providerTypes`, and each type appears once.

  - **settings.twoFactor.providerTypeOverrides.methods**
    array of strings

    Required value

    Second factors of the users of this type, as `methods`.

    - **Element of the array**
      string

      Allowed values: `TOTP`, `WebAuthn`

  - **settings.twoFactor.providerTypeOverrides.providerType**
    string

    Required value

    Type of provider, one of `providerTypes`.

    Allowed values: `Local`, `LDAP`, `Crowd`

  - **settings.twoFactor.providerTypeOverrides.require**
    string

    How the two methods combine, as `require`. Required with two methods, and not allowed with one.

    Allowed values: `Any`, `All`

- **settings.twoFactor.providerTypes**
  array of strings

  Types of the providers whose users have to pass the second factor:

  - `Local`: The local users (User).
  - `LDAP`: The users of every DexProvider of the `LDAP` type.
  - `Crowd`: The users of every DexProvider of the `Crowd` type.

  A user enrolls the authenticator at the first sign-in after the second factor is turned on. Until then, anyone who knows the password can enroll their own device, so ask the users to sign in right after the switch.

  Adding a type does not end the refresh tokens or the Dex browser sessions issued before it. A refresh token keeps issuing tokens without the code until it expires, and a browser session created earlier passes without the code. After enabling 2FA, run a UserOperation of type `Logout` for the users of the providers of the listed types.

The second factor is not possible together with Basic Authentication to the Kubernetes API, which has no page for a code. A provider of a listed type cannot have `enableBasicAuth: true`. The module refuses a DexProvider that would have both, and refuses this setting while such a DexProvider exists.

The OIDC, SAML, GitHub, GitLab and Bitbucket Cloud providers are not on the list. The identity provider handles the second factor for them.

Default: `["Local"]`

- **Element of the array**
  string

  Allowed values: `Local`, `LDAP`, `Crowd`

- **settings.twoFactor.require**
  string

  How the two methods of `methods` combine.

  With `Any`, the user passes one of them. At the first sign-in the user chooses the method and registers it; later Dex asks for a registered method, the one used last first, and a user who has registered both can sign in another way. A user who has registered one method cannot register the other at a sign-in. To change the method, run a `Reset2FA` operation for the registered method or set `All`. With `All`, the user passes both, the code first and then the key. A user who has only one of them confirms the sign-in with it first and only then registers the other.

  Allowed values: `Any`, `All`

- **settings.twoFactor.webAuthn**
  object

  Parameters of the `WebAuthn` method.

  - **settings.twoFactor.webAuthn.maxCredentials**
    integer

    How many keys a user may register.

    The first key is registered at the first sign-in that asks for one. A user adds a further key on the page that confirms a sign-in with a key, after a registered key has confirmed it. A password alone never adds a key.

    Lowering the limit keeps the keys users have; a user with as many keys as the limit, or more, adds none.

    Default: `3`

    Allowed values: `1 <= X <= 10`

  - **settings.twoFactor.webAuthn.rpID**
    string

    Domain a registered key is bound to (the relying party ID). A key works only for this domain and its subdomains.

    The browser takes a domain that is the domain of the Dex address (`dex.<PUBLIC_DOMAIN>`) or its parent, down to a registrable domain (`example.com`), and refuses any other. By default, it is the domain of the Dex address, so a change of `publicDomainTemplate` makes every registered key useless, and every user has to register again. Set it to the stable parent domain to keep the keys through such a change.

    Setting or changing the parameter makes the keys registered before it useless as well.

    A user whose key has become useless can neither sign in nor register a new key, because Dex offers the registration only to an account that has no keys, and the old key cannot be used. Reset the second factor of such a user with a UserOperation of type `Reset2FA`; the user registers a key again at the next sign-in.

    Dex accepts `localhost` and a lowercase domain of two or more labels, such as `example.com` or `dex.example.com`. It refuses any other single label, a final label that is a number (`corp.123`, and a hexadecimal, binary or octal form such as `0x1`), and an IP address.

Pattern: `^(localhost|[a-z0-9]([a-z0-9-]{0,61}[a-z0-9])?(\.[a-z0-9]([a-z0-9-]{0,61}[a-z0-9])?)+)$`

Maximum length: `253`

Example:

```
rpID: example.com
```

> ⚠ The module works only with HTTPS, because OpenID Connect over HTTP is a serious security threat and the Kubernetes API server does not support OIDC over HTTP. With `https.mode` set to `Disabled`, the module is turned off.

Set `https.mode` to a value other than `Disabled` at the cluster level (`modules.https.mode`) or in the module. If you set the `https` section of the module, set `mode` in it too. Without `mode`, `Disabled` applies.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The user-authn module: Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

DexAuthenticator

Short names: dex-auth

Scope: Namespaced

- v1
- v2alpha1
- v1alpha1

After the `DexAuthenticator` object appears in the namespace, the following objects will be created:

- Deployment containing OAuth2-Proxy and Redis containers;
- Service, pointing to OAuth2-Proxy;
- Ingress resource, configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- HTTPRoute resource (optional), configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- Secrets, needed to access Dex.

Warning. DexAuthenticator only works with HTTPS. The application Ingress must have TLS configured.

Warning. After restarting a pod with an OAuth2-Proxy, the current Access Token and ID Token will be queried (using the refresh token) and stored in a Redis memory.

The name of a DexAuthenticator must be a DNS-1035 label of at most 63 characters: it starts with a lowercase letter and contains only lowercase letters, digits and hyphens. The name is a part of the name of its Service and a label value of the objects it creates.

Examples:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-name
  namespace: app-namespace
spec:
  applicationDomain: app-name.kube.my-domain.com
  sendAuthorizationHeader: false
  applicationIngressCertificateSecretName: ingress-tls
  applicationIngressClassName: nginx
  keepUsersLoggedInFor: 720h
  allowedGroups:
  - everyone
  - admins
  allowedProviders:
  - local
  - corp-ldap
  whitelistSourceRanges:
  - 1.1.1.1/32
  - 192.168.0.0/24
  additionalApplications:
  - domain: additional-app-name.kube.my-domain.com
    ingressSecretName: ingress-tls
    ingressClassName: nginx
    signOutURL: "/logout"
    whitelistSourceRanges:
    - 2.2.2.2/32
```

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-alb
  namespace: app-namespace
spec:
  applicationDomain: app.example.com
  gatewayAPI:
    applicationHTTPRouteListenerSetName: app-listeners
```

- **metadata**
  object
  - **metadata.name**
    string

    Maximum length: `63`

- **spec**
  object

  Required value

  - **spec.additionalApplications**
    array of objects

    A list of additional applications for which user authentication is required.

    - **spec.additionalApplications.domain**
      string

      Required value

      An application domain from which the user request will be redirected for authentication in Dex.

      > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.gatewayAPI**
  object

  A set of parameters to use in HTTPRoute object.

  > **Warning.** Only applicable in clusters with Gateway API support.

  > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

  - **spec.additionalApplications.gatewayAPI.httpRouteListenerSetName**
    string

    Required value

    Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    httpRouteListenerSetName: default-listener-set
    ```

  - **spec.additionalApplications.gatewayAPI.httpRouteListenerSetNamespace**
    string

    Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

    If not set, the namespace of the `DexAuthenticator` is used.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `63`

    Example:

    ```
    httpRouteListenerSetNamespace: default
    ```

  - **spec.additionalApplications.gatewayAPI.httpRouteListenerSetSectionName**
    string

    Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    httpRouteListenerSetSectionName: web-listener
    ```

- **spec.additionalApplications.ingressClassName**
  string

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Required unless `gatewayAPI` is specified. If omitted, no Ingress resources are created for this application. Both fields may be specified.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.ingressSecretName**
  string

  The name of the Secret containing the TLS certificate (from the domain) used in the applications Ingress resource. The Secret must be in the same namespace as DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

- **spec.additionalApplications.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.additionalApplications.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec.allowedEmails**
  array of strings

  A list of emails of users are allowed to connect to the client.

  Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose email is no longer listed.

  By default, all users can connect.

  Values must not contain line breaks.

  Default: `All emails are allowed.`

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client.

  Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose stored groups no longer intersect it.

  By default, all groups can connect.

  Values must not contain line breaks.

  Default: `All groups are allowed.`

  - **Element of the array**

string

Pattern: `^[^\r\n]*$`

Maximum length: `512`

- **spec.allowedProviders**
  array of strings

  Names of the DexProvider objects through which users can sign in to the application.

  Use `local` for the users of the built-in password database (User).

  Checked on the sign-in page, on login, and on every refresh-token and token-exchange request. A provider outside the list is not offered on the sign-in page. If the list holds one provider, users go straight to it. Removing a provider from the list stops the refresh tokens that were issued through it.

  A name that matches no DexProvider is accepted with a warning. Nobody can sign in through it until the provider appears.

  By default, all providers can be used.

  Default: `All providers are allowed.`

  - **Element of the array**
    string

    Pattern: `^[a-z0-9]([-a-z0-9.]*[a-z0-9])?$`

    Maximum length: `253`

- **spec.applicationDomain**
  string

  Required value

  An address for the application (DNS domain for Ingress resource) from which the user request will be redirected for authentication in Dex.

  > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  applicationDomain: my-app.domain.com
  ```

- **spec.applicationIngressCertificateSecretName**
  string

  The name of the Secret containing the TLS certificate for the application domain (is used in the Ingress resource). The Secret must be located in the same namespace as the DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

  Example:

  ```
  applicationIngressCertificateSecretName: ingress-tls
  ```

- **spec.applicationIngressClassName**
  string

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Required unless `gatewayAPI` is specified. If omitted, no Ingress resources are created for this application. Both fields may be specified.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

```
applicationIngressClassName: nginx
```

- **spec.gatewayAPI**
  object

  A set of parameters to use in HTTPRoute object.

  > **Warning.** Only applicable in clusters with Gateway API support.

  > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetName**
    string

    Required value

    Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    applicationHTTPRouteListenerSetName: default-listenerset
    ```

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetNamespace**
    string

    Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

    If not set, the namespace of the `DexAuthenticator` is used.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `63`

    Example:

    ```
    applicationHTTPRouteListenerSetNamespace: default
    ```

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetSectionName**
    string

    Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    applicationHTTPRouteListenerSetSectionName: default-listener
    ```

- **spec.highAvailability**
  boolean

  Enables high availability mode for `dex-authenticator`.

  When this mode is enabled, multiple pod replicas will be deployed to ensure fault tolerance.

  Default: `false`

- **spec.keepUsersLoggedInFor**
  string

  Maximum period of user inactivity during which the user session remains active.

Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `20s`, `2h30m10s`, `24h`.

Specified value can't be shorter or equal to the `idTokenTTL` value set in the module settings. If you set a value that is shorter or equal to `idTokenTTL`, the effective logout time will be `idTokenTTL + 1s`.

To force logout sooner than the default `idTokenTTL`, decrease the `idTokenTTL` parameter value in the module settings as well.

Default: `168h`

Pattern: `^([0-9]{1,5}h)?([0-9]{1,7}m)?([0-9]{1,9}s)?$`

Example:

```
keepUsersLoggedInFor: 24h
```

- **spec.nodeSelector**
  object

  If specified, the `dex-authenticator` pods nodeSelector.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.podMetadata**
  object

  Additional labels and annotations for `dex-authenticator` pods.

  - **spec.podMetadata.annotations**
    object

    Additional annotations for `dex-authenticator` pods.

  - **spec.podMetadata.labels**
    object

    Additional labels for `dex-authenticator` pods.

- **spec.resources**
  object

  Container resources (CPU/memory) — requests/limits.

  If this field is set, the specified values are applied and VPA is disabled for this instance. If the field is not set, behavior remains the same: when the VPA module is enabled, resources are managed by VPA, when it is disabled, default values are used.

  Resources can be specified either directly for the `dex-authenticator` container (for backward compatibility) or in nested objects — separately for each container.

  - **spec.resources.limits**
    object

    Upper limit of resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

  - **spec.resources.redis**
    object

    Resources of the `redis` container (CPU/memory) — requests/limits.

    - **spec.resources.redis.limits**
      object

      Upper limit of resources for the `redis` container (CPU/memory)

    - **spec.resources.redis.requests**
      object

      Guaranteed minimum resources for the `redis` container (CPU/memory).

  - **spec.resources.requests**
    object

    Guaranteed minimum resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.sendAuthorizationHeader**
  boolean

  Request to application will be sent with `Authorization: Bearer` header when the option is switched to true.

  When enabled, the header carries a signed Dex ID token (`id_token`) containing the user's email, name, and group membership. This is the only way to pass the user's groups to the application via DexAuthenticator: a separate `X-Auth-Request-Groups` header with groups is not sent.

  > **Warning.** Enable it only if the application can process this header.
  >
  > When setting `sendAuthorizationHeader: true`, list all necessary headers in the application's Ingress resource (if the application is published through an Ingress) or in the HTTPRoute resource (if the application is published through an ALBInstance or ClusterALBInstance of the `alb` module).
  >
  > Also, if the application is published through an Ingress resource, when setting `sendAuthorizationHeader: true`, increase the header buffer size, since a JWT with many groups may not fit into the default buffer.
  >
  > For details on specifying the headers and increasing the buffer, see How to pass the user's login and groups to an application.

- **spec.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.tolerations**
  array of objects

  If specified the `dex-authenticator` pods tolerations.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Defines the taint's effect this toleration is associated with (it matches any effect if empty).

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string

    Defines the taint's key this toleration is associated with (it matches any key if empty).

    If the key is omitted (empty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

  - **spec.tolerations.operator**
    string

    Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

    Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

    Default: `Equal`

    Allowed values: `Exists`, `Equal`

  - **spec.tolerations.tolerationSeconds**

integer

Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the `operator` parameter is set to `Exists`.

- **spec.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

```
whitelistSourceRanges:
- 192.168.42.0/24
```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **metadata**
  object
  - **metadata.name**
    string

    Maximum length: `63`

- **spec**
  object

  Required value

  - **spec.allowedEmails**
    array of strings

    A list of emails of users are allowed to connect to the client.

    Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose email is no longer listed.

    By default, all users can connect.

    Values must not contain line breaks.

    Default: `All users are allowed.`

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `320`

  - **spec.allowedGroups**
    array of strings

    A list of groups whose members are allowed to connect to the client.

    Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose stored groups no longer intersect it.

    By default, all groups can connect.

Values must not contain line breaks.

Default: `All groups are allowed.`

- **Element of the array**
  string

  Pattern: `^[^\r\n]*$`

  Maximum length: `512`

- **spec.allowedProviders**
  array of strings

  Names of the DexProvider objects through which users can sign in to the application.

  Use `local` for the users of the built-in password database (User).

  Checked on the sign-in page, on login, and on every refresh-token and token-exchange request. A provider outside the list is not offered on the sign-in page. If the list holds one provider, users go straight to it. Removing a provider from the list stops the refresh tokens that were issued through it.

  A name that matches no DexProvider is accepted with a warning. Nobody can sign in through it until the provider appears.

  By default, all providers can be used.

  Default: `All providers are allowed.`

  - **Element of the array**
    string

    Pattern: `^[a-z0-9]([-a-z0-9.]*[a-z0-9])?$`

    Maximum length: `253`

- **spec.applications**
  array of objects

  Required value

  A list of applications for which user authentication is required.

  - **spec.applications.domain**
    string

    Required value

    An application domain (for Ingress resources) from which the user request will be redirected for authentication in Dex.

    > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  - **spec.applications.gatewayAPI**
    object

    A set of parameters to use in HTTPRoute object.

    > **Warning.** Only applicable in clusters with Gateway API support.

    > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

    - **spec.applications.gatewayAPI.httpRouteListenerSetName**
      string

      Required value

Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

Maximum length: `253`

Example:

```
httpRouteListenerSetName: default-listener-set
```

- **spec.applications.gatewayAPI.httpRouteListenerSetNamespace**
  string

  Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

  If not set, the namespace of the `DexAuthenticator` is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `63`

  Example:

  ```
  httpRouteListenerSetNamespace: default
  ```

- **spec.applications.gatewayAPI.httpRouteListenerSetSectionName**
  string

  Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `253`

  Example:

  ```
  httpRouteListenerSetSectionName: web-listener
  ```

- **spec.applications.ingressClassName**
  string

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Required unless `gatewayAPI` is specified. If omitted, no Ingress resources are created for this application. Both fields may be specified.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.applications.ingressSecretName**
  string

  The name of the Secret containing the TLS certificate for the application domain (is used in the Ingress resource). The Secret must be located in the same namespace as the DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

- **spec.applications.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

Pattern: `^[^\r\n]*$`

Maximum length: `2048`

- **spec.applications.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, if not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec.highAvailability**
  boolean

  Enables high availability mode for `dex-authenticator`.

  When this mode is enabled, multiple pod replicas will be deployed to ensure fault tolerance.

  Default: `false`

- **spec.keepUsersLoggedInFor**
  string

  Maximum period of user inactivity during which the user session remains active.

  Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `20s`, `2h30m10s`, `24h`.

  Specified value can’t be shorter or equal to the `idTokenTTL` value set in the module settings. If you set a value that is shorter or equal to `idTokenTTL`, the effective logout time will be `idTokenTTL + 1s`.

  To force logout sooner than the default `idTokenTTL`, decrease the `idTokenTTL` parameter value in the module settings as well.

  Default: `168h`

  Pattern: `^([0-9]{1,5}h)?([0-9]{1,7}m)?([0-9]{1,9}s)?$`

- **spec.nodeSelector**
  object

  If specified, the `dex-authenticator` pods nodeSelector.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.podMetadata**
  object

  Additional labels and annotations for `dex-authenticator` pods.

  - **spec.podMetadata.annotations**
    object

    Additional annotations for `dex-authenticator` pods.

  - **spec.podMetadata.labels**
    object

    Additional labels for `dex-authenticator` pods.

- **spec.resources**
  object

  Container resources (CPU/memory) — requests/limits.

  If this field is set, the specified values are applied and VPA is disabled for this instance. If the field is not set, behavior remains the same: when the VPA module is enabled, resources are managed by VPA, when it is disabled, default values are used.

Resources can be specified either directly for the `dex-authenticator` container (for backward compatibility) or in nested objects — separately for each container.

- **spec.resources.limits**
  object

  Upper limit of resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.resources.redis**
  object

  Resources of the `redis` container (CPU/memory) — requests/limits.

  - **spec.resources.redis.limits**
    object

    Upper limit of resources for the `redis` container (CPU/memory).

  - **spec.resources.redis.requests**
    object

    Guaranteed minimum resources for the `redis` container (CPU/memory).

- **spec.resources.requests**
  object

  Guaranteed minimum resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.sendAuthorizationHeader**
  boolean

  Request to application will be sent with `Authorization: Bearer` header when the option is switched to true.

  When enabled, the header carries a signed Dex ID token (`id_token`) containing the user's email, name, and group membership. This is the only way to pass the user's groups to the application via DexAuthenticator: a separate `X-Auth-Request-Groups` header with groups is not sent.

  > **Warning.** Enable it only if the application can process this header.
  >
  > When setting `sendAuthorizationHeader: true`, list all necessary headers in the application's Ingress resource (if the application is published through an Ingress) or in the HTTPRoute resource (if the application is published through an ALBInstance or ClusterALBInstance of the `alb` module).
  >
  > Also, if the application is published through an Ingress resource, when setting `sendAuthorizationHeader: true`, increase the header buffer size, since a JWT with many groups may not fit into the default buffer.
  >
  > For details on specifying the headers and increasing the buffer, see How to pass the user's login and groups to an application.

- **spec.tolerations**
  array of objects

  If specified the `dex-authenticator` pods tolerations.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Defines the taint's effect this toleration is associated with (it matches any effect if empty).

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string

    Defines the taint's key this toleration is associated with (it matches any key if empty).

    If the key is omitted (empty), then `operator` must be set to `Exists` (which means it

matches any `value` and `key`).

- **spec.tolerations.operator**
  string

  Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

  Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

  Default: `Equal`

  Allowed values: `Exists`, `Equal`

- **spec.tolerations.tolerationSeconds**
  integer

  Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

  If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

  The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the `operator` parameter is set to `Exists`.

Deprecated resource. Support for the resource might be removed in a later release.

After the `DexAuthenticator` object appears in the namespace, the following objects will be created:

- Deployment containing OAuth2-Proxy and Redis containers;
- Service, pointing to OAuth2-Proxy;
- Ingress resource, configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- HTTPRoute resource (optional), configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- Secrets, needed to access Dex.

Warning. DexAuthenticator only works with HTTPS. The application Ingress must have TLS configured.

Warning. After restarting a pod with an OAuth2-Proxy, the current Access Token and ID Token will be queried (using the refresh token) and stored in a Redis memory.

The name of a DexAuthenticator must be a DNS-1035 label of at most 63 characters: it starts with a lowercase letter and contains only lowercase letters, digits and hyphens. The name is a part of the name of its Service and a label value of the objects it creates.

Examples:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-name
  namespace: app-namespace
spec:
  applicationDomain: app-name.kube.my-domain.com
  sendAuthorizationHeader: false
  applicationIngressCertificateSecretName: ingress-tls
  applicationIngressClassName: nginx
  keepUsersLoggedInFor: 720h
  allowedGroups:
  - everyone
  - admins
  allowedProviders:
  - local
  - corp-ldap
  whitelistSourceRanges:
  - 1.1.1.1/32
  - 192.168.0.0/24
  additionalApplications:
  - domain: additional-app-name.kube.my-domain.com
    ingressSecretName: ingress-tls
    ingressClassName: nginx
    signOutURL: "/logout"
    whitelistSourceRanges:
    - 2.2.2.2/32
```

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-alb
  namespace: app-namespace
spec:
  applicationDomain: app.example.com
  gatewayAPI:
    applicationHTTPRouteListenerSetName: app-listeners
```

- **metadata**
  object
  - **metadata.name**
    string

    Maximum length: `63`

- **spec**
  object

  Required value

  - **spec.additionalApplications**
    array of objects

    A list of additional applications for which user authentication is required.

    - **spec.additionalApplications.domain**
      string

      Required value

      An application domain from which the user request will be redirected for authentication in Dex.

      > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.gatewayAPI**
  object

  A set of parameters to use in HTTPRoute object.

  > **Warning.** Only applicable in clusters with Gateway API support.

  > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

  - **spec.additionalApplications.gatewayAPI.httpRouteListenerSetName**
    string

    Required value

    Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    httpRouteListenerSetName: default-listener-set
    ```

  - **spec.additionalApplications.gatewayAPI.httpRouteListenerSetNamespace**
    string

    Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

    If not set, the namespace of the `DexAuthenticator` is used.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `63`

    Example:

    ```
    httpRouteListenerSetNamespace: default
    ```

  - **spec.additionalApplications.gatewayAPI.httpRouteListenerSetSectionName**
    string

    Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    httpRouteListenerSetSectionName: web-listener
    ```

- **spec.additionalApplications.ingressClassName**
  string

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Required unless `gatewayAPI` is specified. If omitted, no Ingress resources are created for this application. Both fields may be specified.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.ingressSecretName**
  string

  The name of the Secret containing the TLS certificate (from the domain) used in the applications Ingress resource. The Secret must be in the same namespace as DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

- **spec.additionalApplications.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.additionalApplications.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec.allowedEmails**
  array of strings

  A list of emails of users are allowed to connect to the client.

  Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose email is no longer listed.

  By default, all users can connect.

  Values must not contain line breaks.

  Default: `All emails are allowed.`

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client.

  Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose stored groups no longer intersect it.

  By default, all groups can connect.

  Values must not contain line breaks.

  Default: `All groups are allowed.`

  - **Element of the array**

string

Pattern: `^[^\r\n]*$`

Maximum length: `512`

- **spec.allowedProviders**
  array of strings

  Names of the DexProvider objects through which users can sign in to the application.

  Use `local` for the users of the built-in password database (User).

  Checked on the sign-in page, on login, and on every refresh-token and token-exchange request. A provider outside the list is not offered on the sign-in page. If the list holds one provider, users go straight to it. Removing a provider from the list stops the refresh tokens that were issued through it.

  A name that matches no DexProvider is accepted with a warning. Nobody can sign in through it until the provider appears.

  By default, all providers can be used.

  Default: `All providers are allowed.`

  - **Element of the array**
    string

    Pattern: `^[a-z0-9]([-a-z0-9.]*[a-z0-9])?$`

    Maximum length: `253`

- **spec.applicationDomain**
  string

  Required value

  An address for the application (DNS domain for Ingress resource) from which the user request will be redirected for authentication in Dex.

  > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  applicationDomain: my-app.domain.com
  ```

- **spec.applicationIngressCertificateSecretName**
  string

  The name of the Secret containing the TLS certificate for the application domain (is used in the Ingress resource). The Secret must be located in the same namespace as the DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

  Example:

  ```
  applicationIngressCertificateSecretName: ingress-tls
  ```

- **spec.applicationIngressClassName**
  string

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Required unless `gatewayAPI` is specified. If omitted, no Ingress resources are created for this application. Both fields may be specified.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

```
applicationIngressClassName: nginx
```

- **spec.gatewayAPI**
  object

  A set of parameters to use in HTTPRoute object.

  > **Warning.** Only applicable in clusters with Gateway API support.

  > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetName**
    string

    Required value

    Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    applicationHTTPRouteListenerSetName: default-listenerset
    ```

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetNamespace**
    string

    Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

    If not set, the namespace of the `DexAuthenticator` is used.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `63`

    Example:

    ```
    applicationHTTPRouteListenerSetNamespace: default
    ```

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetSectionName**
    string

    Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

    Example:

    ```
    applicationHTTPRouteListenerSetSectionName: default-listener
    ```

- **spec.highAvailability**
  boolean

  Enables high availability mode for `dex-authenticator`.

  When this mode is enabled, multiple pod replicas will be deployed to ensure fault tolerance.

  Default: `false`

- **spec.keepUsersLoggedInFor**
  string

  Maximum period of user inactivity during which the user session remains active.

Set as a string of whole hours, minutes, and seconds, in this order: `30m`, `20s`, `2h30m10s`, `24h`.

Specified value can't be shorter or equal to the `idTokenTTL` value set in the module settings. If you set a value that is shorter or equal to `idTokenTTL`, the effective logout time will be `idTokenTTL + 1s`.

To force logout sooner than the default `idTokenTTL`, decrease the `idTokenTTL` parameter value in the module settings as well.

Default: `168h`

Pattern: `^([0-9]{1,5}h)?([0-9]{1,7}m)?([0-9]{1,9}s)?$`

Example:

```
keepUsersLoggedInFor: 24h
```

- **spec.nodeSelector**
  object

  If specified, the `dex-authenticator` pods nodeSelector.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.podMetadata**
  object

  Additional labels and annotations for `dex-authenticator` pods.

  - **spec.podMetadata.annotations**
    object

    Additional annotations for `dex-authenticator` pods.

  - **spec.podMetadata.labels**
    object

    Additional labels for `dex-authenticator` pods.

- **spec.resources**
  object

  Container resources (CPU/memory) — requests/limits.

  If this field is set, the specified values are applied and VPA is disabled for this instance. If the field is not set, behavior remains the same: when the VPA module is enabled, resources are managed by VPA, when it is disabled, default values are used.

  Resources can be specified either directly for the `dex-authenticator` container (for backward compatibility) or in nested objects — separately for each container.

  - **spec.resources.limits**
    object

    Upper limit of resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

  - **spec.resources.redis**
    object

    Resources of the `redis` container (CPU/memory) — requests/limits.

    - **spec.resources.redis.limits**
      object

      Upper limit of resources for the `redis` container (CPU/memory)

    - **spec.resources.redis.requests**
      object

      Guaranteed minimum resources for the `redis` container (CPU/memory).

  - **spec.resources.requests**
    object

    Guaranteed minimum resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.sendAuthorizationHeader**
  boolean

  Request to application will be sent with `Authorization: Bearer` header when the option is switched to true.

  When enabled, the header carries a signed Dex ID token (`id_token`) containing the user's email, name, and group membership. This is the only way to pass the user's groups to the application via DexAuthenticator: a separate `X-Auth-Request-Groups` header with groups is not sent.

  > **Warning.** Enable it only if the application can process this header.
  >
  > When setting `sendAuthorizationHeader: true`, list all necessary headers in the application's Ingress resource (if the application is published through an Ingress) or in the HTTPRoute resource (if the application is published through an ALBInstance or ClusterALBInstance of the `alb` module).
  >
  > Also, if the application is published through an Ingress resource, when setting `sendAuthorizationHeader: true`, increase the header buffer size, since a JWT with many groups may not fit into the default buffer.
  >
  > For details on specifying the headers and increasing the buffer, see How to pass the user's login and groups to an application.

- **spec.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.tolerations**
  array of objects

  If specified the `dex-authenticator` pods tolerations.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Defines the taint's effect this toleration is associated with (it matches any effect if empty).

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string

    Defines the taint's key this toleration is associated with (it matches any key if empty).

    If the key is omitted (empty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

  - **spec.tolerations.operator**
    string

    Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

    Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

    Default: `Equal`

    Allowed values: `Exists`, `Equal`

  - **spec.tolerations.tolerationSeconds**

integer

Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the `operator` parameter is set to `Exists`.

- **spec.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

DexClient

Scope: Namespaced

- v1
- v1alpha1

Allows applications that support OIDC authentication to interact with Dex.

After the `DexClient` object appears in the cluster:

- Dex will register a client with a `dex-client-<NAME>@<NAMESPACE>` **clientID**, where `<NAME>` and `<NAMESPACE>` are `metadata.name` and `metadata.namespace` of the DexClient object, respectively.
- A `dex-client-<NAME>` Secret containing the client access password (**clientSecret**) will be created in the corresponding namespace (where `<NAME>` is `metadata.name` of the DexClient object).

Usage example…

- **spec**
  object

  Required value

  - **spec.allowedEmails**
    array of strings

    A list of emails of users are allowed to connect to the client.

    Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose email is no longer listed.

    By default, all users can connect.

    Values must not contain line breaks.

    Default: `All users are allowed.`

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client.

  Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose stored groups no longer intersect it.

  By default, all groups can connect.

  Values must not contain line breaks.

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `512`

- **spec.allowedProviders**
  array of strings

  Names of the DexProvider objects through which users can sign in to the application.

  Use `local` for the users of the built-in password database (User).

  Checked on the sign-in page, on login, and on every refresh-token and token-exchange request. A provider outside the list is not offered on the sign-in page. If the list holds one provider, users go straight to it. Removing a provider from the list stops the refresh tokens that were issued through it.

  The DexClient can also exchange tokens through every TokenExchangeProvider that lists it in `spec.clients`, even when that provider is not in this list.

  A name that matches no DexProvider is accepted with a warning. Nobody can sign in through it until the provider appears.

  By default, all providers can be used.

  Default: `All providers are allowed.`

  - **Element of the array**
    string

    Pattern: `^[a-z0-9]([-a-z0-9.]*[a-z0-9])?$`

    Maximum length: `253`

- **spec.backchannelLogoutURI**
  string

  Address Dex notifies when a browser session through which the user signed in to the application ends (OpenID Connect Back-Channel Logout): the user signs out of the session; the provider of the user answers that the user no longer exists or is no longer allowed in; a UserOperation or the self-service of the web interface ends the session; the user is deleted. Dex sends the notification of a session ended outside Dex within seconds.

  Works only with the browser sessions of Dex enabled. Dex sends the notification once, without retries: the application cannot rely on it to end its own session.

  Must be an HTTPS address whose host is a name with a dot: Dex sends the notification from inside the cluster, so an IP address, `localhost`, a name without a dot or ending with one, and a name under `.svc` or `.cluster.local` are not accepted. A short name such as `<SERVICE>.<NAMESPACE>` cannot be told from an external name: use the full external name of the application.

  Pattern: `^https://[^\r\n]*$`

  Maximum length: `2048`

- **spec.postLogoutRedirectURIs**
  array of strings

  Addresses Dex may send the browser back to after the user signs out of Dex through the application (`post_logout_redirect_uri` of OpenID Connect RP-Initiated Logout).

  Works only with the browser sessions of Dex enabled.

Values must not contain line breaks.

- **Element of the array**
  string

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.redirectURIs**
  array of strings

  Array of URLs that Dex can redirect to after successful authentication.

  Values must not contain line breaks.

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `2048`

- **spec.refreshTokenLifetime**
  string

  How long the refresh tokens of the application live, with the browser sessions of Dex enabled.

  - `Standalone`: The tokens live until they expire, whatever happens to the session of the browser. An application that requests offline access then gets a refresh token only after an interactive sign-in.
  - `Session`: The tokens end when the user signs out of the session of Dex they were issued through. Such an application can sign the user in from the session of the browser.

  Without the parameter, the tokens are `Standalone`.

  Allowed values: `Standalone`, `Session`

- **spec.secretMetadata**
  object

  Labels and annotations to add to the `dex-client-<NAME>` Secret.

  - **spec.secretMetadata.annotations**
    object

    Annotations of the Secret.

  - **spec.secretMetadata.labels**
    object

    Labels of the Secret.

- **spec.trustedPeers**
  array of strings

  OAuth2 client IDs that allowed cross authentication with the current client.

  A peer can ask for a token whose audience is this client through a provider the peer's own `allowedProviders` allows. This client's `allowedProviders` is not checked for that token, and neither are `allowedEmails` and `allowedGroups`.

  Values must not contain line breaks.

  Details...

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `256`

Deprecated resource. Support for the resource might be removed in a later release.

Allows applications that support OIDC authentication to interact with Dex.

After the `DexClient` object appears in the cluster:

- Dex will register a client with a `dex-client-<NAME>@<NAMESPACE>` **clientID**, where `<NAME>` and

`<NAMESPACE>` are `metadata.name` and `metadata.namespace` of the DexClient object, respectively.
- A `dex-client-<NAME>` Secret containing the client access password (**clientSecret**) will be created in the corresponding namespace (where `<NAME>` is `metadata.name` of the DexClient object).

Usage example...

- **spec**
  object

  Required value

  - **spec.allowedEmails**
    array of strings

    A list of emails of users are allowed to connect to the client.

    Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose email is no longer listed.

    By default, all users can connect.

    Values must not contain line breaks.

    Default: `All users are allowed.`

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `320`

  - **spec.allowedGroups**
    array of strings

    A list of groups whose members are allowed to connect to the client.

    Checked on login and on every refresh-token request. Updating the list denies further refresh for sessions whose stored groups no longer intersect it.

    By default, all groups can connect.

    Values must not contain line breaks.

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `512`

  - **spec.allowedProviders**
    array of strings

    Names of the DexProvider objects through which users can sign in to the application.

    Use `local` for the users of the built-in password database (User).

    Checked on the sign-in page, on login, and on every refresh-token and token-exchange request. A provider outside the list is not offered on the sign-in page. If the list holds one provider, users go straight to it. Removing a provider from the list stops the refresh tokens that were issued through it.

    The DexClient can also exchange tokens through every TokenExchangeProvider that lists it in `spec.clients`, even when that provider is not in this list.

    A name that matches no DexProvider is accepted with a warning. Nobody can sign in through it until the provider appears.

    By default, all providers can be used.

    Default: `All providers are allowed.`

    - **Element of the array**
      string

      Pattern: `^[a-z0-9]([-a-z0-9.]*[a-z0-9])?$`

      Maximum length: `253`

- **spec.backchannelLogoutURI**
  string

  Address Dex notifies when a browser session through which the user signed in to the application ends (OpenID Connect Back-Channel Logout): the user signs out of the session; the provider of the user answers that the user no longer exists or is no longer allowed in; a UserOperation or the self-service of the web interface ends the session; the user is deleted. Dex sends the notification of a session ended outside Dex within seconds.

  Works only with the browser sessions of Dex enabled. Dex sends the notification once, without retries: the application cannot rely on it to end its own session.

  Must be an HTTPS address whose host is a name with a dot: Dex sends the notification from inside the cluster, so an IP address, `localhost`, a name without a dot or ending with one, and a name under `.svc` or `.cluster.local` are not accepted. A short name such as `<SERVICE>.<NAMESPACE>` cannot be told from an external name: use the full external name of the application.

  Pattern: `^https://[^\r\n]*$`

  Maximum length: `2048`

- **spec.postLogoutRedirectURIs**
  array of strings

  Addresses Dex may send the browser back to after the user signs out of Dex through the application (`post_logout_redirect_uri` of OpenID Connect RP-Initiated Logout).

  Works only with the browser sessions of Dex enabled.

  Values must not contain line breaks.

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `2048`

- **spec.redirectURIs**
  array of strings

  Array of URLs that Dex can redirect to after successful authentication.

  Values must not contain line breaks.

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `2048`

- **spec.refreshTokenLifetime**
  string

  How long the refresh tokens of the application live, with the browser sessions of Dex enabled.

  - `Standalone`: The tokens live until they expire, whatever happens to the session of the browser. An application that requests offline access then gets a refresh token only after an interactive sign-in.
  - `Session`: The tokens end when the user signs out of the session of Dex they were issued through. Such an application can sign the user in from the session of the browser.

  Without the parameter, the tokens are `Standalone`.

  Allowed values: `Standalone`, `Session`

- **spec.secretMetadata**
  object

  Labels and annotations to add to the `dex-client-<NAME>` Secret.

  - **spec.secretMetadata.annotations**
    object

    Annotations of the Secret.

  - **spec.secretMetadata.labels**

object

Labels of the Secret.

- **spec.trustedPeers**
  array of strings

  OAuth2 client IDs that allowed cross authentication with the current client.

  A peer can ask for a token whose audience is this client through a provider the peer's own `allowedProviders` allows. This client's `allowedProviders` is not checked for that token, and neither are `allowedEmails` and `allowedGroups`.

  Values must not contain line breaks.

  Details...

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `256`

DexProviderCheck

Scope: Cluster
Version: v1

Describes a one-time connectivity check for a DexProvider.

The check verifies that the provider exists, is enabled, Dex is reachable, and the provider endpoint is reachable. It does not perform a full user authentication flow.

- **spec**
  object

  Required value

  - **spec.initiatorType**
    string

    Indicates who initiated the check. Possible values:

    - `Admin`: By an administrator.
    - `System`: Automatically by the system.

    Allowed values: `Admin`, `System`

  - **spec.providerName**
    string

    Required value

    Name of the DexProvider resource to check.

    Example:

    ```
    providerName: my-oidc
    ```

- **status**
  object
  - **status.checks**
    array of objects

    Detailed results for individual check steps.

    - **status.checks.message**
      string

      Optional check step message.

    - **status.checks.name**
      string

      Required value

      Check step name.

        - **status.checks.status**
          string

          Required value

          Check step status. Possible values:

          - `Succeeded`: Step completed successfully.
          - `Failed`: Step failed.
          - `Skipped`: Step was not applicable and was skipped.
          - `Warning`: Step completed, but a setting needs attention (for example, disabled TLS verification or a soon-to-expire certificate). It does not fail the overall check.

          Allowed values: `Succeeded`, `Failed`, `Skipped`, `Warning`

    - **status.completedAt**
      string

      Time when the check completed.

    - **status.message**
      string

      Optional summary of the result or failure reason.

    - **status.observedDexProviderGeneration**
      integer

      DexProvider generation observed by the check.

    - **status.phase**
      string

      Current phase of the check. Possible values:

      - `Pending`: The check has been picked up and is awaiting or in progress.
      - `Succeeded`: Connectivity check completed successfully.
      - `Failed`: Connectivity check failed.

      Allowed values: `Pending`, `Succeeded`, `Failed`

DexProvider

Scope: Cluster

- v1
- v1alpha1

Defines the configuration for connecting a third-party provider.

With it, you can flexibly configure the integration of the account directory with Kubernetes.

Usage example…

Warning. It is forbidden to use users and groups with the `system:` prefix. Authentication attempts by such users or members of such groups will be rejected, and a corresponding warning will appear in the `kube-apiserver` logs.

- **spec**
  object

  Required value

    - **spec.allowedIdentities**
      object

      Limits the identities this provider is allowed to assert, regardless of the provider type.

      Dex refuses to sign in a user whose email is outside `emails` and `emailDomains` when either is set, and narrows the `groups` claim to the intersection with `groups` when it is set (an empty intersection refuses the sign-in). Each list is optional; an omitted or empty list does not limit that attribute.

      Dex also checks the limits at every refresh-token request and at Basic Authentication of an LDAP provider. It revokes a refresh token outside the limits, and the user has to sign in again. For a Crowd or OIDC provider, basic-auth-proxy checks the credentials with the provider directly, so the limits do not apply to Basic Authentication.

The limits also decide who may create or change the provider. A provider that can assert an email or a group that already carries roles in the cluster may be written only by a requester who is allowed to assign those roles. Without an email limit the provider can assert any email, including the ones that hold `SuperAdmin`, so writing it requires `SuperAdmin`. With limits on both attributes only the roles granted to the listed identities count. A Crowd or OIDC provider with `enableBasicAuth: true` counts as a provider without an email limit, because Basic Authentication bypasses the limits.

- **spec.allowedIdentities.emailDomains**
  array of strings

  Email domains this provider may assert, without the `@`.

  Matched exactly against the part of the email after the last `@`; subdomains must be listed explicitly.

  - **Element of the array**
    string
- **spec.allowedIdentities.emails**
  array of strings

  Exact email addresses this provider may assert.

  Compared case-insensitively.

  - **Element of the array**
    string
- **spec.allowedIdentities.groups**
  array of strings

  Group names this provider may assert, with the `groupPrefix` in front when it is set.

  Applied on top of the provider-specific group filters (`allowedGroups`, `groups`, `teams`, `orgs[].teams`), if any.

  - **Element of the array**
    string

    Length: `1..256`

- **spec.bitbucketCloud**
  object

  Parameters of the Bitbucket Cloud (intended for the `type: BitbucketCloud`).

  - **spec.bitbucketCloud.clientID**
    string

    Required value

    Team application ID from BitbucketCloud (Key).

  - **spec.bitbucketCloud.clientSecret**
    string

    Required value

    Team application secret key from BitbucketCloud.

  - **spec.bitbucketCloud.includeTeamGroups**
    boolean

    Optional parameter to include team groups.

    If enabled, the groups claim of Dex id_token will look like this:

    ```
    ["my_team", "my_team/administrators", "my_team/members"]
    ```

    Default: `false`

  - **spec.bitbucketCloud.teams**
    array of strings

    A list of allowed Bitbucket Cloud teams (filter).

    The user token will contain a set intersection of Bitbucket Cloud teams and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

The user token will contain the user teams in the `groups` claim (similar to other providers).

- **spec.crowd**
  object

  Parameters of the Crowd (intended for the `type: Crowd`).

  - **spec.crowd.baseURL**
    string

    Required value

    Base part of Atlassian Crowd URL.

    Example:

    ```
    baseURL: https://crowd.example.com/crowd
    ```

  - **spec.crowd.clientID**
    string

    Required value

    Application ID from Atlassian Crowd (Application Name).

  - **spec.crowd.clientSecret**
    string

    Required value

    Application secret key from Atlassian Crowd (Password).

  - **spec.crowd.enableBasicAuth**
    boolean

    Enables Basic Authentication to the Kubernetes API server with the Crowd user's username and password.

    Works only when the `apiserver.publishAPI` parameter of the `control-plane-manager` module is enabled. Only one DexProvider in the cluster can have `enableBasicAuth` enabled.

    The parameter cannot be turned on while `twoFactor.providerTypes` includes `Crowd`, because Basic Authentication has no page for the second factor.

    Basic Authentication bypasses `spec.allowedIdentities`. Therefore only a `SuperAdmin` can create a provider with this parameter enabled or enable the parameter in an existing provider.

    A successful check is cached together with the user's groups for 2 minutes, and a failed check for 10 seconds. A user whose access is revoked in the identity provider can use the Kubernetes API until the cached result expires.

  - **spec.crowd.groups**
    array of strings

    A list of allowed Crowd groups (filter).

    The user token will contain a set intersection of Crowd groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

    The user token will contain all Crowd groups if the parameter is not set.

  - **spec.crowd.usernamePrompt**
    string

    Prompt for username field.

    Default: `Crowd username`

- **spec.displayName**
  string

  Required value

  The provider name to show on the authentication provider selection page. The selection page will not be displayed if there is only one provider configured.

- **spec.enabled**
  boolean

  Whether the provider is enabled.

  A disabled provider is not shown on the sign-in page, and users cannot sign in through it. The DexProvider and its settings are kept.

  Default: `true`

- **spec.github**
  object

  Parameters of the GitHub provider (intended for the `type: Github` case only).

  - **spec.github.clientID**
    string

    Required value

    Organization application ID from GitHub.

  - **spec.github.clientSecret**
    string

    Required value

    Organization application secret key from GitHub.

  - **spec.github.orgs**
    array of objects

    Filter for user organizations. ID token will contain only organizations from this list. If the user is not in any organization from this list, an authorization will fail.

    By default, all organizations allowed.

    - **spec.github.orgs.name**
      string

      Required value

      Name of organization.

    - **spec.github.orgs.teams**
      array of strings

      A list of allowed GitHub teams (filter).

      The user token will contain a set intersection of teams from GitHub and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

      The user token will contain all GitHub teams if the parameter is not set.

  - **spec.github.teamNameField**
    string

    As an example, group claims for member of ‘Site Reliability Engineers’ in Acme organization would yield:

    - [‘acme:Site Reliability Engineers’] for ‘Name’
    - [‘acme:site-reliability-engineers’] for ‘Slug’
    - [‘acme:Site Reliability Engineers’, ‘acme:site-reliability-engineers’] for ‘Both’

    Default: `Name`

    Allowed values: `Name`, `Slug`, `Both`

  - **spec.github.useLoginAsID**
    boolean

    Flag which will switch from using the internal GitHub id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

    Equals to false by default.

- **spec.gitlab**
  object

Parameters of the GitLab provider (intended for the `type: Gitlab` case only).

- **spec.gitlab.baseURL**
  string

  Base part of GitLab URL.

  Example:

  ```
  baseURL: https://gitlab.example.com
  ```

- **spec.gitlab.clientID**
  string

  Required value

  Application ID from GitLab.

- **spec.gitlab.clientSecret**
  string

  Required value

  Application secret key from GitLab.

- **spec.gitlab.groups**
  array of strings

  A list (filter) of allowed GitLab groups (**group paths** and not names).

  The user token will contain a set intersection of GitLab groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

  The user token will contain all GitLab groups if the parameter is not set;

- **spec.gitlab.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.gitlab.useLoginAsID**
  boolean

  Flag to switch from using the internal GitLab id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.groupPrefix**
  string

  Prefix that Dex puts in front of every group the provider asserts, whatever the type of the provider.

  With a prefix, the groups of this provider are named `<PREFIX><GROUP>` in the tokens and in the rules of the cluster, for example `corp-ldap:admins`. The prefix keeps them apart from the groups of another provider only when every provider that can emit such names has its own prefix.

  The prefix must end with a colon, as in `corp-ldap:`. It must differ from the prefix of every other DexProvider and of every TokenExchangeProvider group, and neither of two prefixes may start with the other. The admission webhooks refuse such a prefix.

  Every name in `allowedIdentities.groups` must start with the prefix, otherwise the API refuses the manifest, because Dex adds the prefix before it compares. The group settings of the provider type (for example, `oidc.allowedGroups`, `gitlab.groups` and `ldap.groupSearch`) take the names of the identity provider, without the prefix.

The prefix cannot start with `system:`, which the Kubernetes API server reserves, or with `peering:`, which is reserved for the ServiceAccounts of the `d8-peering` namespace. It cannot be set together with `enableBasicAuth` of an `OIDC` or `Crowd` provider, because basic-auth-proxy checks the credentials with such a provider directly and passes its groups as they are.

Setting or changing the prefix renames the groups of the provider, and the rules written for the old names stop applying to its users. Rewrite the rules before you set the prefix, as described in Prefix for the groups of a provider.

By default, no prefix.

Pattern: `^[A-Za-z0-9][A-Za-z0-9._:/-]*:$`

Length: `2..64`

Example:

```
groupPrefix: 'corp-ldap:'
```

- **spec.ldap**
  object

  Parameters of the LDAP.

  - **spec.ldap.bindDN**
    string

    The DN for an application service account. The connector uses these credentials to search for users and groups. Not required if the LDAP server provides access for anonymous auth.

    Example:

    ```
    bindDN: uid=serviceaccount,cn=users,dc=example,dc=com
    ```

  - **spec.ldap.bindPW**
    string

    Password of the service account set in `bindDN`.

    Example:

    ```
    bindPW: password
    ```

  - **spec.ldap.enableBasicAuth**
    boolean

    Enables Basic Authentication to the Kubernetes API server with the LDAP user's username and password.

    Works only when the `apiserver.publishAPI` parameter of the `control-plane-manager` module is enabled. Only one DexProvider in the cluster can have `enableBasicAuth` enabled.

    The parameter cannot be turned on while `twoFactor.providerTypes` includes `LDAP`, because Basic Authentication has no page for the second factor.

    A successful check is cached together with the user's groups for 2 minutes, and a failed check for 10 seconds. A user whose access is revoked in the identity provider can use the Kubernetes API until the cached result expires.

  - **spec.ldap.groupSearch**
    object

    Group search queries for groups given a user entry. Details

    - **spec.ldap.groupSearch.baseDN**
      string

      Required value

      BaseDN to start the search from.

      Example:

```
baseDN: cn=users,dc=example,dc=com
```

- **spec.ldap.groupSearch.filter**
  string

  Optional filter to apply when searching the directory.

  Example:

  ```
  filter: "(objectClass=person)"
  ```

- **spec.ldap.groupSearch.nameAttr**
  string

  Required value

  Represents group name.

  Example:

  ```
  nameAttr: name
  ```

- **spec.ldap.groupSearch.userMatchers**
  array of objects

  Required value

  Following list contains field pairs that are used to match a user to a group. It adds a requirement to the filter that an attribute in the group must match the user’s attribute value.

  - **spec.ldap.groupSearch.userMatchers.groupAttr**
    string

    Required value

    The name of the attribute that stores the group member names.

    Example:

    ```
    groupAttr: member
    ```

  - **spec.ldap.groupSearch.userMatchers.recursionGroupAttr**
    string

    Name of the group attribute that stores the DNs of its members.

    When it is set, Dex also looks for the groups that contain the found groups, level by level, and adds them to the groups of the user. Use it for nested groups. The value is usually the same as `groupAttr`, for example `member`.

    Dex makes one more search for every group of every level at each sign-in and each refresh of the tokens, so keep `baseDN` and `filter` of `groupSearch` narrow.

    Example:

    ```
    recursionGroupAttr: member
    ```

  - **spec.ldap.groupSearch.userMatchers.userAttr**
    string

    Required value

    The name of the attribute that stores the user name.

    Example:

    ```
    userAttr: uid
    ```

- **spec.ldap.host**
  string

Required value

Host and optional port of the LDAP server in the form “host:port”. If the port is not supplied, it will be guessed based on “insecureNoSSL”, and “startTLS” flags. 389 for insecure or StartTLS connections, 636 otherwise.

Example:

```
host: ldap.example.com:636
```

- **spec.ldap.insecureNoSSL**
  boolean

  Following field is required if the LDAP host is not using TLS (port 389). This option inherently leaks passwords to anyone on the same network as Dex.

  Mutually exclusive with `startTLS`, `insecureSkipVerify`, and `rootCAData`: when `insecureNoSSL` is true, TLS is disabled and those settings have no effect.

  Default: `false`

- **spec.ldap.insecureSkipVerify**
  boolean

  If a custom certificate isn’t provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn’t be used outside of explorative phases.

  Has no effect when `insecureNoSSL` is true.

  Default: `false`

- **spec.ldap.kerberos**
  object

  Optional Kerberos (SPNEGO) SSO settings for LDAP.

  - **spec.ldap.kerberos.enabled**
    boolean

    Enable Kerberos SPNEGO flow for this LDAP provider.

    Default: `false`

  - **spec.ldap.kerberos.expectedRealm**
    string

    Optional realm to require (case-insensitive).

  - **spec.ldap.kerberos.fallbackToPassword**
    boolean

    If `true`, in the absence of/incorrect `Authorization: Negotiate` header, a login/password form will be displayed instead of a 401 response with `WWW-Authenticate: Negotiate`.

    Default: `false`

  - **spec.ldap.kerberos.keytabSecretName**
    string

    Name of the Secret in the `d8-user-authn` namespace containing the `krb5.keytab` key to mount for Dex.

    Required when `enabled` is `true`.

  - **spec.ldap.kerberos.krb5ConfConfigMapName**
    string

    Not used. Dex validates Kerberos tickets with the keytab only, and the module does not mount this ConfigMap.

  - **spec.ldap.kerberos.krb5ConfSecretName**
    string

    Not used. Dex validates Kerberos tickets with the keytab only, and the module does not mount this Secret.

  - **spec.ldap.kerberos.usernameFromPrincipal**

string

How to map Kerberos principal to LDAP username.

Default: `Localpart`

Allowed values: `Localpart`, `SAMAccountName`, `UserPrincipalName`

- **spec.ldap.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Has no effect when `insecureNoSSL` is true.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.ldap.startTLS**
  boolean

  When connecting to the server, connect using the ldap:// protocol then issue a StartTLS command. If unspecified, connections will use the ldaps:// protocol.

  Mutually exclusive with `insecureNoSSL`.

  Default: `false`

- **spec.ldap.userSearch**
  object

  Required value

  User search maps a username and password entered by a user to a LDAP entry.
  Details...

  - **spec.ldap.userSearch.baseDN**
    string

    Required value

    BaseDN to start the search from.

    Example:

    ```
    baseDN: cn=users,dc=example,dc=com
    ```

  - **spec.ldap.userSearch.emailAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user email entry. When an email address is not available, use another value unique to the user, like uid.

    Example:

    ```
    emailAttr: mail
    ```

  - **spec.ldap.userSearch.filter**
    string

    Optional filter to apply when searching the directory.

    Example:

    ```
    filter: "(objectClass=person)"
    ```

  - **spec.ldap.userSearch.idAttr**
    string

Required value

LDAP attribute that will be matched to Dex user id entry.

The binary GUID attributes of Active Directory, `objectGUID` and `mS-DS-ConsistencyGuid`, are supported: the user ID is then the GUID in its string form, for example `7ed41c2b-e283-4b10-9cb8-a6e7d1f39a4c`.

Example:

```
idAttr: uid
```

- **spec.ldap.userSearch.nameAttr**
  string

  LDAP attribute that will be matched to Dex user name entry. No default value provided.

  Example:

  ```
  nameAttr: name
  ```

- **spec.ldap.userSearch.username**
  string

  Username attribute used for comparing user entries. This will be translated and combined with the other filter as “(=)".

  Example:

  ```
  username: uid
  ```

- **spec.ldap.userSearch.usernames**
  array of strings

  Attributes that the entered username is compared with, instead of `username`.

  The search filter has the form `(|(<ATTR_1>=<USERNAME>)(<ATTR_2>=<USERNAME>))`, so a user can sign in, for example, with a login or an email. A sign-in is refused if the username matches more than one entry.

  The Kerberos principal mapped to a username (after `usernameFromPrincipal`) is compared with every attribute in the list the same way. List only attributes whose values are unique in the directory and consistent with `usernameFromPrincipal`. If a value of another entry equals the principal, SSO stops working for that user. A principal that matches none of the attributes of its own entry is matched to the entry of another user.

  Set either `username` or `usernames`.

  Example:

  ```
  usernames:
  - uid
  - mail
  ```

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Length: `1..256`

- **spec.ldap.usernamePrompt**
  string

  The attribute to display in the provided password prompt. If unset, will display “LDAP Username”.

  Default: `LDAP username`

  Example:

```
usernamePrompt: SSO Username
```

- **spec.oidc**
  object

  Parameters of the OIDC (intended for the `type: OIDC`).

  - **spec.oidc.allowedGroups**
    array of strings

    A list of groups the user must belong to in order to authenticate successfully.

    If none of the specified groups match the user’s groups, authentication will be denied.

    If the parameter is omitted, no group-based filtering will be applied.

  - **spec.oidc.basicAuthUnsupported**
    boolean

    Use POST requests to interact with the provider instead of including the token in the Basic Authorization header. Generally, Dex automatically determines the type of request to make, while in some cases enabling this parameter can help.

    Default: `false`

  - **spec.oidc.claimMapping**
    object

    Some providers return non-standard claims (eg. mail). Claim mappings are hints for Dex how to map claims to standard OIDC claims.

    Dex can only map a non-standard claim to a standard one if it’s not included in the id_token returned by OIDC provider.

    - **spec.oidc.claimMapping.email**
      string

      The claim to use as the user email.

      Default: `email`

    - **spec.oidc.claimMapping.groups**
      string

      The claim to use as the user groups.

      Default: `groups`

    - **spec.oidc.claimMapping.preferred_username**
      string

      The claim to use as the user preferred username.

      Default: `preferred_username`

  - **spec.oidc.claimMappingOverride**
    boolean

    If enabled, the claim mapping will override the standard OIDC claims.

    By default, the claim mapping will be used only if the standard OIDC claims are not present, e.g., if there is no `email` claim in the id_token, the `claimMapping.email` will be used.

    Default: `false`

  - **spec.oidc.clientID**
    string

    Required value

    OIDC issuer application ID.

  - **spec.oidc.clientSecret**
    string

    Required value

    OIDC issuer application secret key.

- **spec.oidc.enableBasicAuth**
  boolean

  Enables Basic Authentication to the Kubernetes API server with the OIDC user's username and password.

  Works only when the `apiserver.publishAPI` parameter of the `control-plane-manager` module is enabled. Only one DexProvider in the cluster can have `enableBasicAuth` enabled.

  Basic Authentication bypasses `spec.allowedIdentities`. Therefore only a `SuperAdmin` can create a provider with this parameter enabled or enable the parameter in an existing provider.

  A successful check is cached together with the user's groups for 2 minutes, and a failed check for 10 seconds. A user whose access is revoked in the identity provider can use the Kubernetes API until the cached result expires.

- **spec.oidc.getUserInfo**
  boolean

  Request additional info about the authenticated user.

  See UserInfo endpoint.

  Default: `false`

- **spec.oidc.insecureSkipEmailVerified**
  boolean

  Allow authentication for clients without verified email address.

  Default: `false`

- **spec.oidc.insecureSkipVerify**
  boolean

  If a custom certificate isn't provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn't be used outside of explorative phases.

  Default: `false`

- **spec.oidc.issuer**
  string

  Required value

  Canonical URL of the provider, also used for configuration discovery. This value MUST match the value returned in the provider config discovery.

  Example:

  ```
  issuer: https://accounts.google.com
  ```

- **spec.oidc.promptType**
  string

  Determines if the Issuer should ask for confirmation and provide hints during the authentication process.

  By default, the confirmation will be requested on the first authentication. Possible values may vary depending on the Issuer.

  Default: `consent`

- **spec.oidc.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.oidc.scopes**
  array of strings

  List of additional scopes to request in token response.

  A scope is a single token and must not contain whitespace: the OAuth2 protocol passes scopes as a space-delimited list.

  Default: `["openid","profile","email","groups","offline_access"]`

  - **Element of the array**
    string

    Pattern: `^\S+$`

- **spec.oidc.upstreamLogout**
  boolean

  Signs the user out of the provider too when the user signs out of Dex.

  Works only with the browser sessions of Dex enabled and only when the provider advertises an `end_session_endpoint`.

  By default, signing out of Dex leaves the session of the provider alone: signing out of one application does not sign the user out of everything else that signs in through the provider. The provider may then sign the user in again without a password. To ask for the password at every sign-in, set `promptType: login`.

  Default: `false`

- **spec.oidc.userIDKey**
  string

  The claim to use as the user id.

  Default: `sub`

- **spec.oidc.userNameKey**
  string

  The claim to use as the user name.

  Default: `name`

- **spec.saml**
  object

  Parameters of a SAML provider (intended for the `type: SAML`).

  - **spec.saml.allowedGroups**
    array of strings

    If set, only members of at least one of the listed groups will be allowed to log in.

  - **spec.saml.emailAttr**
    string

    SAML attribute to map to the email claim.

    Default: `email`

  - **spec.saml.entityIssuer**
    string

    Issuer value that Dex sends in the SAML AuthnRequest (the entity ID of Dex as a service provider). Dex also expects this value in the audience of the SAML assertion.

    If not set, the request carries no Issuer, and Dex expects the callback URL in the audience.

  - **spec.saml.filterGroups**
    boolean

    If `true`, the connector will filter the groups claim to only include groups from the `allowedGroups` list.

    Default: `false`

  - **spec.saml.groupsAttr**

string

SAML attribute to map to the groups claim.

- **spec.saml.groupsDelim**
  string

  Delimiter to split the groups attribute value if it is a single string.

- **spec.saml.insecureSkipSignatureValidation**
  boolean

  Skip signature validation of SAML responses. This is insecure and should only be used for testing.

  Default: `false`

- **spec.saml.nameIDPolicyFormat**
  string

  The NameIDPolicy format to request from the IdP.

  If not set, Dex requests `persistent`.

  A UserOperation `Lock` with `spec.target` applies to the user ID, which Dex takes from the NameID. Use `persistent` or `emailAddress` for such a lock to work. With `transient`, the IdP returns a new NameID at every sign-in, and a lock does not apply to the next sign-in of the user.

  Allowed values: `persistent`, `emailAddress`, `unspecified`, `X509SubjectName`, `WindowsDomainQualifiedName`, `transient`

- **spec.saml.redirectURI**
  string

  Callback URI.

  Overrides the default callback URL. Should be set to `https://<dex-domain>/callback`.

- **spec.saml.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.saml.ssoIssuer**
  string

  Issuer value expected in the SAML response from the IdP.

  If not set, the Issuer of the response is not checked.

- **spec.saml.ssoURL**
  string

  Required value

  SSO URL used for POST value.

  Example:

  ```
  ssoURL: https://idp.example.com/saml/sso
  ```

- **spec.saml.usernameAttr**
  string

  SAML attribute to map to the username claim.

  Default: `name`

- **spec.tokenExchange**

object

Settings of token exchange (RFC 8693) through the provider. Dex exchanges an ID token of the provider's issuer for its own token. Only `OIDC` and `Gitlab` providers can exchange tokens.

The provider's connector does not check the audience of the exchanged token, so any application of the issuer could get a cluster token. Exchange tokens through a TokenExchangeProvider instead. The field is temporary and will be removed after the next LTS release, together with token exchange through a DexProvider.

- **spec.tokenExchange.enabled**
  boolean

  Whether the provider exchanges tokens. Absent means `false`.

  Exchange can only be turned off. An administrator cannot set `true`, either when creating the provider or when changing it. During the upgrade from a release without this field, `user-authn` sets it once on every existing `OIDC` and `Gitlab` provider. It sets `true` on all of them if at least one DexClient has the `dexclient.deckhouse.io/allow-access-to-kubernetes: "true"` annotation, and `false` on all of them otherwise. A DexAuthenticator with access to Kubernetes does not count. Its oauth2-proxy never exchanges tokens, and exchange with its client secret, taken from the Secret in the namespace of the application, is not kept.

- **spec.type**
  string

  Required value

  Type of authentication provider.

  Allowed values: `Github`, `Gitlab`, `BitbucketCloud`, `Crowd`, `OIDC`, `LDAP`, `SAML`

Deprecated resource. Support for the resource might be removed in a later release.

Defines the configuration for connecting a third-party provider.

With it, you can flexibly configure the integration of the account directory with Kubernetes.

Usage example…

- **spec**
  object

  Required value

  - **spec.allowedIdentities**
    object

    Limits the identities this provider is allowed to assert, regardless of the provider type.

    Dex refuses to sign in a user whose email is outside `emails` and `emailDomains` when either is set, and narrows the `groups` claim to the intersection with `groups` when it is set (an empty intersection refuses the sign-in). Each list is optional; an omitted or empty list does not limit that attribute.

    Dex also checks the limits at every refresh-token request and at Basic Authentication of an LDAP provider. It revokes a refresh token outside the limits, and the user has to sign in again. For a Crowd or OIDC provider, basic-auth-proxy checks the credentials with the provider directly, so the limits do not apply to Basic Authentication.

    The limits also decide who may create or change the provider. A provider that can assert an email or a group that already carries roles in the cluster may be written only by a requester who is allowed to assign those roles. Without an email limit the provider can assert any email, including the ones that hold `SuperAdmin`, so writing it requires `SuperAdmin`. With limits on both attributes only the roles granted to the listed identities count. A Crowd or OIDC provider with `enableBasicAuth: true` counts as a provider without an email limit, because Basic Authentication bypasses the limits.

    - **spec.allowedIdentities.emailDomains**
      array of strings

      Email domains this provider may assert, without the `@`.

      Matched exactly against the part of the email after the last `@`; subdomains must be listed explicitly.

        - **Element of the array**
          string
      - **spec.allowedIdentities.emails**
        array of strings

        Exact email addresses this provider may assert.

        Compared case-insensitively.

        - **Element of the array**
          string
      - **spec.allowedIdentities.groups**
        array of strings

        Group names this provider may assert, with the `groupPrefix` in front when it is set.

        Applied on top of the provider-specific group filters (`allowedGroups`, `groups`, `teams`, `orgs[].teams`), if any.

        - **Element of the array**
          string

          Length: `1..256`

  - **spec.bitbucketCloud**
    object

    Parameters of the Bitbucket Cloud (intended for the `type: BitbucketCloud`).

    - **spec.bitbucketCloud.clientID**
      string

      Required value

      Team application ID from BitbucketCloud (Key).

    - **spec.bitbucketCloud.clientSecret**
      string

      Required value

      Team application secret key from BitbucketCloud.

    - **spec.bitbucketCloud.includeTeamGroups**
      boolean

      Optional parameter to include team groups.

      If enabled, the groups claim of Dex id_token will look like this:

      ```
      ["my_team", "my_team/administrators", "my_team/members"]
      ```

      Default: `false`

    - **spec.bitbucketCloud.teams**
      array of strings

      A list of allowed Bitbucket Cloud teams (filter).

      The user token will contain a set intersection of Bitbucket Cloud teams and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

      The user token will contain the user teams in the `groups` claim (similar to other providers).

  - **spec.crowd**
    object

    Parameters of the Crowd (intended for the `type: Crowd`).

    - **spec.crowd.baseURL**
      string

      Required value

      Base part of Atlassian Crowd URL.

      Example:

```
baseURL: https://crowd.example.com/crowd
```

- **spec.crowd.clientID**
  string

  Required value

  Application ID from Atlassian Crowd (Application Name).

- **spec.crowd.clientSecret**
  string

  Required value

  Application secret key from Atlassian Crowd (Password).

- **spec.crowd.enableBasicAuth**
  boolean

  Enables Basic Authentication to the Kubernetes API server with the Crowd user's username and password.

  Works only when the `apiserver.publishAPI` parameter of the `control-plane-manager` module is enabled. Only one DexProvider in the cluster can have `enableBasicAuth` enabled.

  The parameter cannot be turned on while `twoFactor.providerTypes` includes `Crowd`, because Basic Authentication has no page for the second factor.

  Basic Authentication bypasses `spec.allowedIdentities`. Therefore only a `SuperAdmin` can create a provider with this parameter enabled or enable the parameter in an existing provider.

  A successful check is cached together with the user's groups for 2 minutes, and a failed check for 10 seconds. A user whose access is revoked in the identity provider can use the Kubernetes API until the cached result expires.

- **spec.crowd.groups**
  array of strings

  A list of allowed Crowd groups (filter).

  The user token will contain a set intersection of Crowd groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

  The user token will contain all Crowd groups if the parameter is not set.

- **spec.crowd.usernamePrompt**
  string

  Prompt for username field.

  Default: `Crowd username`

- **spec.displayName**
  string

  Required value

  The provider name to show on the authentication provider selection page. The selection page will not be displayed if there is only one provider configured.

- **spec.enabled**
  boolean

  Whether the provider is enabled.

  A disabled provider is not shown on the sign-in page, and users cannot sign in through it. The DexProvider and its settings are kept.

  Default: `true`

- **spec.github**
  object

  Parameters of the GitHub provider (intended for the `type: Github` case only).

  - **spec.github.clientID**

string

Required value

Organization application ID from GitHub.

- **spec.github.clientSecret**
  string

  Required value

  Organization application secret key from GitHub.

- **spec.github.orgs**
  array of objects

  Filter for user organizations. ID token will contain only organizations from this list. If the user is not in any organization from this list, an authorization will fail.

  By default, all organizations allowed.

  - **spec.github.orgs.name**
    string

    Required value

    Name of organization.

  - **spec.github.orgs.teams**
    array of strings

    A list of allowed GitHub teams (filter).

    The user token will contain a set intersection of teams from GitHub and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

    The user token will contain all GitHub teams if the parameter is not set.

- **spec.github.teamNameField**
  string

  As an example, group claims for member of ‘Site Reliability Engineers’ in Acme organization would yield:

  - [‘acme:Site Reliability Engineers’] for ‘name’
  - [‘acme:site-reliability-engineers’] for ‘slug’
  - [‘acme:Site Reliability Engineers’, ‘acme:site-reliability-engineers’] for ‘both’

  Default: `name`

  Allowed values: `name`, `slug`, `both`

- **spec.github.useLoginAsID**
  boolean

  Flag which will switch from using the internal GitHub id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.gitlab**
  object

  Parameters of the GitLab provider (intended for the `type: Gitlab` case only).

  - **spec.gitlab.baseURL**
    string

    Base part of GitLab URL.

    Example:

    ```
    baseURL: https://gitlab.example.com
    ```

  - **spec.gitlab.clientID**
    string

    Required value

Application ID from GitLab.

- **spec.gitlab.clientSecret**
  string

  Required value

  Application secret key from GitLab.

- **spec.gitlab.groups**
  array of strings

  A list (filter) of allowed GitLab groups (**group paths** and not names).

  The user token will contain a set intersection of GitLab groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

  The user token will contain all GitLab groups if the parameter is not set;

- **spec.gitlab.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.gitlab.useLoginAsID**
  boolean

  Flag to switch from using the internal GitLab id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.groupPrefix**
  string

  Prefix that Dex puts in front of every group the provider asserts, whatever the type of the provider.

  With a prefix, the groups of this provider are named `<PREFIX><GROUP>` in the tokens and in the rules of the cluster, for example `corp-ldap:admins`. The prefix keeps them apart from the groups of another provider only when every provider that can emit such names has its own prefix.

  The prefix must end with a colon, as in `corp-ldap:`. It must differ from the prefix of every other DexProvider and of every TokenExchangeProvider group, and neither of two prefixes may start with the other. The admission webhooks refuse such a prefix.

  Every name in `allowedIdentities.groups` must start with the prefix, otherwise the API refuses the manifest, because Dex adds the prefix before it compares. The group settings of the provider type (for example, `oidc.allowedGroups`, `gitlab.groups` and `ldap.groupSearch`) take the names of the identity provider, without the prefix.

  The prefix cannot start with `system:`, which the Kubernetes API server reserves, or with `peering:`, which is reserved for the ServiceAccounts of the `d8-peering` namespace. It cannot be set together with `enableBasicAuth` of an `OIDC` or `Crowd` provider, because basic-auth-proxy checks the credentials with such a provider directly and passes its groups as they are.

  Setting or changing the prefix renames the groups of the provider, and the rules written for the old names stop applying to its users. Rewrite the rules before you set the prefix, as described in Prefix for the groups of a provider.

  By default, no prefix.

  Pattern: `^[A-Za-z0-9][A-Za-z0-9._:/-]*:$`

  Length: `2..64`

  Example:

```
groupPrefix: 'corp-ldap:'
```

- **spec.ldap**
  object

  Parameters of the LDAP.

  - **spec.ldap.bindDN**
    string

    The DN for an application service account. The connector uses these credentials to search for users and groups. Not required if the LDAP server provides access for anonymous auth.

    Example:

    ```
    bindDN: uid=serviceaccount,cn=users,dc=example,dc=com
    ```

  - **spec.ldap.bindPW**
    string

    Password of the service account set in `bindDN`.

    Example:

    ```
    bindPW: password
    ```

  - **spec.ldap.enableBasicAuth**
    boolean

    Enables Basic Authentication to the Kubernetes API server with the LDAP user’s username and password.

    Works only when the `apiserver.publishAPI` parameter of the `control-plane-manager` module is enabled. Only one DexProvider in the cluster can have `enableBasicAuth` enabled.

    The parameter cannot be turned on while `twoFactor.providerTypes` includes `LDAP`, because Basic Authentication has no page for the second factor.

    A successful check is cached together with the user’s groups for 2 minutes, and a failed check for 10 seconds. A user whose access is revoked in the identity provider can use the Kubernetes API until the cached result expires.

  - **spec.ldap.groupSearch**
    object

    Group search queries for groups given a user entry. Details

    - **spec.ldap.groupSearch.baseDN**
      string

      Required value

      BaseDN to start the search from.

      Example:

      ```
      baseDN: cn=users,dc=example,dc=com
      ```

    - **spec.ldap.groupSearch.filter**
      string

      Optional filter to apply when searching the directory.

      Example:

      ```
      filter: "(objectClass=person)"
      ```

    - **spec.ldap.groupSearch.nameAttr**
      string

      Required value

Represents group name.

Example:

```
nameAttr: name
```

- **spec.ldap.groupSearch.userMatchers**
  array of objects

  Required value

  Following list contains field pairs that are used to match a user to a group. It adds a requirement to the filter that an attribute in the group must match the user's attribute value.

  - **spec.ldap.groupSearch.userMatchers.groupAttr**
    string

    Required value

    The name of the attribute that stores the group member names.

    Example:

    ```
    groupAttr: member
    ```

  - **spec.ldap.groupSearch.userMatchers.recursionGroupAttr**
    string

    Name of the group attribute that stores the DNs of its members.

    When it is set, Dex also looks for the groups that contain the found groups, level by level, and adds them to the groups of the user. Use it for nested groups. The value is usually the same as `groupAttr`, for example `member`.

    Dex makes one more search for every group of every level at each sign-in and each refresh of the tokens, so keep `baseDN` and `filter` of `groupSearch` narrow.

    Example:

    ```
    recursionGroupAttr: member
    ```

  - **spec.ldap.groupSearch.userMatchers.userAttr**
    string

    Required value

    The name of the attribute that stores the user name.

    Example:

    ```
    userAttr: uid
    ```

- **spec.ldap.host**
  string

  Required value

  Host and optional port of the LDAP server in the form "host:port". If the port is not supplied, it will be guessed based on "insecureNoSSL", and "startTLS" flags. 389 for insecure or StartTLS connections, 636 otherwise.

  Example:

  ```
  host: ldap.example.com:636
  ```

- **spec.ldap.insecureNoSSL**
  boolean

  Following field is required if the LDAP host is not using TLS (port 389). This option inherently leaks passwords to anyone on the same network as Dex.

  Mutually exclusive with `startTLS`, `insecureSkipVerify`, and `rootCAData`: when

`insecureNoSSL` is true, TLS is disabled and those settings have no effect.

Default: `false`

- **spec.ldap.insecureSkipVerify**
  boolean

  If a custom certificate isn't provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn't be used outside of explorative phases.

  Has no effect when `insecureNoSSL` is true.

  Default: `false`

- **spec.ldap.kerberos**
  object

  Optional Kerberos (SPNEGO) SSO settings for LDAP.

  - **spec.ldap.kerberos.enabled**
    boolean

    Enable Kerberos SPNEGO flow for this LDAP provider.

    Default: `false`

  - **spec.ldap.kerberos.expectedRealm**
    string

    Optional realm to require (case-insensitive).

  - **spec.ldap.kerberos.fallbackToPassword**
    boolean

    If `true`, in the absence of/incorrect `Authorization: Negotiate` header, a login/password form will be displayed instead of a 401 response with `WWW-Authenticate: Negotiate`.

    Default: `false`

  - **spec.ldap.kerberos.keytabSecretName**
    string

    Name of the Secret in the `d8-user-authn` namespace containing the `krb5.keytab` key to mount for Dex.

    Required when `enabled` is `true`.

  - **spec.ldap.kerberos.krb5ConfConfigMapName**
    string

    Not used. Dex validates Kerberos tickets with the keytab only, and the module does not mount this ConfigMap.

  - **spec.ldap.kerberos.krb5ConfSecretName**
    string

    Not used. Dex validates Kerberos tickets with the keytab only, and the module does not mount this Secret.

  - **spec.ldap.kerberos.usernameFromPrincipal**
    string

    How to map Kerberos principal to LDAP username.

    Default: `Localpart`

    Allowed values: `Localpart`, `SAMAccountName`, `UserPrincipalName`

- **spec.ldap.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Has no effect when `insecureNoSSL` is true.

  Example:

```
rootCAData: |
  -----BEGIN CERTIFICATE-----
  MIIFaDC...
  -----END CERTIFICATE-----
```

- **spec.ldap.startTLS**
  boolean

  When connecting to the server, connect using the ldap:// protocol then issue a StartTLS command. If unspecified, connections will use the ldaps:// protocol.

  Mutually exclusive with `insecureNoSSL`.

  Default: `false`

- **spec.ldap.userSearch**
  object

  Required value

  User search maps a username and password entered by a user to a LDAP entry.
  Details...

  - **spec.ldap.userSearch.baseDN**
    string

    Required value

    BaseDN to start the search from.

    Example:

    ```
    baseDN: cn=users,dc=example,dc=com
    ```

  - **spec.ldap.userSearch.emailAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user email entry. When an email address is not available, use another value unique to the user, like uid.

    Example:

    ```
    emailAttr: mail
    ```

  - **spec.ldap.userSearch.filter**
    string

    Optional filter to apply when searching the directory.

    Example:

    ```
    filter: "(objectClass=person)"
    ```

  - **spec.ldap.userSearch.idAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user id entry.

    The binary GUID attributes of Active Directory, `objectGUID` and `mS-DS-ConsistencyGuid`, are supported: the user ID is then the GUID in its string form, for example `7ed41c2b-e283-4b10-9cb8-a6e7d1f39a4c`.

    Example:

    ```
    idAttr: uid
    ```

  - **spec.ldap.userSearch.nameAttr**
    string

LDAP attribute that will be matched to Dex user name entry. No default value provided.

Example:

```
nameAttr: name
```

- **spec.ldap.userSearch.username**
  string

  Username attribute used for comparing user entries. This will be translated and combined with the other filter as “(=)".

  Example:

  ```
  username: uid
  ```

- **spec.ldap.userSearch.usernames**
  array of strings

  Attributes that the entered username is compared with, instead of `username`.

  The search filter has the form `(|(<ATTR_1>=<USERNAME>)(<ATTR_2>=<USERNAME>))`, so a user can sign in, for example, with a login or an email. A sign-in is refused if the username matches more than one entry.

  The Kerberos principal mapped to a username (after `usernameFromPrincipal`) is compared with every attribute in the list the same way. List only attributes whose values are unique in the directory and consistent with `usernameFromPrincipal`. If a value of another entry equals the principal, SSO stops working for that user. A principal that matches none of the attributes of its own entry is matched to the entry of another user.

  Set either `username` or `usernames`.

  Example:

  ```
  usernames:
  - uid
  - mail
  ```

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Length: `1..256`

- **spec.ldap.usernamePrompt**
  string

  The attribute to display in the provided password prompt. If unset, will display “LDAP Username”.

  Default: `LDAP username`

  Example:

  ```
  usernamePrompt: SSO Username
  ```

- **spec.oidc**
  object

  Parameters of the OIDC (intended for the `type: OIDC`).

  - **spec.oidc.allowedGroups**
    array of strings

    A list of groups the user must belong to in order to authenticate successfully.

    If none of the specified groups match the user’s groups, authentication will be denied.

    If the parameter is omitted, no group-based filtering will be applied.

- **spec.oidc.basicAuthUnsupported**
  boolean

  Use POST requests to interact with the provider instead of including the token in the Basic Authorization header. Generally, Dex automatically determines the type of request to make, while in some cases enabling this parameter can help.

  Default: `false`

- **spec.oidc.claimMapping**
  object

  Some providers return non-standard claims (eg. mail). Claim mappings are hints for Dex how to map claims to standard OIDC claims.

  Dex can only map a non-standard claim to a standard one if it’s not included in the id_token returned by OIDC provider.

  - **spec.oidc.claimMapping.email**
    string

    The claim to use as the user email.

    Default: `email`

  - **spec.oidc.claimMapping.groups**
    string

    The claim to use as the user groups.

    Default: `groups`

  - **spec.oidc.claimMapping.preferred_username**
    string

    The claim to use as the user preferred username.

    Default: `preferred_username`

- **spec.oidc.claimMappingOverride**
  boolean

  If enabled, the claim mapping will override the standard OIDC claims.

  By default, the claim mapping will be used only if the standard OIDC claims are not present, e.g., if there is no `email` claim in the id_token, the `claimMapping.email` will be used.

  Default: `false`

- **spec.oidc.clientID**
  string

  Required value

  OIDC issuer application ID.

- **spec.oidc.clientSecret**
  string

  Required value

  OIDC issuer application secret key.

- **spec.oidc.enableBasicAuth**
  boolean

  Enables Basic Authentication to the Kubernetes API server with the OIDC user’s username and password.

  Works only when the `apiserver.publishAPI` parameter of the `control-plane-manager` module is enabled. Only one DexProvider in the cluster can have `enableBasicAuth` enabled.

  Basic Authentication bypasses `spec.allowedIdentities`. Therefore only a `SuperAdmin` can create a provider with this parameter enabled or enable the parameter in an existing provider.

  A successful check is cached together with the user’s groups for 2 minutes, and a failed

check for 10 seconds. A user whose access is revoked in the identity provider can use the Kubernetes API until the cached result expires.

- **spec.oidc.getUserInfo**
  boolean

  Request additional info about the authenticated user.

  See UserInfo endpoint.

  Default: `false`

- **spec.oidc.insecureSkipEmailVerified**
  boolean

  Allow authentication for clients without verified email address.

  Default: `false`

- **spec.oidc.insecureSkipVerify**
  boolean

  If a custom certificate isn't provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn't be used outside of explorative phases.

  Default: `false`

- **spec.oidc.issuer**
  string

  Required value

  Canonical URL of the provider, also used for configuration discovery. This value MUST match the value returned in the provider config discovery.

  Example:

  ```
  issuer: https://accounts.google.com
  ```

- **spec.oidc.promptType**
  string

  Determines if the Issuer should ask for confirmation and provide hints during the authentication process.

  By default, the confirmation will be requested on the first authentication. Possible values may vary depending on the Issuer.

  Default: `consent`

- **spec.oidc.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
   -----BEGIN CERTIFICATE-----
   MIIFaDC...
   -----END CERTIFICATE-----
  ```

- **spec.oidc.scopes**
  array of strings

  List of additional scopes to request in token response.

  A scope is a single token and must not contain whitespace: the OAuth2 protocol passes scopes as a space-delimited list.

  Default: `["openid","profile","email","groups","offline_access"]`

  - **Element of the array**
    string

    Pattern: `^\S+$`

- **spec.oidc.upstreamLogout**
  boolean

  Signs the user out of the provider too when the user signs out of Dex.

  Works only with the browser sessions of Dex enabled and only when the provider advertises an `end_session_endpoint`.

  By default, signing out of Dex leaves the session of the provider alone: signing out of one application does not sign the user out of everything else that signs in through the provider. The provider may then sign the user in again without a password. To ask for the password at every sign-in, set `promptType: login`.

  Default: `false`

- **spec.oidc.userIDKey**
  string

  The claim to use as the user id.

  Default: `sub`

- **spec.oidc.userNameKey**
  string

  The claim to use as the user name.

  Default: `name`

- **spec.saml**
  object

  Parameters of a SAML provider (intended for the `type: SAML`).

  - **spec.saml.allowedGroups**
    array of strings

    If set, only members of at least one of the listed groups will be allowed to log in.

  - **spec.saml.emailAttr**
    string

    SAML attribute to map to the email claim.

    Default: `email`

  - **spec.saml.entityIssuer**
    string

    Issuer value that Dex sends in the SAML AuthnRequest (the entity ID of Dex as a service provider). Dex also expects this value in the audience of the SAML assertion.

    If not set, the request carries no Issuer, and Dex expects the callback URL in the audience.

  - **spec.saml.filterGroups**
    boolean

    If `true`, the connector will filter the groups claim to only include groups from the `allowedGroups` list.

    Default: `false`

  - **spec.saml.groupsAttr**
    string

    SAML attribute to map to the groups claim.

  - **spec.saml.groupsDelim**
    string

    Delimiter to split the groups attribute value if it is a single string.

  - **spec.saml.insecureSkipSignatureValidation**
    boolean

    Skip signature validation of SAML responses. This is insecure and should only be used for testing.

Default: `false`

- **spec.saml.nameIDPolicyFormat**
  string

  The NameIDPolicy format to request from the IdP.

  If not set, Dex requests `persistent`.

  A UserOperation `Lock` with `spec.target` applies to the user ID, which Dex takes from the NameID. Use `persistent` or `emailAddress` for such a lock to work. With `transient`, the IdP returns a new NameID at every sign-in, and a lock does not apply to the next sign-in of the user.

  Allowed values: `persistent`, `emailAddress`, `unspecified`, `X509SubjectName`, `WindowsDomainQualifiedName`, `transient`

- **spec.saml.redirectURI**
  string

  Callback URI.

  Overrides the default callback URL. Should be set to `https://<dex-domain>/callback`.

- **spec.saml.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.saml.ssoIssuer**
  string

  Issuer value expected in the SAML response from the IdP.

  If not set, the Issuer of the response is not checked.

- **spec.saml.ssoURL**
  string

  Required value

  SSO URL used for POST value.

  Example:

  ```
  ssoURL: https://idp.example.com/saml/sso
  ```

- **spec.saml.usernameAttr**
  string

  SAML attribute to map to the username claim.

  Default: `name`

- **spec.tokenExchange**
  object

  Settings of token exchange (RFC 8693) through the provider. Dex exchanges an ID token of the provider's issuer for its own token. Only `OIDC` and `Gitlab` providers can exchange tokens.

  The provider's connector does not check the audience of the exchanged token, so any application of the issuer could get a cluster token. Exchange tokens through a TokenExchangeProvider instead. The field is temporary and will be removed after the next LTS release, together with token exchange through a DexProvider.

  - **spec.tokenExchange.enabled**
    boolean

Whether the provider exchanges tokens. Absent means `false`.

Exchange can only be turned off. An administrator cannot set `true`, either when creating the provider or when changing it. During the upgrade from a release without this field, `user-authn` sets it once on every existing `OIDC` and `Gitlab` provider. It sets `true` on all of them if at least one DexClient has the `dexclient.deckhouse.io/allow-access-to-kubernetes: "true"` annotation, and `false` on all of them otherwise. A DexAuthenticator with access to Kubernetes does not count. Its oauth2-proxy never exchanges tokens, and exchange with its client secret, taken from the Secret in the namespace of the application, is not kept.

- **spec.type**
  string

  Required value

  Type of authentication provider.

  Allowed values: `Github`, `Gitlab`, `BitbucketCloud`, `Crowd`, `OIDC`, `LDAP`, `SAML`

Group

Scope: Cluster
Version: v1alpha1

Contains information about a user group.

- **spec**
  object

  Required value

  - **spec.members**
    array of objects

    Required value

    List of group members.

    - **spec.members.kind**
      string

      Required value

      Type of a group member.

      Allowed values: `User`, `Group`

    - **spec.members.name**
      string

      Required value

      For kind User — User.metadata.name. For kind Group — the nested Group.spec.name (the name that appears in tokens), not metadata.name.

  - **spec.name**
    string

    Required value

    Unique group name that appears in the token `groups` claim and in RBAC subjects. Not `metadata.name`.

TokenExchangeProvider

Scope: Cluster
Version: v1alpha1

Defines a trusted issuer of tokens that Dex exchanges for its own tokens (RFC 8693 token exchange).

The name of the object is at most 50 characters.

A client named in `spec.clients` sends a token of the issuer to the Dex token endpoint and gets a Dex token for the cluster, which the Kubernetes API server accepts like the token of any other Dex user. Typical issuers are CI systems (GitLab CI `id_tokens`, GitHub Actions), the Dex of a neighbouring cluster, and the ServiceAccount token issuer of another cluster.

Dex checks the signature, the issuer, the expiry and the audience of the token and the required claims, then names the subject as `spec.identity` says. The provider serves token exchange only and is never shown on the sign-in page.

> **i** **Warning.** Whoever may create the object chooses the issuer, its keys and the names, and so can get a token for any user or group outside the reserved prefixes. This right is equivalent to the right to impersonate users. Grant it to cluster administrators only.

Deleting the object makes the Kubernetes API refuse every token issued through it within seconds if the `enableMultiTenancy` parameter of the `user-authz` module is enabled and the cluster runs Kubernetes 1.34 or later. Otherwise these tokens stay valid until they expire (the `idTokenTTL` parameter of the module).

- **spec**
  object

  Required value

  - **spec.allowedIdentities**
    object

    Limits the identities this provider may assert, as in DexProvider. Dex refuses a subject whose email is outside `emails` and `emailDomains` when either is set, and keeps only the groups listed in `groups` when it is set.

    - **spec.allowedIdentities.emailDomains**
      array of strings

      Allowed email domains.

    - **spec.allowedIdentities.emails**
      array of strings

      Allowed email addresses.

    - **spec.allowedIdentities.groups**
      array of strings

      Allowed groups. The other groups are removed from the subject.

  - **spec.audiences**
    array of objects

    Required value

    Audiences a token is accepted for. A token is accepted if its `aud` claim matches at least one entry.

    - **spec.audiences.exact**
      string

      Value that `aud` must equal.

    - **spec.audiences.prefix**
      string

      Prefix that `aud` must start with.

  - **spec.claimValidation**
    array of objects

    Claim values a token must carry.

    A string claim must equal `equals`. A boolean or a number must equal `equals` when written as a string. A list must contain `equals`.

    - **spec.claimValidation.claim**
      string

      Required value

      Name of the claim to check.

    - **spec.claimValidation.equals**
      string

Required value

Value the claim must have.

- **spec.clients**
  array of objects

  Required value

  Dex clients that may exchange tokens through this provider. Other clients are refused before their token is checked.

  A listed DexClient can exchange tokens through this provider even when its `allowedProviders` does not name the provider.

  - **spec.clients.dexClient**
    object

    Required value

    DexClient that may exchange tokens. Its client ID is `dex-client-<DEXCLIENT_NAME>@<DEXCLIENT_NAMESPACE>`.

    - **spec.clients.dexClient.name**
      string

      Required value

      Name of the DexClient.

    - **spec.clients.dexClient.namespace**
      string

      Required value

      Namespace of the DexClient.

- **spec.identity**
  object

  Required value

  How the subject of a token is named in the cluster. The Kubernetes API server takes the user name from the email, so the email is the user name unless `email` is set.

  - **spec.identity.email**
    object

    Email of the subject, made of `prefix` and the value of the string claim `claim`. The prefix is required and ends with a colon.

    - **spec.identity.email.claim**
      string

      Required value

      Name of the string claim whose value follows the prefix.

    - **spec.identity.email.prefix**
      string

      Prefix added to the value of the claim. It is required and ends with a colon, such as `ci:`.

  - **spec.identity.groups**
    array of objects

    Groups of the subject, taken from string or list claims.

    With `trimPrefix`, values that do not start with it are dropped, and it is removed from the others. Then `prefix` is added to every remaining value. It is required and ends with a colon.

    - **spec.identity.groups.claim**
      string

      Required value

      Name of the string or list claim that holds the groups.

        - **spec.identity.groups.prefix**
          string

          Prefix added to every group. It is required and ends with a colon, such as `ci:`.

        - **spec.identity.groups.trimPrefix**
          string

          Prefix that group values must start with. It is removed from them, and values without it are dropped.

    - **spec.identity.username**
      object

      Required value

      User name of the subject, made of `prefix` and the value of the string claim `claim`. The prefix is required and ends with a colon.

        - **spec.identity.username.claim**
          string

          Required value

          Name of the string claim whose value follows the prefix.

        - **spec.identity.username.prefix**
          string

          Prefix added to the value of the claim. It is required and ends with a colon, such as `ci:`.

- **spec.issuer**
  string

  Required value

  Issuer of the tokens. It must equal the `iss` claim of a token.

  An https URL without a query or fragment.

  Example:

  ```
  issuer: https://gitlab.example.com
  ```

- **spec.keys**
  object

  Required value

  Source of the keys that sign the tokens, either the discovery document of the issuer or public keys given here.

    - **spec.keys.discovery**
      object

      Settings for reading the keys from the discovery document of the issuer. Dex reads it at the first exchange and again after a failure.

        - **spec.keys.discovery.caData**
          string

          PEM bundle of the CA that the certificate of the issuer chains to, in addition to the system roots.

        - **spec.keys.discovery.url**
          string

          HTTPS address of the discovery document.

          If not set, `<ISSUER>/.well-known/openid-configuration` is used, where `<ISSUER>` is the value of `spec.issuer`.

    - **spec.keys.jwks**
      object

      Public keys of the issuer (JWK Set, RFC 7517). Use it when the issuer has no discovery document reachable from the cluster, or when several issuers share one URL, such as

the ServiceAccount token issuers of different clusters. Private keys are refused. A token that names a key in its `kid` header is verified with the key of that `kid` only, even when the set has one key.

- **spec.keys.jwks.keys**
  array of objects

  Required value

  Public keys in JWK format.

  - **spec.keys.jwks.keys.kty**
    string

    Required value

    Key type, such as `RSA` or `EC`.

- **spec.subjectTokenMaxLifetime**
  string

  Longest time a token may be valid, counted from `iat` to `exp`, or from now to `exp` for a token without `iat`.

  A token valid for longer is refused, so that a leaked long-lived token cannot be exchanged for new Dex tokens until it expires. The value is set in hours, minutes and seconds, such as `24h` or `1h30m`.

  Default: `24h`

  Length: `2..16`

- **status**
  object

  Status of the provider.

  While `metadata.deletionTimestamp` is set, the provider is being revoked, and a client must stop using the tokens it got through it.

  - **status.conditions**
    array of objects

    Conditions of the provider. The `Ready` condition shows whether the provider exchanges tokens, and its `reason` tells why it does not.

    - **status.conditions.lastTransitionTime**
      string

      Time the status last changed.

    - **status.conditions.message**
      string

      Details of the status.

    - **status.conditions.observedGeneration**
      integer

      Generation of the object that the condition was set for.

    - **status.conditions.reason**
      string

      Reason for the status, such as `PrefixConflict`.

    - **status.conditions.status**
      string

      Required value

      Status of the condition, `True`, `False` or `Unknown`.

    - **status.conditions.type**
      string

      Required value

      Type of the condition, such as `Ready`.

  - **status.connectorID**
    string

    ID of the Dex connector of the provider. Use it as `connector id` in the exchange request. Tokens issued through it carry it in the `user-authn.deckhouse.io/dex-provider` extra of the user.

  - **status.observedGeneration**
    integer

    Generation of the object that the controller processed last.

UserAccount

Scope: Cluster
Version: v1alpha1

Controller-projected view of Dex Password, OfflineSessions, and UserIdentity objects for the Deckhouse web UI.

The controller keeps one UserAccount for each local user and one for each user who has signed in through any external provider.

Do not create or edit UserAccount objects. The `user-authn` controller owns them. The source of truth for login credentials and session state remains Dex.

- **spec**
  object

  Empty. UserAccount is controller-owned and has no user-editable specification.

  Do not create UserAccount objects. The controller projects it from Dex.

- **status**
  object

  Observed account state projected from Dex.

  This is a Deckhouse web UI view only and does not store credentials or connector secrets.

  - **status.connectorID**
    string

    Dex connector identifier.

    `local` for local accounts; otherwise the DexProvider name.

  - **status.email**
    string

    Account email as reported by Dex.

  - **status.expireAt**
    string

    Account expiration time, in RFC3339 format.

  - **status.groups**
    array of strings

    Groups associated with the account.

  - **status.incorrectLoginAttempts**
    integer

    Number of consecutive incorrect login attempts recorded in Dex.

    Dex counts them for local accounts, and for accounts of LDAP and Atlassian Crowd providers whose type is listed in the `passwordPolicy.lockout.applyToConnectors` module parameter.

    Allowed values: `0 <= X`

  - **status.kind**
    string

    Account kind.

    Possible values:

- `Local`: Dex Password (static user).
- `External`: Federated identity from a connector.

Allowed values: `Local`, `External`

- **status.lastLogin**
  string

  Time of the last sign-in through Dex, in RFC3339 format.

  Dex records it after the user passes every sign-in step, including 2FA. Basic Authentication to the API server through an LDAP provider with `enableBasicAuth` updates it too, because it goes through Dex.

  For an account that has not signed in since the upgrade to Deckhouse 1.78, this is the time of its last sign-in that issued a refresh token.

- **status.locked**
  boolean

  Whether the account is currently locked.

- **status.lockedByAdministrator**
  boolean

  Whether the current lock was set by an administrator (as opposed to an automatic password-policy lockout).

  This does not make the lock permanent. `lockedUntil` still defines when it expires.

- **status.lockedUntil**
  string

  Time until which the account remains locked, in RFC3339 format.

  After this time the lock is lifted automatically, including an administrator lock set for a limited duration (for example, one hour via UserOperation). A permanent administrator lock is stored as a far-future timestamp.

- **status.providerType**
  string

  External identity provider type.

  Equals `spec.type` of the DexProvider, for example `LDAP`, `Crowd`, `OIDC`, `SAML`, or `Github`.

  Empty for local accounts.

- **status.sessions**
  array of objects

  Devices signed in to the account, the most recently active first.

  A device is one of the following:

  - a browser signed in to Dex while the `sessions` of Dex are enabled, together with the applications whose refresh tokens are bound to its session (the DexAuthenticator objects, and DexClient objects with `refreshTokenLifetime: Session`);
  - a refresh token not bound to a live session of Dex in a browser: kubeconfig, a device flow, an application of a DexClient, Basic Authentication to the API server, a token whose session has ended while the application keeps it, and, while the sessions of Dex are disabled, every sign-in to an application of a DexAuthenticator.

  The list holds at most 50 devices. To sign a device out, create a UserOperation of the `Logout` type with its `id` in `logout.session` (a browser) or `logout.grant` (a refresh token).

  - **status.sessions.clients**
    array of strings

    Dex clients (applications) signed in on the device.

  - **status.sessions.endsAt**
    string

    Time when the session of the device ends unless the device is used again, in RFC3339 format. The session ends at the earlier of two limits: the lifetime counted from the sign-in and the time without use counted from the last use.

    - For a `Browser` device, this is the end of its Dex session (the

`sessions.absoluteLifetime` and `sessions.validIfNotUsedFor` parameters). After it, the browser asks for the password at the next sign-in; the applications it has signed in to stay signed in.
- For a `Grant` device, this is the end of its refresh token (the `refreshTokenAbsoluteLifetime` and `refreshTokenValidIfNotUsedFor` parameters). After it, the device signs in again.

While the device is in use, the time moves forward and is updated with a delay of up to 15 minutes, so the session never ends before the time shown. Not set if the session has no end.

- **status.sessions.id**
  string

  Required value

  Identifier of the device: the identifier of the session of Dex (the `sid` claim of its tokens) for a browser, the identifier of the refresh token for other devices.

- **status.sessions.ipAddress**
  string

  Client address of the last sign-in of the device, as the Ingress controller passed it to Dex. It locates the device only approximately: a proxy, NAT, or VPN changes it. Behind a balancer that hides the address of the client, it is the address of the balancer (for details, see the Which client address does Dex see? section).

  Maximum length: `64`

- **status.sessions.kind**
  string

  Required value

  Kind of the device.

  Possible values:

  - `Browser`: a browser signed in to Dex.
  - `Grant`: a refresh token not bound to a live session of Dex in a browser.

  Allowed values: `Browser`, `Grant`

- **status.sessions.knownSince**
  string

  Time Dex first saw the browser of the device complete a sign-in to the account, in RFC3339 format.

  Set when more than a minute earlier than `signedInAt`: the browser signed in before, signed out, and signed in again. Dex recognizes the browser by a long-lived cookie it sets at sign-in. Signing out of the other devices on the account, signing out everywhere, and the operations that end every session of the user make Dex forget the browsers, and so does ending this device from another device or by an administrator.

- **status.sessions.lastActivity**
  string

  Time of the last use of the device, in RFC3339 format, rounded down to the hour. A device that signed in less than an hour ago shows its sign-in time.

- **status.sessions.signedInAt**
  string

  Time the device signed in, in RFC3339 format.

- **status.sessions.userAgent**
  string

  User-Agent header the device sent at its last sign-in, cut to 512 bytes.

  The device sets the header itself. Treat it as text.

  Maximum length: `512`

- **status.sessionsTruncated**
  boolean

Whether the account has more devices than `sessions` lists. The least recently active ones are not listed.

- **status.twoFactor**
  object

  State of the 2FA of the account in Dex, without secrets.

  The field shows what the settings ask the users of the type of provider of the account for, whether the account has it, and each method it has.

  Set after the first sign-in of the account through Dex. Absent when the second factor does not cover the type of provider of the account.

  - **status.twoFactor.confirmed**
    boolean

    Whether the account has what `methods` and `require` ask for, with the TOTP secret confirmed by a code.

    A WebAuthn credential is complete at the registration.

    Until the code, a sign-in shows the QR code again.

  - **status.twoFactor.enrolled**
    boolean

    Whether the account has what `methods` and `require` ask for: a TOTP secret, at least one WebAuthn credential, both (`All`) or one of them (`Any`).

    A secret or a key of a method that is not asked for does not count. Without `methods`, whether the account has either. Dex creates the TOTP secret when it shows the user the QR code at a sign-in.

  - **status.twoFactor.methods**
    array of strings

    Second factors the settings ask the users of the type of provider of the account for (`twoFactor.methods` of the module, or its `providerTypeOverrides` entry for the type).

    Absent when 2FA is off or does not cover the type.

    - **Element of the array**
      string

      Allowed values: `TOTP`, `WebAuthn`

  - **status.twoFactor.require**
    string

    How the two `methods` combine. With `Any`, the user passes one of them, with `All`, both. Absent with one method.

    Allowed values: `Any`, `All`

  - **status.twoFactor.totp**
    object

    TOTP secret of the account. Absent when there is none.

    A UserOperation of the `Reset2FA` type removes it, unless `spec.reset2FA.methods` lists only `WebAuthn`.

    - **status.twoFactor.totp.confirmed**
      boolean

      Whether the user has entered a code for the secret.

  - **status.twoFactor.webAuthn**
    object

    WebAuthn credentials (security keys) of the account. Absent when there is none.

    A UserOperation of the `Reset2FA` type removes them, unless `spec.reset2FA.methods` lists only `TOTP`.

    - **status.twoFactor.webAuthn.credentials**
      integer

Number of registered security keys.

- **status.twoFactor.webAuthn.maxCredentials**
  integer

  How many credentials the account may register (`twoFactor.webAuthn.maxCredentials` of the module).

- **status.userID**
  string

  Unique user identifier from Dex.

- **status.userRef**
  string

  Name of the related User resource.

  Set for local accounts.

- **status.username**
  string

  Account username as reported by Dex.

UserOperation

Scope: Cluster

- v1
- v1alpha1

Describes a single-use operation to be applied to a user (password reset, 2FA reset, lock/unlock, logout).

A UserOperation runs once, and changes to its spec after creation are ignored. The module processes the operation and writes the result to `status.phase` (`Succeeded` or `Failed`). Operations are automatically deleted after the `retention.userOperations` setting of the module (24 hours by default). To perform a new action, create a new UserOperation.

`Lock`, `ResetPassword`, `Reset2FA`, and `Logout` end the sessions of the user at once. The module raises the generation of the user's Dex account (a provider and a user ID), records the revocation in a Dex Revocation object, and deletes the user's Dex AuthSession (browser session) and RefreshToken objects. Dex refuses everything it issued to the account before, and dex-authenticator stops accepting the user's sessions within seconds. These operations keep the user's 2FA secret. Only `Reset2FA` removes it, and it also deletes the user's Dex OfflineSessions object. `Unlock` and `RequirePasswordChange` end no sessions. What an operation revoked is in `status.revocation`.

- **spec**
  object

  Required value

  - **spec.initiatorType**
    string

    Indicates who initiated the operation. Possible values:

    - `admin`: By an administrator (e.g. via `d8 iam user` CLI or a manual UserOperation).
    - `system`: Reserved. No component sets this value (Dex locks a user after failed sign-in attempts without creating a UserOperation).
    - `self`: By the user (sign-out on all devices or password change in the Deckhouse web interface).
  - **spec.lock**
    object

    Parameters for locking the user.

    - **spec.lock.for**
      string

      Required value

      Lock duration as a Go-style duration string (`30s`, `10m`, `1h`, `2h30m`, `7d`), or `permanent` for an indefinite lock released only by `Unlock`. `1d` equals `24h`.

      Pattern: `^(permanent|([0-9]+(\.[0-9]+)?(s|m|h|d))+)$`

  - **spec.logout**

object

Narrows a `Logout` down. Without it, `Logout` ends every session of the user.

Set at most one of the fields. `session` and `exceptSession` apply to Dex browser sessions.

- **spec.logout.exceptGrant**
  string

  ID of the refresh token to keep, for signing out of the other devices from a device without a browser session of Dex. Every browser session of the user ends, except the one the kept refresh token was issued in, and every other refresh token is revoked. A token issued while the operation runs can survive it. The operation fails if the user has no such refresh token.

  Pattern: `^[a-z2-7]{1,64}$`

- **spec.logout.exceptSession**
  string

  ID of the browser session to keep. Every other browser session of the user ends, and every refresh token not issued in the kept session is revoked. A token issued while the operation runs can survive it. The operation fails if the user has no such session.

  Pattern: `^[a-z2-7]{1,64}$`

- **spec.logout.grant**
  string

  ID of the refresh token to revoke: a device signed in without a browser session of Dex, such as a kubeconfig. It is the `id` of a device of the `Grant` kind in `status.sessions` of the UserAccount and the `d8_gid` claim of the tokens issued with the refresh token. The other devices keep their sessions. If the user has no such refresh token, for example it has expired, has been revoked or belongs to another user, the operation ends nothing and succeeds with the `the user has no such grant` message.

  Pattern: `^[a-z2-7]{1,64}$`

- **spec.logout.session**
  string

  ID of the browser session to end (the `sid` claim of the tokens issued in it), together with the refresh tokens issued in it. If the user has no such session, for example it has expired or belongs to another user, the operation ends nothing and succeeds with the `the user has no such session` message.

  Pattern: `^[a-z2-7]{1,64}$`

- **spec.reset2FA**
  object

  Narrows a `Reset2FA` down. Without it, `Reset2FA` removes every second factor of the user.

  - **spec.reset2FA.methods**
    array of strings

    Second factors to remove: `TOTP`, the secret of the authenticator application, and `WebAuthn`, the security keys. The other method stays. The user registers a removed method again at the next sign-in that asks for it. The sessions of the user end whichever methods are listed.

    - **Element of the array**
      string

      Allowed values: `TOTP`, `WebAuthn`

- **spec.resetPassword**
  object

  Parameters for password reset.

  - **spec.resetPassword.newPasswordHash**
    string

    Bcrypt hash of the new password, without Base64 encoding.

  - **spec.resetPassword.requirePasswordChange**
    boolean

Require the user to change the password at the next sign-in.

With `false`, the new password stays valid until the user changes it or until the rotation interval of the password policy ends. A password that does not meet the complexity rules still has to change at the next sign-in.

Default: `true`

- **spec.target**
  object

  Identifier of an account of an external authentication provider, by email.

  The `Lock`, `Unlock`, `Logout`, and `Reset2FA` operations against `target` apply to the Dex account (UserIdentity object) of the user whose email at the last sign-in was `email`. `connectorID` and `userID` narrow the search down to one provider and one user ID. The operation fails if no account has the email (the user has never signed in) or if more than one account matches; then set `connectorID`, and `userID` if the provider has several users with the email. The operation applies only to the account found: a lock does not lock a local user or a user of another provider with the same email. A local user is addressed by `spec.user` only.

  The lock applies to the user ID that the provider returns at sign-in. A SAML provider must return the same ID at every sign-in, with `nameIDPolicyFormat` set to `persistent` or `emailAddress` or not set. With `transient`, every sign-in gets a new ID, and the lock does not apply to the next sign-in.

  > **i** Only one of the fields can be specified at the same time: `user` or `target`.

  - **spec.target.connectorID**
    string

    ID of the DexProvider (connector) through which the user logs in.

    Examples:

    ```
    connectorID: my-ldap
    ```

    ```
    connectorID: my-crowd
    ```

  - **spec.target.email**
    string

    Required value

    Email of the user, as reported by the provider at the user's last sign-in.

    The comparison is case-insensitive.

    Example:

    ```
    email: jane.doe@example.org
    ```

  - **spec.target.userID**
    string

    ID of the user that the provider returns at sign-in (`userID` of the Dex UserIdentity object). It tells apart accounts of a provider with the same email.

    Example:

    ```
    userID: cn=jane.doe,ou=people,dc=example,dc=org
    ```

- **spec.type**
  string

  Required value

  Type of the user operation. Possible values:

  - `ResetPassword`: Password reset. Applies to local users (`spec.user`) only.
  - `Reset2FA`: Two-factor authentication reset. Supports both local users (`spec.user`) and external users (`spec.target`). Of the external users, only the users of an LDAP or

Atlassian Crowd provider can have a second factor. For a user of a provider of another type, the operation only ends the sessions.
- `Lock`: User lock. Supports both local users (`spec.user`) and external users (`spec.target`).
- `Unlock`: User unlock. Supports both local users (`spec.user`) and external users (`spec.target`).
- `Logout`: Ends the sessions of the user. Without `logout`, ends every session in every application and revokes the refresh tokens of kubeconfig files. Supports both local users (`spec.user`) and external users (`spec.target`).
- `RequirePasswordChange`: The user has to set a new password at the next sign-in. Ends no sessions. Applies to local users (`spec.user`) only.

Allowed values: `ResetPassword`, `Reset2FA`, `Lock`, `Unlock`, `Logout`, `RequirePasswordChange`

- **spec.user**
  string

  Name (username) of the target local User resource.

  Used for operations on users that are managed by DP via the User CRD (the built-in local connector).

  > **i** Only one of the fields can be specified at the same time: `user` or `target`.

  Example:

  ```
  user: jane.doe
  ```

- **status**
  object
  - **status.completedAt**
    string

    Time when the operation was completed, in RFC 3339 format (e.g. `2025-01-15T10:30:00Z`). Empty until the operation finishes processing.

  - **status.message**
    string

    Optional message about the result or failure of the operation.

  - **status.phase**
    string

    Current phase of the operation. Possible values:

    - `Succeeded`: Operation was completed successfully.
    - `Failed`: Operation failed.

    Allowed values: `Succeeded`, `Failed`

  - **status.revocation**
    object

    What the operation revoked. Set by `Lock`, `ResetPassword`, `Reset2FA`, and `Logout`.

    - **status.revocation.authSessionsDeleted**
      integer

      Number of Dex AuthSession objects (browser sessions) of the user the operation deleted.

    - **status.revocation.generation**
      integer

      New generation of the user’s Dex account. Everything issued to the account at a lower generation is revoked. Not set when the operation did not revoke the whole account.

    - **status.revocation.name**
      string

      Name of the Dex Revocation object the operation wrote, or of the first of them.

    - **status.revocation.refreshTokensDeleted**
      integer

Number of Dex RefreshToken objects of the user the operation deleted.

Deprecated resource. Support for the resource might be removed in a later release.

Describes an operation to be applied to a user (password reset, 2FA reset, lock/unlock).

The `Lock`, `ResetPassword`, and `Reset2FA` operations end the sessions of the user at once, as in `v1`. These operations keep the user's 2FA secret. Only `Reset2FA` removes it, and it also deletes the user's Dex OfflineSessions object.

- **spec**
  object

  Required value

  - **spec.initiatorType**
    string

    Indicates who initiated the operation. Possible values:

    - `admin`: By an administrator.
    - `system`: Reserved. No component sets this value.
    - `self`: By the user.
  - **spec.lock**
    object

    Parameters for locking the user.

    - **spec.lock.for**
      string

      Required value

      Lock duration as a Go-style duration string (`30s`, `10m`, `1h`, `2h30m`, `7d`), or `permanent` for an indefinite lock released only by `Unlock`. `1d` equals `24h`.

      Pattern: `^(permanent|([0-9]+(\.[0-9]+)?(s|m|h|d))+)$`
  - **spec.resetPassword**
    object

    Parameters for password reset.

    - **spec.resetPassword.newPasswordHash**
      string

      Bcrypt hash of the new password.
  - **spec.type**
    string

    Required value

    Type of the user operation. Possible values:

    - `ResetPassword`: Password reset.
    - `Reset2FA`: Two-factor authentication reset.
    - `Lock`: User lock.
    - `Unlock`: User unlock.

    Allowed values: `ResetPassword`, `Reset2FA`, `Lock`, `Unlock`
  - **spec.user**
    string

    Required value

    Name (username) of the target User resource.

    Example:

    ```
    user: jane.doe
    ```
- **status**
  object
  - **status.completedAt**
    string

Time when the operation was completed.

- **status.message**
  string

  Optional message about the result or failure of the operation.

- **status.phase**
  string

  Current phase of the operation. Possible values:

  - `Succeeded`: Operation completed successfully.
  - `Failed`: Operation failed.

  Allowed values: `Succeeded`, `Failed`

User

Scope: Cluster

- v1
- v1alpha1

Contains information about the static user.

Creating a user

- **spec**
  object

  Required value

  - **spec.email**
    string

    Required value

    User email. Must be in lowercase and at most 150 bytes long (150 characters of Latin letters, digits and punctuation): Dex names the object that keeps the password of the user after the email, and the name of a Kubernetes object is at most 253 characters.

    To grant this user access, use the `email` value as the `User` subject name in a RoleBinding or ClusterRoleBinding of the granular role-based model.

    Important! Email addresses are case-insensitive for uniqueness validation. Dex automatically converts emails to lowercase during authentication. For new users, uppercase letters in email addresses are not allowed. Existing users with uppercase emails can be updated without changing the email field.

    Length: `1..150`

    Example:

    ```
    email: user@domain.com
    ```

  - **spec.groups**
    Deprecated
    array of strings

    Static user groups.

    Since the parameter has been deprecated, use the Group resource to add users to groups.

  - **spec.password**
    string

    Required value

    User password hash in plaintext or Base64 encoded.

    Use the following command to encode the password hash in Base64: `echo -n '<PASSWORD>' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' | base64 -w0; echo`. You can also create the user with `d8 iam user create`, which computes the hash locally.

> **Caution.** If the password does not meet the complexity rules of the password policy, the user has to change it at the first sign-in. To make the user change the password at the first sign-in in any case, set `requirePasswordChangeOnFirstLogin`.

> **Caution.** This field is immutable after the User is created. Changing the password via `kubectl edit` does not update Dex credentials and will be rejected. To reset the password, use the UserOperation resource (or `d8 iam user`).

Example:

```
password:
JDJ5JDEwJGRNWGVGUVBkdUdYYVMyWDFPcGdZdk9HSy81LkdsNm5sdU9mUkhnNWlQdDhuSlh6Szhp
eS5H
```

- **spec.requirePasswordChangeOnFirstLogin**
  boolean

  Require the user to change the password at the first sign-in.

  Applies when the module creates the Dex credentials of the user from `password`: when the User is created, created again, or restored from a backup.

  Can be set only when the User is created. Adding, changing, or removing the field later is rejected.

- **spec.ttl**
  string

  Static user TTL.

  It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

  You can only set the TTL once. The `expireAt` date will not be updated if you change it again.

  Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

  Example:

  ```
  ttl: 24h
  ```

- **spec.userID**
  Deprecated
  string

  Deprecated. Ignored if set. Dex Password.userID is User.metadata.name.

- **status**
  object
  - **status.expireAt**
    string

    User account expiration time. Set only when `spec.ttl` is set. At this time the User is deleted and removed from all Groups.

  - **status.groups**
    array of strings

    Groups the user belongs to, computed from Group membership. Values are Group.spec.name.

  - **status.lock**
    object

    Information about user account lock. If present, the user cannot authenticate until the specified time or until the lock is manually lifted by an administrator.

    Actions on the account (lock, unlock, password reset, forced password change, 2FA reset, logout) are performed via the UserOperation resource. A lock, a password reset, a 2FA reset and a logout end the sessions of the user at once. After a password reset or a forced password change, the user is presented with a password change form on the next successful login. Only a 2FA reset removes the user’s 2FA secret.

- **status.lock.message**
  string

  Human-readable explanation of the lock reason.

- **status.lock.reason**
  string

  Machine-readable reason for the account lock. Used for programmatic checks and policy enforcement.

  Allowed values: `PasswordPolicyLockout`, `LockedByAdministrator`

- **status.lock.state**
  boolean

  Indicates whether the user account is currently locked.

  - `true` — account is locked.
  - `false` — account is active.
- **status.lock.until**
  string

  The time until which the user is locked, in RFC3339 format. After this time, the account lock will be automatically lifted.

Deprecated resource. Support for the resource might be removed in a later release.

Contains information about the static user.

Creating a user

- **spec**
  object

  Required value

  - **spec.email**
    string

    Required value

    User email. Must be in lowercase and at most 150 bytes long (150 characters of Latin letters, digits and punctuation): Dex names the object that keeps the password of the user after the email, and the name of a Kubernetes object is at most 253 characters.

    To grant this user access, use the `email` value as the `User` subject name in a RoleBinding or ClusterRoleBinding of the granular role-based model.

    Important! Email addresses are case-insensitive for uniqueness validation. Dex automatically converts emails to lowercase during authentication. For new users, uppercase letters in email addresses are not allowed. Existing users with uppercase emails can be updated without changing the email field.

    Length: `1..150`

    Example:

    ```
    email: user@domain.com
    ```

  - **spec.groups**
    Deprecated
    array of strings

    Static user groups.

    Since the parameter has been deprecated, use the Group resource to add users to groups.

  - **spec.password**
    string

    Required value

    User password hash in plaintext or Base64 encoded.

    Use the following command to encode the password hash in Base64: `echo -n '<PASSWORD>' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' | base64 -w0; echo`. You can also create the user with `d8 iam user create`, which computes the hash locally.

> **Caution.** If the password does not meet the complexity rules of the password policy, the user has to change it at the first sign-in. To make the user change the password at the first sign-in in any case, set `requirePasswordChangeOnFirstLogin`.

> **Caution.** This field is immutable after the User is created. Changing the password via `kubectl edit` does not update Dex credentials and will be rejected. To reset the password, use the UserOperation resource (or `d8 iam user`).

Example:

```
password:
JDJ5JDEwJGRNWGVGUVBkdUdYYVMyWDFPcGdZdk9HSy81LkdsNm5sdU9mUkhnNWlQdDhuSlh6Szhp
eS5H
```

- **spec.requirePasswordChangeOnFirstLogin**
  boolean

  Require the user to change the password at the first sign-in.

  Applies when the module creates the Dex credentials of the user from `password`: when the User is created, created again, or restored from a backup.

  Can be set only when the User is created. Adding, changing, or removing the field later is rejected.

- **spec.ttl**
  string

  Static user TTL.

  It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

  You can only set the TTL once. The `expireAt` date will not be updated if you change it again.

  Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

  Example:

  ```
  ttl: 24h
  ```

- **spec.userID**
  string

  Deprecated. Ignored if set. Dex Password.userID is User.metadata.name.

  Example:

  ```
  userID: '08a8684b-db88-4b73-90a9-3cd1661f5466'
  ```

- **status**
  object
  - **status.expireAt**
    string

    User account expiration time. Set only when `spec.ttl` is set. At this time the User is deleted and removed from all Groups.

  - **status.groups**
    array of strings

    Groups the user belongs to, computed from Group membership. Values are Group.spec.name.

  - **status.lock**
    object

    Information about user account lock. If present with `state: true`, the user cannot authenticate until the specified time or until the lock is manually lifted by an administrator.

    Actions on the account (lock, unlock, password reset, forced password change, 2FA reset, logout) are performed via the UserOperation resource. A lock, a password reset, a 2FA reset

and a logout end the sessions of the user at once. After a password reset or a forced password change, the user is presented with a password change form on the next successful login. Only a 2FA reset removes the user's 2FA secret.

- **status.lock.message**
  string

  Human-readable explanation of the lock reason.

- **status.lock.reason**
  string

  Machine-readable reason for the account lock. Used for programmatic checks and policy enforcement.

  Allowed values: `PasswordPolicyLockout`, `LockedByAdministrator`

- **status.lock.state**
  boolean

  Indicates whether the user account is currently locked.

  - `true` — account is locked.
  - `false` — account is active.
- **status.lock.until**
  string

  The time until which the user is locked, in RFC3339 format. After this time, the account lock will be automatically lifted.

The user-authn module: usage

> The module lifecycle stage: General Availability

An example of the module configuration

The example adds a direct access method to the API server for the kubeconfig that users generate in the Deckhouse web UI.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 3
  enabled: true
  settings:
    kubeconfigGenerator:
    - id: direct
      masterURI: https://192.0.2.10:6443
      description: "Direct access to kubernetes API"
```

Configuring a provider

In the examples below, `<DEX_DOMAIN>` is the Dex domain. It is the `publicDomainTemplate` value with `%s` replaced by `dex`, for example `dex.example.com`.

Checking provider connectivity

The provider page in the Deckhouse web UI has a “Check connection” action. It creates a DexProviderCheck resource and waits for the `user-authn` controller to write the result to its `status`.

The check verifies that:

- the referenced DexProvider exists and is enabled;
- the Dex discovery endpoint inside the cluster is reachable;
- the external provider endpoint is reachable.

For OIDC providers, the check also reads the discovery document and JWKS. For LDAP providers, it verifies TCP/TLS/StartTLS reachability and, when Kerberos is enabled, that the keytab Secret exists. The check also verifies that the provider accepts the client or service account credentials (GitHub, GitLab, Bitbucket Cloud, Crowd, OIDC, LDAP bind) and warns about disabled TLS verification and certificates that expire soon. The check does not perform a full login flow and does not validate a test user password.

To run the check without the web UI, create a DexProviderCheck:

```
apiVersion: deckhouse.io/v1
kind: DexProviderCheck
metadata:
  name: check-github
spec:
  providerName: github
```

Then read its status:

```
d8 k get dexproviderchecks check-github -o yaml
```

Limiting the identities of a provider

A user who signs in through a DexProvider gets the email and the groups that the identity provider reports. The email is the Kubernetes username. So the provider gives its users every permission already granted in the cluster to these emails and groups.

To limit them, use `spec.allowedIdentities`. The `emails` and `emailDomains` lists limit the email, and Dex refuses sign-in for any other email. The `groups` list limits the groups. Dex keeps only the listed groups in the token and refuses sign-in if none is left.

The limits apply to every provider type, in addition to the group filters of the type (`oidc.allowedGroups`, `gitlab.groups`, `crowd.groups`, `bitbucketCloud.teams` without `includeTeamGroups`, `github.orgs[].teams` in every organization, `saml.allowedGroups` with `filterGroups: true`). Group names are compared exactly. Nesting of Group objects does not extend the list, because a token from an external provider carries only the groups that the provider reports.

Dex checks the limits at sign-in, at every refresh-token request and at Basic Authentication to the API server through an LDAP provider. Dex revokes a refresh token that falls outside the limits. Narrowing the limits therefore ends the existing sessions of the users it excludes, and they have to sign in again. For a Crowd or OIDC provider, basic-auth-proxy checks the credentials with the provider directly, so the limits do not apply to Basic Authentication.

The same limits define who can create or change the provider. You must be able to assign every role already granted to the emails and groups that the provider can report. A provider without an email limit can report the email of a SuperAdmin, so only a SuperAdmin can create or change it. A Crowd or OIDC provider with `enableBasicAuth: true` counts as a provider without an email limit, because Basic Authentication through it bypasses the limits. Only a SuperAdmin can create such a provider or turn on `enableBasicAuth` in an existing one.

Example of a provider limited by an email domain and a group:

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: contractors
spec:
  type: OIDC
  displayName: Contractors
  oidc:
    issuer: https://idp.contractor.example
    clientID: dex
    clientSecret: secret
  allowedIdentities:
    emailDomains: [contractor.example]
    groups: [contractors]
```

The following changes are not checked: rotating `clientSecret` or `bindPW`, changing `displayName`, disabling the provider, narrowing the limits, applying the same manifest again, and deleting the provider. Any other change is checked as a new provider, including enabling a disabled provider.

If the check fails, the error lists the roles that the provider could reach, for example:

```
dexproviders.deckhouse.io "corp": the provider can assert identities that already carry roles [user-
authz:super-admin]; the requester's can-assign range is basic<=ClusterAdmin and does not cover them.
Narrow spec.allowedIdentities (emails, emailDomains, groups) or ask a SuperAdmin
```

Prefix for the groups of a provider

The cluster knows the groups a provider reports by their names, so a rule for the group `admins` applies to every member of any group `admins`. When two providers report a group of the same name, for example an LDAP directory and a GitLab, the members of both get the rights of the rule.

`spec.groupPrefix` of a DexProvider puts a prefix in front of every group the provider asserts, whatever its type. With `groupPrefix: corp-ldap:`, the group `admins` of the directory is `corp-ldap:admins` in the tokens, in the rules (the subjects of the AuthorizationRule objects) and in the `allowedGroups` of DexClient and DexAuthenticator. A prefix keeps the groups of the providers apart only when every provider that can emit such names has its own prefix. A provider without a prefix passes the group names as they are (OIDC, a GitHub team named `org:team`, GitLab, SAML and the local groups) and can emit a name that starts with the prefix. When the rules rely on prefixed groups, set a prefix on every provider.

The following provider prefixes the groups of an LDAP directory with `corp-ldap:`:

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: corp-ldap
spec:
  type: LDAP
  displayName: Corp
  groupPrefix: "corp-ldap:"
  allowedIdentities:
    groups:
    - "corp-ldap:admins"
    - "corp-ldap:developers"
  ldap:
    host: ldap.example.com:636
    userSearch:
      baseDN: ou=people,dc=example,dc=com
      username: mail
      idAttr: DN
      emailAttr: mail
```

Keep the following in mind when you set a prefix:

- There is no prefix by default. The prefix renames the groups, and the rules written for the old

names stop applying to the users of the provider and so would lock them out. An existing provider takes the prefix only when you set it. Rewrite the rules first, then set the prefix.
- Rewrite the subjects of ClusterAuthorizationRule and AuthorizationRule, the groups of ClusterRoleBinding and RoleBinding, `auth.allowedUserGroups` in the ModuleConfig of `openvpn`, `documentation`, `istio`, `cilium-hubble` and `deckhouse-tools` (those modules render a DexAuthenticator from the setting), `allowedIdentities.groups` of the DexProvider and `allowedGroups` of DexAuthenticator and DexClient.
- After the prefix is set or changed, the users of the provider sign in again, and the new tokens carry the prefix.
- The access and ID tokens already issued keep the old names only until they expire. A rule that still names a group without the prefix, including a cluster-admin rule, stops matching as soon as those tokens are gone.
- A token that a Dex pod still running the old configuration issues later than 30 minutes after the change can keep the old names. The rules rewritten for the prefix do not match them.
- The lists that name the groups of Dex take the names with the prefix: `allowedIdentities.groups` of the provider, and `allowedGroups` of a DexClient or a DexAuthenticator. Every name in `allowedIdentities.groups` must start with `groupPrefix`, otherwise the API refuses the manifest, because Dex adds the prefix before it compares.
- The group settings of the provider type (for example, `oidc.allowedGroups`, `gitlab.groups`, `crowd.groups` and `ldap.groupSearch`) are about the groups of the identity provider and take its names, without the prefix.
- A group that already starts with the prefix keeps its name.
- The prefix ends with a colon, as in `corp-ldap:`, and differs from the prefix of every other DexProvider and from the group prefixes of every TokenExchangeProvider. Neither of two prefixes may start with the other. The admission webhooks refuse a prefix that breaks this, whichever of the objects is created or changed last.
- The prefix cannot start with `system:`, which the Kubernetes API server reserves, or with `peering:`, which is reserved for the ServiceAccounts of the `d8-peering` namespace. It cannot be set together with `enableBasicAuth` of an `OIDC` or `Crowd` provider, because basic-auth-proxy checks the credentials with such a provider directly and passes its groups as they are, so the prefix would not apply to them. Basic Authentication of an `LDAP` provider goes through Dex and gets the prefix.
- With a prefix, the provider can assert only groups that start with it. Therefore the check of who may create or change the provider (“Limiting the identities of a provider”) counts, of the roles granted to groups, only the roles of the groups with this prefix.

GitHub

The example shows the provider’s settings for integration with GitHub.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: github
spec:
  type: Github
  displayName: My Company Github
  # Optional: disable the provider without deleting CR
  # enabled: false
  github:
    clientID: plainstring
    clientSecret: plainstring
```

In your GitHub organization, register an OAuth application. To do this, go to `Settings` → `Developer settings` → `OAuth Apps` → `New OAuth App` and set `Authorization callback URL` to `https://<DEX_DOMAIN>/callback`.

Paste the generated `Client ID` and `Client Secret` into the DexProvider.

If the organization restricts third-party applications, request approval in `Settings` → `Applications` → `Authorized OAuth Apps` → `<APPLICATION_NAME>` → `Send Request`, and ask an organization owner to approve the request.

GitLab

The example shows the provider’s settings for integration with GitLab.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: gitlab
spec:
  type: Gitlab
  displayName: Dedicated GitLab
  gitlab:
    baseURL: https://gitlab.example.com
    clientID: plainstring
    clientSecret: plainstring
    groups:
    - administrators
    - users
```

Create a new application in GitLab.

To do this:

- **Self-hosted**: Go to `Admin area` → `Application` → `New application`, set `Redirect URI (Callback URL)` to `https://<DEX_DOMAIN>/callback` and select the `read_user` and `openid` scopes.
- **Cloud GitLab.com**: Under the main project account, go to `User Settings` → `Application` → `New application`, set `Redirect URI (Callback URL)` to `https://<DEX_DOMAIN>/callback` and select the `read_user` and `openid` scopes.
- **GitLab 16 and later**: Enable the `Trusted`/`Trusted applications are automatically authorized on GitLab OAuth flow` checkbox when creating the application.

Paste the generated `Application ID` and `Secret` into the DexProvider.

Atlassian Crowd

The example shows the provider’s settings for integration with Atlassian Crowd.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: crowd
spec:
  type: Crowd
  displayName: Crowd
  crowd:
    baseURL: https://crowd.example.com/crowd
    clientID: plainstring
    clientSecret: plainstring
    groups:
    - administrators
    - users
```

Create a new `Generic` application in the corresponding Atlassian Crowd project. To do this, go to `Applications` → `Add application`.

Paste the generated `Application Name` and `Password` into the DexProvider.

Specify Crowd groups in the DexProvider in lowercase.

Bitbucket Cloud

The example shows the provider’s settings for integration with Bitbucket Cloud.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: bitbucket
spec:
  type: BitbucketCloud
  displayName: Bitbucket
  bitbucketCloud:
    clientID: plainstring
    clientSecret: plainstring
    includeTeamGroups: true
    teams:
    - administrators
    - users
```

Create a new OAuth consumer in the Bitbucket team menu. To do this, go to `Settings` → `OAuth consumers` → `New application`, set `Callback URL` to `https://<DEX_DOMAIN>/callback` and allow access for `Account: Read` and `Workspace membership: Read`.

Paste the generated `Key` and `Secret` into the DexProvider.

OIDC (OpenID Connect)

Authentication through an OIDC provider requires registering a client (or “creating an application”). Register it as the provider’s documentation describes (for example, Okta, Keycloak, Gluu).

Paste the generated `clientID` and `clientSecret` into the DexProvider.

Keycloak

After selecting a `realm` to configure, adding a user in the Users section, and creating a client in the Clients section with authentication enabled, which is required to generate the `clientSecret`, you need to perform the following steps:

- Create a `scope` named `groups` in the Client scopes section and assign it the predefined mapping `groups`. (“Client scopes” → “Client scope details” → “Mappers” → “Add predefined mappers”)
- In the previously created client, add this `scope` in the Client scopes tab (“Clients” → “Client details” → “Client Scopes” → “Add client scope”).
- In the “Valid redirect URIs”, “Valid post logout redirect URIs”, and “Web origins” fields of the client configuration, specify `https://<DEX_DOMAIN>/*`.

The example shows the provider’s settings for integration with Keycloak.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: keycloak
spec:
  type: OIDC
  displayName: My Company Keycloak
  oidc:
    issuer: https://keycloak.my-company.com/realms/myrealm # Use the name of your
realm
    clientID: plainstring
    clientSecret: plainstring
    insecureSkipEmailVerified: true
    getUserInfo: true
    scopes:
      - openid
      - profile
      - email
      - groups
```

If email verification is not enabled in Keycloak, to properly use it as an identity provider, adjust the

`Client Scopes` settings in one of the following ways:

- Delete the `Email verified` mapping (“Client Scopes” → “Email” → “Mappers”). This is required for proper processing of the `insecureSkipEmailVerified` field when it’s set to `true` and for correct permission assignment to users with unverified emails.
- If you can’t modify or delete the `Email verified` mapping, create a new Client Scope named `email_dkp` (or any other name) and add two mappings:
  - `email`: “Client Scopes” → `email_dkp` → “Add mapper” → “From predefined mappers” → `email`.
  - `email verified`: “Client Scopes” → `email_dkp` → “Add mapper” → “By configuration” → “Hardcoded claim”. Specify the following fields:
    - “Name”: `email verified`
    - “Token Claim Name”: `emailVerified`
    - “Claim value”: `true`
    - “Claim JSON Type”: `boolean`

  After that, in the client registered for the Deckhouse Platform cluster in “Clients”, change `Client scopes` from `email` to `email_dkp`.

  In the DexProvider resource, specify `insecureSkipEmailVerified: true` and in the `.spec.oidc.scopes` field, change the Client Scope name to `email_dkp` following the example:

  ```
  scopes:
    - openid
    - profile
    - email_dkp
    - groups
  ```

⚠ With `insecureSkipEmailVerified: true`, Dex accepts unverified email addresses. Permissions are granted by email, so use this parameter only if the identity provider does not let users set an arbitrary email address.

Okta

The example shows the provider’s settings for integration with Okta.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: okta
spec:
  type: OIDC
  displayName: My Company Okta
  oidc:
    issuer: https://my-company.okta.com
    clientID: plainstring
    clientSecret: plainstring
    getUserInfo: true
```

Blitz Identity Provider

When you register the application in the Blitz Identity Provider, specify `https://<DEX_DOMAIN>/callback` as the URL to redirect the user to after authorization.

The example below shows the provider settings for integration with Blitz Identity Provider.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: blitz
spec:
  displayName: Blitz Identity Provider
  oidc:
    basicAuthUnsupported: false
    claimMapping:
      email: email
      groups: your_claim # Claim for getting user groups, configured on the Blitz
    clientID: clientID
    clientSecret: clientSecret
    getUserInfo: true
    insecureSkipVerify: false
    issuer: https://yourdomain.idblitz.ru/blitz
    promptType: consent
    scopes:
    - profile
    - openid
    userIDKey: sub
    userNameKey: email
  type: OIDC
```

For the application logout to work correctly (the token is revoked and the user must sign in again), set the `promptType` parameter to `login`.

To ensure granular user access to applications, you have to:

- Add the `allowedUserGroups` parameter to the `ModuleConfig` of the target application.
- Add the user to the groups (group names should be the same for Blitz and Deckhouse).

Below is an example for prometheus:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus
spec:
  version: 2
  settings:
    auth:
      allowedUserGroups:
        - adm-grafana-access
        - grafana-access
```

LDAP

The example shows the provider’s settings for integration with Active Directory.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: active-directory
spec:
  type: LDAP
  displayName: Active Directory
  ldap:
    host: ad.example.com:636
    rootCAData: |
      -----BEGIN CERTIFICATE-----
      MIIFaDC...
      -----END CERTIFICATE-----

    bindDN: cn=dex-readonly,cn=users,dc=example,dc=com
    bindPW: <PASSWORD>

    usernamePrompt: Email Address

    enableBasicAuth: true

    userSearch:
      baseDN: cn=Users,dc=example,dc=com
      filter: "(objectClass=person)"
      username: userPrincipalName
      idAttr: DN
      emailAttr: userPrincipalName
      nameAttr: cn

    groupSearch:
      baseDN: cn=Users,dc=example,dc=com
      filter: "(objectClass=group)"
      userMatchers:
      - userAttr: DN
        groupAttr: member
      nameAttr: cn
```

To configure authentication, create a read-only service account in LDAP. Specify its DN and password in the `bindDN` and `bindPW` fields of the DexProvider. Enter the password in `bindPW` in plain text. Hashed passwords are not supported.

If LDAP allows anonymous read access, you can omit `bindDN` and `bindPW`.

Nested groups

By default, Dex adds to the token only the groups of which the user is a direct member. A group that contains the user's group is not added. To add the groups of the higher levels, set `recursionGroupAttr` in `userMatchers` to the attribute of a group that stores its members. Dex then looks for the groups that contain each found group, level by level, and adds them to the groups of the user. A cycle of groups ends the search.

The following `groupSearch` adds the groups of every level through the `member` attribute:

```
    groupSearch:
      baseDN: cn=Users,dc=example,dc=com
      filter: "(objectClass=group)"
      userMatchers:
      - userAttr: DN
        groupAttr: member
        recursionGroupAttr: member
      nameAttr: cn
```

Dex makes one more search for every group of every level at each sign-in and each refresh of the tokens. Keep `baseDN` and `filter` of `groupSearch` narrow, and expect a longer sign-in on a deep

hierarchy.

Signing in with one of several attributes

`userSearch.username` names one attribute that the entered username is compared with. To let users sign in with a login or an email, list the attributes in `userSearch.usernames` instead of `username` (set one of the two parameters). Dex searches for an entry in which any of them matches. A sign-in is refused if the username matches more than one entry.

The following `userSearch` lets users sign in with `sAMAccountName` or `userPrincipalName`:

```
    userSearch:
      baseDN: cn=Users,dc=example,dc=com
      filter: "(objectClass=person)"
      usernames: [sAMAccountName, userPrincipalName]
      idAttr: DN
      emailAttr: userPrincipalName
      nameAttr: cn
```

Configuring Basic Authentication

To enable Basic Authentication for the Kubernetes API using LDAP credentials:

1. Ensure that the `apiserver.publishAPI` parameter is enabled in the `control-plane-manager` module configuration.
2. Set `enableBasicAuth: true` in the LDAP DexProvider.

> **i** Only one provider in the cluster can have `enableBasicAuth` enabled.

After configuration, users can access the Kubernetes API via `kubectl`, using their LDAP username and password.

Example kubeconfig for the user:

```
apiVersion: v1
kind: Config
clusters:
- name: my-cluster
  cluster:
    server: https://api.example.com
    # Path to CA certificate or insecure-skip-tls-verify: true
    certificate-authority: /path/to/ca.crt
users:
- name: ldap-user
  user:
    username: janedoe@example.com
    password: userpassword
contexts:
- name: default
  context:
    cluster: my-cluster
    user: ldap-user
current-context: default
```

Kerberos (SPNEGO) SSO for LDAP

Dex supports passwordless Kerberos (SPNEGO) flow for the LDAP connector. When enabled, a browser that trusts the Dex host will send `Authorization: Negotiate …` and Dex will validate the Kerberos ticket using a service keytab, skip the login form, map the Kerberos principal to an LDAP username, query groups, and complete the OIDC flow.

The principal mapped to a username is compared with every attribute listed in `userSearch.usernames` (or with `username`, when that is set), with the same filter as a password sign-in. With `usernameFromPrincipal: UserPrincipalName`, the principal is compared as `user@REALM`, with `Localpart` or `SAMAccountName` as the part before `@`. The value must match an attribute of the user's own entry. List only attributes whose values are unique in the directory and consistent with `usernameFromPrincipal`. If a value of another entry equals the principal, SSO stops working for that user (`multiple results`). A principal that matches none of the attributes of its own entry is matched to the entry of another user. The password is not checked on this path.

Minimal example extending the LDAP provider spec:

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: active-directory
spec:
  type: LDAP
  displayName: Active Directory
  ldap:
    host: ad.example.com:636
    bindDN: cn=dex-readonly,cn=users,dc=example,dc=com
    bindPW: <PASSWORD>
    userSearch:
      baseDN: cn=Users,dc=example,dc=com
      username: sAMAccountName
      idAttr: uid
      emailAttr: mail
      nameAttr: cn
    groupSearch:
      baseDN: cn=Users,dc=example,dc=com
      nameAttr: cn
      userMatchers:
      - userAttr: uid
        groupAttr: memberUid
    kerberos:
      enabled: true
      keytabSecretName: dex-kerberos-keytab  # Secret in d8-user-authn with key
'krb5.keytab'
      expectedRealm: EXAMPLE.COM           # optional, case-insensitive match
      usernameFromPrincipal: SAMAccountName  #
Localpart|SAMAccountName|UserPrincipalName
      fallbackToPassword: false            # default false; if true, render form when
header missing/invalid
```

Notes:

- The Secret `dex-kerberos-keytab` must exist in the `d8-user-authn` namespace and have a data key named exactly `krb5.keytab`.
- A single Dex Pod can serve multiple LDAP+Kerberos providers. Each provider mounts its own keytab; a shared `krb5.conf` is not required (Dex validates tickets offline using the keytab).
- A DexProvider with `enabled: true` must have `keytabSecretName` set, otherwise the object is rejected when saved. To turn Kerberos off and keep its settings, set `enabled: false`.

SAML

The example shows the provider's settings for integration with a SAML 2.0 Identity Provider (e.g., AD FS, Okta, Keycloak).

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: saml-provider
spec:
  type: SAML
  displayName: Corporate SAML
  saml:
    ssoURL: https://saml-idp.example.com/saml/sso
    rootCAData: |
      -----BEGIN CERTIFICATE-----
      MIIFaDC...
      -----END CERTIFICATE-----
    entityIssuer: https://dex.example.com/callback
    ssoIssuer: https://saml-idp.example.com
    usernameAttr: name
    emailAttr: email
    groupsAttr: groups
    nameIDPolicyFormat: persistent
```

To configure the SAML Identity Provider:

1. Register Dex as a Service Provider (SP) with your identity provider using the following settings:
   - **ACS URL (Assertion Consumer Service)**: `https://<DEX_DOMAIN>/callback`
   - **Entity ID**: `https://<DEX_DOMAIN>/callback`
   - **Name identifier format**: `persistent` or `emailAddress`
2. Configure attribute mapping in the identity provider to send `email`, `name` (username), and `groups` attributes in the SAML assertion.
3. Export the identity provider signing certificate and specify it in the `rootCAData` field of the DexProvider resource.

> **i** SAML does not natively support refresh tokens. Dex caches the user identity from the initial SAML assertion and returns it on subsequent refresh requests. The session lifetime is limited by the `refreshTokenAbsoluteLifetime` module parameter.

Configuring the OAuth2 client in Dex for connecting an application

This configuration is suitable for applications that can perform OAuth2 authentication themselves, without an OAuth2 proxy. The DexClient lets such applications use Dex.

```
apiVersion: deckhouse.io/v1
kind: DexClient
metadata:
  name: myname
  namespace: mynamespace
spec:
  redirectURIs:
  - https://app.example.com/callback
  - https://app.example.com/callback-reserve
  allowedGroups:
  - Everyone
  - admins
  trustedPeers:
  - opendistro-sibling
```

In the authorization code flow, Dex accepts only the `S256` method of Proof Key for Code Exchange (PKCE). An application that sends a `code_challenge` with `code_challenge_method=plain`, or without `code_challenge_method` (the OAuth2 default is `plain`), is sent back to its redirect URI with the `invalid_request` error “Unsupported PKCE challenge method”. Such an application has to switch to `S256`. PKCE stays optional, and an application that sends no `code_challenge` signs in without it. The device flow (`/device/code`) is not affected by this check. Dex accepts `plain` for it, because the device code itself serves as the secret.

The DexClient group and email allow-lists are enforced on login and on every refresh-token request. Changing the lists denies further refresh for sessions that no longer match; those users must sign in again.

After the DexClient is created, Dex registers a client with the `dex-client-myname@mynamespace` ID (**clientID**).

The client access password (**clientSecret**) will be stored in the secret object:

```
apiVersion: v1
kind: Secret
metadata:
  name: dex-client-myname
  namespace: mynamespace
type: Opaque
data:
  clientSecret: c2VjcmV0
```

Granting an application access to the Kubernetes API

A DexClient or a DexAuthenticator can be allowed to obtain tokens that the Kubernetes API server accepts. To do that, set one of the following annotations on the object to `"true"`:

- `dexclient.deckhouse.io/allow-access-to-kubernetes` on a DexClient.
- `dexauthenticator.deckhouse.io/allow-access-to-kubernetes` on a DexAuthenticator.

The following is a DexClient configuration example:

```
apiVersion: deckhouse.io/v1
kind: DexClient
metadata:
  name: myname
  namespace: mynamespace
  annotations:
    dexclient.deckhouse.io/allow-access-to-kubernetes: "true"
spec:
  redirectURIs:
  - https://app.example.com/callback
```

The annotation registers the client as a trusted peer of the privileged `kubernetes` OAuth2 client, allowing it to request ID tokens intended for the API server. In such a token, the username is determined by the `email` claim and groups by the `groups` claim. As a result, the application accesses the API server on behalf of the authenticated user and with the permissions granted to that user.

⚠ Access granted this way applies at the cluster level, even though DexClient and DexAuthenticator are namespaced objects. Therefore, only a subject allowed to `create` the `dexclients/allow-access-to-kubernetes` subresource (for DexClient) or the `dexauthenticators/allow-access-to-kubernetes` subresource (for DexAuthenticator) in the namespace of the object can add the annotation or change its value to `"true"`. The `d8:system-capability:user-authn:edit` role and the `ClusterAdmin` access level carry this permission. To grant it in one namespace, create a Role with the `create` verb on these subresources and bind it with a RoleBinding in that namespace. Permissions to create DexClient or DexAuthenticator objects are not sufficient.

Adding the annotation is restricted regardless of its value, including `"false"`. This is required for compatibility with Deckhouse Platform versions earlier than 1.77, where access is granted based on the presence of the annotation regardless of its value. If access to the Kubernetes API server is not required, do not add the annotation.

The restriction does not apply to resources that already have the annotation. A user with permissions to modify such a resource can continue to modify it, including removing the annotation or changing its value to disable access.

Limiting the providers of an application

By default, the sign-in page of an application offers every DexProvider of the cluster and the built-in users (User). To offer only some of them, list their names in `spec.allowedProviders` of the DexClient

or the DexAuthenticator. The name of a DexProvider is its `metadata.name`. The built-in users are `local`.

The following DexAuthenticator lets users sign in to the application only through the `corp-ldap` provider and as built-in users:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: admin-panel
  namespace: team
spec:
  applicationDomain: panel.example.com
  applicationIngressClassName: nginx
  allowedProviders:
  - corp-ldap
  - local
```

Dex hides the other providers on the sign-in page and refuses a sign-in through them even when the user opens the address of the provider directly. If the list holds one provider, the user goes straight to it, without the choice page. Dex also checks the provider at every refresh-token request and token exchange of the application, so a token issued through a provider that is no longer in the list stops refreshing, and its user has to sign in again.

The list works together with the other limits: `allowedEmails` and `allowedGroups` of the application, and `allowedIdentities` of the provider. A user has to pass all of them. An empty or missing list allows every provider. `trustedPeers` is the exception. A peer client can ask for a token whose audience is this client through a provider the peer itself allows, and this client's `allowedProviders` is not checked for that token. The same exception applies to `allowedEmails` and `allowedGroups`.

The users who signed in to the application through a provider that left the list have to sign in again even if the provider is added back. With `sessions.enabled`, Dex keeps the browser session of such a user. Once the provider is back in the list, the user can be signed in by that session without entering the credentials until the session ends.

A name that matches no DexProvider is accepted with a warning. Nobody can sign in through it until the provider is created. Therefore a DexAuthenticator or DexClient applied before its provider by a GitOps tool does not fail.

Exchanging tokens of other issuers

A TokenExchangeProvider lets Dex exchange a token of another issuer for its own token (RFC 8693 token exchange). The Kubernetes API server accepts the Dex token like the token of any other Dex user. Typical issuers are CI systems, the Dex of a neighbouring cluster and the ServiceAccount token issuer of another cluster.

Dex accepts a token if all of the following hold:

- The signature verifies with the keys of the issuer, from its discovery document (`keys.discovery`) or given in the object (`keys.jwks`).
- If the token header has `kid`, the signature is checked with the key of that `kid` only.
- The `iss` claim equals `issuer`, and the token has not expired.
- The token is valid for no longer than `subjectTokenMaxLifetime` (24 hours by default), counted from `iat` to `exp`, or from now to `exp` for a token without `iat`. The `exp` claim is required.
- The `aud` claim matches an entry of `audiences`.
- The claims listed in `claimValidation` carry the required values.
- The DexClient that sends the request is listed in `clients`.

The subject is named by `identity`. The user name is a prefix followed by the value of a claim, and groups are taken from claims in the same way. The API server takes the user name from the `email` claim. Without `identity.email`, the user name in the cluster is the result of `identity.username`; with `identity.email`, it is the result of `identity.email`. RBAC subjects use this name.

Example for users of a neighbouring cluster A. The Dex of cluster A issues the tokens for its DexClient `cluster-b` in the `d8-user-authn` namespace, so `aud` is `dex-client-cluster-b@d8-user-authn`. In cluster B, the DexClient `cluster-a-exchange` that exchanges them needs the `dexclient.deckhouse.io/allow-access-to-kubernetes` annotation. Apply the following manifest in cluster B:

```
apiVersion: deckhouse.io/v1alpha1
kind: TokenExchangeProvider
metadata:
  name: cluster-a
spec:
  issuer: https://dex.cluster-a.example.com/
  keys:
    discovery:
      caData: |
        -----BEGIN CERTIFICATE-----
        <CA_OF_CLUSTER_A>
        -----END CERTIFICATE-----
  audiences:
  - exact: dex-client-cluster-b@d8-user-authn
  identity:
    username:
      claim: email
      prefix: "cluster-a:"
    groups:
    - claim: groups
      prefix: "cluster-a:"
  allowedIdentities:
    emailDomains:
    - example.com
  clients:
  - dexClient:
      name: cluster-a-exchange
      namespace: d8-user-authn
```

The client exchanges a token at the Dex token endpoint with `connector_id` set to `status.connectorID` of the object. An example for CI systems is in Access for CI/CD.

A TokenExchangeProvider has the following features:

- It serves token exchange only and is not shown on the sign-in page.
- A DexClient listed in `spec.clients` can exchange tokens through the provider even when its `allowedProviders` does not name the provider.
- A token of the issuer is accepted only as a JWT ID token. Access tokens are not accepted.
- A change of the object takes effect without a restart of Dex and applies to new exchanges. Dex tokens issued earlier stay valid until they expire. They are refused earlier if the provider loses its connector, that is, if the object is deleted or created again under the same name, or if the provider gives way to an earlier one (`PrefixConflict`). The refusal works under the same condition as for a deleted object, described below. After `PrefixConflict` is gone, the provider gets a connector with a new `status.connectorID`.
- A change refused as invalid (`InvalidSpec`, for example a malformed key or `caData` without a certificate) is not applied. The provider keeps working with its previous spec until the spec is fixed.
- Every prefix is required and ends with a colon. The prefix sets the subjects of the provider apart from people and from the subjects of other providers. Two providers cannot give the same names. A provider whose user name or group prefix overlaps one of a provider created earlier is not ready (`PrefixConflict`) and exchanges nothing until the conflict is removed.
- With `keys.discovery`, the provider becomes ready only after the discovery document and the keys of the issuer are read. Otherwise it is not ready (`DiscoveryFailed`) and is checked again every minute; its connector is written all the same, so a change that narrows the provider applies at once. The discovery document is read over https only.
- Deleting the object makes the Kubernetes API refuse every token issued through it within seconds if the `enableMultiTenancy` parameter of the `user-authz` module is enabled and the cluster runs Kubernetes 1.34 or later. Otherwise these tokens stay valid until they expire (the `idTokenTTL` parameter).
- User and group names starting with `peering:` are reserved for the ServiceAccounts of the `d8-peering` namespace. No DexProvider and no other TokenExchangeProvider can assert them.
- TokenExchangeProvider objects are managed by the `d8:system-capability:user-authn:edit` role, which the `d8:subsystem:iam:manager` role and the roles that include it carry, and in the basic role model by the `ClusterAdmin` access level. Whoever creates a TokenExchangeProvider chooses the issuer, its keys and the names, and so can get a token for any user or group outside the reserved prefixes. This right is equivalent to the right to impersonate users. Grant it to cluster administrators only. The module writes the Dex connectors and revocations in the `d8-user-authn` namespace; only a cluster administrator can change them.

Token exchange through a DexProvider is deprecated and off by default. An `OIDC` or `Gitlab` DexProvider exchanges tokens only with `spec.tokenExchange.enabled: true`. The parameter can only be turned off; nobody but the module can set `true`. During the upgrade from a release without this parameter, the module sets it once on the existing `OIDC` and `Gitlab` providers. It sets `true` if some DexClient has the `dexclient.deckhouse.io/allow-access-to-kubernetes` annotation, so that a cluster that may exchange tokens keeps doing it, and `false` otherwise. A DexAuthenticator with access to Kubernetes does not count. Its oauth2-proxy never exchanges tokens, and exchange with its client secret is not kept. The parameter and token exchange through a DexProvider will be removed after the next LTS release.

While a DexProvider exchanges tokens, the `D8UserAuthnDexProviderTokenExchangeDeprecated` alert fires. Move the exchange to a TokenExchangeProvider as described in Migration from DexProvider, then set `spec.tokenExchange.enabled: false`.

Browser sessions of Dex

By default, Dex does not remember a user between sign-ins: every application that sends the user to Dex gets the sign-in form. With the browser sessions of Dex enabled, Dex remembers the user signed in to the browser. To enable the sessions, set the `sessions.enabled` parameter:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 3
  enabled: true
  settings:
    sessions:
      enabled: true
```

What changes with the sessions:

- The web interfaces of Deckhouse share the sign-in: the user enters the password and the second factor once and opens the others without them. These are the applications of the DexAuthenticator objects in the `d8-*` namespaces. User DexAuthenticator and DexClient objects do not share the sign-in. To turn the sharing off, set `sessions.sso` to `None`. The shared sign-in lasts while the browser uses any of these applications, up to `sessions.absoluteLifetime`. After `sessions.validIfNotUsedFor` without using them, the next application asks for the password again. A user of an external provider shares the sign-in while the user data Dex stored is fresh: after `sessions.identityRefresh.maxAge` without a sign-in or a refresh of the tokens of an application, the next application asks for the password again.
- The sign-in form shows the “Remember me” checkbox. With it, the session survives closing the browser.
- When a user signs out of an application of a DexAuthenticator, DexAuthenticator sends the browser to Dex, and Dex ends the session. Within seconds, the browser is signed out of every application of a DexAuthenticator it signed in to through this session. If the application and Dex are on different sites (different registrable domains), Dex asks the user to confirm the sign-out. An application signs out with a navigation of the browser: a script request (`fetch`, XHR) does not follow the redirect to Dex, and the session of Dex stays.
- Signing out of Dex does not sign the user out of an external OIDC provider: the provider may sign the user in again without a password. To end the session at the provider too, enable `upstreamLogout` of the provider, or set `promptType: login` to ask for the password at every sign-in.
- Dex reads the data of the user (such as the groups) from the provider again when the stored data is older than `sessions.identityRefresh.maxAge`. If the provider answers that the user no longer exists or is no longer allowed in, Dex ends all the sessions and tokens of the user of this provider.

What does not change:

- Tokens for `kubectl` (kubeconfig, `d8 login`) are issued only after an interactive sign-in, never from a session of the browser.
- An application of a DexAuthenticator stays signed in for `keepUsersLoggedInFor`, even when the session of Dex ends by its lifetime or idle timeout. Only signing out ends it.

How long a session lasts

A session of Dex ends at the first of these:

- `sessions.absoluteLifetime` after the sign-in, a week by default, however much the browser is

used;
- `sessions.validIfNotUsedFor` without use, a day by default;
- the sign-out of the user, or an end of the session by an administrator;
- the closing of the browser, if the user did not select “Remember me” at the sign-in.

The browser uses the session when it signs in to an application through it, and when an application signed in through it refreshes its tokens: an application of a DexAuthenticator object or of a DexClient object with `refreshTokenLifetime: Session`. Such an application refreshes its tokens every `idTokenTTL` while it is open and sends requests. A closed application, or one open in the browser of a sleeping computer, does not use the session.

With the defaults, a user who works every day enters the password and the second factor once a week, and once more after a break longer than a day, such as a weekend. The session survives a night.

When the session ends, the applications already open stay signed in for `keepUsersLoggedInFor`, but signing in to another web interface asks for the password again.

To ask for the password more often, shorten `sessions.validIfNotUsedFor`, for example to `1h`: the user then enters it again after every break of an hour. `sessions.validIfNotUsedFor` must not be longer than `sessions.absoluteLifetime`; when only `sessions.absoluteLifetime` is set and is shorter than a day, an unused session ends after `sessions.absoluteLifetime`.

Signing out of the application of a DexClient

An application of a DexClient object signs the user out of Dex by sending the browser to `https://dex.<PUBLIC_DOMAIN>/logout` with the `client_id` and `post_logout_redirect_uri` parameters. Dex returns the browser only to the addresses listed in `postLogoutRedirectURIs` of the DexClient:

```
https://dex.example.com/logout?client_id=dex-client-
myapp@mynamespace&post_logout_redirect_uri=https%3A%2F%2Fmyapp.example.com%2F
```

To learn that a session of a user ended, the application can set `backchannelLogoutURI`. Dex sends the notification once, without retries, when the user signs out of the session, the provider answers that the user is gone, a UserOperation or the self-service of the web interface ends the session, or the user is deleted; for a session ended outside Dex, within seconds. An application that must not miss the end can also check its tokens at the introspection endpoint of Dex (`/token/introspect`), which reports the tokens of an ended session or device inactive.

An application that requests offline access (refresh tokens) gets them only after an interactive sign-in. With `refreshTokenLifetime: Session`, the application can sign the user in from the session of the browser, and its tokens end when the user signs out of this session.

Local Authentication

Local authentication provides user verification and access management with support for configurable password policies, two-factor authentication (2FA), and group management.
In the module parameters, you can configure password complexity, password history, password rotation, lockout after failed sign-in attempts and per-IP rate limiting of failed attempts. No external authentication system is required.

Creating a user

The recommended way to create a local user is the `d8 iam user create` command. It supports interactive password entry, automatic password generation, group assignment, and time-to-live (TTL) for temporary users.

Examples:

Interactive password prompt (default when stdin is a terminal):

```
d8 iam user create anton --email anton@abc.com
```

Automatically generate a password (the generated password is shown in the command output once):

```
d8 iam user create anton --email anton@abc.com --generate-password
```

Read the password from stdin (for CI/CD pipelines):

```
echo "s3cret" | d8 iam user create anton --email anton@abc.com --password-stdin
```

Use a pre-computed bcrypt hash (e.g. from htpasswd):

```
d8 iam user create anton --email anton@abc.com --password-hash '$2y$10$abcdef...'
```

Create the user and add them to groups (auto-creating groups if missing):

```
d8 iam user create anton --email anton@abc.com --generate-password --member-of admins --
create-groups
```

Create a temporary user with a TTL:

```
d8 iam user create anton --email anton@abc.com --generate-password --ttl 24h
```

Preview the manifest without applying it:

```
d8 iam user create anton --email anton@abc.com --generate-password --dry-run -o yaml
```

As an alternative, you can create the User resource manually. Create a password and enter its hash encoded in base64 in the `password` field. The email address must be in lowercase.

Use the command below to calculate the password hash:

```
echo -n '3xAmpl3Pa$$wo#d' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' | base64 -w0;
echo
```

i If the `htpasswd` command is not available, install the appropriate package:

- `apache2-utils` — for Debian-based distributions.
- `httpd-tools` — for CentOS-based distributions.
- `apache2-htpasswd` — for ALT Linux.

Note that in the below example the `ttl` parameter is set.

```
apiVersion: deckhouse.io/v1
kind: User
metadata:
  name: admin
spec:
  email: admin@yourcompany.com
  # echo -n '3xAmpl3Pa$$wo#d' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' |
base64 -w0; echo
  password:
'JDJ5JDEwJGRNWGVGUVBkdUdYYVMyWDFPcGdZdk9HSy81LkdsNm5sdU9mUkhnNWlQdDhuSlh6SzhpeS5H'
  ttl: 24h
```

To make the user change the password at the first sign-in, set `requirePasswordChangeOnFirstLogin: true`. The field can be set only when the User is created.

Authorization rules grant permissions to users based on the email address from the issued token. Therefore, a User resource cannot be created if its `spec.email` value matches a `User` subject in an existing AuthorizationRule or ClusterAuthorizationRule resource. This prevents permissions from being unintentionally granted to a new user.

If the match is intentional, for example, if the authorization rule was created in advance, use a different email address or add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the User resource. The annotation acknowledges the name collision only. Assigning the grant still requires covering permissions or a can-assign range that includes the target roles.

Email addresses are converted to lowercase when matched, as this is how they are stored in the token. For example, `Admin@Example.com` matches the `admin@example.com` subject.

The restriction does not apply to existing users whose email addresses match subjects in authorization rules. Such users continue to work, and a warning is issued when a match is detected.

Consider this restriction when managing users and authorization rules declaratively. If a user and the

corresponding rule are created at the same time, the rule may be created first, causing creation of the User resource to be rejected. To allow such a match, add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the User manifest.

Deleting a user does not automatically remove the corresponding subject from the authorization rule. As long as the subject remains in the rule, permissions continue to be granted to the specified email address, and a warning is issued that no corresponding user exists. If a user with the same email address is created later, that user receives these permissions. If this behavior is not required, remove the corresponding subject from the authorization rule.

Deleting a user

To delete a local user, use the `d8 iam user delete` command. By default, it also removes the user from all Group resources they belong to.

Examples:

Delete the user (and automatically remove them from all groups):

```
d8 iam user delete anton
```

Delete the user but keep their references in groups:

```
d8 iam user delete anton --keep-memberships
```

When a user is deleted, manually or after its `ttl` expires, the module ends the user's sessions in the same way as the `Logout` operation (see UserOperation lifecycle and side effects) and deletes the user's 2FA (TOTP) secret and lock in Dex. A user created again with the same name does not inherit the sessions, the 2FA secret or the lock.

Local user operations

Password reset, forced password change, 2FA reset, lock, unlock and logout operations are performed via the UserOperation resource. The `initiatorType` field indicates who initiated the operation: an administrator (`admin`) or the user (`self`).

> ⚠ Do not change `User.spec.password` after the User is created (for example, with `d8 k edit`). The field is immutable and does not update Dex credentials. Reset passwords with a UserOperation or `d8 iam user reset-password`.

Administrative operations

Use the `d8 iam user` commands for administrative actions on local users. They create a UserOperation resource with `initiatorType: admin`, wait for the operation to complete, and print the result.

You can delete or recreate a local user, or run a UserOperation (`ResetPassword`, `RequirePasswordChange`, `Reset2FA`, `Lock`, `Unlock`, `Logout`) against them, only if you can assign every role already granted to the user's email or groups (covering permissions or an explicit can-assign range). `initiatorType: self` does not bypass this check. The same rule applies to DexProvider objects. For details, see Limiting the identities of a provider.

After an administrator resets the password with `ResetPassword`, the user signs in with that password once. Dex then asks the user to set a new password that complies with the password policy. To keep the new password, set `resetPassword.requirePasswordChange: false` in the UserOperation.

Interactive password reset example:

```
d8 iam user reset-password admin
```

Example of reading the new password from stdin:

```
echo "N3wPa$$wo#d" | d8 iam user reset-password admin --password-stdin
```

Example of generating a new password automatically:

```
d8 iam user reset-password admin --generate-password
```

If the password is already hashed, pass the bcrypt hash without Base64 encoding:

```
d8 iam user reset-password admin --password-hash '$2y$10$abcdef...'
```

2FA reset example:

```
d8 iam user reset2fa admin
```

Example of locking a user for 30 minutes:

```
d8 iam user lock admin 30m
```

The `d8 iam user lock` command locks a local user and accepts a duration in seconds, minutes or hours, for example `30s`, `10m` or `1h`. To lock a user for several days (`lock.for: 7d`) or permanently (`lock.for: permanent`), create a UserOperation as described in Creating UserOperation manually.

User unlock example:

```
d8 iam user unlock admin
```

By default, commands wait for the operation to complete. To only create a UserOperation and print its name, use the `--wait=false` flag.

Self-service operations

A user can sign out on all devices, and a local user can change their password, in the Deckhouse Platform web interface. The web interface creates a UserOperation with `initiatorType: self` for the user who is signed in:

- Signing out on all devices creates a `Logout` operation. It ends every session of the user, including kubeconfig files and the session in the web interface. Basic Authentication to the Kubernetes API through an LDAP provider keeps working with the password.
- Changing the password creates a `RequirePasswordChange` operation. At the next sign-in, Dex asks for the current password and a new one that complies with the password policy. The operation ends no sessions.

Changing the password is available only for local accounts (the built-in `Local` connector). Users who sign in through external authentication providers change their password in the corresponding system.

A user can also see the devices signed in to their account (the `status.sessions` field of their UserAccount) and sign out of them one by one:

- Signing out of one device creates a `Logout` operation with `logout.session` for a browser or `logout.grant` for another device, such as a kubeconfig file. The other devices keep their sessions. If the device is already signed out, for example its session has expired, signing out of it succeeds.
- Signing out of the other devices creates a `Logout` operation with `logout.exceptSession` or `logout.exceptGrant`. It keeps only the device the user acts from.

Signing out on all devices, signing out of the other devices or of another device, and changing the password are available only on a trusted device: one signed in at least `devices.trustedAfter` ago, 24 hours by default. A device signed in more recently can sign the user out only of itself. Someone who has just signed in with a stolen password therefore can neither sign the owner out nor change the password, while the owner sees the new device in the list on a trusted device and signs it out. A user without a trusted device asks an administrator: the operations of an administrator are not limited. With `devices.trustedAfter: 0s`, every device is trusted at once.

The age of a device counts from the first sign-in of its browser, not only the last one. At sign-in, Dex gives the browser a long-lived cookie and remembers when it first saw that browser sign in to the account (the `knownSince` field). A browser that signed out and signed in again keeps its age. Dex forgets the browser, and its next sign-in counts as new, when:

- the last sign-in of the browser is ended from another device or by an administrator. While the browser holds another active session or token of the account, it stays known;
- the user signs out of the other devices: every browser but the current one is forgotten, signed in or not;
- the user signs out on all devices, or an administrator locks the user, resets the password, resets 2FA, or signs the user out;

- the account has more remembered browsers than `devices.rememberedBrowsers` (20 by default): the browser seen longest ago is forgotten. With `0`, Dex remembers no browser, and every sign-in is a new device.

Someone who signs in with a stolen password uses a browser without that cookie, so the device is new for them. A stolen session is not covered: the age is that of the session or token of the request, so a copied cookie of Dex or of the web interface has the age of the owner's device.

If the password may have been stolen, act from a trusted device in this order:

1. Request a password change.
2. Right away, sign out on this device and sign in again: Dex asks for the current and the new password. The browser keeps its age.
3. Only then sign out of the other devices. The current browser stays known, so it stays trusted, and every other device, the intruder's included, is signed out.

Do steps 1 and 2 one right after the other. Until the new password is set, any sign-in asks for it, the intruder's with the stolen password included, and the age of the device is not checked on that page.

Do not start with signing out on all devices: it makes the current browser new as well, and for `devices.trustedAfter` it can neither request a password change nor sign out a device that signs in again with the stolen password.

A compromised password alone signs in to an account without 2FA. Enable 2FA with the `twoFactor` parameter.

Creating UserOperation manually

When the `d8 iam user` CLI is unavailable (for example, in CI/CD or automation scripts), create a UserOperation resource directly. Use `apiVersion: deckhouse.io/v1` and set `initiatorType: admin`.

Do not keep a UserOperation in a GitOps repository. The module deletes the operation after `retention.userOperations`, and an operation created again runs again.

Example — reset a local user's password (the `newPasswordHash` contains a bcrypt hash without Base64 encoding; the module encodes it automatically):

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: reset-password-admin
spec:
  user: admin
  type: ResetPassword
  initiatorType: admin
  resetPassword:
    newPasswordHash: "$2y$10$..."
```

Example — lock a local user for 1 hour:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: lock-admin-1h
spec:
  user: admin
  type: Lock
  initiatorType: admin
  lock:
    for: "1h"
```

Example — permanent lock:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: lock-admin-permanent
spec:
  user: admin
  type: Lock
  initiatorType: admin
  lock:
    for: "permanent"
```

Example — unlock:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: unlock-admin
spec:
  user: admin
  type: Unlock
  initiatorType: admin
```

Example — reset 2FA:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: reset-2fa-admin
spec:
  user: admin
  type: Reset2FA
  initiatorType: admin
```

Example — require a new password at the next sign-in without resetting the current one:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: require-password-change-admin
spec:
  user: admin
  type: RequirePasswordChange
  initiatorType: admin
```

Example — end every session of a user in every application and kubeconfig file:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: logout-admin
spec:
  user: admin
  type: Logout
  initiatorType: admin
```

Example — sign a user out of one device and keep the sessions on the others. Take the `id` of the device from `status.sessions` of the user's UserAccount (for details, see the Viewing account state section). For a device of the `Browser` kind, set it in `logout.session`; for a device of the `Grant` kind, such as a kubeconfig file, in `logout.grant`:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: logout-admin-kubeconfig
spec:
  user: admin
  type: Logout
  initiatorType: admin
  logout:
    grant: qx3w2ttiyq5ovzvbuehdcbbse
```

If the user has no such session or refresh token, for example the session has expired or the user has signed out of it, the operation ends nothing and completes with the `Succeeded` status and the `the user has no such session` or `the user has no such grant` message. The operation does not check whether the ID belongs to another user: the session of another user gives the same result and stays active. Take the ID from the UserAccount of the user set in `spec.user` or `spec.target`.

Operations on external users

For users of external providers of any type (LDAP, Atlassian Crowd, OIDC, SAML, GitHub, GitLab, Bitbucket Cloud), use the `spec.target` field instead of `spec.user`. The `Lock`, `Unlock`, `Logout` and `Reset2FA` operation types are supported for external users. Only the users of the LDAP and Atlassian Crowd providers can have a second factor. For a user of a provider of another type, `Reset2FA` only ends the sessions.

The operation finds the user's account by the email the provider reported at the user's last sign-in. The `connectorID` and `userID` fields narrow the search down to one provider and one user ID. A lock applies to one pair of a provider and a user. It blocks only the account found and does not block a local user or a user of another provider with the same email. A local user is addressed by `spec.user` only. Dex checks the lock at every sign-in through the provider, at every refresh-token request, at token exchange, and at Basic Authentication to the API server through an LDAP provider. For a Crowd or OIDC provider, basic-auth-proxy checks the credentials with the provider directly, so the lock does not apply to Basic Authentication.

The operation fails if no account has the email (the user has never signed in) or if more than one account matches. In that case, set `connectorID`, and `userID` if the provider has several users with the email.

A lock applies to the user ID that the provider returns at sign-in, so this ID must stay the same at every sign-in of the user. For a SAML provider, set `nameIDPolicyFormat` to `persistent` or `emailAddress`, or leave it unset (Dex then requests `persistent`). With `transient`, the provider returns a new ID at every sign-in. A lock then does not apply to the next sign-in of the user, and once the user has signed in twice, the operation fails because more than one user of the provider has the email.

Example — lock an external user by `connectorID` + email for 30 minutes:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: lock-external-user
spec:
  target:
    connectorID: my-ldap
    email: jane.doe@example.org
  type: Lock
  initiatorType: admin
  lock:
    for: "30m"
```

Users of a deleted provider

If you delete a DexProvider and create it again under the same name within 30 days, the second factor and the lock of its users are kept. If you create it later, the 2FA of a user who has not signed in for 30 days is registered again at the first sign-in. A user whose lock is still in force keeps the lock and the second factor until the lock ends.

UserOperation lifecycle and side effects

Using a UserOperation object has the following specifics:

- A UserOperation is a **single-use** object. After creation, the module processes it and writes the result to `status.phase` (`Succeeded` or `Failed`).
- Operations are **automatically deleted** after `retention.userOperations` (24 hours by default).
- A UserOperation runs once. Changes to its spec after creation are ignored.
- To perform a new action, create a new UserOperation.

⚠ The `Lock`, `ResetPassword`, `Reset2FA` and `Logout` operations end the sessions of the user at once:

- Dex refuses every refresh token, authorization code and browser session it issued to the user before the operation. Applications and kubeconfig files ask the user to sign in again.
- DexAuthenticator stops accepting the sessions of the user within seconds.
- The Kubernetes API refuses the ID tokens issued to the user before the operation within seconds if the `enableMultiTenancy` parameter of the `user-authz` module is enabled and the cluster runs Kubernetes 1.34 or later. Otherwise these ID tokens stay valid for the Kubernetes API until they expire (the `idTokenTTL` parameter).
- Basic Authentication to the Kubernetes API through an LDAP provider checks the password with Dex again. After `Logout`, it keeps working with the password.

`Unlock` and `RequirePasswordChange` end no sessions. Only `Reset2FA` removes the user's 2FA secret. A `Lock` refuses sign-in, refresh-token requests and token exchange until the lock ends. The `status.revocation` field of the operation shows what it revoked.

Checking operation status

To check the operation status, follow these steps:

1. Get the list of all operations:

   ```
   d8 k get useroperations
   ```

2. Get the full status of an operation:

   ```
   d8 k get useroperation <name> -o yaml
   ```

3. Get only the completion status:

   ```
   d8 k get useroperation <name> -o jsonpath='{.status.phase}'
   ```

Viewing account state

The module keeps a UserAccount object for each local user and for each user who has signed in through an external provider. It shows when the user last signed in, whether the user has set up 2FA, whether the account is locked, until when, and how many failed login attempts were counted. Do not create or edit UserAccount objects.

To list the accounts, run:

```
d8 k get useraccounts
```

The `status.sessions` field lists the devices signed in to the account, the most recently active first: browsers signed in to Dex (the `Browser` kind) and devices holding a refresh token not bound to a live browser session of Dex, such as kubeconfig files (the `Grant` kind). For each device, it shows the applications, the client address and User-Agent of the last sign-in, the time of the sign-in, the hour of the last activity, and when the session of the device ends unless the device is used again (`endsAt`). The client address is right only when the Ingress controller sees it (for details, see the Which client address does Dex see? section). To view the devices of an account, run:

```
d8 k get useraccount <NAME> -o jsonpath='{range .status.sessions[*]}{.kind}{"\t"}{.id}
{"\t"}{.clients}{"\t"}{.ipAddress}{"\t"}{.lastActivity}{"\t"}{.endsAt}{"\n"}{end}'
```

While the browser sessions of Dex are disabled, every sign-in to an application of a DexAuthenticator is a device of its own.

The maximum number of devices on which a user can remain logged in to a single application at the same time is set by the `devices.maxPerApplication` parameter (default: 10). A browser counts as one device for all domains of the application, while each kubeconfig file counts as a separate device. If a user logs in from a new device and the limit in `devices.maxPerApplication` has already been reached, the session is terminated on the device that has been unused the longest. Trusted devices (a device becomes trusted after the time specified in the `devices.trustedAfter` parameter has elapsed) are disconnected last.

Automatic lockout

If the number of failed sign-in attempts exceeds `passwordPolicy.lockout.maxAttempts`, Dex locks the user for `lockout.lockDuration` and then unlocks them automatically. For LDAP and Crowd users, this works only if the provider type is listed in `lockout.applyToConnectors`. Dex does not create a UserOperation for this lockout. To unlock the user earlier, run `d8 iam user unlock` or create a UserOperation of type `Unlock`.

While a local, LDAP or Crowd user is locked, Dex refuses a password sign-in whether the password is correct or not: with the `429` status code and the “Account temporarily locked” page after an automatic lockout, with the `403` status code and the “Account locked by an administrator” page while a lock set by an administrator is in force. The password change page refuses a locked user in the same way. An automatic lockout does not shorten a lock that ends later, including a lock set by an administrator.

Adding a user to a group

Users can be grouped to manage access rights. The recommended way to manage groups is the `d8 iam group` command.

Examples:

Create a group:

```
d8 iam group create admins
```

Add a user to a group:

```
d8 iam group add-member admins user anton
```

Add a nested group:

```
d8 iam group add-member admins group devops
```

Remove a user from a group:

```
d8 iam group remove-member admins user anton
```

Delete a group:

```
d8 iam group delete admins
```

As an alternative, you can create the Group resource manually. Example manifest of the Group resource for a group:

```
apiVersion: deckhouse.io/v1alpha1
kind: Group
metadata:
  name: admins
spec:
  name: admins
  members:
    - kind: User
      name: admin
```

Where `members` is a list of members: `kind: User` with `name` = `User.metadata.name`, or a nested `kind: Group` with `name` = `Group.spec.name` (the name in the token, not `metadata.name`).

Nested groups must not form a cycle. A change to a Group resource is rejected if after it a group becomes its own member, directly or through other groups. If the hierarchy already contains a cycle, changes that do not create a new one are accepted with a warning that shows the path of the cycle, where each group is a member of the previous one. To break the cycle, remove one of these groups from the members of the previous group.

The group name is stored in the issued token without modification. It is indistinguishable from a group name received from an external authentication provider. Therefore, a Group resource cannot be created if its `spec.name` value matches a `Group` subject in an existing AuthorizationRule or ClusterAuthorizationRule resource. This prevents permissions from being unintentionally granted to members of a new group.

If the match is intentional, use a different group name or add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the Group resource.

Unlike email addresses, group names are not converted to lowercase when matched. Therefore, group names that differ only in letter case are considered different.

The restriction does not apply to existing groups whose names match subjects in authorization rules. Such groups continue to work, and a warning is issued when a match is detected.

Consider this restriction when managing groups and authorization rules declaratively. If a group and the corresponding rule are created at the same time, the rule may be created first, causing creation of the Group resource to be rejected. To allow such a match, add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the Group manifest.

Deleting a group does not automatically remove the corresponding subject from the authorization rule. As long as the subject remains in the rule, permissions continue to be granted to a group with the specified name. If a group with the same name is created later, its members receive these permissions. If this behavior is not required, remove the corresponding subject from the authorization rule.

Viewing users and groups

Use the `d8 iam get` and `d8 iam list` commands to view users, groups, and their effective access (groups, grants, and access level).

Examples:

List all users with effective access:

```
d8 iam list users
```

Details for a specific user (groups, grants, access level):

```
d8 iam get user anton
```

List all groups:

```
d8 iam list groups
```

Details for a specific group (members, grants):

```
d8 iam get group admins
```

Password policy

Password policy settings allow controlling password complexity, rotation, and user lockout:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 3
  enabled: true
  settings:
    passwordPolicy:
      complexityLevel: Fair
      passwordHistoryLimit: 10
      lockout:
        lockDuration: 15m
        maxAttempts: 3
      rotation:
        interval: "30d"
```

Field description:

- `complexityLevel`: Password complexity level. One of `None`, `Low`, `Fair`, `Good`, `Excellent` or `Custom`.
- `custom`: Custom complexity rules (used only with `complexityLevel: Custom`):
  - `custom.minLength`: Minimum number of characters in a password.
  - `custom.specialCharacters`: If `true`, require at least one special character.
  - `custom.numbers`: If `true`, require at least one digit.
  - `custom.capitalized`: If `true`, require at least one uppercase letter.
  - `custom.repeatedChars`: If `true`, forbid more than 2 identical characters in a row.
- `passwordHistoryLimit`: Number of previous passwords stored in the system to prevent their reuse.
- `lockout`: Lockout settings after exceeding the limit of failed login attempts:
  - `lockout.maxAttempts`: Limit of allowed failed login attempts.
  - `lockout.lockDuration`: User lockout duration.
  - `lockout.applyToConnectors`: External provider types the lockout also applies to: `LDAP`, `Crowd`. Local users are always covered.
- `rotation`: Password rotation settings:
  - `rotation.interval`: Period for mandatory password change.

To limit failed login attempts per client IP address, use the `rateLimit` parameter.

When a local user signs in with a password that has to change, Dex opens the password change page instead of the application. A password has to change after an administrator resets it with `ResetPassword`, when it does not meet the complexity rules, and when it is older than `rotation.interval`. The page asks only for the new password, twice, because the sign-in form has just checked the current one. If 2FA is enabled, Dex first asks for the code and opens the password change page only after it, so someone who knows only the password cannot change it. After the change, the sign-in continues as usual and opens the application.

The password change page opens only during the sign-in that led to it and in the same browser. If the page is opened in another browser or after the sign-in has expired, Dex does not open it, and the user signs in again.

Example with a custom complexity rules:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 3
  enabled: true
  settings:
    passwordPolicy:
      complexityLevel: Custom
      custom:
        minLength: 10
        specialCharacters: true
        numbers: false
        capitalized: true
        repeatedChars: false
      passwordHistoryLimit: 10
```

Two-factor authentication (2FA)

2FA increases security by requiring a code from a `TOTP` authenticator application (for example, Google Authenticator) or a security key (`WebAuthn`) during login. It can be required from the local users and from the users of the LDAP and Atlassian Crowd providers.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 4
  enabled: true
  settings:
    twoFactor:
      enabled: true
      issuerName: "awesome-app"
      providerTypes: [Local, LDAP]
```

Field description:

- `enabled`: Enables or disables 2FA.
- `issuerName`: Name displayed in the authenticator application when adding an account (with `WebAuthn`, in the dialog of the browser that registers the key).
- `methods`: The second factors: `TOTP` (the default), `WebAuthn`, or both, see Several methods.
- `require`: How two `methods` combine. Required with two methods, not allowed with one.
- `providerTypeOverrides`: Other `methods` for one type of provider, see Several methods.
- `webAuthn`: Parameters of the `WebAuthn` method, see Security keys.
- `providerTypes`: Types of the providers whose users have to pass the second factor: `Local` (the built-in users), `LDAP` and `Crowd`. The users of every provider of a listed type are asked for it. The OIDC, SAML, GitHub, GitLab and Bitbucket Cloud providers are not on the list. The identity provider handles the second factor for them.

The `twoFactor` parameter replaces `staticUsers2FA`, which covered the local users only. A ModuleConfig of version 3 with `staticUsers2FA` keeps working, because the module converts it.

> **i** After enabling 2FA, each user must register in the authenticator application during their first login. Until then, anyone who knows the password can register their own device, so ask the users to sign in right after you turn 2FA on.

Dex asks the user for the code (or the key) at a sign-in through a provider of a listed type, except while a browser session of Dex is valid. Sign-ins through the other providers go without it. Turning 2FA on for a provider type does not end the refresh tokens or the Dex browser sessions issued before. A refresh token keeps issuing tokens without the code until it expires (by default, up to `refreshTokenAbsoluteLifetime`, 4380h), and a browser session created before the change passes without the code. After enabling 2FA, run a UserOperation of type `Logout` for the users of the providers

of the listed types.

Basic Authentication to the Kubernetes API (`enableBasicAuth` of an LDAP or Crowd provider) has no page for a code, so it is not possible for a provider of a listed type. The module refuses the settings that turn 2FA on while such a provider exists, and a provider that turns `enableBasicAuth` on while 2FA covers its type. To use both, give the Kubernetes API users a kubeconfig file with the web interface instead of Basic Authentication.

Security keys (WebAuthn)

With `methods: [WebAuthn]`, Dex asks the user to touch a security key (for example, a YubiKey) or to confirm the sign-in with the Touch ID or Windows Hello of the device, instead of entering a code. The key confirms a sign-in only for the domain it is bound to, so a fake sign-in page on another domain gets no response it can reuse.

The following settings ask the users for a security key:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 4
  enabled: true
  settings:
    twoFactor:
      enabled: true
      methods: [WebAuthn]
      issuerName: "Example"
      webAuthn:
        rpID: example.com
```

The method works as follows:

- A key is bound to the domain set by the `rpID` parameter. By default, it is the domain of the Dex address (`dex.<PUBLIC_DOMAIN>`). To keep the keys through a change of `publicDomainTemplate`, set `rpID` to the stable parent domain of the Dex address, for example `example.com` for `dex.example.com`. A change of `rpID`, or of `publicDomainTemplate` while `rpID` is not set, makes every registered key unusable. A user with such a key can neither sign in nor register a new one. Reset the second factor of the user with a UserOperation of type `Reset2FA`, and the user registers a key again at the next sign-in.
- Dex accepts a security key of any make and model and does not check which key it is.
- The browser has to support WebAuthn.
- The user registers the key at the first sign-in after the method is turned on, as the user of TOTP registers the application. The maximum number of keys that a user can have is specified in the `webAuthn.maxCredentials` parameter (3 by default). A user adds one with the “Add a key” button on the page that confirms a sign-in with a key, after a registered key has confirmed it. Until the registration, anyone who knows the password can register their own key, so ask the users to sign in right after the switch.
- A single key cannot be removed. If any of the keys has been lost or compromised, reset the user’s `WebAuthn` method with a `Reset2FA` operation. Until then, such a key still confirms a sign-in for whoever knows the password. The operation removes every key of the user, and the user registers the keys again at the next sign-in.
- When the methods change, the TOTP secret and the keys the user had stay until a `Reset2FA`, so asking for a method again brings them back.

Several methods

If two methods are specified in the `methods` parameter, the `require` parameter defines how they are combined. With `Any`, the user passes one of them. At the first sign-in the user chooses the method and registers it. Later Dex asks for a registered method, the one used last first, and a user who has registered both can sign in another way. A user who has registered one method cannot register the other at a sign-in, because otherwise anyone who knows the password could add a method of their own. To let a user switch, remove the registered method with a `Reset2FA` operation. With `All`, the user passes both, the code first and then the key. A user who has only one of them confirms the sign-in with it first and only then registers the other.

The following settings let each user choose a code or a key:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 4
  enabled: true
  settings:
    twoFactor:
      enabled: true
      methods: [TOTP, WebAuthn]
      require: Any
      webAuthn:
        rpID: example.com
```

A Deckhouse Platform version without `require: Any` refuses such settings. Before a rollback to it, switch `require` to `All` or keep one method.

`providerTypeOverrides` sets other methods for one type of provider from `providerTypes`, for example a key for the users of the LDAP providers and a code for the local users:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 4
  enabled: true
  settings:
    twoFactor:
      enabled: true
      methods: [TOTP]
      providerTypes: [Local, LDAP, Crowd]
      providerTypeOverrides:
      - providerType: LDAP
        methods: [WebAuthn]
      - providerType: Crowd
        methods: [TOTP, WebAuthn]
        require: All
      webAuthn:
        rpID: example.com
```

A type without an entry takes `methods` and `require`. Each type appears once, and only a type listed in `providerTypes`.

The second factor of an account

UserAccount shows in `status.twoFactor` the `methods` and `require` asked of the users of its type of provider, and in `enrolled` whether the account has them. `totp` and `webAuthn` show the TOTP secret and the number of keys the account has, including those of a method no longer asked for, which do not count for `enrolled`.

To make a user register the second factor again, for example after losing the device, reset the user's 2FA. For a local user, use `d8 iam user reset2fa <USERNAME>` or a UserOperation of the `Reset2FA` type with `spec.user`. For a user of an external provider, use a UserOperation of the `Reset2FA` type with `spec.target`. Without other parameters the operation removes every method. To remove one, list it in `spec.reset2FA.methods`:

```
apiVersion: deckhouse.io/v1
kind: UserOperation
metadata:
  name: reset-key-jane
spec:
  type: Reset2FA
  initiatorType: admin
  user: jane
  reset2FA:
    methods: [WebAuthn]
```

The operation also ends the sessions of the user. Other operations, including `Lock` and `ResetPassword`, keep the second factor.

Assigning permissions to a user or group

To grant permissions to a user or a group, bind one of the `user-authz` roles with a RoleBinding or ClusterRoleBinding, using the user's email or the group name as the subject. See the granular role-based model.

> **i** **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The user-authn module: FAQ

> **i** The module lifecycle stage: General Availability

How to secure my application?

To enable Dex authentication for your application, follow these steps:

1. Create a DexAuthenticator.

   When you create a DexAuthenticator in a cluster, an instance of oauth2-proxy is created and connected to Dex. A Deployment, a Service and a Secret are created in the specified namespace, plus an Ingress if `applicationIngressClassName` is set and an HTTPRoute if `gatewayAPI` is set.

   Example of the DexAuthenticator custom resource:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  # Dex authenticator pod name prefix.
  # For example, if the name prefix is `app-name`, then Dex authenticator pods
will look like `app-name-dex-authenticator-7f698684c8-c5cjg`.
  name: app-name
  # Namespace to deploy Dex authenticator to.
  namespace: app-ns
spec:
  # Your application's domain. Requests to it will be redirected for Dex
authentication.
  applicationDomain: "app-name.kube.my-domain.com"
  # A parameter that determines whether to send the `Authorization: Bearer`
header to the application.
  # This one is useful in combination with auth_request in NGINX.
  # If sendAuthorizationHeader is true, add Authorization to the
nginx.ingress.kubernetes.io/auth-response-headers annotation of the
application's Ingress or to the alb.network.deckhouse.io/auth-response-headers
annotation of its HTTPRoute.
  sendAuthorizationHeader: false
  # The name of the Secret containing the SSL certificate.
  applicationIngressCertificateSecretName: "ingress-tls"
  # The name of the Ingress class to use in the Ingress resource created for the
Dex authenticator.
  applicationIngressClassName: "nginx"
  # The duration of the active user session.
  keepUsersLoggedInFor: "720h"
  # The list of groups whose users are allowed to authenticate.
  allowedGroups:
  - everyone
  - admins
  # The list of addresses and networks for which authentication is allowed.
  whitelistSourceRanges:
  - 1.1.1.1/32
  - 192.168.0.0/24
```

To add labels and annotations to the `dex-authenticator` pods, for example to disable Istio sidecar injection, use `spec.podMetadata`:

```
spec:
  podMetadata:
    annotations:
      sidecar.istio.io/inject: "false"
```

2. Connect your application to Dex.

   To do this, add annotations to the resource through which the app is published. The set of annotations depends on how the application is published. Choose the relevant option:

- Through an Ingress resource
- Through ALBInstance or ClusterALBInstance

Add the following annotations to the application's Ingress resource:

- `nginx.ingress.kubernetes.io/auth-signin: https://$host/dex-authenticator/sign_in`
- `nginx.ingress.kubernetes.io/auth-response-headers: X-Auth-Request-User,X-Auth-Request-Email`
- `nginx.ingress.kubernetes.io/auth-url: https://<SERVICE_NAME>.<NS>.svc.{{ C_DOMAIN }}/dex-authenticator/auth`, where:
  - `SERVICE_NAME`: Name of the authenticator's Service. Usually, it is `<NAME>-dex-authenticator` (`<NAME>` is the `metadata.name` of the DexAuthenticator).
  - `NS`: Value of the `metadata.namespace` parameter of the DexAuthenticator.
  - `C_DOMAIN`: Cluster domain (the `clusterDomain` parameter of the `control-plane-manager` module).

> **i** If the DexAuthenticator `<NAME>` is too long, the Service name may be truncated. To find the correct service name, use the following command (specify the namespace name and DexAuthenticator name):
>
> ```
> d8 k get service -n <NS> -l "deckhouse.io/dex-authenticator-for=<NAME>" -o
> jsonpath='{.items[0].metadata.name}'
> ```

Example of annotations for an application's Ingress resource for connecting to Dex:

```
annotations:
  nginx.ingress.kubernetes.io/auth-signin: https://$host/dex-authenticator/sign_in
  nginx.ingress.kubernetes.io/auth-url: https://app-name-dex-authenticator.app-
ns.svc.cluster.local/dex-authenticator/auth
  nginx.ingress.kubernetes.io/auth-response-headers: X-Auth-Request-User,X-Auth-
Request-Email
```

An application that specifies only `applicationIngressClassName` gets no HTTPRoute. If Ingress publication is turned off with `global.modules.ingress.enabled`, it gets no Ingress either. The application itself stays reachable through the route you publish it with, but none of its `/dex-authenticator` endpoints are, so the redirect to sign in lands on the application and no one can log in. Other applications are unaffected.

If the application is published through an ALBInstance or ClusterALBInstance resource (for details, see the `alb` module documentation), add the following annotations to the application's HTTPRoute resource:

- `alb.network.deckhouse.io/auth-signin: https://<application-domain>/dex-authenticator/sign_in` — unlike nginx, the `alb` controller does not support the `$host` variable, so the application's domain must be specified explicitly.
- `alb.network.deckhouse.io/auth-response-headers: X-Auth-Request-User,X-Auth-Request-Email`.
- `alb.network.deckhouse.io/auth-url: https://<SERVICE_NAME>.<NS>.svc.<C_DOMAIN>/dex-authenticator/auth`, where `SERVICE_NAME`, `NS`, and `C_DOMAIN` are determined the same way as for an Ingress resource.

Example of annotations for an application's HTTPRoute resource for connecting to Dex:

```
annotations:
  alb.network.deckhouse.io/auth-signin: https://app-name.kube.my-domain.com/dex-
authenticator/sign_in
  alb.network.deckhouse.io/auth-url: https://app-name-dex-authenticator.app-
ns.svc.cluster.local/dex-authenticator/auth
  alb.network.deckhouse.io/auth-response-headers: X-Auth-Request-User,X-Auth-Request-
Email
```

Also, in the DexAuthenticator resource, specify the same ListenerSet used to publish the application's domain:

```
spec:
  gatewayAPI:
    applicationHTTPRouteListenerSetName: my-listenerset
```

The HTTPRoute created for the DexAuthenticator attaches to that same ListenerSet, so the ListenerSet must accept routes from the namespace of the DexAuthenticator.

An application that specifies only `gatewayAPI` gets no Ingress. If Gateway API is turned off with `global.modules.gatewayAPI.enabled`, or the cluster serves no HTTPRoute API, it gets no HTTPRoute either, with the same result: the application stays reachable, its `/dex-authenticator` endpoints do not, and no one can log in. Other applications are unaffected.

⚠ When setting `sendAuthorizationHeader: true`, list all necessary headers in the Ingress (or in the HTTPRoute, if the `alb` module is used) in the corresponding annotation, since the `Authorization` header is not transmitted by default.

For details on what is passed in the `Authorization` header and how to specify it in the annotation, see How to pass the user's login and groups to an application .

⚠ The application Ingress must have TLS configured. DexAuthenticator does not support HTTP-only Ingress resources.

Setting up CIDR-based restrictions

To allow authentication only from specific networks, list them in `whitelistSourceRanges`. The limit applies to the `/dex-authenticator` endpoints. To restrict access to the application itself, or to let some networks in without authentication, use the annotations of the application's Ingress:

- To restrict access by IP and keep Dex authentication, add the annotation with a comma-separated list of allowed CIDRs:

  ```
  nginx.ingress.kubernetes.io/whitelist-source-range: 192.168.0.0/32,1.1.1.1
  ```

- To allow access without Dex authentication for users from specified networks while requiring authentication for others, add the annotation:

  ```
  nginx.ingress.kubernetes.io/satisfy: "any"
  ```

How to pass the user's login and groups to an application?

By default DexAuthenticator passes only two headers to the application: `X-Auth-Request-User` (based on the opaque `sub` claim) and `X-Auth-Request-Email`. The user's groups are not passed as a header. It grows unboundedly with the number of groups, so it is disabled in DP, and it cannot be enabled.

To give the application full information about the user, including groups, enable `sendAuthorizationHeader`:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-name
  namespace: app-ns
spec:
  applicationDomain: "app-name.kube.my-domain.com"
  applicationIngressClassName: "nginx"
  applicationIngressCertificateSecretName: "ingress-tls"
  sendAuthorizationHeader: true
```

In this case, the application receives the `Authorization: Bearer <id_token>` header, where `<id_token>` is a JWT signed by Dex (for details on the token contents and how to process it in your application, see JWT token contents and processing considerations).

Regardless of how the application is published, this header is not passed to the application automatically. It must be explicitly listed in the annotation of the resource through which the application is published. Choose the relevant option depending on how the application is published:

- Through an Ingress resource
- Through ALBInstance or ClusterALBInstance

If the application is published through an Ingress resource (for details, see the `ingress-nginx` module documentation), when setting `sendAuthorizationHeader: true`, you need to:

- Specify the headers to pass to the application in the `nginx.ingress.kubernetes.io/auth-response-headers` annotation.
- Also increase the buffer size using the `nginx.ingress.kubernetes.io/proxy-buffer-size` annotation, since a JWT with many groups does not fit into the default buffer.

Example of specifying the headers and buffer size using the corresponding annotations:

```
annotations:
  nginx.ingress.kubernetes.io/auth-signin: https://$host/dex-authenticator/sign_in
  nginx.ingress.kubernetes.io/auth-url: https://app-name-dex-authenticator.app-
ns.svc.cluster.local/dex-authenticator/auth
  nginx.ingress.kubernetes.io/auth-response-headers: X-Auth-Request-User,X-Auth-
Request-Email,Authorization
  nginx.ingress.kubernetes.io/proxy-buffer-size: 32k
```

If the `Authorization` header is not listed in `auth-response-headers`, the application won't receive it. If `proxy-buffer-size` is not increased, requests will fail with a 500 error, and the Ingress controller log will show `upstream sent too big header while reading response header from upstream`.

If the application is published through an ALBInstance or ClusterALBInstance resource (for details, see the `alb` module documentation), when setting `sendAuthorizationHeader: true`, specify the headers to pass to the application in the `alb.network.deckhouse.io/auth-response-headers` annotation of the HTTPRoute resource:

```
annotations:
  alb.network.deckhouse.io/auth-signin: https://app-name.kube.my-domain.com/dex-
authenticator/sign_in
  alb.network.deckhouse.io/auth-url: https://app-name-dex-authenticator.app-
ns.svc.cluster.local/dex-authenticator/auth
  alb.network.deckhouse.io/auth-response-headers: Authorization
```

For the `alb.network.deckhouse.io/auth-response-headers` annotation, it is enough to specify only `Authorization`, since it already passes the base set of headers by default.

Also, in the DexAuthenticator resource, specify the same ListenerSet used to publish the application's domain:

```
spec:
  gatewayAPI:
    applicationHTTPRouteListenerSetName: my-listenerset
```

JWT token contents and processing considerations

Example of the JWT payload for a static user (the User and Group resources):

```
{
  "iss": "https://dex.kube.my-domain.com/",
  "sub": "Cg1qb2huLmRvZUBleGFtcGxlEgVsb2NhbA",
  "aud": "dex-authenticator-app-name@app-ns",
  "exp": 1757000600,
  "iat": 1757000000,
  "email": "john.doe@example.com",
  "email_verified": true,
  "name": "john-doe",
  "preferred_username": "",
  "groups": ["everyone", "developers"]
}
```

When parsing the token in your application, keep in mind the following:

- Use the `email` field to identify the user. The `sub` field is opaque (it is not predictable and cannot be used as a meaningful user identifier outside the context of a specific system), and `preferred_username` is empty for static users (external authentication providers may populate it).
- The `name` field contains the object's name (from the `metadata.name` field of the User object), not the user's display name.
- The `aud` field contains the authenticator client identifier (`dex-authenticator-<name>@<namespace>`), not your application's own OIDC client identifier. An application that validates `aud` against its own `client_id` will reject such a token.
- Verify the signature with the JWKS endpoint `https://<DEX DOMAIN>/keys`, where `<DEX_DOMAIN>` is the `publicDomainTemplate` value with `%s` replaced by `dex`.

- The token's lifetime is defined by the `idTokenTTL` parameter (10 minutes by default). DexAuthenticator refreshes the token on its own, so the application always gets a current one.

If the application supports OIDC on its own, use the DexClient resource instead of DexAuthenticator: the application will request the required scope itself and get a `refresh_token` in addition to the `id_token`.

Authentication flow with DexAuthenticator

DexAuthenticator sets its cookies with the `Secure` attribute, so they are sent only over HTTPS.

1. Dex redirects the user to the provider's login page in most cases and waits for the user to be redirected back to the `/callback` URL. However, some providers like LDAP or Atlassian Crowd do not support this flow. The user must enter credentials in the Dex login form instead, and Dex will validate them by making a request to the provider's API.
2. DexAuthenticator starts the sign-in with Proof Key for Code Exchange (PKCE) using the `S256` method and gets the tokens and the signing keys from the `dex` Service in the `d8-user-authn` namespace. It checks the certificate of Dex against the certificate authority (CA) of the internal Dex certificate. `user-authn` adds this CA to the Secret of every DexAuthenticator.
3. DexAuthenticator sets the cookie with the full refresh token (instead of issuing a ticket as for the ID token) because Redis does not persist data. If no ID token is found in Redis by the ticket, the user can request a new ID token by providing the refresh token from the cookie.
4. DexAuthenticator sets the `Authorization` HTTP header to the ID token value from Redis. This is not required for services like `upmeter`, as `upmeter` permissions are less granular. For the Kubernetes Dashboard, it is critical: the Dashboard passes the ID token on to access the Kubernetes API.

Handling an expired session in a single-page application

Without a session, a request to the application is redirected to the sign-in page from the `auth-signin` annotation (`/dex-authenticator/sign_in`). DexAuthenticator sends the user to Dex only when the browser navigates to that page. A request with the `Sec-Fetch-Mode: navigate` header is a navigation. If the browser does not send `Sec-Fetch-Mode`, a request without the `Accept: application/json` and `X-Requested-With: XMLHttpRequest` headers is a navigation. A script request (`fetch`, XHR) gets the `401` status code with the `{}` body instead of a redirect to Dex, which the browser would block as a cross-origin request.

To send the user to sign in, reload the page when a script request gets `401`:

```
const response = await fetch("/api/items");
if (response.status === 401) {
  window.location.reload();
}
```

A sign-in that took longer than 10 minutes

The system stores the temporary login state (a one-time authentication request) for 10 minutes. If the user does not complete it within this time (for example, due to slow entry of the login/password on the external provider's page, a long wait for the code during MFA, a lengthy recovery of a forgotten password, etc.), the login must be started over.

Ending a DexAuthenticator session

DexAuthenticator ends the sessions of a user within seconds after a `Lock`, `ResetPassword`, `Reset2FA` or `Logout` operation and after the user is deleted. A request with an ended session gets the same answer as a request without a session.

DexAuthenticator receives the revocations from the `revocation-feed` Service in the `d8-user-authn` namespace. If a NetworkPolicy restricts egress traffic in the namespace of a DexAuthenticator, allow traffic to the pods with the `app: user-authn-controller` label in the `d8-user-authn` namespace on port `8443`. Without the revocations, DexAuthenticator checks every session older than 30 seconds with Dex, and the `D8UserAuthnRevocationFeedNotConsumed` alert fires after 15 minutes.

When a user signs out of an application, DexAuthenticator revokes the refresh token of the session in Dex. A copy of the session cookie stops working too.

With the browser sessions of Dex enabled, DexAuthenticator then sends the browser to Dex to end the

session of Dex, and the browser is signed out of the other applications it signed in to through this session. Sign the user out with a navigation, not with a script request, which does not follow the redirect to Dex:

```
window.location.assign("/dex-authenticator/sign_out");
```

How to generate a kubeconfig and access Kubernetes API?

To generate a kubeconfig, refer to the «How to generate a kubeconfig to access the Kubernetes API?» section of the `control-plane-manager` module documentation.

Configuring kube-apiserver

Using the `control-plane-manager` module, DP passes `kube-apiserver` an AuthenticationConfiguration with a JWT authenticator for Dex: issuer `https://<DEX_DOMAIN>/` (where `<DEX_DOMAIN>` is the `publicDomainTemplate` value with `%s` replaced by `dex`), audience `kubernetes`, the username from the `email` claim and the groups from the `groups` claim. If `controlPlaneConfigurator.dexCAMode` provides a CA, it is embedded in the configuration. Usernames and groups that start with `system:` are rejected.

The flow of accessing Kubernetes API with generated kubeconfig

1. `kube-apiserver` reads the Dex configuration (issuer and JWKS endpoint). In Kubernetes 1.30 and later, it reads it through the Dex Service inside the cluster.
2. The kubeconfig generated in the Deckhouse web UI contains the ID token and the refresh token.
3. After receiving a request with an ID token, `kube-apiserver` verifies that the token is signed by the provider configured in step 1 using keys from the JWKS endpoint. It then compares the token's `iss` and `aud` claim values with the configuration.

How to rotate the secret of the kubernetes OAuth2 client?

The secret of the privileged `kubernetes` OAuth2 client is stored in the `kubernetes-dex-client-app-secret` Secret of the `d8-user-authn` namespace. The same value is used by the `kubeconfig-generator`, `kubeconfig-generator-<index>`, `kubeconfig-publish-api` and `kubeconfig-<slug>` OAuth2 clients, and by basic-auth-proxy when basic authentication is enabled for an LDAP provider.

Deleting the Secret does not rotate the value: while it is still present in the module's values, the owning hook renders the very same one back.

To rotate the secret, do the following:

1. If a GitOps tool controls the `d8-user-authn` namespace, exclude the `kubernetes-dex-client-app-secret` Secret from syncing. Otherwise the GitOps tool will restore the previous value.
2. Empty the `secret` field:

   ```
   d8 k -n d8-user-authn patch secret kubernetes-dex-client-app-secret --type merge -p '{"data": {"secret":""}}'
   ```

3. Restart DP so that the hook picks the empty field up and generates a new value:

   ```
   d8 k -n d8-system rollout restart deployment/deckhouse
   ```

4. Verify that the secret value changed:

   ```
   d8 k -n d8-user-authn get secret kubernetes-dex-client-app-secret -o jsonpath='{.data.secret}'
   ```

   If it did not, repeat the steps 2 and 3. The module may have restored the previous value before DP was restarted.

Once the secret has been rotated, the configuration of components that use it will be updated automatically and the corresponding pods will be restarted.

Kubeconfig files generated in the Deckhouse web UI before the rotation carry the old client secret and stop refreshing tokens. Generate them again. ID tokens issued before the rotation keep working until they expire, which is configured via `settings.idTokenTTL` (10 minutes by default).

How to enable Kerberos (SPNEGO) SSO for LDAP?

If clients run in a corporate SSO environment (browser trusts the Dex host), Dex can accept Kerberos tickets via `Authorization: Negotiate` and log in without the password form.

Enabling Kerberos (SPNEGO) SSO for LDAP:

1. In AD/KDC, create/provision an SPN `HTTP/<DEX_FQDN>` for a service account and generate a `keytab`.
2. In the cluster, create a Secret in the `d8-user-authn` namespace with the `krb5.keytab` data key.
3. In the LDAP DexProvider resource, enable `spec.ldap.kerberos`:
   - `enabled: true`
   - `keytabSecretName: <secret name>`
   - optional: `expectedRealm`, `usernameFromPrincipal`, `fallbackToPassword`

Dex will mount the `keytab` automatically and start accepting SPNEGO. A server-side `krb5.conf` is not required — tickets are validated using the keytab.

How to configure Basic Authentication for accessing Kubernetes API via LDAP?

Use the `control-plane-manager` module settings:

1. Enable the `apiserver.publishAPI` parameter in the `control-plane-manager` module configuration.
2. Create a DexProvider of type `LDAP` and set `enableBasicAuth: true`.
3. Grant the LDAP groups access with a RoleBinding or ClusterRoleBinding of the granular role-based model.
4. Provide users with a kubeconfig configured for Basic Authentication (LDAP username and password).

> ⚠ Only one authentication provider in the cluster can have `enableBasicAuth` enabled.

A detailed example is described in the Usage section.

How is Dex protected against credential brute-forcing?

Dex limits failed sign-in attempts per client IP address on the sign-in form, the token endpoint, the password change page and the 2FA steps. Configure the limit with the `rateLimit` parameter. It is turned off by default.

Dex also locks an account after failed sign-in attempts. Configure the lockout with the `passwordPolicy.lockout` parameter. It applies to local users, and to LDAP and Crowd users if their types are listed in `applyToConnectors`.

Which client address does Dex see?

Dex uses the address of the client in three places:

- the limit of failed attempts per address (`rateLimit`);
- the sign-in log (the `client remote_addr` key);
- the devices of a user (`ipAddress` in the UserAccount object).

Dex takes the address that the Ingress controller of the platform passes on (see `rateLimit` for the headers it trusts). So the address is right only when the Ingress controller sees the address of the client itself. A balancer in front of the Ingress controller that replaces the address of the client with its own hides it. Then Dex sees the address of the balancer for every user:

- the limit counts the failed attempts of all users together, so the failures of one user can make Dex refuse the sign-ins of the others;
- the sign-in log and the devices of a user show the address of the balancer.

To pass the address of the client to the Ingress controller, configure the IngressNginxController object:

- if the balancer supports the PROXY protocol, use an inlet with it, such as `LoadBalancerWithProxyProtocol` or `HostPortWithProxyProtocol`;
- if the requests come through an HTTP proxy that adds the `X-Forwarded-For` header, enable `behindL7Proxy` for the inlet and list the addresses of the proxy in `acceptClientIPHeadersFrom`.

The `realIPHeader` parameter selects another header and works only with `behindL7Proxy`.

To check the address Dex sees, sign in and compare the `client_remote_addr` key of the `login successful` line in the Dex log with the address of your computer.

How to find out why a sign-in was refused?

Dex logs every sign-in in JSON. A refused sign-in is logged at the `WARN` level with the `reason` field:

- `invalid_credentials`: The login or the password is wrong, or the password change page was opened outside the sign-in that led to it.
- `invalid_totp`: The 2FA code is wrong or has already been used.
- `not_in_allowed_groups`: The user is not in the groups that the provider settings require.
- `not_allowed`: The user is not on an allow-list. The `rule` field names the list.
- `account_locked`: The user is locked.
- `rate_limited`: Too many failed attempts came from the client IP address. The line contains the requested `path` instead of the provider, the client and the user.
- `upstream_refused`: The provider refused to extend the session because the user no longer exists in the provider or has lost access.
- `revoked`: The refresh token, the authorization code or the browser session was issued before a `Lock`, `ResetPassword`, `Reset2FA` or `Logout` operation or before the user was deleted.
- `login_expired`: The sign-in request expired or was not found (the sign-in already finished, or it never existed, including a forged or replayed `state`). The line contains the requested `path` and, if the request path contains the provider ID, `connector_id` instead of the client and the user.

The line also contains `connector_id`, `client_id` and the known user attributes, such as `username` and `email`. A group refusal also contains `user_groups` and `allowed_groups`. A failure of Dex or of the provider is logged at the `ERROR` level.

To find the refusals in the Dex logs, run:

```
d8 k -n d8-user-authn logs -l app=dex -c dex --tail=-1 | grep '"reason"'
```

A UserOperation is in the Failed status — what should I do?

Check the `status.message` field of the UserOperation for the error description:

```
d8 k get useroperation <name> -o jsonpath='{.status.message}'
```

Fix the cause (for example, an invalid password hash or a non-existent user), then create a new UserOperation. A UserOperation runs once, and changes to its spec after creation are ignored.

How do I unlock a user?

Use the command:

```
d8 iam user unlock <USERNAME>
```

The command unlocks a local user. To unlock a user of an external provider, create a UserOperation with `type: Unlock` and `spec.target` as described in Operations on external users. A UserOperation with `spec.user` unlocks a local user as well. The `Lock` operation has already ended the sessions of the user, and `Unlock` does not restore them, so the user signs in again. Only `Reset2FA` removes the user's 2FA secret.

A user was locked automatically — why?

The number of failed login attempts exceeded `passwordPolicy.lockout.maxAttempts`. The user is locked for the duration specified in `passwordPolicy.lockout.lockDuration` and is unlocked automatically afterwards. Local users are always covered. LDAP and Crowd users are locked only if their type is listed in `passwordPolicy.lockout.applyToConnectors`. Dex stores the lock itself and does not create a UserOperation. An administrator can also unlock the user manually with `d8 iam user unlock <USERNAME>` (local users) or by creating a UserOperation with `type: Unlock` (with `spec.user` for local users, with `spec.target` for LDAP and Crowd users).

The `Locked` and `LockedUntil` columns of `d8 k get useraccounts` show whether a user is locked and until when. The module keeps a UserAccount object for each local user and for each user who has signed in through an external provider.

Can I delete a UserIdentity object?

No. Dex keeps the 2FA secret, the lock and the last sign-in of an account in a UserIdentity object in the `d8-user-authn` namespace. The object also holds the generation of the account in the `user-authn.deckhouse.io/generation` annotation, which the module uses to revoke the account's tokens. The module refuses a request to delete a UserIdentity. To remove a local user, delete the User. To reset 2FA or a lock, use a UserOperation of the `Reset2FA` or `Unlock` type.

Can I cancel a UserOperation?

No. A UserOperation runs once. To reverse its effect, create an opposite operation, for example a UserOperation with `type: Unlock` after a `Lock` operation.

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The user-authz module

> Available with limitations in: **Open/CE**
>
> Available without limitations in: **Core, BE, SE, SE+, Ultimate/EE**

> The module lifecycle stage: General Availability

The module generates role-based access model objects based on the standard Kubernetes RBAC mechanism. The module creates a set of cluster roles (ClusterRole) suitable for most user and group access management tasks.

> ⚠ The module implements two role-based models: the granular one (recommended) and the basic one, built around the ClusterAuthorizationRule and AuthorizationRule resources (its support will be discontinued in future releases).
>
> The models are not resource-compatible — automatic conversion is impossible — but they can be used at the same time: the permissions of both models are summed up.

The bindings that grant users the access levels of ClusterAuthorizationRule and AuthorizationRule are reconciled by the `user-authz-controller` component: it watches the rules and keeps their ClusterRoleBindings and RoleBindings in sync, and reports the result in the `status` of each rule (`d8 k get clusterauthorizationrules` shows the `READY` and `BINDINGS` columns). A rule with an unsupported `accessLevel` gets `Ready=False` with the `InvalidSpec` reason instead of breaking the module. The controller exports metrics on the rules it sees, the bindings they need, the bindings that exist, and the drift between them. The module ships alerts on controller unavailability, persistent drift, and rules whose bindings are not applied (for details, see the FAQ).

Granular role-based model

Unlike the basic Deckhouse Platform role-based model, the granular role-based one does not use ClusterAuthorizationRule and AuthorizationRule resources. Access rights are configured in the standard Kubernetes RBAC way: by creating RoleBinding or ClusterRoleBinding resources and specifying one of the roles prepared by the `user-authz` module in them. To grant access to all namespaces of a project at once, use the ProjectRoleBinding and ClusterProjectRoleBinding resources of the `multitenancy-manager` module.

> Access does not have to be granted by hand-writing YAML manifests: the Deckhouse web UI provides an access grant wizard. It walks you through the steps (who gets access → where → at which level), picks the right binding kind itself (RoleBinding, ClusterRoleBinding, ProjectRoleBinding, or ClusterProjectRoleBinding), and lets you assemble a custom role from ready-made building blocks without writing YAML.

The module creates special aggregated cluster roles (ClusterRole). By using these roles in RoleBinding or

ClusterRoleBinding, you can do the following:

- Manage access to modules of a specific subsystem.

  For example, you can use the `d8:subsystem:network:manager` role in ClusterRoleBinding to allow a network administrator to configure *network* modules (such as `cni-cilium`, `ingress-nginx`, `istio`, etc.).

- Manage access to *user* resources of modules within namespaces.

  For example, the `d8:namespace:manager` role in RoleBinding enables deleting/creating/editing the PodLoggingConfig resource in the namespace. At the same time, it does not grant access to the cluster-wide ClusterLoggingConfig and ClusterLogDestination resources of the `log-shipper` module, nor does it allow configuration of the `log-shipper` module itself.

Role scopes

Every role operates in one of four scopes. The scope defines *where* the granted permissions apply and *which resource* is used to assign the role:

Scope	Role name format	Intended for	Which resource is used to assign the role
Namespace	`d8:namespace:<level>`	Application users (developers)	RoleBinding in a specific namespace.
Project	`d8:project:<level>`	Teams working with projects	ProjectRoleBinding or ClusterProjectRoleBinding for the whole project, RoleBinding for one namespace of the project.
Subsystem	`d8:subsystem:<subsystem>:<level>`	Administrators of a part of the platform	ClusterRoleBinding.
Whole platform	`d8:system:<level>`	Platform administrators	ClusterRoleBinding.

The roles created by the module are divided into the following classes:

- Namespace roles — for assigning rights to users (such as application developers) **in a specific namespace**.
- Project roles — for assigning rights **in all namespaces of a project at once**.
- System and subsystem roles — for assigning rights to platform administrators and administrators of a part of the platform.

Access levels

Each scope provides several access levels for roles:

- The “namespace” and “project” scopes have five levels: `viewer` → `user` → `manager` → `admin` → `superadmin`.
- The “subsystem” and “whole platform” scopes have three levels: `viewer` → `manager` → `superadmin`. There are no `user` and `admin` levels here: the system level has no “user” resources that could be used without administering them.

Access levels form a hierarchy with a cumulative principle: each next level inherits all permissions of the previous one and extends them. For example, the `manager` level in the namespace scope includes everything the `user` level allows, which in turn includes everything the `viewer` level allows.

Using ClusterAuthorizationRule and AuthorizationRule together with RBAC

If multitenancy mode is enabled in the cluster (via `enableMultiTenancy: true`), the effective permissions of a user are the combination of all permissions granted by the following sources:

- **Permissions granted by ClusterAuthorizationRule**: Applied only inside the namespaces allowed by its `namespaceSelector` parameter (or the deprecated `limitNamespaces` parameter).
- **Permissions granted by AuthorizationRule**: Applied inside the namespace the AuthorizationRule is created in.
- **Permissions granted by ordinary RoleBinding**: Applied inside the namespace the RoleBinding is created in.
- **Permissions granted by ordinary ClusterRoleBinding** that aren’t generated by the `user-authz` module: Applied cluster-wide.

The namespace restrictions set in a ClusterAuthorizationRule apply only to the permissions granted by that ClusterAuthorizationRule. They do not cancel permissions granted via RoleBinding, ClusterRoleBinding, or AuthorizationRule in other namespaces. Likewise, the permissions granted by ClusterAuthorizationRule do not extend to those namespaces.

The namespace restrictions are enforced by the authorization webhook, so they do not apply to the identities that the webhook does not check: control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. A ClusterAuthorizationRule that names such a ServiceAccount, directly or through a group such as `system:serviceaccounts`, grants its access level in every namespace. Create the ServiceAccounts of external systems in ordinary namespaces.

For example, if a user has a ClusterAuthorizationRule with `accessLevel: Editor` limited to the `ns-a` namespace and a RoleBinding with the `view` role in the `ns-b` namespace, they get the `Editor` permissions in the `ns-a` namespace and read-only permissions in the `ns-b` namespace. Permissions granted by the RoleBinding aren't restricted by the ClusterAuthorizationRule, and the `Editor` level set in the ClusterAuthorizationRule doesn't apply to the `ns-b` namespace.

Namespace roles

> ⚠ A namespace role cannot be assigned through a ClusterRoleBinding. Use a RoleBinding in a namespace, or a ProjectRoleBinding or ClusterProjectRoleBinding for all namespaces of a project.

Namespace roles are intended to assign rights to a user **in a specific namespace**. Users refer to, for example, developers who use a cluster configured by an administrator to deploy their applications. Such users don't need to manage Deckhouse Platform modules or a cluster, but they need to be able to, for example, create their Ingress resources, configure application authentication, and collect logs from applications.

The namespace role defines permissions for accessing namespaced resources of modules and standard namespaced resources of Kubernetes (Pod, Deployment, Secret, ConfigMap, etc.).

The module creates the following namespace roles:

- `d8:namespace:viewer` — allows viewing standard Kubernetes resources (except for Secrets and RBAC resources), Gateway API resources, pod logs and metrics in a specific namespace, as well as authenticating in the cluster;
- `d8:namespace:user` — in addition to the role `d8:namespace:viewer` it allows viewing secrets in a specific namespace, connecting to pods (`kubectl exec`, `kubectl attach`), deleting pods (but not creating or modifying them), executing `kubectl port-forward` and `kubectl proxy`, as well as changing the number of replicas of controllers;
- `d8:namespace:manager` — in addition to the role `d8:namespace:user` it allows managing module resources (for example, Certificate, PodLoggingConfig, etc.) and standard namespaced Kubernetes resources (Pod, Deployment, ConfigMap, Secret, Service, Ingress, NetworkPolicy, CronJob, etc.), as well as Gateway API resources (Gateway, ListenerSet, HTTPRoute, GRPCRoute, ReferenceGrant, etc.) in a specific namespace;
- `d8:namespace:admin` — in addition to the role `d8:namespace:manager` it allows managing the resources ResourceQuota, LimitRange, ServiceAccount, Role, RoleBinding in a specific namespace;
- `d8:namespace:superadmin` — in addition to the role `d8:namespace:admin` it allows security-sensitive operations: minting ServiceAccount tokens and making requests on behalf of ServiceAccounts.

The detailed split of permissions between `admin` and `superadmin` is described in the section Admin level restrictions and superadmin rights.

Automatic access to cluster-wide catalog resources

Working in a namespace requires reading some cluster-wide "catalogs": for example, to set `storageClassName` or `ingressClassName` in a manifest, one needs to see the list of StorageClasses and IngressClasses. Therefore, every subject that receives a RoleBinding to any `d8:namespace:*` or `d8:project:*` role automatically also gets read access to such catalog resources (StorageClass, IngressClass, PriorityClass, RuntimeClass, VolumeSnapshotClass, ClusterLogDestination, etc.).

Technically this appears as an automatically created ClusterRoleBinding to the `d8:dict` role labelled `rbac.deckhouse.io/dict: "true"`. These objects are managed by the platform: they appear when the subject gets its first namespace binding and are removed when the subject has none left — no manual editing is needed.

Project roles

> ⚠ A project role cannot be assigned via ClusterRoleBinding — such an attempt is rejected. To assign a role across a whole project, use ProjectRoleBinding or ClusterProjectRoleBinding. A plain RoleBinding in one of the project namespaces is also allowed — the role then applies in that namespace only.

Project roles (`d8:project:<level>`) are intended for working with projects — isolated environments that may span several namespaces. The levels are the same as for namespace roles: `viewer`, `user`, `manager`, `admin`, `superadmin`.

Each project role includes all permissions of the namespace role of the same level and additionally grants permissions to manage the project itself:

- `d8:project:viewer` — the permissions of `d8:namespace:viewer` plus viewing the project's ProjectNamespace and ProjectRoleBinding resources;
- `d8:project:user` — the permissions of `d8:namespace:user` plus viewing the project's ProjectNamespace and ProjectRoleBinding resources;
- `d8:project:manager` — the permissions of `d8:namespace:manager` plus managing the project's additional namespaces (ProjectNamespace resources);
- `d8:project:admin` — the permissions of `d8:namespace:admin` plus managing access to the project (ProjectRoleBinding resources) and the right to bind the built-in `d8:project:*` and `d8:namespace:*` roles (except the `superadmin` level) to other users within the project;
- `d8:project:superadmin` — analogous to the relation between `d8:namespace:superadmin` and `d8:namespace:admin`.

A role assigned via ProjectRoleBinding automatically applies in **all** namespaces of the project — the main one as well as the additional ones, including those created later.

System and subsystem roles

> ⚠ The system and subsystem roles do not grant access to the namespace of user applications.
>
> They grant access only to system namespaces (starting with `d8-` or `kube-`), and only to those system namespaces where the modules of the corresponding role subsystem are running.
>
> Whether a role lets you grant access to other people is described in Who can assign roles.

System and subsystem roles are intended for assigning rights to manage the entire platform or a part of it (the subsystem), but not the users applications themselves. The subsystem role, for example, can allow a security administrator to manage security modules (responsible for the security functions of the cluster). Thus, the security administrator will be able to configure security policies, certificate issuance, etc., but will not be able to manage other cluster functions (such as access management, network and monitoring settings) or change settings in the namespaces of users applications.

> ⚠ A system/subsystem role limits which modules and namespaces a subject can address, but it does not limit the privileges a subject can obtain through the modules it is allowed to manage. This matters most for the `iam` subsystem, because the right to manage authentication and authorization is equivalent to full control over the cluster.
>
> A subject that can manage the `user-authn` module can register an identity provider or reset the credentials of any local user. A subject that can manage the `user-authz` module can modify authorization rules. In both cases, they can obtain an identity with any privileges, including cluster administrator, so treat an `iam` subsystem role as a cluster administrator role when planning access.

The system/subsystem role defines access rights:

- to cluster-wide Kubernetes resources;
- to manage Deckhouse Platform modules (ModuleConfig resource) within the subsystem of the role, or to all Deckhouse Platform modules for the role `d8:system:*`;
- to manage cluster-wide resources of Deckhouse Platform modules within the subsystem of the role, or to all resources of Deckhouse Platform modules for the role `d8:system:*`;
- to read the namespaces of the modules of the role's subsystem, or of all Deckhouse Platform modules for the role `d8:system:*`; writing there is reserved for the `superadmin` level (see Access of system and subsystem roles to the namespaces of the modules).

The role name format is `d8:system:<ACCESS_LEVEL>` for the system roles and `d8:subsystem:<SUBSYSTEM>:<ACCESS_LEVEL>` for the subsystem roles, where:

- `SUBSYSTEM` is the role's subsystem;
- `ACCESS_LEVEL` is the access level.

  Examples:

  - `d8:system:viewer` — access to view the configuration of all Deckhouse Platform modules (ModuleConfig resource), their cluster-wide resources, their namespaced resources, and standard Kubernetes objects (except Secrets and RBAC resources) in the namespaces of all Deckhouse Platform modules;
  - `d8:system:manager` — similar to the role `d8:system:viewer`, but with the right to view/create/modify/delete the configuration of all Deckhouse Platform modules (ModuleConfig resource) and their cluster-wide resources; in the namespaces of all Deckhouse Platform modules it keeps the read access of `d8:system:viewer`;
  - `d8:subsystem:observability:viewer` — access to view the configuration of Deckhouse Platform modules (ModuleConfig resource) from the `observability` area, their cluster-wide resources, their namespaced resources, and standard Kubernetes objects (except secrets and RBAC resources) in the system namespaces `d8-log-shipper`, `d8-monitoring`, `d8-okmeter`, `d8-operator-prometheus`, `d8-upmeter`, `kube-prometheus-pushgateway`.

The module provides three access levels for system and subsystem roles:

- `viewer` — allows viewing standard Kubernetes resources, the configuration of modules (ModuleConfig resources), cluster-wide resources of modules, and namespaced resources of modules in the module namespace;
- `manager` — in addition to the level `viewer` it allows managing the configuration of modules (ModuleConfig resources) and the cluster-wide resources of modules; in the module namespaces it grants the same read access as `viewer`;
- `superadmin` — in addition to the level `manager` it allows everything in the module namespaces: managing standard Kubernetes resources and the namespaced resources of modules, reading secrets, connecting to pods, issuing ServiceAccount tokens and managing the system resources of the subsystem modules.

Access of system and subsystem roles to the namespaces of the modules

The holder of a system or subsystem role automatically gets a RoleBinding to a namespace role in every system namespace in which the modules of the role's subsystem run (a `d8:system:*` role covers all system namespaces): the `viewer` and `manager` levels get `d8:namespace:viewer`, the `superadmin` level gets `d8:namespace:superadmin`. The platform creates and removes these RoleBindings itself (they carry the label `rbac.deckhouse.io/automated: "true"`), one per ClusterRoleBinding of the role.

The namespaces of the modules belong to the platform. They hold ServiceAccounts with cluster-wide rights (the Deckhouse controller among them) and the credentials of the modules, so any write there, and any read of a Secret there, is in effect the right to act as those ServiceAccounts anywhere in the cluster. This is why a `manager` configures its subsystem through ModuleConfig objects and the cluster-wide resources of the modules, and in the module namespaces only looks: objects, logs, metrics and events, but no secrets, no `kubectl exec`, `attach` or `port-forward`, no deleting or scaling of pods and no creating of anything. A `superadmin` can do all of that. Grant this level deliberately and to a named subject: it is the emergency path into the platform, and its actions are visible in the audit log. Do not use impersonation of system users (`--as`) as a substitute.

Keep in mind:

- A RoleBinding to `d8:namespace:user` or a higher level in a system namespace, created by hand, grants the subject the rights of every ServiceAccount of that namespace. The same holds for the `allowAccessToSystemNamespaces: true` option of a ClusterAuthorizationRule of the previous role model: with it, the `Admin` and `ClusterAdmin` access levels are equivalent to a cluster administrator.
- The system namespaces are those the multitenancy-manager module never turns into projects: `d8-*`, `kube-*`, `upmeter-*`, `default` and the namespaces labelled `heritage: deckhouse` or `heritage: upmeter`.
- A custom system or subsystem role (`d8:custom:*`) is projected as `viewer` whatever its `rbac.deckhouse.io/use-role` label says: the webhook refuses a higher value, and a role created with one earlier is projected as `viewer` with a `ProjectionCapped` event on the role.
- For module authors: the system capability of a module (the one aggregated into the `manager` role of its subsystem) must not grant write access to namespaced objects of the module's namespace that produce workloads with a ServiceAccount, tokens or identities (pods and pod controllers, Secrets, ServiceAccounts, Roles and RoleBindings): such a right would hand the `manager` the ServiceAccounts of the module. The `dmt` linter will check this for the `rbac.yaml` of a module.

Who can assign roles

A system or subsystem role does not, by itself, let you grant access to other people.

Creating a User or Group that is not already a grant subject is ordinary object creation.

Creating a User for an email that already carries a grant, writing or deleting a ClusterAuthorizationRule, or resetting that identity through UserOperation, is granting roles. The request is admitted only if the requester already has covering permissions or is explicitly allowed to assign those roles.

Connecting a DexProvider is measured the same way against the identities the provider can assert: `spec.allowedIdentities` (emails, email domains, groups) and the provider's own group filters bound that set, and only the roles already granted inside it count. A provider without an email limit can assert every email, including the ones that hold SuperAdmin, so writing it requires SuperAdmin. Basic Authentication of an OIDC or a Crowd provider bypasses Dex and its limits, so such a provider counts as one without an email limit, and an OIDC one also without a group limit; a Crowd provider keeps only `crowd.groups` on the group axis. Details and the list of changes admitted without a check are in the user-authn module documentation.

The ClusterAuthorizationRule `spec.accessLevel` field is a basic-model level: `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, `ClusterAdmin`, `SuperAdmin`. An `iam` subsystem manager and a holder of `d8:system:manager` assign the levels `ClusterEditor` includes: `User`, `PrivilegedUser`, `Editor` and `ClusterEditor`, but not `Admin`, `ClusterAdmin` or `SuperAdmin`, and neither the Kubernetes `cluster-admin` ClusterRole.

A ClusterAuthorizationRule that opens the system namespaces counts as a `ClusterAdmin` assignment whatever its `accessLevel`, so these managers cannot write it: a rule with `allowAccessToSystemNamespaces: true`, with `namespaceSelector.matchAny`, with a `namespaceSelector.labelSelector` that does not name its namespaces by the `kubernetes.io/metadata.name` label, a rule for a subject that another rule already lets into them (the rules of a subject add up), or any rule while multitenancy mode is disabled. Without multitenancy mode, as in CE, these managers therefore cannot write ClusterAuthorizationRule objects at all.

The rules of a request add up: those of its user, of every group in its token and of its ServiceAccount. A rule therefore also opens the system namespaces when another rule already lets in one of the requests it applies to: a local user it names or a member of its groups at any depth of nesting, with the groups that user is in and the groups above them; the requester, with the groups of its own token; any request, through `system:authenticated` (a ServiceAccount also through `system:serviceaccounts` and `system:serviceaccounts:<namespace>`).

A rule for `system:authenticated` applies to every request, so it opens the system namespaces as soon as any other rule opens them. A rule for `system:serviceaccounts` does so as soon as another rule lets in a ServiceAccount, and a rule for `system:serviceaccounts:<namespace>` as soon as another rule lets in a ServiceAccount of that namespace. A User subject named `system:serviceaccount:<namespace>:<name>` is that ServiceAccount.

A member of a Group gets the rules of every group above it, so writing a Group needs the range for their roles too. For the same reason, these managers cannot add a member that another rule already lets into the system namespaces to a Group that has a ClusterAuthorizationRule, or is in a group that has one. The groups an identity provider asserts for other users are unknown to the webhook and are not taken into account.

For the same reason a user or a group that such a rule names counts as a `ClusterAdmin` target: these managers cannot create a User for its email, add members to such a Group, run a UserOperation on such a user or connect a DexProvider that can assert such an identity. Turning multitenancy mode off in the `user-authz` ModuleConfig opens the system namespaces to every rule and requires the `ClusterAdmin` range as well. Within the granular model the IAM manager assigns the `iam` subsystem roles up to `d8:subsystem:iam:manager`, and the system manager assigns the roles of any scope up to the `manager` level.

These managers do not write admission webhooks and policies (ValidatingWebhookConfiguration, MutatingWebhookConfiguration, ValidatingAdmissionPolicy and ValidatingAdmissionPolicyBinding): the superadmins of the `security` and `cluster` subsystems and `d8:system:superadmin` do. A mutating webhook can change any object the platform creates, its own pods included, and removing a webhook or a policy switches off what it enforces, such as the limits above. The ValidatingWebhookConfigurations `d8-deckhouse-validating-webhook-handler-*`, which hold the webhooks of the Deckhouse modules, can be created, changed or deleted only by webhook-handler, the platform components and the superadmins, including the holders of a role that grants every verb on everything.

A requester with every permission across the cluster counts as SuperAdmin in these checks and can assign any role, including `SuperAdmin` and `cluster-admin`. For example, a subject of the Kubernetes `cluster-admin` ClusterRole has such permissions if the role is granted by a ClusterRoleBinding or by a ClusterAuthorizationRule without `namespaceSelector` and `limitNamespaces`. If multitenancy mode is enabled, such a rule reaches the system namespaces only with `namespaceSelector.matchAny: true` (or the deprecated `allowAccessToSystemNamespaces: true`). Permissions from a ClusterAuthorizationRule with `namespaceSelector` or `limitNamespaces` do not count toward this, even if the rule grants `cluster-admin`. Any non-empty `limitNamespaces` counts as a limit on purpose, even if its entries match every namespace, such as `.*` together with `allowAccessToSystemNamespaces: true`. Such a rule still counts through its `accessLevel`. For example, `accessLevel: SuperAdmin` gives

the SuperAdmin range whatever the namespace limits of the rule.

`limitNamespaces` and `namespaceSelector` restrict access to namespaced resources only. A subject with the `ClusterAdmin` or `SuperAdmin` access level can still create ClusterRoleBinding and ClusterAuthorizationRule objects, so these fields do not confine what it can grant across the cluster. Give these levels only to subjects that may hold access to the whole cluster. A ClusterAuthorizationRule counts only through the bindings that `user-authz-controller` has created for it.

Webhook deny messages call the `accessLevel` values basic, so they are not confused with the granular role levels (`viewer` / `manager` / `superadmin`).

Permission to create User and Group objects in the `user-authn` module is not enough: it does not grant the roles already attached to that email.

Global resource dictionaries

In addition to the roles and capabilities of the granular model, the module creates a special ClusterRole `d8:dict`. It grants **read-only** access to cluster-scoped “reference” resources that users commonly need to discover when creating objects — for example, a user creating a PersistentVolumeClaim needs to see the available StorageClasses, and a user creating an Ingress needs to see the IngressClasses.

The role grants `get`, `list`, `watch` on the following resources:

- `storageclasses` (storage.k8s.io), plus `csidrivers`, `csinodes`, `volumeattachments`
- `volumesnapshotclasses` (snapshot.storage.k8s.io)
- `ingressclasses` (networking.k8s.io)
- `priorityclasses` (scheduling.k8s.io)
- `runtimeclasses` (node.k8s.io)
- `virtualmachineclasses`, `clustervirtualimages` (virtualization.deckhouse.io)
- `clusterlogdestinations` (deckhouse.io)
- `customresourcedefinitions` (apiextensions.k8s.io) — `get`, `list` only

Automatic binding

`user-authz-controller` keeps one ClusterRoleBinding to `d8:dict` for every subject that holds one of the following RoleBindings:

- a RoleBinding to a `d8:namespace:*` or `d8:project:*` role, including the RoleBindings that `multitenancy-manager` creates from a ProjectRoleBinding or a ClusterProjectRoleBinding;
- a RoleBinding that the module creates for an AuthorizationRule (the `User`, `PrivilegedUser`, `Editor`, and `Admin` levels).

The `system:multitenancy-manager:*` users, which `multitenancy-manager` acts as, get none. This means that project users can discover reference resources without any manual configuration. The binding is removed when the subject has no such RoleBinding left. You do not create it yourself.

> **i** The `d8:dict` role is independent of the `multitenancy-manager` cluster-wide resource access management mechanism: it only gives **read** access to reference resources so users can discover them. The mechanism controls *which resource values* a project may actually reference when creating objects.

Subsystems of the role-based model

Each Deckhouse Platform module belongs to a specific subsystem. For each subsystem, there is a set of roles with different levels of access. Roles are updated automatically when the module is enabled or disabled.

The subsystems of the platform are `iam`, `security`, `cluster`, `delivery`, `network`, `storage`, `observability` and `managed-services`.

For example, for the `network` subsystem, there are the following subsystem roles that can be used in `ClusterRoleBinding`:

- `d8:subsystem:network:viewer`;
- `d8:subsystem:network:manager`;
- `d8:subsystem:network:superadmin`.

The scope of a role depends on which subsystem it belongs to:

- The scope of the `d8:system:*` roles is the namespaces of all enabled Deckhouse Platform modules, that is, the namespaces that their capabilities name in the `rbac.deckhouse.io/namespace` label.

- The scope of subsystem roles includes the namespaces in which the subsystem’s modules operate (see the subsystem composition table), as well as all cluster-wide objects of the subsystem’s modules.

Role-based model subsystems composition table.

Subsystem	Subsystem modules	Namespaces in which modules of a scope operate
all	All modules	All namespaces
iam	• multitenancy-manager • namespace-configurator • user-authn • user-authz	• d8-multitenancy-manager • d8-system • d8-user-authn
security	• admission-policy-engine • cert-manager • neuvector • operator-trivy • runtime-audit-engine • secret-copier • secrets-store-integration	• d8-admission-policy-engine • d8-cert-manager • d8-operator-trivy • d8-runtime-audit-engine
cluster	• chrony • cloud-provider-aws • cloud-provider-azure • cloud-provider-dynamix • cloud-provider-gcp • cloud-provider-huaweicloud • cloud-provider-openstack • cloud-provider-vcd • cloud-provider-vsphere • cloud-provider-yandex • cloud-provider-zvirt • commander-agent • console • control-plane-manager • csi-vsphere • dashboard • deckhouse • deckhouse-tools • descheduler • documentation • node-manager • pod-reloader • registry • registry-packages-proxy • terraform-manager • vertical-pod-autoscaler • virtualization	• d8-chrony • d8-cloud-instance-manager • d8-cloud-provider-aws • d8-cloud-provider-azure • d8-cloud-provider-dynamix • d8-cloud-provider-gcp • d8-cloud-provider-huaweicloud • d8-cloud-provider-openstack • d8-cloud-provider-vcd • d8-cloud-provider-vsphere • d8-cloud-provider-yandex • d8-cloud-provider-zvirt • d8-csi-vsphere • d8-descheduler • d8-system • kube-system
delivery	• delivery-kit • operator-helm	• d8-operator-helm

Subsystem	Subsystem modules	Namespaces in which modules of a scope operate
network	• cilium-hubble • cni-cilium • cni-flannel • cni-simple-bridge • ingress-nginx • istio • keepalived • kube-dns • kube-proxy • metallb • monitoring-ping • network-gateway • network-policy-engine • node-local-dns • openvpn • sdn • service-with-healthchecks • static-routing-manager	• d8-cni-cilium • d8-cni-flannel • d8-cni-simple-bridge • d8-ingress-nginx • d8-istio • d8-keepalived • d8-metallb • d8-monitoring • d8-network-gateway • d8-openvpn • d8-service-with-healthchecks • d8-static-routing-manager • d8-system • kube-system

managed-services	• managed-memcached • managed-postgres	

How the roles are built: aggregation and capabilities

No built-in role contains a list of permissions directly. Permissions are described in separate small cluster roles — **capabilities**. Each capability is responsible for one kind of action (for example, “view logs”, “manage quotas”, “connect to pods”) and contains concrete RBAC rules. A role (`d8:namespace:admin`, `d8:system:viewer`, etc.) is an empty ClusterRole with an aggregation rule (`aggregationRule`): Kubernetes automatically collects into it the rules from all capabilities with matching labels.

Membership of objects in the role model is defined by the `rbac.deckhouse.io/*` labels — for example, the label `rbac.deckhouse.io/aggregate-to-namespace-as: admin` includes a capability into the `d8:namespace:admin` role (and, thanks to the level hierarchy, into all levels above). The complete list of labels and annotations is in the reference below.

This design has two practical consequences:

- Deckhouse Platform modules extend the roles automatically: when a module is enabled, its capabilities are added to the corresponding built-in roles; when it is disabled, they are removed. The permission list of a role always matches the set of enabled modules.
- You can assemble your own roles from ready-made capabilities without writing RBAC rules by hand. How to do this is described in the FAQ.

The names of built-in roles and capabilities start with the `d8:` prefix. This namespace is reserved: you cannot create your own ClusterRole with a `d8:*` name — the only exception is the `d8:custom:*` prefix, which is dedicated to user-defined roles and capabilities. The labels `rbac.deckhouse.io/kind: role` and `rbac.deckhouse.io/kind: capability` are also reserved for built-in objects — use `custom-role` and `custom-capability` for your own.

Reference of role labels and annotations

Labels the role model uses on ClusterRole objects:

Label	Found on	Purpose
`rbac.deckhouse.io/kind`	All role model objects	Object type: `role` or `capability` — built-in (reserved), `custom-role` or `custom-capability` — user-defined. An object without this label is refused if it carries the aggregation label of a platform scope.
`rbac.deckhouse.io/scope`	Roles and capabilities	Scope: `namespace`, `project`, `subsystem`, `system`.
`rbac.deckhouse.io/subsystem`	Subsystem objects	The subsystem name (for example, `network`) — only with `scope: subsystem`.
`rbac.deckhouse.io/aggregate-to-<scope>-as: <level>`	Capabilities and lower-level roles	The aggregation rule: includes the object into the role of the given scope and level. `<scope>` is `system`, `namespace`, `project`, or a subsystem name; `<level>` is `viewer`, `user`, `manager`, `admin`, `superadmin`. These are exactly the labels referenced by `aggregationRule` selectors.
`rbac.deckhouse.io/capability`	Capabilities	The globally unique name of the capability (for example, `namespace-capability.kubernetes.view_logs`) — used to include the capability into a custom role selectively.
`rbac.deckhouse.io/use-role: <level>`	System and subsystem roles	Which namespace-role level the holder of this role automatically gets in the system namespaces of its subsystem. On the built-in roles: `viewer` → `viewer`, `manager` → `viewer`, `superadmin` → `superadmin`; a role that is not built into the platform gets `viewer` at most. The access is granted by automatically created RoleBinding objects (labelled `rbac.deckhouse.io/automated: "true"`).

Label	Found on	Purpose
`rbac.deckhouse.io/namespace: <namespace>`	Capabilities	The namespace of a module where a RoleBinding is automatically created for the holders of a system/subsystem role. Read only on the capabilities Deckhouse ships; on a custom capability it is ignored (how to give access to another namespace).
`rbac.deckhouse.io/delegatable: "true"`	The `d8:namespace:*`, `d8:project:*`, and user-defined roles	The role may be referenced by a RoleBinding inside project namespaces. Add this label to your custom roles that should be available in projects.
`rbac.deckhouse.io/deprecated: "true"`	Deprecated alias roles	The role is deprecated and will be removed; migrate the bindings to the new role.
`module`	Built-in objects	The name of the Deckhouse Platform module the object belongs to. Convenient for aggregation selectors (for example, all capabilities of one module).
`heritage: deckhouse`	Built-in objects	Marks a platform object. Must not be set on your own objects.

Annotations on ClusterRole objects:

Annotation	Added by	Purpose
`ru.meta.deckhouse.io/title`, `ru.meta.deckhouse.io/description`	Platform	The display title and description in Russian.
`en.meta.deckhouse.io/title`, `en.meta.deckhouse.io/description`	Platform	The display title and description in English.
`custom.meta.deckhouse.io/title`, `custom.meta.deckhouse.io/description`	Administrator	Overrides the display title/description; the only allowed modification of built-in roles.
`rbac.deckhouse.io/bindable-only-via`	Platform	The binding kinds the role is intended for (on project roles — `ProjectRoleBinding,ClusterProjectRoleBinding`). It is informational: the platform does not check it.
`rbac.deckhouse.io/disabled-for-direct-use-in-projects: "true"`	Administrator	Forbids granting the role in projects: existing bindings keep working, new ones cannot be created (details).
`rbac.deckhouse.io/deprecated-replaced-by`	Platform	On deprecated alias roles: the name of the role to migrate to.

Admin level restrictions and superadmin rights

The role model provides two administration levels:

- `admin` — the everyday administrator. Manages resources, quotas, and access within their scope, but cannot perform operations that would let them break out of that scope or disrupt platform components.
- `superadmin` — the “break-glass” administrator. Has all the rights of `admin` and can additionally perform dangerous operations. Grant this level deliberately and only to those who really need it.

Only the `superadmin` level allows **minting ServiceAccount tokens** (`kubectl create token`) **and**

making requests on behalf of a ServiceAccount (`kubectl --as system:serviceaccount:...`). A ServiceAccount token is a ready-to-use identity: by obtaining the token of a platform component's service account, one could gain its permissions far beyond the namespace. Therefore `admin` manages the `ServiceAccount` objects themselves (create, delete) but cannot mint tokens for them or act on their behalf.

`superadmin` also has some restrictions:

- Objects labeled `heritage: deckhouse` belong to the platform: nobody may create, modify or delete them, `superadmin` and cluster administrators included. Some platform components place such objects in user namespaces, for example the pods of a DexAuthenticator. `kubectl exec`, `kubectl attach`, `kubectl port-forward` and `kubectl debug` into such pods and `kubectl scale` of such Deployment, StatefulSet, ReplicaSet and ReplicationController objects are denied too. `kubectl rollout restart` of such objects is allowed. The users these checks do not apply to are listed in the FAQ of the `deckhouse` module.
- Resources created from a project template (the `heritage: multitenancy-manager` label) cannot be modified by **anyone**, including `superadmin` and a cluster administrator — they are managed exclusively by the project controller. To change such a resource, change the project template or the project itself.
- A role is assigned via RoleBinding and applies only in the namespace where it was granted: a `superadmin` of one namespace gets no special rights in another.

Built-in protection mechanisms of the role model

The role model is protected by a set of checks at the API server level. They require no configuration and prevent typical mistakes and privilege escalation attempts:

- **A scoped role cannot be granted cluster-wide.** A ClusterRoleBinding to the `d8:namespace:*` or `d8:project:*` roles (and their `d8:custom:*` variants) is rejected — otherwise a role designed for one namespace or project would apply in every namespace at once. Use a RoleBinding in the desired namespace, or ProjectRoleBinding/ClusterProjectRoleBinding for a project. A ClusterRoleBinding is only allowed for system and subsystem roles — those are cluster-scoped by nature.
- **A capability cannot be granted cluster-wide.** A ClusterRoleBinding to any capability (`d8:*-capability:*`, including custom ones) is rejected: a capability is a building block for roles, not a standalone role. Binding a capability via a RoleBinding in a single namespace is allowed.
- **Project management cannot be obtained through a custom role.** Creating a Role or ClusterRole that grants permissions to modify project management resources (`projects`, `projecttemplates`, `projectrolebindings`, `clusterprojectrolebindings`, `projectnamespaces`) is rejected. These permissions are granted only by the built-in `d8:project:*` roles. Without this protection, a namespace administrator could create a role with the right to create ProjectRoleBinding objects and grant themselves access to the whole project. Read-only roles on these resources are allowed.
- **A namespace or project role cannot include platform capabilities.** A custom role with `scope: namespace`, `scope: project`, or no scope may not select system or subsystem capabilities by the `rbac.deckhouse.io/capability` label, nor the `system` or a subsystem scope by the `rbac.deckhouse.io/aggregate-to-<scope>-as` label. No custom role may combine the capabilities of the `namespace`/`project` scopes with those of the `system`/`subsystem` scopes — this rules out a "super-role" combining access to applications and to the platform.
- **A custom capability carries rules and cannot have an `aggregationRule`.**
- **The name must match the scope**: `d8:custom:namespace:<name>`, `d8:custom:project:<name>`, `d8:custom:system:<name>`, `d8:custom:<subsystem>:<name>`, and `d8:custom:<scope>-capability:<name>` for a capability.
- **Only a custom capability may carry an `rbac.deckhouse.io/aggregate-to-<scope>-as` label of a platform scope.**
- **The `rbac.deckhouse.io/delegatable: "true"` label is accepted only on a role that aggregates only namespace and project capabilities.**
- **Custom roles cannot contain direct RBAC rules** — they may only aggregate capabilities. Permissions are described in separate custom capabilities, which keeps the contents of any role transparent. See the FAQ for details.

Display names of roles

Every built-in role and capability carries a localized title and description in annotations:

- `ru.meta.deckhouse.io/title`, `ru.meta.deckhouse.io/description` — in Russian;
- `en.meta.deckhouse.io/title`, `en.meta.deckhouse.io/description` — in English.

These annotations are used, for example, by the Deckhouse web UI when displaying the list of roles.

If the standard title does not fit (for example, you want to name roles in your company's terms), add the `custom.meta.deckhouse.io/title` and `custom.meta.deckhouse.io/description` annotations to the role — the interface will show them instead of the standard ones. Example:

```
d8 k annotate clusterrole d8:namespace:admin custom.meta.deckhouse.io/title='Team administrator'
```

This is the only allowed modification of built-in roles: changing their rules, aggregation, or labels is rejected.

Deprecated role names

The previous role names of the granular model (`d8:manage:<subsystem>:<level>`, `d8:manage:all:<level>`, and `d8:use:role:<level>`) are deprecated and will be removed in the next release. For backward compatibility they are temporarily kept as alias roles. A binding to an alias aggregates the **new** role's capabilities, except where the list of subsystems changed (see below). The rights of an alias are not identical to the pre-upgrade ones. `d8:use:role:admin` no longer grants ServiceAccount token minting or impersonation, which moved to `superadmin`. The `d8:manage:*` aliases are not `delegatable`. The `d8:use:role:*` aliases are, so a RoleBinding to them inside a project namespace keeps working, but a new ProjectRoleBinding or ClusterProjectRoleBinding to an old name is refused.

A ClusterRoleBinding to a `d8:manage:*` alias keeps the RoleBindings that the previous release created for it in the namespaces of the modules of the old subsystem. For a `viewer` alias they are named `d8:use:viewer:binding:<ClusterRoleBinding name>` and refer to `d8:use:role:viewer`, for a `manager` alias `d8:use:user:binding:<ClusterRoleBinding name>` and `d8:use:role:user`. They bind the subjects of the ClusterRoleBinding and are kept in sync as before. The namespaces are those of the platform modules that were in the old subsystem and of the capabilities of modules that still carry the old labels, `rbac.deckhouse.io/kind: manage` together with the aggregation label of the old subsystem. For `d8:manage:all:<level>` they also include the namespaces that the subsystem roles of the modules with a subsystem of their own reach at its level, for example `d8-virtualization`. A binding to an alias therefore gets no RoleBinding in the namespace of a module that joined the subsystem later or of a module released on its own that already carries the new labels. A ClusterRole created by a user adds no namespace, whatever labels it carries. The RoleBindings that the previous release created for the binding stay while the binding refers to the old name, even in a namespace that is no longer among these, for example when a module released on its own moves to the new labels. A ClusterRoleBinding that is deleted and created again under the same name keeps them only in these namespaces. When you recreate the binding on a new role name, these RoleBindings are replaced by `d8:namespace:<level>:binding:<ClusterRoleBinding name>` ones in the namespaces of the modules of the new subsystem, with the namespace role of the new role (`admin` for a `manager` role). The RoleBindings that the previous release created for a binding to a custom role of the previous scheme with `rbac.deckhouse.io/kind: manage`, such as `custom:manage:mycustom:manager`, are removed on the upgrade, because `user-authz-controller` keeps such RoleBindings for the roles of Deckhouse only. They come back as `d8:namespace:<level>:binding:<ClusterRoleBinding name>` once the role is recreated as a `d8:custom:*` role with `rbac.deckhouse.io/scope: system` or `subsystem` and `rbac.deckhouse.io/use-role` and the binding refers to the new role, but only in the namespaces of the modules that already carry the new labels. A module that still carries the old labels gets no such RoleBinding until it moves to the new ones. Until then, create RoleBinding objects in the namespace of that module for the subjects of the binding: one to `d8:namespace:<level>` and one to each ClusterRole of the module that the `D8UserAuthzLegacyUseCapability` alert names. None of these roles is an alias, so the RoleBinding objects do not hold the next release, and the webhook that checks RoleBinding objects in project namespaces does not check the namespace of a module. Delete them once the module carries the new labels and the controller creates its own RoleBinding there. A RoleBinding to `d8:use:role:<level>` gives these rights as well, but the `D8UserAuthzDeprecatedRBACv2RoleInUse` alert reports it, and it holds the release that removes the aliases.

Name mapping:

Deprecated name	New name
`d8:manage:all:<level>`	`d8:system:<level>`
`d8:manage:deckhouse:<level>`, `d8:manage:infrastructure:<level>`, `d8:manage:kubernetes:<level>`	`d8:subsystem:cluster:<level>`, which grants more. The modules that moved to other subsystems come with the roles of those subsystems
`d8:manage:networking:<level>`	`d8:subsystem:network:<level>`, which also grants the rights for `keepalived`
`d8:manage:security:<level>`	`d8:subsystem:security:<level>` together with `d8:subsystem:iam:<level>`, which grants the rights for `user-authz` and `user-authn` and more
`d8:manage:observability:<level>`	`d8:subsystem:observability:<level>`
`d8:manage:storage:<level>`	`d8:subsystem:storage:<level>`, which also grants the rights for `local-path-provisioner`

Deprecated name	New name
`d8:use:role:<level>`	`d8:namespace:<level>`
`d8:use:role:<level>:kubernetes`	`d8:namespace:<level>` (full namespace role, not kubernetes-only)

The list of subsystems changed together with the role names. `deckhouse`, `infrastructure` and `kubernetes` were merged into `cluster`, which also took over modules from other subsystems, `networking` was renamed to `network`, and `user-authz`, `user-authn` and `multitenancy-manager` moved to `iam`.

The aliases of the `deckhouse`, `infrastructure` and `kubernetes` roles therefore do not aggregate the whole `cluster` subsystem. They select the capabilities of the platform modules that were in the old subsystem, wherever those modules are now. `d8:subsystem:cluster:<level>` grants more, so when you recreate such a binding, check which subsystem roles its subjects need. The alias of `d8:manage:security:<level>` also keeps the rights for `user-authz` and `user-authn`, which now come with `d8:subsystem:iam:<level>`. That role also grants the rights for `multitenancy-manager` and, at the `manager` level, the right to assign roles, which `d8:subsystem:security:<level>` does not grant. So a binding to `d8:manage:security:<level>` is replaced by two bindings with the same subjects, to `d8:subsystem:iam:<level>` and to `d8:subsystem:security:<level>`. The `rbac.deckhouse.io/deprecated-replaced-by` annotation of the alias names only the second one. The aliases of `networking` and `storage` leave out `keepalived` and `local-path-provisioner`, which moved to `network` and `storage` from `infrastructure`, so the new roles grant more than these aliases.

The `rbac.deckhouse.io/deprecated-replaced-by` annotation of an alias names its main replacement, and the description of the alias names the roles of the other subsystems its modules moved to. These roles cover whole subsystems. To grant the rights for some modules only, create a custom role that selects their system capabilities by the `rbac.deckhouse.io/capability` label, for example `system-capability.multitenancy-manager.view` (see How do I extend a role or create a new one?).

The aliases of the `deckhouse`, `infrastructure`, `kubernetes` and `networking` roles and `d8:manage:all:<level>` also select the labels of these old subsystems, such as `rbac.deckhouse.io/aggregate-to-deckhouse-as`. Modules released on their own and custom capabilities may still carry them. No role of the new model collects these labels, so such capabilities reach the holders of the old names only, and the `D8UserAuthzRetiredAggregationLabel` alert names them. A module released on its own that has moved to its new subsystem is no longer selected by the alias of its old one. `d8:manage:all:<level>` also selects `rbac.deckhouse.io/kind: manage` together with `rbac.deckhouse.io/aggregate-to-all-as` at its level, as the previous release did. Modules with a subsystem of their own carry this label on their subsystem roles, for example `d8:manage:virtualization:<level>`, until they move to the new labels.

The `d8:use:role:<level>` and `d8:use:role:<level>:kubernetes` aliases also select the use capabilities of the previous release, `rbac.deckhouse.io/kind: use` together with `rbac.deckhouse.io/aggregate-to-kubernetes-as` at the level of the alias or below. Modules released on their own and custom capabilities may still carry them, for example the `log-shipper` capabilities for PodLoggingConfig objects. `d8:use:role:<level>` also selects `rbac.deckhouse.io/kind: use` together with `rbac.deckhouse.io/aggregate-to-all-as` at its own level, as the previous release did. Modules with a subsystem of their own carry this label on their use roles, for example `d8:use:role:<level>:virtualization`. `d8:namespace:<level>` does not select them, so a RoleBinding to an old name keeps these rights, and a RoleBinding to the new name gets them only once the module or the capability carries `rbac.deckhouse.io/aggregate-to-namespace-as`. The `D8UserAuthzLegacyUseCapability` alert names the use capabilities with `rbac.deckhouse.io/aggregate-to-kubernetes-as` and the use roles with `rbac.deckhouse.io/aggregate-to-all-as`. The alert also names a ClusterRole with `rbac.deckhouse.io/kind: use` and the aggregation label of the system scope, of a built-in subsystem, or of `deckhouse`, `infrastructure` or `networking`. No role collects such a ClusterRole, so only a binding to the ClusterRole itself gives its rules. The `rbacv2-cluster-roles.deckhouse.io` webhook does not let a user create such a ClusterRole, and lets a user change one left from the previous release only by removing the aggregation label from it.

Until a module carries the new labels, create a RoleBinding to the ClusterRole that `D8UserAuthzLegacyUseCapability` names, such as `d8:use:role:<level>:virtualization` or the use capability itself, for the subjects that need these rights, in the namespace where they have their RoleBinding to `d8:namespace:<level>`. Neither role is an alias, so these RoleBinding objects do not hold the next release. In a project namespace, the `cluster-objects-grants-validator.multitenancy.deckhouse.io` webhook admits such a RoleBinding only if the ClusterRole has the `rbac.deckhouse.io/delegatable: "true"` label, and the use capabilities of the previous release do not have it. Where the webhook refuses it, keep the RoleBinding on the old name. It keeps these rights, but it holds the release that removes the aliases, so update the module before that release and then move the RoleBinding to `d8:namespace:<level>`.

Within the modules it covers, a binding to an old name gets their capabilities as they are in this release.

These differ from the previous release, because the modules added resources to them. For example, the `multitenancy-manager` capabilities include the ProjectRoleBinding, ClusterProjectRoleBinding and ProjectNamespace objects, and the `iam` and `security` managers can inspect the access of any subject.

> ⚠ The deprecated `d8:use:role:admin` role maps to `d8:namespace:admin` and, just like it, no longer grants the right to mint ServiceAccount tokens or impersonate ServiceAccounts — that now requires the `superadmin` level.

As long as bindings to the deprecated names remain in the cluster, the `D8UserAuthzDeprecatedRBACv2RoleInUse` (a binding to an alias role) and `D8UserAuthzDeprecatedRBACv2CapabilityInUse` (a binding to a deprecated name that no ClusterRole has, such as a capability of the previous release, so the binding grants nothing) alerts fire. The release that removes the aliases carries the `deprecatedRBACv2BindingsCount` release requirement: the upgrade stays pending, with the offending bindings listed in the `DeckhouseRelease` status, until every binding to an alias role is recreated on a new role name. A binding that grants nothing does not hold the release: removing the aliases changes nothing for it. An alias role here is a ClusterRole of the `user-authz` module with the `rbac.deckhouse.io/deprecated` label. A module released on its own may still ship roles and capabilities of the previous release under the deprecated names, such as `d8:manage:virtualization:<level>`, `d8:use:role:<level>:virtualization` or `d8:manage:permission:module:ingress-nginx:edit`. A binding to such a ClusterRole keeps working, raises neither alert and does not hold the release. The alerts and the release requirement leave out the RoleBindings that `user-authz-controller` keeps for a ClusterRoleBinding to an alias, because these follow the ClusterRoleBinding.

A module that renames a role of its own keeps the old name the same way: a ClusterRole labelled `rbac.deckhouse.io/deprecated` in the module's `templates/rbacv2-compat/`, with the new name in the `rbac.deckhouse.io/deprecated-replaced-by` annotation. A binding to such an alias raises `D8UserAuthzDeprecatedRBACv2ModuleRoleInUse`, which names the new role, and does not hold the Deckhouse release: the module removes the alias in a release of its own. The annotation is required (an alias without it is ignored), and the alias may have any `d8:` name except the platform's own role families (`d8:system:`, `d8:subsystem:`, `d8:namespace:`, `d8:project:`, `d8:custom:`, `d8:dict`), the reserved prefixes `d8:binding:` and `d8:prb:`, and the previous platform names `d8:manage:` and `d8:use:`.

Migrate your existing RoleBinding and ClusterRoleBinding objects to the new role names. A ClusterRoleBinding named `user-authz:<rule>:additional-role:<role>` is rendered by `user-authz-controller` from `spec.additionalRoles` of the ClusterAuthorizationRule `<rule>`, and the controller creates it again when it is deleted. So change the role name in `spec.additionalRoles` of that rule, not the binding. A binding that a project template renders is changed in the ProjectTemplate the same way, because `multitenancy-manager` renders it again from the template. You can find bindings that still use the deprecated names, without the RoleBindings that `user-authz-controller` keeps for them, with the command:

```
d8 k get clusterrolebindings,rolebindings -A -o json \
  | jq -r '.items[] | select(.roleRef.name | test("^d8:(manage|use):")) |
select(.metadata.labels["rbac.deckhouse.io/automated"] != "true") | "\(.kind) \
(.metadata.namespace // "-") \(.metadata.name) -> \(.roleRef.name)"'
```

Basic role-based model

Features:

- Access is configured with the ClusterAuthorizationRule and AuthorizationRule custom resources, on top of Kubernetes RBAC;
- Manages access to scaling tools (the `allowScale` parameter of the ClusterAuthorizationRule or AuthorizationRule custom resource);
- Manages access to port forwarding (the `portForwarding` parameter of the ClusterAuthorizationRule or AuthorizationRule custom resource);
- Manages the list of allowed namespaces with a labelSelector (the `namespaceSelector` parameter of the ClusterAuthorizationRule custom resource);
- Namespace restrictions (multi-tenancy mode, `namespaceSelector`, `limitNamespaces`) are available in the BE, SE, SE+, EE, and CSE editions.

In addition to the RBAC, you can use a set of high-level roles in the module:

- `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
- `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
- `Editor` — the same as `PrivilegedUser` + can create, edit, and delete the objects that are

usually required for application tasks;
- `Admin` — the same as `Editor` + can create and modify pods, create ServiceAccount tokens (`serviceaccounts/token`), manage Role, RoleBinding, and AuthorizationRule objects, and delete auxiliary objects (for example, ReplicaSet and the challenges and orders of the `acme.cert-manager.io` group);
- `ClusterEditor` — the same as `Editor` + can manage a limited set of cluster-wide objects used in application tasks (DaemonSet, StorageClass, CustomResourceDefinition, GatewayClass, and the objects that modules add at this level, for example, KeepalivedInstance). This role is best suited for cluster operators.
- `ClusterAdmin` — the same as both `ClusterEditor` and `Admin` + can manage cluster-wide service objects (namespaces, quotas, NetworkPolicy, the proxy subresources of nodes, ClusterAuthorizationRule, ClusterRole, and ClusterRoleBinding). This role is best suited for cluster administrators. **Warning.** `ClusterAdmin` can create ClusterAuthorizationRule objects only up to the `ClusterAdmin` level, and ClusterRoleBinding objects only to roles whose permissions it already holds;
- `SuperAdmin` — can perform any actions with any objects (note that `namespaceSelector` and `limitNamespaces` restrictions remain valid).

> ⚠ Multi-tenancy mode restricts access to namespaced resources only. Subjects with the `ClusterAdmin` or `SuperAdmin` access level can still create cluster-wide bindings. The authorization webhook does not check control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`, so the namespace restrictions do not apply to them.

If a ClusterAuthorizationRule custom resource contains the `namespaceSelector` field, the deprecated `limitNamespaces` and `allowAccessToSystemNamespaces` fields are not taken into consideration.

In multi-tenancy mode, if the authorization webhook becomes unavailable, requests are **denied**, not allowed: the webhook runs before RBAC and is configured with `failurePolicy: Deny`, so a request it cannot answer does not reach RBAC. The exception is the identities listed in `matchConditions` of the AuthorizationConfiguration: control plane components, `kubernetes-api-proxy`, kubelets, the ServiceAccounts of the `kube-system` and `d8-*` namespaces, and anonymous kube-apiserver health probes (`/livez`, `/readyz`, `/healthz`) bypass the webhook, so the cluster keeps running and Deckhouse can restore the webhook.

In multi-tenancy mode on Kubernetes 1.34 or later, the API server also asks the authorization webhook whether the `user-authn` module has revoked the ID token of a user. The module revokes tokens on a `Lock`, `ResetPassword` or `Reset2FA` UserOperation, on a `Logout` UserOperation without the `logout` field, and when a User is deleted. The API server denies a revoked token within seconds with the `user-authn: the credentials of this user were revoked; sign in again` message. This check does not deny requests when the webhook is unavailable or the `user-authn` module is disabled; a revoked ID token then stays valid until it expires. The check does not apply to Basic Authentication, ServiceAccount tokens, client certificates and requests that are already running, such as `watch` or `exec`. The check is not configured when the `apiserver.authz.webhookURL` parameter of the `control-plane-manager` module is set.

Default access list for each role

Each next role inherits permissions from the previous roles. A role block shows only the permissions added by that role.

The list below includes:

- standard permissions from the basic role-based model (k8s permissions);
- permissions created by Deckhouse's built-in modules.

It does not include permissions for modules from source.

When enabled in a cluster, modules from source create permissions for the resources they provide. When a module from source is disabled, the permissions it created are removed.

To view the permissions created by source modules, use the command.

`verbs` aliases:

- read - `get`, `list`, `watch`
- read-write - `get`, `list`, `watch`, `create`, `delete`, `deletecollection`, `patch`, `update`
- write - `create`, `delete`, `deletecollection`, `patch`, `update`

Role `User`:

You can get additional list of access rules for module role from cluster (rules added by the administrator and non-default rules of other Deckhouse modules):

```
D8_ROLE_NAME=Editor
d8 k get clusterrole -o jsonpath="{range .items[?(@.metadata.annotations.user-authz\.deckhouse\.io/access-level=='$D8_ROLE_NAME')]}{.rules}{'\n'}{end}" | jq -s add
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Configuration

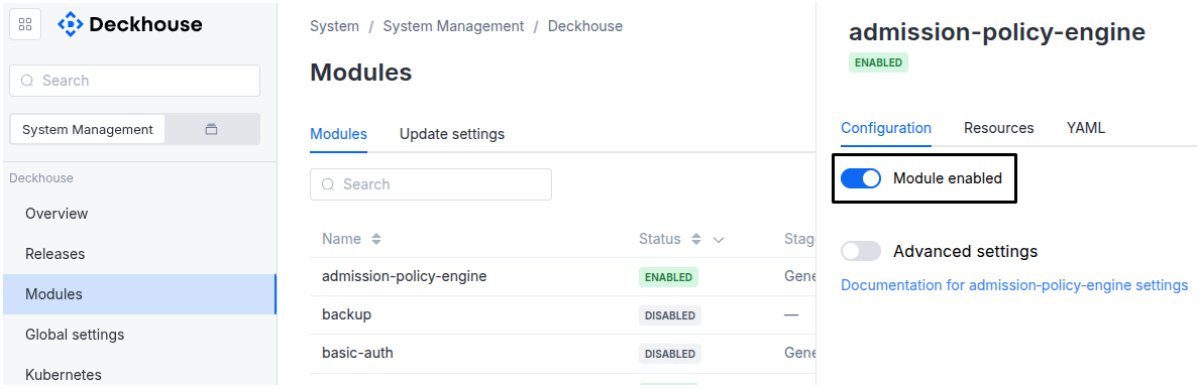
> Available with limitations in: **Open/CE**
>
> Available without limitations in: **Core, BE, SE, SE+, Ultimate/EE**

> **i** The module lifecycle stage: General Availability

> **⚠** Do not create Pods and ReplicaSets directly: these objects are secondary and should be created by controllers (Deployment, StatefulSet, Job, and others). The `User`, `PrivilegedUser`, `Editor`, and `ClusterEditor` access levels cannot create or modify Pods, and no access level below `SuperAdmin` can create or modify ReplicaSets.

In multi-tenancy mode, the `allowAccessToSystemNamespaces`, `namespaceSelector`, and `limitNamespaces` fields of ClusterAuthorizationRule are enforced by the authorization webhook. If the webhook is unavailable, the requests it has to answer are **denied**. The webhook does not check control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. For details, see Basic role-based model.

Access rights are configured with the roles of the granular model in RoleBinding and ClusterRoleBinding objects, or with the custom resources of the basic model.



The module has 26 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `user-authz` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

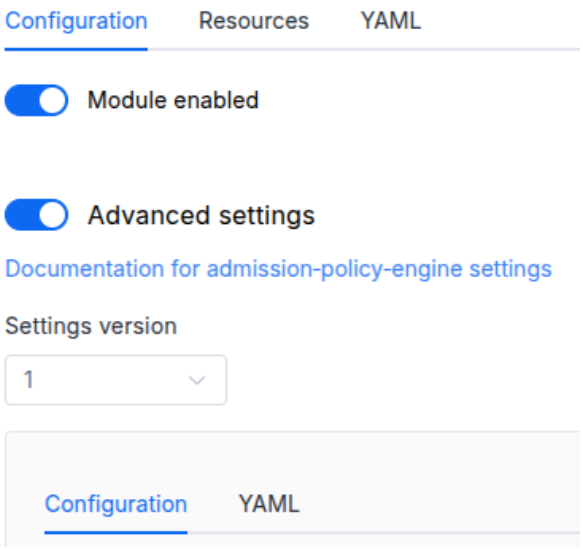
```
d8 system module enable user-authz
```

- **Using ModuleConfig `user-authz`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `user-authz` (create it if necessary);

  Example of a manifest to enable module `user-authz`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authz
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `user-authz` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `user-authz` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `user-authz`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `user-authz` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc user-authz
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `user-authz` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `user-authz`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: user-authz
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.controlPlaneConfigurator**

object

Parameters of the control-plane-manager module.

- **settings.controlPlaneConfigurator.enabled**
  boolean

  Passes parameters for configuring `authz-webhook` to the `control-plane-manager` module (see the parameters of the control-plane-manager module).

  If this parameter is disabled, the `control-plane-manager` module assumes that Webhook-based authorization is disabled by default. In this case (if no additional settings are provided), the `control-plane-manager` module will try to delete all references to the Webhook plugin from the manifest (even if you configure the manifest manually).

  Default: `true`

  Examples:

  ```
  enabled: true
  ```

  ```
  enabled: false
  ```

- **settings.enableMultiTenancy**
  boolean

  Available in editions: BE, SE, SE+, Ultimate/EE

  Enable namespace-based authorization (multi-tenancy mode).

  When enabled, the module deploys the authorization webhook on the master nodes and Permission Browser. They enforce the `namespaceSelector`, `limitNamespaces`, and `allowAccessToSystemNamespaces` fields of ClusterAuthorizationRule and serve WhoCan, SubjectAccessReport, and the filtered list of namespaces. The `kube-apiserver` settings are applied automatically by the control-plane-manager module, see Configuring kube-apiserver for multi-tenancy mode.

  Default: `false`

  Examples:

  ```
  enableMultiTenancy: true
  ```

  ```
  enableMultiTenancy: false
  ```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

Custom Resources

> The Deckhouse Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

AuthorizationRule

Scope: Namespaced
Version: v1alpha1

Manages RBAC and authorization settings within a particular namespace.

> **i** The AuthorizationRule resource belongs to the basic role-based model. Its permissions add up with those of the granular model.

- **status**
  object

  Observed state of the rule, maintained by user-authz-controller.

  - **status.bindings**
    integer

    Number of bindings rendered for the rule.

  - **status.conditions**
    array of objects

    Conditions of the rule. `Ready=True` means every binding of the rule is applied; `Ready=False` with reason `InvalidSpec` means the rule cannot be rendered and no binding was changed, with reason `ApplyError` that the API server rejected a write (the message names the binding and the error).

    - **status.conditions.lastTransitionTime**
      string

      Time of the last change of the condition status.

    - **status.conditions.message**
      string

      Details of the status.

    - **status.conditions.observedGeneration**
      integer

      Generation of the rule that the condition refers to.

    - **status.conditions.reason**
      string

      Reason of the status, `BindingsApplied`, `InvalidSpec` or `ApplyError`.

    - **status.conditions.status**
      string

      Required value

      Condition status.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Condition type. The controller sets `Ready`.

  - **status.observedGeneration**
    integer

    Generation of the rule the status refers to.

- **spec**
  object

  Required value

  - **spec.accessLevel**
    string

    Access level:

    - `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
    - `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
    - `Editor` — the same as `PrivilegedUser` + can create, edit, and delete the objects that

are usually required for application tasks;
- `Admin` — the same as `Editor` + can create and modify pods, create ServiceAccount tokens (`serviceaccounts/token`), manage `Role`, `RoleBinding`, and `AuthorizationRule` objects, and delete auxiliary objects (for example, `ReplicaSet` and the challenges and orders of the `acme.cert-manager.io` group).

Allowed values: `User`, `PrivilegedUser`, `Editor`, `Admin`

Example:

```
accessLevel: PrivilegedUser
```

- **spec.allowScale**
  boolean

  Defines if scaling of Deployments and StatefulSets is allowed/not allowed.

  Default: `false`

- **spec.portForwarding**
  boolean

  Allow/disallow the user to do `port-forwarding`.

  Default: `false`

- **spec.subjects**
  array of objects

  Required value

  Users, groups, and ServiceAccounts to grant the access level to.

  Kubernetes API reference

  Pay attention to the following nuances if this module is used together with the user-authn module:

  - Use the user's `email` as the username to grant privileges to the specific user;
  - When specifying a group, make sure that the necessary groups are allowed to be received from the provider, i.e., they are defined in the corresponding custom resource DexProvider.
  - **spec.subjects.kind**
    string

    Required value

    Type of user identification resource.

    Allowed values: `User`, `Group`, `ServiceAccount`

    Example:

    ```
    kind: Group
    ```

  - **spec.subjects.name**
    string

    Required value

    Resource name.

    Example:

    ```
    name: some-group-name
    ```

  - **spec.subjects.namespace**
    string

    ServiceAccount namespace.

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

ClusterAuthorizationRule

Scope: Cluster

- v1
- v1alpha1

This object manages RBAC and namespace-based authorization.

The settings determine which access level is assigned to the user and/or group.

> **i** The ClusterAuthorizationRule resource belongs to the basic role-based model. Its permissions add up with those of the granular model.

- **status**
  object

  Observed state of the rule, maintained by user-authz-controller.

  - **status.bindings**
    integer

    Number of bindings rendered for the rule.

  - **status.conditions**
    array of objects

    Conditions of the rule. `Ready=True` means every binding of the rule is applied; `Ready=False` with reason `InvalidSpec` means the rule cannot be rendered and no binding was changed, with reason `ApplyError` that the API server rejected a write (the message names the binding and the error).

    - **status.conditions.lastTransitionTime**
      string

      Time of the last change of the condition status.

    - **status.conditions.message**
      string

      Details of the status.

    - **status.conditions.observedGeneration**
      integer

      Generation of the rule that the condition refers to.

    - **status.conditions.reason**
      string

      Reason of the status, `BindingsApplied`, `InvalidSpec` or `ApplyError`.

    - **status.conditions.status**
      string

      Required value

      Condition status.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Condition type. The controller sets `Ready`.

  - **status.observedGeneration**
    integer

    Generation of the rule the status refers to.

- **spec**
  object

  Required value

  - **spec.accessLevel**

string

Access level:

- `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
- `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
- `Editor` — the same as `PrivilegedUser` + can create, edit, and delete the objects that are usually required for application tasks;
- `Admin` — the same as `Editor` + can create and modify pods, create ServiceAccount tokens (`serviceaccounts/token`), manage `Role`, `RoleBinding`, and `AuthorizationRule` objects, and delete auxiliary objects (for example, `ReplicaSet` and the challenges and orders of the `acme.cert-manager.io` group);
- `ClusterEditor` — the same as `Editor` + can manage a limited set of cluster-wide objects used in application tasks (`DaemonSet`, `StorageClass`, `CustomResourceDefinition`, `GatewayClass`, and the objects that modules add at this level, for example, `KeepalivedInstance`). This role is best suited for cluster operators.
- `ClusterAdmin` — the same as both `ClusterEditor` and `Admin` + can manage cluster-wide service objects (namespaces, quotas, `NetworkPolicy`, the proxy subresources of nodes, `ClusterAuthorizationRule`, `ClusterRole`, and `ClusterRoleBinding`). This role is best suited for cluster administrators.

  Warning. `ClusterAdmin` can create ClusterAuthorizationRule objects only up to the `ClusterAdmin` level, and ClusterRoleBinding objects only to roles whose permissions it already holds.
- `SuperAdmin` — can perform any actions with any objects (note that `limitNamespaces` and `namespaceSelector` (see below) restrictions remain valid).

Allowed values: `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, `ClusterAdmin`, `SuperAdmin`

Example:

```
accessLevel: PrivilegedUser
```

- **spec.additionalRoles**
  array of objects

  Additional roles to bind for subjects.

  Use the `accessLevel` parameter instead; this parameter is for exceptional cases.

  Example:

```
additionalRoles:
- apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: cluster-admin
```

  - **spec.additionalRoles.apiGroup**
    string

    Required value

    API group of the role. Only `rbac.authorization.k8s.io` is supported.

    Example:

```
apiGroup: rbac.authorization.k8s.io
```

  - **spec.additionalRoles.kind**
    string

    Required value

    Kind of the role.

    Allowed values: `ClusterRole`

    Example:

```
kind: ClusterRole
```

- **spec.additionalRoles.name**
  string

  Required value

  Name of the role.

  Example:

  ```
  name: cluster-admin
  ```

- **spec.allowAccessToSystemNamespaces**
  Deprecated
  boolean

  Available in editions: BE, SE, SE+, Ultimate/EE

  Allow access to system namespaces (`kube-*`, `d8-*`, `default`).

  Requires the enableMultiTenancy parameter. While it is disabled, a rule with this field is refused, and a rule that already has it is applied without its namespace limits, in every namespace of the cluster.

  The namespace limits of the rule are enforced by the authorization webhook, so they do not apply to the subjects that the webhook does not check: control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. For them, the access level of the rule applies in every namespace.

  Deprecated. Use the namespaceSelector field instead.

  Default: `false`

- **spec.allowScale**
  boolean

  Defines if scaling of Deployments and StatefulSets is allowed/not allowed.

  Default: `false`

- **spec.limitNamespaces**
  Deprecated
  array of strings

  Available in editions: BE, SE, SE+, Ultimate/EE

  List of regex-patterns that define namespaces accessible by the user.

  Each pattern must match the whole namespace name: `team` does not match `team-2`. A pattern that is not a valid RE2 regular expression is refused when the rule is written. If the check misses it, the pattern is ignored, the rule opens fewer namespaces, and the `D8UserAuthzWebhookRulesQuarantined` alert fires.

  The decision making process:

  - If the list is defined, then only its constituents are accessible.
  - If the list is not defined, then all namespaces are accessible (except for the system ones, see the `allowAccessToSystemNamespaces` field).

  Requires the enableMultiTenancy parameter. While it is disabled, a rule with this field is refused, and a rule that already has it is applied without its namespace limits, in every namespace of the cluster.

  The namespace limits of the rule are enforced by the authorization webhook, so they do not apply to the subjects that the webhook does not check: control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. For them, the access level of the rule applies in every namespace.

  Deprecated. Use the namespaceSelector field instead.

  Example:

  ```
  limitNamespaces: production-.*
  ```

  - **Element of the array**

string

- **spec.namespaceSelector**
  object

  Available in editions: BE, SE, SE+, Ultimate/EE

  Defines a set of namespaces accessible by the user, using the value of the `namespaceSelector.labelSelector` parameter.

  If the `namespaceSelector` parameter is specified, the values of the `limitNamespaces` and `allowAccessToSystemNamespaces` parameters are **ignored**. If the `namespaceSelector.matchAny` field is specified, then all namespaces (including system namespaces) will be accessible. Otherwise, only the namespaces with labels matching the `namespaceSelector.labelSelector` conditions will be accessible (including system namespaces).

  If the `namespaceSelector` parameter is not specified, then the set of available namespaces is determined by the value of the `limitNamespaces` and `allowAccessToSystemNamespaces` parameters. If none of the parameters `namespaceSelector`, `limitNamespaces` and `allowAccessToSystemNamespaces` are specified, then all namespaces will be available, except for the system ones (`kube-*`, `d8-*`, `default`).

  Requires the enableMultiTenancy parameter. While it is disabled, a rule with this field is refused, and a rule that already has it is applied without its namespace limits, in every namespace of the cluster.

  The namespace limits of the rule are enforced by the authorization webhook, so they do not apply to the subjects that the webhook does not check: control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. For them, the access level of the rule applies in every namespace.

  - **spec.namespaceSelector.labelSelector**
    object

    Defines the label selector-based filter of the namespaces.

    Cannot be used together with the `matchAny` parameter.

    If both `matchExpressions` and `matchLabels` parameters are set, their requirements are ANDed together — they must all be satisfied in order to match. If multiple `matchExpression` conditions are provided, they all must be satisfied in order to match.

    - **spec.namespaceSelector.labelSelector.matchExpressions**
      array of objects

      An array of set-based expressions.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      - key: tier
        operator: NotIn
        values:
        - production
      ```

      - **spec.namespaceSelector.labelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.namespaceSelector.labelSelector.matchExpressions.operator**
        string

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.namespaceSelector.labelSelector.matchExpressions.values**
        array of strings

A label value.

- **Element of the array**
  string

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

- **spec.namespaceSelector.labelSelector.matchLabels**
  object

  A set of labels a namespace must have to match.

  Example:

  ```
  matchLabels:
    foo: bar
    baz: who
  ```

- **spec.namespaceSelector.matchAny**
  boolean

  Unconditionally permits access to any namespace in the cluster, including system namespaces.

  Cannot be used together with the `labelSelector` parameter.

  Since `labelSelector` provides access to a limited number of the namespaces that match it, `matchAny` is needed in cases where access to all namespaces is to be granted.

  Allowed values: `true`

- **spec.portForwarding**
  boolean

  Allow/disallow the user to do `port-forwarding`.

  Default: `false`

- **spec.subjects**
  array of objects

  Required value

  Users, groups, and ServiceAccounts to grant the access level to.

  Kubernetes API reference

  Pay attention to the following nuances if this module is used together with the user-authn module:

  - Use the user's `email` as the username to grant privileges to the specific user;
  - When specifying a group, make sure that the necessary groups are allowed to be received from the provider, i.e., they are defined in the corresponding custom resource DexProvider.
  - **spec.subjects.kind**
    string

    Required value

    Type of user identification resource.

    Allowed values: `User`, `Group`, `ServiceAccount`

    Example:

    ```
    kind: Group
    ```

  - **spec.subjects.name**
    string

    Required value

    Resource name.

    Example:

```
name: some-group-name
```

- **spec.subjects.namespace**
  string

  ServiceAccount namespace. The namespace limits of the rule do not apply to the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`: the authorization webhook does not check them.

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

Deprecated resource. Support for the resource might be removed in a later release.

This cluster-wide object manages RBAC and authorization.

> **i** The ClusterAuthorizationRule resource belongs to the basic role-based model. Its permissions add up with those of the granular model.

- **status**
  object

  Observed state of the rule, maintained by user-authz-controller.

  - **status.bindings**
    integer

    Number of bindings rendered for the rule.

  - **status.conditions**
    array of objects

    Conditions of the rule. `Ready=True` means every binding of the rule is applied; `Ready=False` with reason `InvalidSpec` means the rule cannot be rendered and no binding was changed, with reason `ApplyError` that the API server rejected a write (the message names the binding and the error).

    - **status.conditions.lastTransitionTime**
      string

      Time of the last change of the condition status.

    - **status.conditions.message**
      string

      Details of the status.

    - **status.conditions.observedGeneration**
      integer

      Generation of the rule that the condition refers to.

    - **status.conditions.reason**
      string

      Reason of the status, `BindingsApplied`, `InvalidSpec` or `ApplyError`.

    - **status.conditions.status**
      string

      Required value

      Condition status.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Condition type. The controller sets `Ready`.

  - **status.observedGeneration**
    integer

Generation of the rule the status refers to.

- **spec**
  object

  Required value

  - **spec.accessLevel**
    string

    Access level:

    - `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
    - `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
    - `Editor` — the same as `PrivilegedUser` + can create, edit, and delete the objects that are usually required for application tasks;
    - `Admin` — the same as `Editor` + can create and modify pods, create ServiceAccount tokens (`serviceaccounts/token`), manage `Role`, `RoleBinding`, and `AuthorizationRule` objects, and delete auxiliary objects (for example, `ReplicaSet` and the challenges and orders of the `acme.cert-manager.io` group);
    - `ClusterEditor` — the same as `Editor` + can manage a limited set of cluster-wide objects used in application tasks (`DaemonSet`, `StorageClass`, `CustomResourceDefinition`, `GatewayClass`, and the objects that modules add at this level, for example, `KeepalivedInstance`). This role is best suited for cluster operators.
    - `ClusterAdmin` — the same as both `ClusterEditor` and `Admin` + can manage cluster-wide service objects (namespaces, quotas, `NetworkPolicy`, the proxy subresources of nodes, `ClusterAuthorizationRule`, `ClusterRole`, and `ClusterRoleBinding`). This role is best suited for cluster administrators.

      Warning. `ClusterAdmin` can create ClusterAuthorizationRule objects only up to the `ClusterAdmin` level, and ClusterRoleBinding objects only to roles whose permissions it already holds.
    - `SuperAdmin` — can perform any actions with any objects (note that `limitNamespaces` (see below) restrictions remain valid).

    Allowed values: `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, `ClusterAdmin`, `SuperAdmin`

    Example:

    ```
    accessLevel: PrivilegedUser
    ```

  - **spec.additionalRoles**
    array of objects

    Additional roles to bind for subjects.

    Use the `accessLevel` parameter instead; this parameter is for exceptional cases.

    Example:

    ```
    additionalRoles:
    - apiGroup: rbac.authorization.k8s.io
      kind: ClusterRole
      name: cluster-admin
    ```

    - **spec.additionalRoles.apiGroup**
      string

      Required value

      API group of the role. Only `rbac.authorization.k8s.io` is supported.

      Example:

      ```
      apiGroup: rbac.authorization.k8s.io
      ```

    - **spec.additionalRoles.kind**
      string

Required value

Kind of the role.

Allowed values: `ClusterRole`

Example:

```
kind: ClusterRole
```

- **spec.additionalRoles.name**
  string

  Required value

  Name of the role.

  Example:

  ```
  name: cluster-admin
  ```

- **spec.allowAccessToSystemNamespaces**
  Deprecated
  boolean

  Available in editions: BE, SE, SE+, Ultimate/EE

  Allow access to system namespaces (`kube-*`, `d8-*`, `default`).

  Requires the enableMultiTenancy parameter. While it is disabled, a rule with this field is refused, and a rule that already has it is applied without its namespace limits, in every namespace of the cluster.

  The namespace limits of the rule are enforced by the authorization webhook, so they do not apply to the subjects that the webhook does not check: control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. For them, the access level of the rule applies in every namespace.

  Deprecated. Use the namespaceSelector parameter (API version `v1` of the CR) instead.

  Default: `false`

- **spec.allowScale**
  boolean

  Defines if scaling of Deployments and StatefulSets is allowed/not allowed.

  Default: `false`

- **spec.limitNamespaces**
  Deprecated
  array of strings

  Available in editions: BE, SE, SE+, Ultimate/EE

  List of regex-patterns that define namespaces accessible by the user.

  Each pattern must match the whole namespace name: `team` does not match `team-2`. A pattern that is not a valid RE2 regular expression is refused when the rule is written. If the check misses it, the pattern is ignored, the rule opens fewer namespaces, and the `D8UserAuthzWebhookRulesQuarantined` alert fires.

  The decision making process:

  - If the list is defined, then only its constituents are accessible.
  - If the list is not defined, then all namespaces are accessible (except for the system ones, see the `allowAccessToSystemNamespaces` field).

  Requires the enableMultiTenancy parameter. While it is disabled, a rule with this field is refused, and a rule that already has it is applied without its namespace limits, in every namespace of the cluster.

  The namespace limits of the rule are enforced by the authorization webhook, so they do not apply to the subjects that the webhook does not check: control plane components, kubelets, and the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`. For them, the access level of the rule applies in every namespace.

Deprecated. Use the namespaceSelector parameter (API version `v1` of the CR) instead.

Example:

```
limitNamespaces: production-.*
```

- **Element of the array**
  string

- **spec.portForwarding**
  boolean

  Allow/disallow the user to do `port-forwarding`.

  Default: `false`

- **spec.subjects**
  array of objects

  Required value

  Users, groups, and ServiceAccounts to grant the access level to.

  Kubernetes API reference

  Pay attention to the following nuances if this module is used together with the user-authn module:

  - Use the user's `email` as the username to grant privileges to the specific user;
  - When specifying a group, make sure that the necessary groups are allowed to be received from the provider, i.e., they are defined in the corresponding custom resource DexProvider.
  - **spec.subjects.kind**
    string

    Required value

    Type of user identification resource.

    Allowed values: `User`, `Group`, `ServiceAccount`

    Example:

    ```
    kind: Group
    ```

  - **spec.subjects.name**
    string

    Required value

    Resource name.

    Example:

    ```
    name: some-group-name
    ```

  - **spec.subjects.namespace**
    string

    ServiceAccount namespace. The namespace limits of the rule do not apply to the ServiceAccounts of `kube-system` and of the namespaces whose names start with `d8-`: the authorization webhook does not check them.

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Usage

> The module lifecycle stage: General Availability

Example of assigning rights to a cluster administrator

> The example uses the granular role-based model.

To grant access to a cluster administrator, use the role `d8:system:manager` in ClusterRoleBinding.

Example of assigning rights to a cluster administrator (User `jane.doe@example.com`):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: cluster-admin-jane
subjects:
- kind: User
  name: jane.doe@example.com
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:system:manager
  apiGroup: rbac.authorization.k8s.io
```

The rights that the user will get

The user gets access to cluster-wide resources, to the configuration of Deckhouse Platform modules, and to the namespaces of the enabled Deckhouse Platform modules. The user gets no access to the namespaces of user applications.

The user will be able to:

- View, modify, delete, and create Kubernetes resources and Deckhouse Platform modules;
- Modify module configurations (view, modify, delete, and create `moduleConfig` resources);
- Execute the following commands on pods and services:
  - `kubectl attach`
  - `kubectl exec`
  - `kubectl port-forward`
  - `kubectl proxy`

Example of assigning rights to a network administrator

> The example uses the granular role-based model.

To grant a network administrator access to manage the network subsystem of the cluster, use the role `d8:subsystem:network:manager` in ClusterRoleBinding.

Example of assigning rights to a network administrator (User `jane.doe@example.com`):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: network-admin-jane
subjects:
- kind: User
  name: jane.doe@example.com
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:subsystem:network:manager
  apiGroup: rbac.authorization.k8s.io
```

The rights that the user will get

The rights that the user will get will be limited to the following list of Deckhouse Platform module namespaces from the `network` subsystem (the actual list depends on the list of modules included in the cluster):

- `d8-cni-cilium`
- `d8-cni-flannel`
- `d8-cni-simple-bridge`
- `d8-ingress-nginx`
- `d8-istio`
- `d8-keepalived`
- `d8-metallb`
- `d8-monitoring`
- `d8-network-gateway`
- `d8-openvpn`
- `d8-service-with-healthchecks`
- `d8-static-routing-manager`
- `d8-system`
- `kube-system`

The user will be able to:

- View, modify, delete, and create *standard* Kubernetes resources in the module namespace from the `network` subsystem.

  Example of resources that the user will be able to manage (the list is not exhaustive):

  - `Certificate`
  - `CertificateRequest`
  - `ConfigMap`
  - `ControllerRevision`
  - `CronJob`
  - `DaemonSet`
  - `Deployment`
  - `Event`
  - `HorizontalPodAutoscaler`
  - `Ingress`
  - `Issuer`
  - `Job`
  - `Lease`
  - `LimitRange`
  - `NetworkPolicy`
  - `PersistentVolumeClaim`
  - `Pod`
  - `PodDisruptionBudget`
  - `ReplicaSet`
  - `ReplicationController`
  - `ResourceQuota`
  - `Role`
  - `RoleBinding`
  - `Secret`
  - `Service`
  - `ServiceAccount`
  - `StatefulSet`
  - `VerticalPodAutoscaler`
  - `VolumeSnapshot`

- View, modify, delete, and create the following resources in the modules namespace from the `network` subsystem:

  A list of resources that the user will be able to manage:

  - `EgressGateway`
  - `EgressGatewayPolicy`
  - `FlowSchema`
  - `IngressClass`
  - `IngressIstioController`
  - `IngressNginxController`
  - `IPRuleSet`
  - `IstioFederation`
  - `IstioMulticluster`
  - `KeepalivedInstance`
  - `RoutingTable`

- Modify the configuration of modules (view, change, delete, and create moduleConfig resources) from the `network` subsystem.

  List of modules that the user will be able to manage:

  - `cilium-hubble`
  - `cni-cilium`
  - `cni-flannel`
  - `cni-simple-bridge`
  - `ingress-nginx`
  - `istio`
  - `keepalived`
  - `kube-dns`
  - `kube-proxy`
  - `metallb`
  - `monitoring-ping`
  - `network-gateway`
  - `network-policy-engine`
  - `node-local-dns`
  - `openvpn`
  - `sdn`
  - `service-with-healthchecks`
  - `static-routing-manager`

- Execute the following commands with pods and services in the modules namespace from the `network` subsystem:

  - `kubectl attach`
  - `kubectl exec`
  - `kubectl port-forward`
  - `kubectl proxy`

Example of assigning administrative rights to a user within a namespace

> **i** The example uses the granular role-based model.

To assign rights to a user to manage application resources within a namespace (including some namespaced Deckhouse Platform module resources such as DexAuthenticator), use the role `d8:namespace:admin` in a RoleBinding in the corresponding namespace. Cluster-wide module configuration is not included.

Example of assigning rights to an application developer (User `app-developer`) in namespace `myapp`:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: myapp-developer
  namespace: myapp
subjects:
- kind: User
  name: app-developer@example.com
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:namespace:admin
  apiGroup: rbac.authorization.k8s.io
```

The rights that the user will get

In the `myapp` namespace, the user will be able to:

- View, modify, delete, and create Kubernetes resources. For example, the following resources (the list is not exhaustive):
  - `Certificate`
  - `CertificateRequest`
  - `ConfigMap`
  - `ControllerRevision`
  - `CronJob`
  - `DaemonSet`
  - `Deployment`
  - `Event`
  - `HorizontalPodAutoscaler`
  - `Ingress`
  - `Issuer`
  - `Job`
  - `Lease`
  - `LimitRange`
  - `NetworkPolicy`
  - `PersistentVolumeClaim`
  - `Pod`
  - `PodDisruptionBudget`
  - `ReplicaSet`
  - `ReplicationController`
  - `ResourceQuota`
  - `Role`
  - `RoleBinding`
  - `Secret`
  - `Service`
  - `ServiceAccount`
  - `StatefulSet`
  - `VerticalPodAutoscaler`
  - `VolumeSnapshot`
- View, edit, delete, and create the following Deckhouse Platform module resources:
  - `DexAuthenticator`
  - `DexClient`
  - `PodLoggingConfig`
- Execute the following commands for pods and services:
  - `kubectl attach`
  - `kubectl exec`
  - `kubectl port-forward`
  - `kubectl proxy`

The user will **not** get the operations reserved for the `superadmin` level (see the section Admin level restrictions and superadmin rights): minting ServiceAccount tokens, making requests on behalf of ServiceAccounts, modifying platform system resources in this namespace, and connecting to system pods.

An example of assigning rights across all namespaces of a project

> **i** The example uses the granular role-based model and the multitenancy-manager module.

If the namespaces are grouped into a project, a role can be granted for the whole project at once — it will automatically apply in all of its namespaces, including those created later. To do that, use a ProjectRoleBinding in the main namespace of the project instead of RoleBinding:

```
apiVersion: deckhouse.io/v1alpha3
kind: ProjectRoleBinding
metadata:
  name: team-developers
  namespace: my-project
spec:
  subjects:
    - kind: Group
      name: developers
  roleRef:
    kind: ClusterRole
    name: d8:project:user
```

For more details on role bindings in projects, see the multitenancy-manager module documentation.

An example of a ClusterAuthorizationRule

> **i** The example uses the basic role-based model.

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: test-rule
spec:
  subjects:
  - kind: User
    name: some@example.com
  - kind: ServiceAccount
    name: gitlab-runner-deploy
    namespace: ci
  - kind: Group
    name: some-group-name
  accessLevel: PrivilegedUser
  portForwarding: true
  # This option is only available if the enableMultiTenancy parameter is set.
  namespaceSelector:
    labelSelector:
      matchExpressions:
      - key: stage
        operator: In
        values:
        - test
        - review
      matchLabels:
        team: frontend
```

A `User` or `Group` subject is matched by name against the user identity in the token. A locally managed identity is indistinguishable from one asserted by an external authentication provider. Because of that, you can't create a User whose `spec.email` or a Group whose `spec.name` matches a subject of an existing ClusterAuthorizationRule or AuthorizationRule. This prevents any unnoticed attempt to grant the identity privileges.

If the match is intentional, for example, if the ClusterAuthorizationRule has been written in advance, set the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation on the User or Group. The annotation only acknowledges the name collision. It does not let a requester assign roles they cannot cover or that sit outside their can-assign range.

Deleting a ClusterAuthorizationRule uses the same can-assign check as creating or updating it. You can

remove a grant only if you could assign those roles. An update is checked against both the previous and the new grants, so lowering `SuperAdmin` to `User` still requires being able to assign `SuperAdmin`.

Write an email for the `User` subject in lowercase. It's recorded to the token in lowercase so a subject spelled `Admin@Example.com` won't match `admin@example.com`. Names of `Group` subjects are matched exactly, because group names are not lowercased anywhere.

This restriction is applied when a User or Group is created and when its `spec.email` or `spec.name` is changed. Deleting a User or Group whose name a rule still grants privileges to is allowed with a warning: the name stays granted, and recreating the object restores the privileges. The restriction doesn't prevent adding existing users or groups to a ClusterAuthorizationRule or AuthorizationRule. If a matching User or Group already exists, it receives the privileges immediately after it's added to the rule.

Managing permissions via CLI

> **i** The `d8 iam access` command uses the basic role-based model.

The `d8 iam access` command provides a convenient way to manage authorization rules without writing YAML manifests. `d8 iam access grant` creates ClusterAuthorizationRule and AuthorizationRule objects, and `d8 iam access revoke` deletes only the objects created by `grant`.

The command works with the basic role-based model, and with users and groups only. Grant roles of the granular model with RoleBinding and ClusterRoleBinding objects. Give access to a ServiceAccount with a manifest, see Creating a ServiceAccount for a machine and granting it access. The `d8 iam get user` and `d8 iam list users` commands count only ClusterAuthorizationRule and AuthorizationRule objects. To see all the access of a subject, use SubjectAccessReport.

Available access levels: `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, `ClusterAdmin`, `SuperAdmin`.

Examples of granting permissions with the `d8 iam access` command:

Grant the Admin role to a user in the `dev` namespace:

```
d8 iam access grant user anton --access-level Admin -n dev
```

Grant the Admin role to a user in multiple namespaces:

```
d8 iam access grant user anton --access-level Admin -n dev -n stage
```

Grant a cluster-wide role to a user (excluding system namespaces):

```
d8 iam access grant user anton --access-level ClusterAdmin --scope cluster
```

Grant a cluster-wide role to a user in all namespaces (including system namespaces):

```
d8 iam access grant user anton --access-level ClusterAdmin --scope all-namespaces
```

Grant a role to group members by a namespace label selector:

```
d8 iam access grant group admins --access-level Editor --scope labels=team=platform,tier=prod
```

`--scope cluster` leaves out the system namespaces only in multi-tenancy mode; without it, the rule grants its access level in every namespace, system ones included. `--scope labels=...` and `--scope all-namespaces` need multi-tenancy mode: without it, the rule is refused. A rule created with `-n` is an AuthorizationRule and applies only in its namespace.

Grant a role to group members with additional capabilities:

```
d8 iam access grant group admins --access-level Editor -n dev --port-forwarding --allow-scale
```

Preview the manifest without applying it:

```
d8 iam access grant user anton --access-level Admin -n dev --dry-run -o yaml
```

Revoke a user’s permissions in a namespace:

```
d8 iam access revoke user anton --access-level Admin -n dev
```

Revoke a user’s cluster-wide permissions:

```
d8 iam access revoke user anton --access-level ClusterAdmin --scope cluster
```

The access level and the scope must match the original grant.

List all access rules in the cluster:

```
d8 iam list rules
```

Show detailed information about a specific rule. Name a ClusterAuthorizationRule as `CAR/<NAME>` and an AuthorizationRule as `AR/<NAMESPACE>/<NAME>`:

```
d8 iam get rule CAR/<NAME>
d8 iam get rule AR/<NAMESPACE>/<NAME>
```

Example of granting access to all namespaces

> **i** The example refers to the basic role-based model.

In multi-tenancy mode (`userAuthz.enableMultiTenancy`), namespace-based restrictions are configured using the ClusterAuthorizationRule resource fields.

Configuration options:

- **Allow access to all namespaces, including system namespaces** (`kube-*`, `d8-*`, `default`). To allow access to all namespaces, including system namespaces, set `spec.namespaceSelector.matchAny: true`. If the `namespaceSelector` parameter is specified, the values of the deprecated `limitNamespaces` and `allowAccessToSystemNamespaces` parameters are **ignored**. Access to the system namespaces with the `Admin` or `ClusterAdmin` level is equivalent to a cluster administrator: those namespaces hold the ServiceAccounts of the platform (see Access of system and subsystem roles to the namespaces of the modules).

  Example:

  ```
  apiVersion: deckhouse.io/v1
  kind: ClusterAuthorizationRule
  metadata:
    name: all-namespaces-including-system
  spec:
    subjects:
    - kind: User
      name: user@example.com
    accessLevel: Editor
    namespaceSelector:
      matchAny: true
  ```

- **Allow access to all namespaces except system namespaces**. To grant a user access to all namespaces except system namespaces, do not specify `namespaceSelector` or the deprecated `limitNamespaces` and `allowAccessToSystemNamespaces` parameters when creating a ClusterAuthorizationRule. For a list of system namespaces, see the CR field description.

> **i** The `SuperAdmin` access level **does not lift** the namespace restrictions specified in the `namespaceSelector` and `limitNamespaces` parameters. If you need to grant access to all namespaces, specify the scope explicitly, including via `namespaceSelector.matchAny`.

If several `ClusterAuthorizationRule` resources match the same subject, the allowed namespaces are **combined**; the effective `accessLevel` is the **most powerful** among all matching rules. For details, refer to the FAQ.

⚠ Namespace restrictions from ClusterAuthorizationRule are enforced by the authorization webhook. The API server calls it before RBAC with `failurePolicy: Deny`, so if the webhook is unavailable, the requests it has to answer are **denied**. The webhook does not check control plane components, kubelets, and the ServiceAccounts of the `kube-system` namespace and of the namespaces whose names start with `d8-`. Namespace restrictions do not apply to them. For details, see the module description.

Granular role-based model

In the granular model, bind `d8:namespace:*` roles with a RoleBinding in each namespace, or use a ProjectRoleBinding to cover every namespace of a project. `d8:system:*` / `d8:subsystem:*` roles do not cover namespaces for user workloads; they only apply to system namespaces (`d8-*`, `kube-*`) within the subsystem.

Creating a user

There are two types of users in Kubernetes:

- Service accounts managed by Kubernetes via the API;
- Regular users and groups managed by some external tool that the cluster administrator configures. There are many authentication mechanisms and, accordingly, many ways to create users. Currently, two authentication methods are supported:
  - Via the `user-authn` module. The module supports the following external providers and authentication protocols: GitHub, GitLab, Bitbucket Cloud, Atlassian Crowd, LDAP, OIDC, SAML, and local users (the User object). More details — in the documentation of the `user-authn` module.
  - Via the certificates.

When issuing the authentication certificate, you need to specify the name (`CN=<name>`), the required number of groups (`O=<group>`), and sign it using the root CA of the cluster. It is this mechanism that authenticates you in the cluster when, for example, you use kubectl on a master node.

Creating a ServiceAccount for a machine and granting it access

ℹ The example uses the basic role-based model.

You may need to create a ServiceAccount with access to the Kubernetes API when, for example, an application is deployed using a CI system.

1. Create a namespace for CI, for example `ci`, and a ServiceAccount in it:

```
d8 k create -f - <<EOF
apiVersion: v1
kind: Namespace
metadata:
  name: ci
---
apiVersion: v1
kind: ServiceAccount
metadata:
  name: gitlab-runner-deploy
  namespace: ci
---
apiVersion: v1
kind: Secret
metadata:
  name: gitlab-runner-deploy-token
  namespace: ci
  annotations:
    kubernetes.io/service-account.name: gitlab-runner-deploy
type: kubernetes.io/service-account-token
EOF
```

2. Grant it the necessary privileges (using the ClusterAuthorizationRule custom resource):

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: gitlab-runner-deploy
spec:
  subjects:
  - kind: ServiceAccount
    name: gitlab-runner-deploy
    namespace: ci
  accessLevel: Editor
EOF
```

   If multi-tenancy mode is enabled (the `enableMultiTenancy` parameter), limit the namespaces the ServiceAccount has access to with the `namespaceSelector` parameter.

   ⚠ Do not create ServiceAccounts for external systems in `kube-system` or in namespaces whose names start with `d8-`. The authorization webhook does not check the ServiceAccounts of these namespaces, so the namespace limits of a ClusterAuthorizationRule (`namespaceSelector`, `limitNamespaces`, `allowAccessToSystemNamespaces`) do not apply to them. Their access level applies in every namespace of the cluster, including system namespaces.

3. Set the variable values (they will be used later) by running the following commands (**insert your own values**):

```
export CLUSTER_NAME=my-cluster
export USER_NAME=gitlab-runner-deploy.my-cluster
export CONTEXT_NAME=${CLUSTER_NAME}-${USER_NAME}
export FILE_NAME=kube.config
```

4. Generate the `cluster` section in the kubectl configuration file:

   Use one of the following options to access the cluster API server:

   - If there is direct access to the API server:
     1. Get a Kubernetes cluster CA certificate:

```
d8 k get cm kube-root-ca.crt -o jsonpath='{ .data.ca\.crt }' > /tmp/ca.crt
```

2. Generate the `cluster` section (the API server's IP address is used for access):

```
d8 k config set-cluster $CLUSTER_NAME --embed-certs=true \
  --server=https://$(d8 k get endpointslices -l kubernetes.io/service-name=kubernetes
-o json | jq -rc '.items[0] | "\(.endpoints[0].addresses[0]):\
(.ports[0].port)"') \
  --certificate-authority=/tmp/ca.crt \
  --kubeconfig=$FILE_NAME
```

- If there is no direct access to the API server, use one of the following options:
  - enable access to the API-server over the Ingress controller (the apiserver.publishAPI parameter of the `control-plane-manager` module) and specify the addresses from which requests originate (the whitelistSourceRanges parameter);
  - specify addresses from which requests will originate in a separate Ingress controller (the acceptRequestsFrom parameter).
- If a non-public CA is used:

  1. Get the CA certificate from the Secret of the `kubernetes-api` Ingress in the `kube-system` namespace. It is the certificate of the `api.%s` domain:

```
d8 k -n kube-system get secrets -o json \
  $(d8 k -n kube-system get ing kubernetes-api -o jsonpath="
{.spec.tls[0].secretName}") \
  | jq -rc '.data."ca.crt" // .data."tls.crt"' \
  | base64 -d > /tmp/ca.crt
```

  2. Generate the `cluster` section (an external domain and a CA for access are used):

```
d8 k config set-cluster $CLUSTER_NAME --embed-certs=true \
  --server=https://$(d8 k -n kube-system get ing kubernetes-api -ojson | jq
'.spec.rules[].host' -r) \
  --certificate-authority=/tmp/ca.crt \
  --kubeconfig=$FILE_NAME
```

- If a public CA is used. Generate the `cluster` section (an external domain is used for access):

```
d8 k config set-cluster $CLUSTER_NAME \
  --server=https://$(d8 k -n kube-system get ing kubernetes-api -ojson | jq
'.spec.rules[].host' -r) \
  --kubeconfig=$FILE_NAME
```

- If the API server is published through Gateway API, the cluster has the `kubernetes-api` HTTPRoute in the `kube-system` namespace instead of the Ingress. Take the host from it instead of `.spec.rules[].host` in the commands above:

```
d8 k -n kube-system get httproute kubernetes-api -o jsonpath='{.spec.hostnames[0]}'
```

  Take the name of the Secret with the CA certificate from the `control-plane-manager` ListenerSet instead of `.spec.tls[0].secretName`:

```
d8 k -n kube-system get listenerset control-plane-manager -o
jsonpath='{.spec.listeners[?(@.name=="api")].tls.certificateRefs[0].name}'
```

5. Generate the `user` section using the token from the Secret's ServiceAccount in the kubectl configuration file:

```
d8 k config set-credentials $USER_NAME \
  --token=$(d8 k -n ci get secret gitlab-runner-deploy-token -o json |jq -r
'.data["token"]' | base64 -d) \
  --kubeconfig=$FILE_NAME
```

6. Generate the context in the kubectl configuration file:

```
d8 k config set-context $CONTEXT_NAME \
  --cluster=$CLUSTER_NAME --user=$USER_NAME \
  --kubeconfig=$FILE_NAME
```

7. Set the generated context as the default one in the kubectl configuration file:

```
d8 k config use-context $CONTEXT_NAME --kubeconfig=$FILE_NAME
```

How to create a user using a client certificate

> **i** This method is recommended for system needs (authentication of kubelets, control plane components, etc.). If you need to create a “normal” user (e.g. with console access, `kubectl`, etc.), use kubeconfig generation.

To create a user with a client certificate, you can use either OpenSSL or the Kubernetes API (via the CertificateSigningRequest object).

> **⚠** Certificates issued by any of these methods cannot be revoked. If a certificate is compromised, you will need to remove all permissions for that user (this can be difficult if the user is added to any groups: you will also need to remove all relevant groups).

Creating a user using a certificate issued via OpenSSL

> **⚠** Consider security risks when using this method.
>
> The `ca.crt` and `ca.key` must not leave the master node: sign the CSR only on the master node.
>
> Signing CSRs outside the master node risks compromising the cluster root certificate.

The features of this method are:

- The client certificate must be signed on the master node to prevent the cluster certificate from being compromised.
- Access to the cluster CA key (`ca.key`) is required. Only the cluster administrator can sign certificates.

To create a user using a client certificate issued through OpenSSL, follow these steps:

1. Make sure you have access to a master node. The cluster CA files `ca.crt` and `ca.key` are in `/etc/kubernetes/pki/` on it.
2. Generate the user key:

```
openssl ecparam -name prime256v1 -genkey -out myuser.key
```

3. Create a CSR file and specify the username in it (`myuser`) and groups to which this user belongs (`mygroup1` and `mygroup2`):

```
openssl req -new -key myuser.key -out myuser.csr -subj
"/CN=myuser/O=mygroup1/O=mygroup2"
```

4. Upload the CSR created in the previous step (`myuser.csr` in this example) to the master node

and sign it with the cluster root certificate. Example command to sign the CSR on the master node (make sure that the paths to `myuser.csr`, `ca.crt` and `ca.key` are correct for your case):

```
openssl x509 -req -in myuser.csr -CA /etc/kubernetes/pki/ca.crt -CAkey
/etc/kubernetes/pki/ca.key -CAcreateserial -out myuser.crt -days 10
```

Now the certificate can be specified in the config file:

```
cat << EOF
apiVersion: v1
clusters:
- cluster:
    certificate-authority-data: $(cat /etc/kubernetes/pki/ca.crt | base64 -w0)
    server: https://<cluster_host>:6443
  name: kubernetes
contexts:
- context:
    cluster: kubernetes
    user: myuser
  name: myuser@kubernetes
current-context: myuser@kubernetes
kind: Config
preferences: {}
users:
- name: myuser
  user:
    client-certificate-data: $(cat myuser.crt | base64 -w0)
    client-key-data: $(cat myuser.key | base64 -w0)
EOF
```

Creating a user by issuing a certificate via the Kubernetes API

This is a more secure method because a special kubernetes API is used to sign the certificate.

The features of this method are:

- API-based certificate signing: CSRs are processed through the Kubernetes API without requiring access to the CA's private key (`ca.key`).
- Not only the cluster administrator can issue client certificates. The right to create CSRs and sign them can be assigned to a specific user.

To create a user using a client certificate issued through the Kubernetes API, follow these steps:

1. Generate the user key:

   ```
   openssl ecparam -name prime256v1 -genkey -out myuser.key
   ```

2. Create a CSR file and specify in it the username (`myuser`) and groups to which this user belongs (`mygroup1` and `mygroup2`):

   ```
   openssl req -new -key myuser.key -out myuser.csr -subj
   "/CN=myuser/O=mygroup1/O=mygroup2"
   ```

3. Create a manifest for the CertificateSigningRequest object and save it to a file (`csr.yaml` in this example):

   > **i** In the `request` field, replace `<CSR_BASE64>` with the contents of `myuser.csr` encoded in Base64 without line breaks, for example, the output of `base64 < myuser.csr | tr -d '\n'` .

```
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
metadata:
  name: demo-client-cert
spec:
  request: <CSR_BASE64>
  signerName: "kubernetes.io/kube-apiserver-client"
  expirationSeconds: 7200
  usages:
  - "digital signature"
  - "client auth"
```

4. Apply the manifest to create a certificate signing request:

   ```
   d8 k apply -f csr.yaml
   ```

5. Check that the certificate has been approved and issued:

   ```
   d8 k get csr demo-client-cert
   ```

   If the certificate is issued, it will have the value `Approved,Issued` in the `CONDITION` column. Example output:

   ```
    NAME               AGE     SIGNERNAME                                    REQUESTOR
   REQUESTEDDURATION   CONDITION
    demo-client-cert   8m24s   kubernetes.io/kube-apiserver-client   kubernetes-
   admin   120m                Approved,Issued
   ```

   If the certificate is not automatically verified, verify it:

   ```
   d8 k certificate approve demo-client-cert
   ```

   Then, confirm that the certificate has been successfully approved.

6. Extract the encoded certificate from the CSR named `demo-client-cert`, decode it from Base64 and save it to a file (`myuser.crt` in this example):

   ```
   d8 k get csr demo-client-cert -ojsonpath="{.status.certificate}" | base64 -d >
   myuser.crt
   ```

Now the certificate can be specified in the config file:

```
cat << EOF
apiVersion: v1
clusters:
- cluster:
    certificate-authority-data: $(cat /etc/kubernetes/pki/ca.crt | base64 -w0)
    server: https://<cluster_host>:6443
  name: kubernetes
contexts:
- context:
    cluster: kubernetes
    user: myuser
  name: myuser@kubernetes
current-context: myuser@kubernetes
kind: Config
preferences: {}
users:
- name: myuser
  user:
    client-certificate-data: $(cat myuser.crt | base64 -w0)
    client-key-data: $(cat myuser.key | base64 -w0)
EOF
```

Granting access to the created user

> **i** The example uses the basic role-based model.

To grant access to the created user, create a ClusterAuthorizationRule.

Example of a `ClusterAuthorizationRule`:

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: myuser
spec:
  subjects:
  - kind: User
    name: myuser
  accessLevel: PrivilegedUser
  portForwarding: true
```

Configuring kube-apiserver for multi-tenancy mode

The multi-tenancy mode, which allows you to restrict access to namespaces, is enabled by the enableMultiTenancy module's parameter.

Working in multi-tenancy mode requires enabling the Webhook authorization plugin and configuring a `kube-apiserver.` All actions necessary for the multi-tenancy mode are performed **automatically** by the control-plane-manager module; no additional steps are required.

Multi-tenancy mode is available in the editions listed in the parameter description. The API server is configured automatically while the `controlPlaneConfigurator.enabled` parameter is `true`.

Changes to the `kube-apiserver` manifest that will occur after enabling multi-tenancy mode:

- The `--authorization-mode=Node,RBAC` flag is replaced with the structured authorization configuration (`--authorization-config=/etc/kubernetes/deckhouse/extra-files/authorization-config.yaml`) with the `Node`, `Webhook`, and `RBAC` authorizers;
- The `kubeconfig` for the authorization webhook will be created at `/etc/kubernetes/deckhouse/extra-files/webhook-config.yaml`. Both files are in the `/etc/kubernetes/deckhouse/extra-files` directory, which is already mounted into `kube-`

`apiserver`.

How do I check that a user has access?

Execute the command below with the following parameters:

- `resourceAttributes` (the same as in RBAC) - target resources;
- `user` - the name of the user;
- `groups` - user groups;

> **i** If this module is used together with the `user-authn` module, you can find the groups and the username of a user in the Dex logs (`d8 k -n d8-user-authn logs -l app=dex`). The logs have them only after the user has signed in.

```
cat  <<EOF | 2>&1 d8 k  create --raw
/apis/authorization.k8s.io/v1/subjectaccessreviews -f - | jq .status
{
  "apiVersion": "authorization.k8s.io/v1",
  "kind": "SubjectAccessReview",
  "spec": {
    "resourceAttributes": {
      "namespace": "dev",
      "verb": "watch",
      "version": "v1",
      "resource": "pods"
    },
    "user": "user@example.com",
    "groups": [
      "developers"
    ]
  }
}
EOF
```

You will see if access is allowed and what role is used:

```
{
  "allowed": true,
  "reason": "RBAC: allowed by RoleBinding \"<BINDING_NAME>/dev\" of ClusterRole
\"<ROLE_NAME>\" to User \"user@example.com\""
}
```

The answer of the API server already includes the decision of the authorization webhook. To see the answer of the webhook alone, run the following command as root on a master node:

```
cat <<EOF | 2>&1 d8 k --kubeconfig /etc/kubernetes/deckhouse/extra-files/webhook-
config.yaml create --raw / -f - | jq .status
{
  "apiVersion": "authorization.k8s.io/v1",
  "kind": "SubjectAccessReview",
  "spec": {
    "resourceAttributes": {
      "namespace": "dev",
      "verb": "watch",
      "version": "v1",
      "resource": "pods"
    },
    "user": "user@example.com",
    "groups": [
      "developers"
    ]
  }
}
EOF
```

```
{
  "allowed": false
}
```

The `allowed: false` message means that the webhook doesn’t block access. In case of webhook denying the request, you will see, e.g., the following message:

```
{
  "allowed": false,
  "denied": true,
  "reason": "either you have no access to the namespace or the namespace does not
exist"
}
```

Customizing rights of high-level roles

If you want to grant more privileges to a specific high-level role, you only need to create a ClusterRole with the `user-authz.deckhouse.io/access-level: <AccessLevel>` annotation.

The module automatically sets the `user-authz.deckhouse.io/access-level` label on such ClusterRoles and includes their rules in the aggregated ClusterRole `user-authz:<access-level>:custom`. The label is internal: the module keeps it equal to the annotation and removes it when the annotation is absent, so there is no need to set it by hand. In audit logs, access granted through an annotated ClusterRole is attributed to that aggregated role.

The annotation accepts `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, and `ClusterAdmin`. Other values, including `SuperAdmin`, are ignored. In the name of the aggregated role, the level is written in kebab case, for example, `user-authz:cluster-editor:custom`. The rules of a level are also included in the aggregated roles of every higher level.

An example:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  annotations:
    user-authz.deckhouse.io/access-level: Editor
  name: user-editor
rules:
- apiGroups:
  - kuma.io
  resources:
  - trafficroutes
  - trafficroutes/finalizers
  verbs:
  - get
  - list
  - watch
  - create
  - update
  - patch
  - delete
- apiGroups:
  - flagger.app
  resources:
  - canaries
  - canaries/status
  - metrictemplates
  - metrictemplates/status
  - alertproviders
  - alertproviders/status
  verbs:
  - get
  - list
  - watch
  - create
  - update
  - patch
  - delete
```

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

FAQ

> The module lifecycle stage: General Availability

How do I create a user?

Creating a user.

How do I limit user rights to specific namespaces?

To limit a user's rights to specific namespaces in the granular role-based model, use RoleBinding with the namespace role that has the appropriate level of access. See the example of assigning administrative rights to a user within a namespace.

In the basic role-based model, use the `namespaceSelector` or `limitNamespaces` (deprecated)

parameters in the ClusterAuthorizationRule CR. These parameters require the `enableMultiTenancy` parameter: while it is disabled, a ClusterAuthorizationRule with them is refused. A rule that already has them is applied without the limits, see Why is a rule reported as needing multi-tenancy?

What if there are two ClusterAuthorizationRules matching a single user?

In the example, the user `jane.doe@example.com` is in the `administrators` group. There are two cluster authorization rules:

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: jane
spec:
  subjects:
    - kind: User
      name: jane.doe@example.com
  accessLevel: User
  namespaceSelector:
    labelSelector:
      matchLabels:
        env: review
---
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: admin
spec:
  subjects:
  - kind: Group
    name: administrators
  accessLevel: ClusterAdmin
  namespaceSelector:
    labelSelector:
      matchExpressions:
      - key: env
        operator: In
        values:
        - prod
        - stage
```

1. `jane.doe@example.com` has the right to get and list any objects in the namespaces labeled `env=review`
2. `Administrators` can get, edit, list, and delete objects at the cluster level and in the namespaces labeled `env=prod` and `env=stage`.

Because `Jane Doe` matches two rules, the resulting permissions are calculated as follows:

- `Jane Doe` will have the highest accessLevel across all matching rules — `ClusterAdmin`.
- The `namespaceSelector` options will be combined, so that Jane will have access to all the namespaces with the `env` label set to one of the following values: `review`, `stage`, or `prod`.

> ⚠ If there is a rule without the `namespaceSelector` option and `limitNamespaces` deprecated option, it means that all namespaces are allowed excluding system namespaces, which will affect the resulting limit namespaces calculation.

Can the basic and the granular role-based models be used at the same time?

Yes. Both models ultimately boil down to the standard Kubernetes RBAC mechanism, and RBAC is a permissive model: permissions from all sources are **summed up**. If an action is allowed by at least one source — a ClusterAuthorizationRule, an AuthorizationRule, a RoleBinding to a granular-model role, or a ProjectRoleBinding — it will be allowed. Nothing needs to be “switched over”: you can keep the existing ClusterAuthorizationRule objects and gradually add granular-model role bindings.

This holds in the multitenancy mode (`enableMultiTenancy`) as well, with one rule about levels. The namespace restriction of a ClusterAuthorizationRule (`limitNamespaces` or `namespaceSelector`) limits the permissions of that rule only: in a namespace outside the list the user keeps whatever a RoleBinding, an AuthorizationRule or a ProjectRoleBinding grants there, at the level of that binding — the `accessLevel` of the ClusterAuthorizationRule does not leak into it. A namespace where the user has no source at all stays denied. See the module description for the full set of sources and an example.

How do I get an equivalent of the ClusterAdmin and SuperAdmin roles in the granular model?

There is no single-object counterpart of the basic model's `ClusterAdmin` and `SuperAdmin` roles in the granular model — it deliberately separates platform administration (system roles) from application access (namespace and project roles). The equivalent is assembled from **two bindings**: a ClusterRoleBinding to a system role and a ClusterProjectRoleBinding to a project role (the latter applies in all projects, including those created later).

Approximate level mapping:

Basic model role	Granular model equivalent
`User`	`d8:namespace:viewer` (via RoleBinding or ProjectRoleBinding).
`PrivilegedUser`	`d8:namespace:user`.
`Editor`	`d8:namespace:manager` — the same level; the scope differs: the granular role is bound per namespace (RoleBinding) or per project (ProjectRoleBinding), not cluster-wide with a namespace filter.
`Admin`	`d8:namespace:admin`.
`ClusterEditor`	No direct counterpart. `ClusterEditor` is the `Editor` level in every namespace, system ones included, plus cluster-scoped objects. Assemble it from a ClusterProjectRoleBinding to `d8:project:manager` (all projects) and a system role for the platform part; `d8:system:manager` alone is not an equivalent: it gives no access to the user namespaces.
`ClusterAdmin`	`d8:system:manager` + a ClusterProjectRoleBinding to `d8:project:admin`.
`SuperAdmin`	`d8:system:superadmin` + a ClusterProjectRoleBinding to `d8:project:superadmin`.

An example for `ClusterAdmin` (the `k8s-admins` group):

```
# Platform: Deckhouse Platform module configuration, cluster-wide resources, system
namespaces.
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: k8s-admins-platform
subjects:
  - kind: Group
    name: k8s-admins
    apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:system:manager
  apiGroup: rbac.authorization.k8s.io
---
# Applications: administrator in all namespaces of all projects (including future
ones).
apiVersion: deckhouse.io/v1alpha3
kind: ClusterProjectRoleBinding
metadata:
  name: k8s-admins-projects
spec:
  subjects:
    - kind: Group
      name: k8s-admins
  roleRef:
    kind: ClusterRole
    name: d8:project:admin
```

For `SuperAdmin`, replace the roles with `d8:system:superadmin` and `d8:project:superadmin`.

Specifics:

- With the `multitenancy-manager` module enabled, every user namespace is a project, so the “system role + ClusterProjectRoleBinding” pair covers both the platform and all user namespaces. Only the `default` namespace is not covered — it is neither a project nor a system namespace.
- You cannot create a custom “all permissions” role (`apiGroups: ["*"], resources: ["*"], verbs: ["*"]`): such a role gives, among other things, project management permissions and is rejected by the built-in protections. If you need truly unrestricted access to the whole API (outside the platform role model), use a ClusterRoleBinding to the built-in Kubernetes `cluster-admin` role — only someone who already has such permissions can assign it.

How do I grant a user access to the resources of one module only?

A typical request: a user in a namespace should only work with the resources of one module (for example, only with virtual machines) without seeing the other resources (Pod, Deployment, etc.).

Every Deckhouse Platform module ships separate capabilities for its resources, so such access is granted without writing RBAC rules. Assemble a custom role that aggregates only the capabilities of the desired module. Select each capability by its `rbac.deckhouse.io/capability` label: a role with the `rbac.deckhouse.io/delegatable: "true"` label may select capabilities only by this label or by the `rbac.deckhouse.io/aggregate-to-namespace-as` and `rbac.deckhouse.io/aggregate-to-project-as` labels, and a selector by `module` or by any other label is refused. To list the capabilities of the module, run:

```
d8 k get clusterroles -l
rbac.deckhouse.io/kind=capability,module=virtualization,rbac.deckhouse.io/scope=namespace -o custom-
columns='NAME:.metadata.name,CAPABILITY:.metadata.labels.rbac\.deckhouse\.io/capabili
ty'
```

An example of the role, where `<ACTION>` is to be replaced with the values from the list:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:namespace:virtualization-only
  labels:
    rbac.deckhouse.io/kind: custom-role
    rbac.deckhouse.io/scope: namespace
    rbac.deckhouse.io/delegatable: "true"   # Allows using the role in a RoleBinding
inside projects.
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/capability: namespace-capability.virtualization.<ACTION>
    - matchLabels:
        rbac.deckhouse.io/capability: namespace-capability.virtualization.<ACTION>
rules: []
```

Values without the `custom.` prefix are reserved for the capabilities Deckhouse ships, and a ClusterRole a user writes with such a value is refused, so these selectors pick only the capabilities of the module.

Grant the role via a RoleBinding in the desired namespace or via a ProjectRoleBinding across the whole project. The user will get access only to the module's resources — the standard Kubernetes resources will not be visible to them.

> **i** Do not bind the capability of the module directly. Inside **project** namespaces a plain RoleBinding may only reference roles available to the project, and capabilities are not among them by default. The custom role above has the `rbac.deckhouse.io/delegatable: "true"` label, which makes it available there, so the same role works in every namespace.

What happens to the bindings when the cluster is updated to the release with the controller?

Nothing is recreated and access is not interrupted. In Deckhouse Platform 1.78, the `user-authz-controller` component adopts the bindings that the Helm chart used to render: the same objects with the same names, with an `ownerReference` to the rule added.

Plan for the release that performs the migration: it processes every existing binding once, so it takes longer than usual. Subsequent releases are not affected.

Bindings in the release	What to expect
Up to 5000	The release runs longer than usual and completes on its own
More than 5000	The release can exceed the 20-minute module timeout and fail

Count the bindings before you update. To get the number of cluster role bindings, use the following command:

```
d8 k get clusterrolebindings -l heritage=deckhouse,module=user-authz --no-headers | wc -l
```

To get the number of namespaced bindings, use the following command:

```
d8 k get rolebindings -A -l heritage=deckhouse,module=user-authz --no-headers | wc -l
```

If there are more than 5000, raise the release timeout or switch to the previous release engine for the duration of the update, and revert the setting afterwards:

To increase the release timeout, use the following command:

```
d8 k -n d8-system set env deploy/deckhouse HELM_TIMEOUT=60m
```

To switch back to the previous engine, use the following command:

```
d8 k -n d8-system set env deploy/deckhouse USE_NELM=false
```

If the migration cannot prepare every binding, the release does not start and the bindings stay as they were.

After the migration, the release no longer grows with the number of rules. The `D8UserAuthzReleaseSlow` alert fires when applying the module release repeatedly takes more than 5 minutes, and `D8UserAuthzRenderSlow` fires when rendering its templates repeatedly takes more than 30 seconds. Both point at the API server or at a Deckhouse Pod short of CPU rather than at the rules.

How do I check that the controller keeps the bindings in sync?

The `user-authz-controller` component reconciles the ClusterRoleBinding and RoleBinding objects of every ClusterAuthorizationRule and AuthorizationRule, the `d8:dict` ClusterRoleBindings of the granular model, and the RoleBinding objects that give the subjects of system and subsystem roles the namespace role named by `rbac.deckhouse.io/use-role` in module namespaces. Its state is shown by the object status, the metrics, and the alerts.

Object status. Every rule carries a `Ready` condition and the number of its bindings:

To list all ClusterAuthorizationRules in the cluster, run:

```
d8 k get clusterauthorizationrules
```

Example output:

```
NAME        ACCESS LEVEL   READY   BINDINGS   AGE
my-rule     Admin          True    3          5d
```

To list all AuthorizationRules in all namespaces of the cluster, run:

```
d8 k get authorizationrules -A
```

Example output:

```
NAMESPACE   NAME       ACCESS LEVEL   READY   BINDINGS   AGE
default     app-rule   Editor         True    2          3d
team-a      dev-rule   User           False   0          1h
```

To get only the conditions of a specific ClusterAuthorizationRule, run:

```
d8 k get clusterauthorizationrule <name> -o jsonpath='{.status.conditions}'
```

Example output:

```
[
  {
    "lastTransitionTime": "2026-09-11T10:00:00Z",
    "message": "3 bindings applied",
    "observedGeneration": 1,
    "reason": "BindingsApplied",
    "status": "True",
    "type": "Ready"
  }
]
```

`Ready=True` with the reason `BindingsApplied` means the bindings match the rule. `Ready=False` indicates the problem: `InvalidSpec` (the rule cannot be rendered into bindings; the message says why) or `ApplyError` (the API server rejected a write; the message names the binding and the error). Events with the same reasons are recorded on the rule.

Metrics. The controller exposes them on the `metrics` port of its Pod and the `PodMonitor` `user-authz-controller` collects them (the `operator-prometheus` module must be enabled). The `kind` label is `ClusterAuthorizationRule`, `AuthorizationRule`, `dict` or `manage`.

Metric	Description
`d8_user_authz_authorization_rules{kind}`	Objects of the kind known to the controller
`d8_user_authz_bindings_desired{kind}`	Bindings the objects of the kind must have
`d8_user_authz_bindings_actual{kind}`	Bindings of the kind that exist
`d8_user_authz_bindings_drift{kind,reason}`	Bindings not in the desired state at the last reconcile; `reason` is `missing`, `extra` or `changed`. Stays above zero only while the controller fails to converge
`d8 user authz_bindings_apply_total{kind,op,result}`	Write operations issued by the controller (`op`: `create`, `update`, `delete`; `result`: `success`, `error`)
`d8 user authz_authorization_rules_invalid{kind,reason}`	Rules whose `Ready` condition is `False`, by kind and reason
`d8 user authz authorization rule_invalid{kind,name,rule_namespace,reason}`	`1` for every such rule (at most 50 rules are named; the aggregate above is always complete)
`controller runtime reconcile total`, `controller_runtime_reconcile_errors_total`, `controller_runtime_reconcile_time_seconds`	Standard controller-runtime metrics per reconciler (`controller` label: `clusterauthorizationrule-bindings`, `authorizationrule-bindings`, `dict-bindings`, `manage-bindings`)

Deckhouse exports the following metrics of the module hooks:

Metric	Description
`d8_user_authz_custom_cluster_roles{level}`	Custom `ClusterRole` objects (annotated with `user-authz.deckhouse.io/access-level`) per access level
`d8 user_authz_custom_aggregation_missing{level}`	`1` when the aggregated ClusterRole `user-authz:<level>:custom` has no rules although custom roles it must aggregate exist
`d8_user_authz_bindings_keep_stamped_total`, `d8_user_authz_keep_stamp_duration_seconds`	Work of the migration hook that protects chart-rendered bindings from being pruned by the release: objects stamped and the duration of its last run

Alerts. The module ships the following alerts for the controller:

- `D8UserAuthzControllerUnavailable` and `D8UserAuthzControllerTargetDown` when the controller has unavailable replicas or is not scraped for 5 minutes.
- `D8UserAuthzControllerReconcileErrorsHigh` on a sustained reconcile error rate.
- `D8UserAuthzBindingsDrift` when bindings of some kind stay out of the desired state for 15 minutes.
- `D8UserAuthzAuthorizationRulesInvalid` and `D8UserAuthzAuthorizationRuleInvalid` counting and naming the rules whose bindings cannot be applied for 10 minutes.
- `D8UserAuthzCustomRolesNotAggregated` when the aggregated ClusterRole of an access level stays empty although custom roles for it exist.

When a rule stays `Ready=False` with `ApplyError` because a binding's `roleRef` was changed by hand, delete that binding: `roleRef` is immutable and the controller recreates the binding with the right one.

How do I check that the authorization webhook has the current rules?

The authorization webhook and Permission Browser read the multi-tenancy options of ClusterAuthorizationRules (`limitNamespaces`, `namespaceSelector`, `allowAccessToSystemNamespaces`) from the API, so a change reaches them within a few seconds.

To check that the webhook Pods are running, run:

```
d8 k -n d8-user-authz get pods -l app=user-authz-webhook -o wide
```

Example output (one Pod per master, on the host network; both containers must be ready):

```
NAME                          READY   STATUS    RESTARTS   AGE   IP           NODE
NOMINATED NODE   READINESS GATES
user-authz-webhook-qrm2n      2/2     Running   0          2d    10.0.0.11    master-0
<none>           <none>
user-authz-webhook-h6jbh      2/2     Running   0          2d    10.0.0.12    master-1
<none>           <none>
user-authz-webhook-97fvs      2/2     Running   0          2d    10.0.0.13    master-2
<none>           <none>
```

To see the last 100 log lines of the webhook container of every such Pod, run:

```
d8 k -n d8-user-authz logs -l app=user-authz-webhook -c webhook --tail=100
```

Example output:

```
2026/09/11 10:00:00 server is starting to listen on  127.0.0.1:40443 ...
2026/09/11 10:00:01 rules source: directory rebuilt from 12 rules (18 subjects, 0
quarantined) in 4.2ms
```

The `rules source: directory rebuilt from N rules` line shows the informer has listed the rules and how many it holds; `quarantined` counts the rules the instance could not fully use: a `limitNamespaces` pattern or a `namespaceSelector` that does not compile, or a rule that cannot be read.

An instance that has not read the rules yet is not ready and answers authorization requests with an error instead of a denial. In the seconds between a rule being created and the webhook observing it, the subjects of that rule that no observed rule covers yet are denied access to all namespaces. A subject that another rule already covers keeps the scope of that rule.

The webhook exposes metrics through a `kube-rbac-proxy` sidecar; the PodMonitor `user-authz-webhook` collects them, and the `operator-prometheus` module must be enabled. There is one series per master node.

Metric	Description
`user_authz_webhook_rules_informer_synced`	`1` once the instance has read the ClusterAuthorizationRules at least once
`user_authz_webhook_rules_observed`	Rules the instance currently uses
`user_authz_webhook_rules_subjects`	Distinct subjects in those rules
`user_authz_webhook_rules_max_resource_version`	Highest `resourceVersion` among the observed rules. Compare it with the cluster to measure the lag
`user_authz_webhook_rules_quarantined`	Rules the instance could not fully use: a `limitNamespaces` pattern or `namespaceSelector` that does not compile, or a rule that cannot be read at all
`user_authz_webhook_rules_directory_updated_timestamp_seconds`	Time of the last rules update
`user_authz_webhook_rules_directory_rebuilds_total`, `user_authz_webhook_rules_directory_rebuild_duration_seconds`	Number of rules updates and their duration
`user_authz_webhook_rules_watch_errors_total`	List and watch errors of the rules informer

Permission Browser exposes the same metrics with the `user_authz_permission_browser` prefix; the PodMonitor `permission-browser-apiserver` collects them.

The module ships the following alerts for both components:

Alert	Fires when

Alert	Fires when
`D8UserAuthzWebhookTargetDown`	Prometheus has not scraped at least one webhook instance for 5 minutes
`D8UserAuthzWebhookRulesQuarantined`	A rule has not compiled for 10 minutes
`D8UserAuthzWebhookRulesWatchErrors`	The rules informer has been failing to watch the rules for 10 minutes
`D8UserAuthzWebhookDirectoryDiverged`	Instances have been using different sets of rules for 10 minutes, so the same request is answered differently depending on the master node that receives it
`D8UserAuthzRulePropagationLag`	One instance has not updated its rules for an hour while another one has
`D8UserAuthzPermissionBrowserUnavailable`	Permission Browser has unavailable replicas

Why does a change to a ClusterAuthorizationRule take up to 30 seconds to take effect?

The API server caches the answers of the authorization webhook. In the `AuthorizationConfiguration` that `control-plane-manager` renders, the webhook has `authorizedTTL: 5m`, `unauthorizedTTL: 30s` and `timeout: 3s`. The cache key is the whole SubjectAccessReview, so an identical repeated request is answered from the cache.

The webhook never allows a request: it either denies it or gives no opinion, and both answers are cached for `unauthorizedTTL`, which is 30 seconds. Creating a rule or narrowing an existing one therefore takes effect for a particular request within 30 seconds of the last identical request:

```
d8 k auth can-i --as=user@example.com get pods -n other-namespace
sleep 30
d8 k auth can-i --as=user@example.com get pods -n other-namespace
```

The cache cannot be flushed without restarting `kube-apiserver`.

For the resource of a CRD installed a moment ago, the delay reaches 40 seconds. The webhook learns whether a resource is namespaced from discovery, which it queries no more often than once every 10 seconds, and the API server then caches the answer for another 30 seconds.

During those seconds the namespace limits do not apply to that resource: the webhook does not know it exists, gives no opinion, and RBAC alone answers — so a subject whose rule limits it to some namespaces can list the new resource across the whole cluster. Installing a CRD requires far more privilege than that yields, which is why discovery is queried at a bounded rate rather than on every request. Permission Browser has a window of the same order for its own report, up to 30 seconds.

Why is a rule reported as needing multi-tenancy?

The `limitNamespaces`, `namespaceSelector` and `allowAccessToSystemNamespaces` options are enforced by the authorization webhook, which is deployed only when `enableMultiTenancy` is enabled. A rule that uses these options while multi-tenancy is disabled is applied without them: the subjects named in the rule hold its access level in **every** namespace of the cluster, including the system ones.

While multi-tenancy is disabled, the `d8-user-authz-car-multitenancy-related-options.deckhouse.io` admission webhook refuses a ClusterAuthorizationRule with any of these options, even `allowAccessToSystemNamespaces: false`. It also refuses disabling `enableMultiTenancy` while a rule uses them. So a rule reaches this state only if it was written before these checks applied, for example before an update. Any change to such a rule must also remove the options.

Only options that ask for a limit are counted. A rule with `allowAccessToSystemNamespaces: false`, or with an empty `limitNamespaces` list, is not reported.

Two metrics report the situation:

Metric	Description
`d8_user_authz_rule_needs_multitenancy{name,options}`	One series per affected rule, up to 50, with the options that will not take effect

Metric	Description
`d8_user_authz_rules_needing_multitenancy`	Total number of affected rules, including those past the first 50

An individual rule is listed in the `D8UserAuthzRuleNeedsMultiTenancy` alert, and `D8UserAuthzRulesNeedMultiTenancy` fires when there are more affected rules than the first alert lists. Both belong to the `D8UserAuthzMisconfigured` group.

To resolve the situation, either enable multi-tenancy, or remove the options from the rules.

To check whether multi-tenancy is enabled, use the following command:

```
d8 k get moduleconfig user-authz -o jsonpath='{.spec.settings.enableMultiTenancy}'
```

To retrieve the names of ClusterAuthorizationRules that restrict access by namespace or allow access to system namespaces, use the following command:

```
d8 k get clusterauthorizationrule -o json | jq -r '.items[] | select((.spec.limitNamespaces
// [] | length > 0) or (.spec.namespaceSelector != null) or
(.spec.allowAccessToSystemNamespaces == true)) | .metadata.name'
```

How do I extend a role or create a new one?

The granular role model is based on the aggregation principle; it compiles smaller roles into larger ones, thus providing easy ways to enhance the model with custom roles.

Creating a new role subsystem

Suppose that the current subsystems do not fit the role distribution in the company. You need to create a new subsystem that includes roles from the `cluster` subsystem, the `network` subsystem and the user-authn module.

To meet this need, create the following role:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:mycustom:manager
  labels:
    rbac.deckhouse.io/use-role: viewer
    rbac.deckhouse.io/kind: custom-role
    rbac.deckhouse.io/scope: subsystem
    rbac.deckhouse.io/subsystem: mycustom
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-cluster-as: manager
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-network-as: manager
    - matchLabels:
        rbac.deckhouse.io/scope: system
        module: user-authn
rules: []
```

The labels for the new role listed at the top suggest that:

- The namespace role `user-authz-controller` gives the subjects of the role in the module namespaces; a custom role is projected as `viewer` at most:

  ```
  rbac.deckhouse.io/use-role: viewer
  ```

- The role is a custom role (custom roles never define their own rules, they only aggregate capabilities):

```
rbac.deckhouse.io/kind: custom-role
```

> **i** This label is mandatory.

- The role is a subsystem one, and it shall be handled accordingly:

```
rbac.deckhouse.io/scope: subsystem
```

- There is a subsystem for which the role is responsible:

```
rbac.deckhouse.io/subsystem: mycustom
```

Then there are selectors that implement aggregation:

- This one aggregates the manager role from the `cluster` subsystem:

```
rbac.deckhouse.io/aggregate-to-cluster-as: manager
```

- This one aggregates all the system-scope capabilities defined for the `user-authn` module:

```
rbac.deckhouse.io/scope: system
module: user-authn
```

This way, your role will combine the permissions of the `cluster` subsystem, `network` subsystem, and the `user-authn` module.

Notes:

- Custom roles and capabilities must be named with the `d8:custom:` prefix (the rest of the `d8:` prefix space is reserved for Deckhouse Platform built-in objects). The name must agree with the declared scope: a subsystem role is `d8:custom:<subsystem>:<name>` (the segment is the subsystem itself, as in the example above), a namespace or project role is `d8:custom:namespace:<name>` or `d8:custom:project:<name>`, and a capability is `d8:custom:<scope>-capability:<name>`. A name that disagrees with the `rbac.deckhouse.io/scope` label is rejected.
- RoleBindings with a namespace role (`d8:namespace:<level>`) will be created in the namespaces of the aggregated subsystems' modules, the level is specified by the `rbac.deckhouse.io/use-role` label, `viewer` at most for a custom role. Without the label no such RoleBinding is created.
- A custom role cannot be aggregated into `d8:system:<level>`, because only a custom capability may carry the `rbac.deckhouse.io/aggregate-to-system-as` label. To give the role to the holders of `d8:system:manager`, bind it to them with a ClusterRoleBinding.

Extending the custom role

Suppose a new cluster CRD object, MySuperResource, has been created in the cluster (a manage role example), and you need to extend the custom role from the example above to include the permissions to interact with this resource.

First, you have to add a new selector to the role:

```
rbac.deckhouse.io/aggregate-to-mycustom-as: manager
```

This selector would enable capabilities to be aggregated to a new subsystem by specifying this label. After adding the new selector, the role will look as follows:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:mycustom:manager
  labels:
    rbac.deckhouse.io/use-role: viewer
    rbac.deckhouse.io/kind: custom-role
    rbac.deckhouse.io/scope: subsystem
    rbac.deckhouse.io/subsystem: mycustom
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-cluster-as: manager
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-network-as: manager
    - matchLabels:
        rbac.deckhouse.io/scope: system
        module: user-authn
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-mycustom-as: manager
rules: []
```

Next, you need to create a new capability and define permissions for the new resource, e. g., the read-only permission:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  labels:
    rbac.deckhouse.io/aggregate-to-mycustom-as: manager
    rbac.deckhouse.io/kind: custom-capability
    rbac.deckhouse.io/scope: subsystem
    rbac.deckhouse.io/subsystem: mycustom
    rbac.deckhouse.io/capability: "custom.subsystem-
capability.mycustom.superresource_view"
  name: d8:custom:subsystem-capability:mycustom:superresource:view
rules:
- apiGroups:
  - mygroup.io
  resources:
  - mysuperresources
  verbs:
  - get
  - list
  - watch
```

The capability will add its permissions to the subsystem role. so that holders of the role will be able to view the new object.

Notes:

- Name a custom capability `d8:custom:<SCOPE>-capability:<NAME>`, where `<SCOPE>` is the value of its `rbac.deckhouse.io/scope` label. A name that disagrees with the label is rejected.

Extending the existing subsystem roles

To extend an existing role, follow the procedure outlined in the section above. Be sure to change the labels and the role name!

For example, here’s how you can extend the manager role from the `cluster` (`d8:subsystem:cluster:manager`) subsystem:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  labels:
    rbac.deckhouse.io/aggregate-to-cluster-as: manager
    rbac.deckhouse.io/kind: custom-capability
    rbac.deckhouse.io/scope: subsystem
    rbac.deckhouse.io/subsystem: cluster
    rbac.deckhouse.io/capability: "custom.subsystem-
capability.cluster.superresource_view"
  name: d8:custom:subsystem-capability:cluster:superresource:view
rules:
- apiGroups:
  - mygroup.io
  resources:
  - mysuperresources
  verbs:
  - get
  - list
  - watch
```

This way, the new capability will extend the `d8:subsystem:cluster:manager` role.

Extending subsystem roles and adding a new namespace

The namespaces where the holders of a system or subsystem role get a RoleBinding with the namespace role are the namespaces of its modules: `user-authz-controller` takes them from the `rbac.deckhouse.io/namespace` label of the system capabilities Deckhouse ships, which have a `d8:` name and the `heritage: deckhouse` label. On a custom capability the label is ignored: the capability adds its rules to the roles that aggregate it, but no namespace.

To give the subjects of such a role access to another namespace, bind them to a namespace role there with a RoleBinding:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: cluster-managers-viewer
  namespace: my-namespace
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: d8:namespace:viewer
subjects:
- apiGroup: rbac.authorization.k8s.io
  kind: Group
  name: cluster-managers
```

Extending the existing namespace roles

If the resource belongs to a namespace, you need to extend the namespace role instead of the system/subsystem role. The only difference is the labels and the name:

```
 apiVersion: rbac.authorization.k8s.io/v1
 kind: ClusterRole
 metadata:
   labels:
     rbac.deckhouse.io/aggregate-to-namespace-as: user
     rbac.deckhouse.io/kind: custom-capability
     rbac.deckhouse.io/scope: namespace
     rbac.deckhouse.io/capability: "custom.namespace-
capability.mycustom.superresource_view"
   name: d8:custom:namespace-capability:mycustom:superresource:view
 rules:
 - apiGroups:
   - mygroup.io
   resources:
   - mysuperresources
   verbs:
   - get
   - list
   - watch
```

This capability will be added to the `d8:namespace:user` role.

Creating a custom namespace or project role

Sometimes the built-in hierarchy of levels does not fit: for example, you need a “developer” role — full view of the namespace plus terminal access to pods (`exec`, `attach`), but without the right to change quotas or RBAC. Such a role is assembled from ready-made capabilities, without writing RBAC rules by hand.

The rules for custom roles:

- the name must start with `d8:custom:` (for example, `d8:custom:namespace:developer`);
- the role must carry the `rbac.deckhouse.io/kind: custom-role` label;
- a namespace or project role that will be used in a RoleBinding must also carry `rbac.deckhouse.io/delegatable: "true"`. Every user namespace is a project, and a RoleBinding there is accepted only for roles with this label. Do not put it on system or subsystem roles — the admission webhook rejects that;
- the role **cannot contain its own rules** (`rules`) — it may only aggregate capabilities via `aggregationRule`. Permissions are described in separate capabilities, so the contents of the role stay transparent;
- a single role cannot aggregate capabilities of the user-facing scopes (`namespace`, `project`) together with the administrative ones (`system`, subsystems) — such a role is rejected.

An example: a role that includes everything allowed by `d8:namespace:viewer`, plus one specific capability (connecting to pods), selected precisely by its unique `rbac.deckhouse.io/capability` label:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:namespace:developer
  labels:
    rbac.deckhouse.io/kind: custom-role
    rbac.deckhouse.io/scope: namespace
    rbac.deckhouse.io/delegatable: "true"   # Required for a RoleBinding inside a
project namespace.
  annotations:
    custom.meta.deckhouse.io/title: "Developer"
    custom.meta.deckhouse.io/description: "View resources and connect to pods,
without managing quotas and RBAC"
aggregationRule:
  clusterRoleSelectors:
    # Everything included in the viewer level of the namespace lineage.
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-namespace-as: viewer
    # Plus one specific capability selected by its unique name.
    - matchLabels:
        rbac.deckhouse.io/capability: "namespace-
capability.kubernetes.access_terminal"
rules: []
```

If no existing capability grants the permissions you need, create your own (a `custom-capability` may contain rules) and add a selector by its `rbac.deckhouse.io/capability` label to the role's `aggregationRule` (in the example below — `matchLabels: {rbac.deckhouse.io/capability: "custom.namespace-capability.port-forward"}`). The label value of a custom capability is `custom.<SCOPE>-capability.<NAME>`, and a role bindable in a project may select only the `namespace-capability` and `project-capability` scopes:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:namespace-capability:port-forward
  labels:
    rbac.deckhouse.io/kind: custom-capability
    rbac.deckhouse.io/scope: namespace
    rbac.deckhouse.io/capability: "custom.namespace-capability.port-forward"
rules:
  - apiGroups: [""]
    resources: ["pods/portforward"]
    verbs: ["create"]
```

To get a list of all available capabilities and their unique names, use the command:

```
d8 k get clusterroles -l rbac.deckhouse.io/kind=capability -o custom-
columns='NAME:.metadata.name,CAPABILITY:.metadata.labels.rbac\.deckhouse\.io/capabili
ty'
```

The created role is assigned exactly like a built-in one: via a RoleBinding in a namespace or via a ProjectRoleBinding across a whole project (for project roles, use `rbac.deckhouse.io/scope: project` and aggregate `aggregate-to-project-as`). A RoleBinding in a project namespace requires the `delegatable` label on the role; a ProjectRoleBinding does not (it has its own prefix allow-list). The role cannot be assigned via a ClusterRoleBinding — just like the built-in roles of these scopes.

> **i** You can also assemble such a role without YAML — with the access grant wizard in the Deckhouse web UI: it shows the available capabilities, builds a role out of them, and immediately creates the required binding.

How do I migrate custom roles to the new scheme?

Along with the role renaming, the label scheme that drives aggregation has changed.

> ⚠ The built-in capabilities no longer carry the `rbac.deckhouse.io/kind: manage` and `rbac.deckhouse.io/kind: use` labels. A custom role of the old scheme that selects capabilities by these labels has lost their permissions, and so have its subjects. Custom roles get no compatibility aliases, so repair such roles as described below.

An aggregation selector of a custom role that requires one of these labels (for example, `rbac.deckhouse.io/kind: manage` + `rbac.deckhouse.io/aggregate-to-<SUBSYSTEM>-as`) matches none of the built-in capabilities. From such a selector, the Kubernetes aggregation controller takes only the rules of the custom capabilities that still carry the old labels. Deckhouse Platform creates the RoleBinding objects for the subjects of a role with the `rbac.deckhouse.io/use-role` label in the namespaces of the modules only when the role has the `rbac.deckhouse.io/scope: system` or `subsystem` label. A custom role of the old scheme with `use-role` and without that scope has lost these objects, even if its selectors are already rewritten. A selector that requires the aggregation label of a lineage that no built-in role collects matches none of the built-in capabilities either, because the modules label their capabilities only with the lineages that the built-in roles collect. Such a label is, for example, `rbac.deckhouse.io/aggregate-to-all-as` of the old scheme, the label of a subsystem the role model no longer has, or the label of a subsystem a module has left. A lineage that a custom capability carries is an exception, because the selector still gets the rules of that capability. A custom capability here is a ClusterRole without the `heritage: deckhouse` label and without an `aggregationRule` field. So is the lineage of the role's own subsystem, from its `rbac.deckhouse.io/subsystem` label, because the custom capabilities of that subsystem carry it (for details, see Extending the custom role). Neither exception applies to the `all`, `deckhouse`, `infrastructure`, `kubernetes` and `networking` lineages, which do not count as custom ones. A compatibility alias of an old role, a ClusterRole with the `rbac.deckhouse.io/deprecated: "true"` label, does not count as a built-in role that collects a lineage, because it collects the lineage of an old subsystem only for the bindings to the old name. A custom capability of the old scheme may also have moved to other roles (for details, see Replacing a capability).

Such roles are listed in the `D8UserAuthzLegacyRBACv2CustomRoleFound` alert. It fires for every ClusterRole without the `heritage: deckhouse` label and with an `aggregationRule` field that has a selector requiring `rbac.deckhouse.io/kind: manage` or `use`, has a selector requiring such an aggregation label, or carries `rbac.deckhouse.io/use-role` without `rbac.deckhouse.io/scope: system` or `subsystem`, whatever the name of the role. A role without `aggregationRule`, such as a role frozen earlier, is not listed. To list such roles, use the command:

```
d8 k get clusterroles -o json | jq -r '
  def lineages: [((.matchLabels // {}) | keys[]), (.matchExpressions[]? |
select(.operator == "In" or .operator == "Exists") | .key)]
    | map(capture("^rbac\\.deckhouse\\.io/aggregate-to-(?<lineage>.+)-
as$").lineage);
  ([.items[] | select(.metadata.labels.heritage == "deckhouse" and
.metadata.labels["rbac.deckhouse.io/deprecated"] != "true")
        | .aggregationRule.clusterRoleSelectors[]? | lineages[]] + ["system",
"namespace", "project"]) as $collected
  | ([.items[] | select(.metadata.labels.heritage != "deckhouse" and
.aggregationRule == null) | (.metadata.labels // {}) | keys[]
        | capture("^rbac\\.deckhouse\\.io/aggregate-to-(?<lineage>.+)-
as$").lineage]) as $carried
  | .items[]
  | select(.metadata.labels.heritage != "deckhouse" and .aggregationRule != null)
  | (.metadata.labels["rbac.deckhouse.io/subsystem"] // "") as $own
  | select(
      (
        ((.metadata.labels["rbac.deckhouse.io/use-role"] // "") != "")
        and (((.metadata.labels["rbac.deckhouse.io/scope"] // "") | IN("system",
"subsystem")) | not)
      )
      or (
        [
          .aggregationRule.clusterRoleSelectors[]?
          | (.matchLabels["rbac.deckhouse.io/kind"] // empty),
            (.matchExpressions[]? | select(.key == "rbac.deckhouse.io/kind" and
.operator == "In") | .values[])
        ]
        | any(IN("manage", "use"))
      )
      or (
        [
          .aggregationRule.clusterRoleSelectors[]? | lineages[]
          | select((IN($collected[]) | not)
              and (IN("all", "deckhouse", "infrastructure", "kubernetes",
"networking") or (. != $own and (IN($carried[]) | not))))
        ]
        | length > 0
      )
    )
  | .metadata.name'
```

Mapping between the old and the new scheme:

Before (old scheme)	After (new scheme)
Arbitrary role name (for example, `custom:manage:mycustom:manager`)	Mandatory `d8:custom:` prefix (for example, `d8:custom:mycustom:manager`)
`rbac.deckhouse.io/kind: manage` or `use` on your role	`rbac.deckhouse.io/kind: custom-role`
`rbac.deckhouse.io/kind: manage` or `use` on your capability	`rbac.deckhouse.io/kind: custom-capability`, name prefixed with `d8:custom:`
`rbac.deckhouse.io/level: all | subsystem | module`	`rbac.deckhouse.io/scope: system | subsystem | namespace`
`rbac.deckhouse.io/kind: manage` + `rbac.deckhouse.io/aggregate-to-all-as: <level>` on your capability	`rbac.deckhouse.io/aggregate-to-system-as: <level>`

Before (old scheme)	After (new scheme)
`rbac.deckhouse.io/kind: use` + `rbac.deckhouse.io/aggregate-to-all-as: <level>` on your capability	`rbac.deckhouse.io/kind: custom-capability` + `rbac.deckhouse.io/scope: namespace` + `rbac.deckhouse.io/aggregate-to-namespace-as: <level>`, name `d8:custom:namespace-capability:<name>`
`rbac.deckhouse.io/kind: manage` + `rbac.deckhouse.io/aggregate-to-all-as: <level>` on your role	A ClusterRoleBinding of the role to the subjects of `d8:manage:all:<level>` and `d8:system:<level>`, because a custom role cannot carry `rbac.deckhouse.io/aggregate-to-system-as`
`rbac.deckhouse.io/kind: use` + `rbac.deckhouse.io/aggregate-to-kubernetes-as: <level>` on your capability	`rbac.deckhouse.io/kind: custom-capability` + `rbac.deckhouse.io/scope: namespace` + `rbac.deckhouse.io/aggregate-to-namespace-as: <level>`, name `d8:custom:namespace-capability:<name>`
Aggregation selector: `rbac.deckhouse.io/kind: manage` + `rbac.deckhouse.io/aggregate-to-<subsystem>-as: <level>`	Only `rbac.deckhouse.io/aggregate-to-<subsystem>-as: <level>`
Selector for use permissions: `rbac.deckhouse.io/kind: use` + `rbac.deckhouse.io/aggregate-to-kubernetes-as: <level>`	`rbac.deckhouse.io/aggregate-to-namespace-as: <level>`
Per-module selector: `rbac.deckhouse.io/kind: manage` + `module: <module>`	`rbac.deckhouse.io/scope: system` + `module: <module>`
Labels of the `deckhouse`, `infrastructure` and `kubernetes` subsystems (`rbac.deckhouse.io/aggregate-to-deckhouse-as` and the others)	One label of the `cluster` subsystem, `rbac.deckhouse.io/aggregate-to-cluster-as`
Label of the `networking` subsystem, `rbac.deckhouse.io/aggregate-to-networking-as`	`rbac.deckhouse.io/aggregate-to-network-as`
The `user-authz`, `user-authn` and `multitenancy-manager` modules with the labels of the `security` and `deckhouse` subsystems	The label of the `iam` subsystem, `rbac.deckhouse.io/aggregate-to-iam-as`

The names of the built-in capabilities changed as well (no aliases):

- `d8:manage:permission:module:<module>:view|edit` → `d8:system-capability:<module>:view|edit`
- `d8:use:capability:module:<module>:view|edit` → `d8:namespace-capability:<module>:view|edit`

Aggregation selectors match labels, not names. Bind roles, not capabilities.

Fixing a role

Fix every role that is listed in the `D8UserAuthzLegacyRBACv2CustomRoleFound` alert. Keep the order of the steps, so that the old role and its bindings stay in place until the new ones grant the access:

1. Create a role of the new scheme next to the old one, with the `d8:custom:` name prefix, the `rbac.deckhouse.io/kind: custom-role` label, and the aggregation selectors of the new scheme, without `rbac.deckhouse.io/kind` (for details, see the before and after example). Replace a selector by the aggregation label of a lineage that no built-in role collects as described in Selectors by a lineage no built-in role collects. Choose the scope of the role, and name it accordingly:
    - A role with the `rbac.deckhouse.io/use-role` label, or with the `rbac.deckhouse.io/level: subsystem` or `all` label, gets `rbac.deckhouse.io/scope: subsystem` and `rbac.deckhouse.io/subsystem: <SUBSYSTEM>` with the name `d8:custom:<SUBSYSTEM>:<NAME>`, or `rbac.deckhouse.io/scope: system` with the name `d8:custom:system:<NAME>`. Set the `rbac.deckhouse.io/use-role` label on it to `viewer`. For the subjects of its ClusterRoleBinding objects, Deckhouse then creates RoleBinding objects to `d8:namespace:viewer` in the namespaces of the modules whose system capabilities the role aggregates: a custom role is projected as `viewer` at most, and the

webhook refuses a higher value. Without the label the role is not projected into those namespaces at all. The `rbacv2-cluster-roles.deckhouse.io` webhook refuses a custom role without the `rbac.deckhouse.io/scope` label whose selectors name the aggregation label of a subsystem or of the system scope, such as `rbac.deckhouse.io/aggregate-to-deckhouse-as`.
    - A namespace or project role that you bind with a RoleBinding gets `rbac.deckhouse.io/scope: namespace` and `rbac.deckhouse.io/delegatable: "true"` with the name `d8:custom:namespace:<NAME>` (for details, see Creating a custom namespace or project role).
2. Create capabilities of the new scheme in place of the custom capabilities of the old scheme that the role aggregates, as described in Replacing a capability. Keep the old capabilities for now.
3. For every RoleBinding and ClusterRoleBinding object to the old role, create an object with the same subjects to the new role. The `roleRef` field is immutable, so create a new object instead of editing the old one. If the old role has the `rbac.deckhouse.io/kind: manage` and `rbac.deckhouse.io/aggregate-to-all-as` labels, also bind the new role as described in Roles aggregated into the system roles. With `rbac.deckhouse.io/kind: use`, it extended the namespace roles, see the same section.
4. Check the permissions of the subjects:

   Check whether the specified user can perform an action on a resource across the whole cluster (for cluster-wide resources) or in the current default namespace (for namespaced resources):

   ```
   d8 k auth can-i <VERB> <RESOURCE> --as=<USER_NAME>
   ```

   Check whether the specified user can perform an action on a resource in the specified namespace:

   ```
   d8 k auth can-i <VERB> <RESOURCE> -n <NAMESPACE> --as=<USER_NAME>
   ```

   To check the permissions of a group, add `--as-group=<GROUP_NAME>` to `--as`.
5. Delete the old RoleBinding and ClusterRoleBinding objects, the old role, and the old capabilities.

If the objects are applied from a Git repository (for example, by Argo CD or Flux), make the same changes in the repository. Otherwise, the next apply creates the old objects again.

Roles aggregated into the system roles

In the old scheme, the `rbac.deckhouse.io/aggregate-to-all-as: <LEVEL>` label meant one of two things, depending on the kind label next to it. With `rbac.deckhouse.io/kind: use`, it extended the `d8:use:role:<LEVEL>` roles in every namespace. Their counterpart is `d8:namespace:<LEVEL>`, which selects `rbac.deckhouse.io/aggregate-to-namespace-as: <LEVEL>`, so move such permissions into a namespace capability as described in Replacing a capability. With `rbac.deckhouse.io/kind: manage`, a role with this label extended `d8:manage:all:<LEVEL>`, and the rest of this section is about it. No role of the new model selects this label. Only the deprecated `d8:manage:all:<LEVEL>` and `d8:use:role:<LEVEL>` aliases still select it, depending on the kind label next to it, until they are removed. The `d8:manage:all:<LEVEL>` alias and the `d8:system:<LEVEL>` role select `rbac.deckhouse.io/aggregate-to-system-as: <LEVEL>`, and the `rbacv2-cluster-roles.deckhouse.io` webhook admits this label only on a custom capability. A custom role therefore cannot extend these roles, and the subjects that got the old role through them get the new role only through a ClusterRoleBinding of their own.

The following commands create such a ClusterRoleBinding for each ClusterRoleBinding to `d8:manage:all:<LEVEL>` and `d8:system:<LEVEL>`:

```
NEW_ROLE=<NEW_ROLE_NAME>
LEVEL=<LEVEL>
d8 k get clusterrolebindings -o json > clusterrolebindings.json
jq --arg role "$NEW_ROLE" --arg level "$LEVEL" '
  {apiVersion: "v1", kind: "List", items: [.items[]
    | select(.roleRef.kind == "ClusterRole" and (.roleRef.name | IN("d8:manage:all:"
+ $level, "d8:system:" + $level)))
    | {apiVersion, kind, metadata: {name: ($role + ":" + .metadata.name)},
       roleRef: {apiGroup: "rbac.authorization.k8s.io", kind: "ClusterRole", name:
$role}, subjects}]}' \
  clusterrolebindings.json > new-clusterrolebindings.json
d8 k apply -f new-clusterrolebindings.json
```

Review `new-clusterrolebindings.json` before you create the objects, and remove the subjects that must not get the role. Deckhouse Platform does not keep these objects in sync with the ClusterRoleBinding objects they are copied from. When you revoke the access of a subject, delete both. The name of a copy ends with the name of its source.

Selectors by a lineage no built-in role collects

A selector by the aggregation label of a lineage selected the capabilities that carried this label. For example, `rbac.deckhouse.io/aggregate-to-virtualization-as: <LEVEL>` selected the capabilities of the `virtualization` module. Once the module labels them with the lineage of the subsystem it is in now, a selector by that lineage selects the capabilities of every module of the subsystem, which can be much more than the role gave before. To keep the new role as narrow as the old one, select the capabilities themselves by the `rbac.deckhouse.io/capability` label. Its value does not depend on the subsystem. It is `system-capability.<MODULE NAME>.<ACTION>` for a system capability and `namespace-capability.<MODULE_NAME>.<ACTION>` for a namespace capability.

1. List the capabilities of the module with the levels of the roles that collect them:

   ```
   d8 k get clusterroles -l rbac.deckhouse.io/kind=capability,module=<MODULE_NAME> -o json | jq -r '
     .items[]
     | [.metadata.labels["rbac.deckhouse.io/capability"],
        (.metadata.labels | to_entries
          | map(select(.key | test("^rbac\\.deckhouse\\.io/aggregate-to-.+-as$"))
   | (.key | ltrimstr("rbac.deckhouse.io/aggregate-to-") | rtrimstr("-as")) + "="
   + .value)
          | join(","))]
     | @tsv'
   ```

2. Keep the capabilities that the old selector matched. A selector with the `<LEVEL>` value matched the capabilities of this level and, through the built-in roles of the lower levels, the capabilities of those levels as well.
3. In the new role, put one selector by the `rbac.deckhouse.io/capability` label for each of them. To give all the system capabilities of the module whatever their level, a single selector by `rbac.deckhouse.io/scope: system` and `module: <MODULE_NAME>` is enough.

For example, the following namespace role gives in a namespace what a selector by `rbac.deckhouse.io/aggregate-to-virtualization-as: user` gave, without the other modules of the subsystem. Replace `<ACTION>` with the values from the list:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:namespace:virtualization-user
  labels:
    rbac.deckhouse.io/kind: custom-role
    rbac.deckhouse.io/scope: namespace
    rbac.deckhouse.io/delegatable: "true"
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/capability: namespace-capability.virtualization.<ACTION>
    - matchLabels:
        rbac.deckhouse.io/capability: namespace-capability.virtualization.<ACTION>
rules: []
```

A role of the system or subsystem scope selects the `system-capability.<MODULE_NAME>.<ACTION>` values the same way.

Replacing a capability

A custom capability of the old scheme carries the `rbac.deckhouse.io/kind: manage` or `use` label and an aggregation label, and it is listed in the `D8UserAuthzForeignAggregationLabel` alert. While it carries the aggregation label of the system scope, of the namespace or project scope, or of a built-in subsystem, the `rbacv2-cluster-roles.deckhouse.io` webhook refuses every update of it. The webhook admits such a label only together with `rbac.deckhouse.io/kind: custom-capability`, and

that label requires the `d8:custom:` name prefix, which an existing object cannot get. Create a capability of the new scheme with the same rules in its place, and delete the old one once the new one grants the access.

The labels of the old capability define the new one:

Old capability	New capability
`rbac.deckhouse.io/kind: use` + `rbac.deckhouse.io/aggregate-to-kubernetes-as: <LEVEL>`	`d8:custom:namespace-capability:<NAME>` with `rbac.deckhouse.io/scope: namespace` and `rbac.deckhouse.io/aggregate-to-namespace-as: <LEVEL>`
`rbac.deckhouse.io/kind: manage` + `rbac.deckhouse.io/aggregate-to-<SUBSYSTEM>-as: <LEVEL>`, for a built-in subsystem or a subsystem of your own	`d8:custom:subsystem-capability:<NAME>` with `rbac.deckhouse.io/scope: subsystem`, `rbac.deckhouse.io/subsystem: <SUBSYSTEM>` and the same aggregation label
`rbac.deckhouse.io/kind: use` + `rbac.deckhouse.io/aggregate-to-all-as: <LEVEL>`	`d8:custom:namespace-capability:<NAME>` with `rbac.deckhouse.io/scope: namespace` and `rbac.deckhouse.io/aggregate-to-namespace-as: <LEVEL>`
`rbac.deckhouse.io/kind: manage` + `rbac.deckhouse.io/aggregate-to-all-as: <LEVEL>`	`d8:custom:system-capability:<NAME>` with `rbac.deckhouse.io/scope: system` and `rbac.deckhouse.io/aggregate-to-system-as: <LEVEL>`

Each new capability also gets the `rbac.deckhouse.io/kind: custom-capability` label.

An old capability with the `rbac.deckhouse.io/namespace: <NAMESPACE>` label gave the subjects of the roles that aggregate it RoleBinding objects in that namespace, the namespace of a module. Deckhouse Platform reads this label only on the ClusterRoles it ships, so neither the old capability nor its custom replacement gives such RoleBinding objects. To keep the access in that namespace, bind the subjects to a namespace role there with a RoleBinding (for details, see Extending subsystem roles and adding a new namespace).

A capability with the `rbac.deckhouse.io/kind: use` and `rbac.deckhouse.io/aggregate-to-kubernetes-as: <LEVEL>` labels extended the `d8:use:role:<LEVEL>` roles. Only the deprecated `d8:use:role:<LEVEL>` aliases still select it, until they are removed. `d8:namespace:<LEVEL>` and `d8:project:<LEVEL>` select `rbac.deckhouse.io/aggregate-to-namespace-as`, so a RoleBinding moved to a new role does not get the rules of the capability. Such a capability is listed in the `D8UserAuthzLegacyUseCapability` alert. Replace it before you move the RoleBinding objects to the new roles. For example, the following commands create its counterpart for the namespace roles:

```
OLD_CAPABILITY=<OLD_CAPABILITY_NAME>
NEW_CAPABILITY=d8:custom:namespace-capability:<NAME>
LEVEL=<LEVEL>
d8 k get clusterrole "$OLD_CAPABILITY" -o json | jq --arg name "$NEW_CAPABILITY" --arg level
"$LEVEL" '
  {apiVersion, kind, metadata: {name: $name, labels: {
     "rbac.deckhouse.io/kind": "custom-capability",
     "rbac.deckhouse.io/scope": "namespace",
     "rbac.deckhouse.io/aggregate-to-namespace-as": $level}},
   rules}' > new-capability.json
d8 k apply -f new-capability.json
```

Check the permissions of the subjects of the namespace roles, and then delete the old capability:

```
d8 k delete clusterrole "$OLD_CAPABILITY"
```

The `d8:use:role:<LEVEL>` aliases collect the new capability as well, so deleting the old one takes nothing away from their subjects.

Roles frozen earlier

A role frozen before the built-in capabilities got the new labels, by removing its `aggregationRule` field and keeping its rules, keeps its permissions and is not listed in the `D8UserAuthzLegacyRBACv2CustomRoleFound` alert.

- The explicit RoleBinding objects that replaced its automatic ones point at `d8:use:role:<LEVEL>`, which the new scheme keeps only as a deprecated alias of `d8:namespace:<LEVEL>`. They are listed in the `D8UserAuthzDeprecatedRBACv2RoleInUse` alert. Move them to `d8:namespace:<LEVEL>`, because a binding to an alias grants nothing once the alias is removed. The following commands do this for the RoleBinding objects with the `explicit:` name prefix:

  ```
  d8 k get rolebindings -A -o json | jq '{apiVersion: "v1", kind: "List", items:
  [.items[]
    | select(.roleRef.kind == "ClusterRole" and (.roleRef.name |
  startswith("d8:use:role:")) and (.metadata.name | startswith("explicit:")))]}' \
    > use-role-rolebindings.json
  jq '.items |= map({apiVersion, kind,
      metadata: {name: ("namespace:" + .metadata.name), namespace:
  .metadata.namespace,
        annotations: ((.metadata.annotations // {}) | with_entries(select(.key ==
  "rbac.deckhouse.io/related-with")))},
      roleRef: (.roleRef | .name |= (sub("^d8:use:role:"; "d8:namespace:") |
  sub(":kubernetes$"; "")))), subjects})' \
    use-role-rolebindings.json > namespace-rolebindings.json
  d8 k apply -f namespace-rolebindings.json && d8 k get -f namespace-rolebindings.json > /dev/null
  && d8 k delete -f use-role-rolebindings.json
  ```

  The old objects are deleted only when all the new ones exist, and the commands can be run again after a failure.

- If the role still carries the `rbac.deckhouse.io/aggregate-to-all-as` label, it is listed in the `D8UserAuthzForeignAggregationLabel` alert, and the `rbacv2-cluster-roles.deckhouse.io` webhook refuses every update of the role that keeps the label, a new apply of its manifest included. No role of the new model selects this label. The deprecated `d8:manage:all:<LEVEL>` alias still selects it on a role with `rbac.deckhouse.io/kind: manage`, and the deprecated `d8:use:role:<LEVEL>` alias on a role with `rbac.deckhouse.io/kind: use`, until the aliases are removed.

  With `rbac.deckhouse.io/kind: manage`, the subjects of `d8:manage:all:<LEVEL>` keep the role through the ClusterRoleBinding objects that the freeze created for them, so remove the label:

  ```
  d8 k label clusterrole <ROLE_NAME> rbac.deckhouse.io/aggregate-to-all-as-
  ```

  With `rbac.deckhouse.io/kind: use`, the role gives its rules to the subjects of every RoleBinding to `d8:use:role:<LEVEL>` through this label, and the freeze created no binding for them. Removing the label takes these rules away from them. First create a namespace capability with the rules of the role as described in Replacing a capability. Both `d8:namespace:<LEVEL>` and the `d8:use:role:<LEVEL>` alias collect it. Check the permissions of the subjects, and only then remove the label from the role or delete the role.

- A frozen role does not gain permissions for resources added later, such as the resources of a new module. To get them, replace it with a role of the new scheme as described in Fixing a role.

The RoleBindings that the previous release created in the module namespaces for a binding to a custom role with `rbac.deckhouse.io/kind: manage` and `rbac.deckhouse.io/use-role` are removed on the upgrade. Once the new role carries `rbac.deckhouse.io/scope: system` or `subsystem` and `rbac.deckhouse.io/use-role` and the binding refers to it, they come back as `d8:namespace:<level>:binding:<ClusterRoleBinding name>`, but only in the namespaces of the modules that already carry the new labels and whose system capabilities the new role aggregates. A module that still carries the old labels, such as `rbac.deckhouse.io/kind: manage`, gets no such RoleBinding until it moves to the new ones. Until then, create RoleBinding objects in the namespace of that module for the subjects of the binding: one to `d8:namespace:<level>` and one to each ClusterRole of the module that is listed in the `D8UserAuthzLegacyUseCapability` alert. None of these roles is an alias, so the RoleBinding objects do not hold the next release, and the webhook that checks RoleBinding objects in project namespaces does not check the namespace of a module. Delete them once the module carries the new labels and the controller creates its own RoleBinding there. A RoleBinding to `d8:use:role:<level>` gives these rights as well, but the `D8UserAuthzDeprecatedRBACv2RoleInUse` alert reports it, and it holds the release that removes the aliases.

Examples

Custom role before and after

The following is a configuration example of a role combining the permissions of the `deckhouse` and `kubernetes` subsystems and the `user-authn` module.

- Before (old scheme):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: custom:manage:mycustom:manager
  labels:
    rbac.deckhouse.io/use-role: admin
    rbac.deckhouse.io/kind: manage
    rbac.deckhouse.io/level: subsystem
    rbac.deckhouse.io/subsystem: custom
    rbac.deckhouse.io/aggregate-to-all-as: manager
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-deckhouse-as: manager
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-kubernetes-as: manager
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        module: user-authn
rules: []
```

- After (new scheme):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:mycustom:manager
  labels:
    rbac.deckhouse.io/use-role: viewer
    rbac.deckhouse.io/kind: custom-role
    rbac.deckhouse.io/scope: subsystem
    rbac.deckhouse.io/subsystem: mycustom
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/aggregate-to-cluster-as: manager
    - matchLabels:
        rbac.deckhouse.io/scope: system
        module: user-authn
rules: []
```

What changed:

- The name got the mandatory `d8:custom:` prefix and names the subsystem of the role
- `rbac.deckhouse.io/kind: manage` → `rbac.deckhouse.io/kind: custom-role`
- `rbac.deckhouse.io/level: subsystem` → `rbac.deckhouse.io/scope: subsystem`
- The `rbac.deckhouse.io/aggregate-to-all-as` label is removed. The subjects of `d8:system:manager` get the role through a ClusterRoleBinding (for details, see Roles aggregated into the system roles)
- The `rbac.deckhouse.io/kind: manage` label is removed from the aggregation selectors
- All system permissions of a module are now selected with `rbac.deckhouse.io/scope: system` + `module: <module>`
- The `deckhouse` and `kubernetes` subsystems are part of the `cluster` subsystem now, so their two selectors became one. It selects the whole `cluster` subsystem, which is wider than the two old ones. To keep the role as narrow as before, select the system capabilities of the modules you need by `module: <module>` and `rbac.deckhouse.io/scope: system` instead

Custom capability before and after

The following is an example configuration of a capability, which grants read access to the MySuperResource resource and is aggregated into the role from the example above (its `aggregationRule` field must contain the `rbac.deckhouse.io/aggregate-to-mycustom-as: manager` selector).

- Before (old scheme):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: custom:manage:permission:mycustom:superresource:view
  labels:
    rbac.deckhouse.io/kind: manage
    rbac.deckhouse.io/aggregate-to-mycustom-as: manager
rules:
  - apiGroups:
      - mygroup.io
    resources:
      - mysuperresources
    verbs:
      - get
      - list
      - watch
```

- After (new scheme):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: d8:custom:subsystem-capability:mycustom:superresource:view
  labels:
    rbac.deckhouse.io/kind: custom-capability
    rbac.deckhouse.io/scope: subsystem
    rbac.deckhouse.io/subsystem: mycustom
    rbac.deckhouse.io/aggregate-to-mycustom-as: manager
rules:
  - apiGroups:
      - mygroup.io
    resources:
      - mysuperresources
    verbs:
      - get
      - list
      - watch
```

Labels and annotations: before and after

Labels on ClusterRole objects:

Label	Before	After	Purpose
`rbac.deckhouse.io/kind`	`manage` or `use`	`custom-role` / `custom-capability` for your own objects; `role` / `capability` on built-in ones (reserved)	The object type in the role model. Mandatory, objects without it are not processed
`rbac.deckhouse.io/level`	`all` | `subsystem` | `module`	Removed	The old role level; replaced by the `scope` label

Label	Before	After	Purpose
`rbac.deckhouse.io/scope`	—	`system` | `subsystem` | `namespace`	The scope of a role or capability
`rbac.deckhouse.io/subsystem`	Subsystem name	Unchanged	The role's subsystem; used with `scope: subsystem`
`rbac.deckhouse.io/use-role`	A use-role level	A namespace-role level	Defines which namespace role is automatically granted to the holder of a system/subsystem role in the system namespaces of its modules (via automatically created RoleBinding objects); `viewer` at most for a custom role
`rbac.deckhouse.io/aggregate-to-all-as`	`<level>`	With `rbac.deckhouse.io/kind: manage`, replaced by `rbac.deckhouse.io/aggregate-to-system-as` on a custom capability, which a custom role cannot carry. With `rbac.deckhouse.io/kind: use`, replaced by `rbac.deckhouse.io/aggregate-to-namespace-as` on a custom capability	Aggregates the object into the system-wide role (`d8:system:<level>`)
`rbac.deckhouse.io/aggregate-to-<subsystem>-as`	Used in selectors together with `rbac.deckhouse.io/kind: manage`	Used in selectors on its own	Aggregates the object into the subsystem role of the given level
`rbac.deckhouse.io/aggregate-to-kubernetes-as`	`<level>` (for use and manage permissions)	Not used. The kubernetes subsystem is part of the `cluster` subsystem (`aggregate-to-cluster-as`), and the old *use*-role meaning moved to `aggregate-to-namespace-as`	Aggregated into the old `d8:manage:kubernetes:<level>` and `d8:use:role:<level>:kubernetes` roles
`rbac.deckhouse.io/namespace`	Namespace	Unchanged	An additional namespace where a RoleBinding is automatically created for the role holders; read only on the capabilities Deckhouse ships, ignored on a custom one
`rbac.deckhouse.io/capability`	—	A unique capability name (for example, `system-capability.deckhouse.view`)	A machine-readable identifier of a built-in capability
`rbac.deckhouse.io/deprecated`	—	`"true"` on alias roles	The role is deprecated and will be removed; migrate the bindings to the new role

Label	Before	After	Purpose
`module`	Module name	Unchanged	Marks a built-in object as belonging to a Deckhouse Platform module; handy in aggregation selectors together with `scope`
`heritage: deckhouse`	Platform object marker	Unchanged	Must not be set on custom objects

Annotations on ClusterRole objects (the old scheme did not use annotations):

Annotation	Purpose
`ru.meta.deckhouse.io/title`, `ru.meta.deckhouse.io/description`	The displayed name and description of a role/capability in Russian (the platform sets them on built-in objects; you can set your own on custom ones)
`en.meta.deckhouse.io/title`, `en.meta.deckhouse.io/description`	Same in English
`rbac.deckhouse.io/deprecated-replaced-by`	Set on the alias roles of the previous names and names the new role to move the bindings to. An alias aggregates the capabilities of the **new** role, so the existing bindings to the previous name keep granting access until the aliases are removed. The permissions are not identical to the previous ones, because `d8:use:role:admin` no longer grants ServiceAccount token minting or impersonation

Adding a custom capability (in the new scheme)

A capability is a regular ClusterRole object with rules that is automatically included into the chosen role via an aggregation label. In the new scheme, a custom capability is created as follows:

1. Decide which role you want to extend: a namespace role, a subsystem role, the system role, or your own custom role.
2. Create a ClusterRole named `d8:custom:<SCOPE>-capability:<NAME>` with the `rbac.deckhouse.io/kind: custom-capability` label, the `rbac.deckhouse.io/scope: <SCOPE>` label, and the aggregation label of the target role:
   - `rbac.deckhouse.io/aggregate-to-namespace-as: <viewer|user|manager|admin|superadmin>`: Into the `d8:namespace:<level>` namespace role.
   - `rbac.deckhouse.io/aggregate-to-<subsystem>-as: <viewer|manager|superadmin>`: Into the `d8:subsystem:<subsystem>:<level>` subsystem role.
   - `rbac.deckhouse.io/aggregate-to-system-as: <viewer|manager|superadmin>`: Into the `d8:system:<level>` system role.
   - `rbac.deckhouse.io/aggregate-to-<your subsystem name>-as: <level>`: Into your own custom role (its `aggregationRule` field must contain such a selector).
3. Define the permissions in `rules`.

Kubernetes aggregates the rules automatically: right after the capability is created, its permissions appear for all holders of the target role. You can verify the result with `d8 k auth can-i --as <user>` or by inspecting the resulting role rules: `d8 k get clusterrole <role> -o yaml`.

For configuration examples, refer to the “Custom role before and after” and “Custom capability before and after” subsections.

How do I rename a built-in role?

The permissions of built-in roles cannot be changed, but their display title and description can — for example, so that the interface shows them in your company’s terms. Add the `custom.meta.deckhouse.io/title` and `custom.meta.deckhouse.io/description` annotations to the role:

```
d8 k annotate clusterrole d8:namespace:admin custom.meta.deckhouse.io/title='Team administrator'
custom.meta.deckhouse.io/description='Manages resources and access in the team namespace'
```

This is the only modification allowed for objects with the `d8:` prefix (except `d8:custom:*`): an attempt to change the rules, aggregation, or labels of a built-in role is rejected.

How do I find out who has access to a resource?

With the multitenancy mode enabled (`enableMultiTenancy`), a reverse authorization query is available — the WhoCan resource. It answers the question “who can perform action X on resource Y?” and returns the list of users, groups, and ServiceAccounts:

```
d8 k create -o yaml -f - <<EOF
apiVersion: authorization.deckhouse.io/v1alpha1
kind: WhoCan
metadata:
  name: who-can-create-networkpolicies
spec:
  resourceAttributes:
    namespace: my-namespace
    verb: create
    group: networking.k8s.io
    resource: networkpolicies
EOF
```

The answer is returned in the `status` field (`users`, `groups`, `serviceAccounts`) directly in the command output; the object is not stored anywhere.

The right to create WhoCan queries is granted by the `d8:user-authz:who-can-checker` cluster role. It is not bound to anyone by default: the query result discloses access subjects across all namespaces, so grant it only to trusted administrators via a ClusterRoleBinding.

The managers of the `iam` and `security` subsystems have this right as well. It comes with the `d8:subsystem-capability:iam:inspect_access` capability of `d8:subsystem:iam:manager` and `d8:subsystem:security:manager`, and so the roles above them have it too (`d8:subsystem:iam:superadmin`, `d8:subsystem:security:superadmin`, `d8:system:manager` and `d8:system:superadmin`).

How do I find out what a specific user, group, or ServiceAccount is allowed to do?

With the multitenancy mode enabled (`enableMultiTenancy`), the SubjectAccessReport resource is available — the counterpart of WhoCan. It answers the question “what is this subject allowed to do” and returns a ready-made report: which roles are granted through which bindings, which actions on which resources are allowed cluster-wide and in every namespace, and where each permission comes from.

```
d8 k create -o yaml -f - <<EOF
apiVersion: authorization.deckhouse.io/v1alpha1
kind: SubjectAccessReport
metadata:
  name: what-can-jane-do
spec:
  subject:
    kind: User
    name: jane@example.com
EOF
```

The `spec.subject.kind` field accepts `User`, `Group`, and `ServiceAccount` (for the latter, `spec.subject.namespace` is required). If `spec.subject` is omitted, the report is built for the caller.

Report specifics:

- The user’s groups are resolved automatically from the Group catalog, including nested ones: if the user belongs to group `B` and `B` belongs to `A`, the permissions of `A` are included as well. The groups taken into account are returned in `status.subject.groups`. Groups that are not in the catalog (for example, the ones coming from an external identity provider) can be passed in `spec.groups`.
- Every source of a permission (`status.scopes[].resources[].sources[]`) carries a `matchedBy` field showing whether the permission was granted to the subject personally or through a group, which makes it possible to view the access with group-derived grants excluded.
- Namespaces with identical access are merged into a single section

(`status.scopes[].namespaces`), so a project with a dozen namespaces does not turn into a dozen identical tables.
- Permissions granted by a ClusterRoleBinding are reported once, in the cluster-wide scope (`status.scopes[].cluster: true`), since they apply in every namespace.
- The report can be limited to specific namespaces with `spec.namespaces`.

The report is built from RBAC data. Admission webhooks can still refuse a write that RBAC allows, for example a change of an object labeled `heritage: deckhouse`, and the report does not show such refusals. If the subject's permissions are limited by a ClusterAuthorizationRule, this is reported in `status.notes`.

The right to build a report about **another** subject is granted by the `d8:user-authz:subject-access-checker` cluster role. Like `who-can-checker`, it is intentionally not bound to anyone by default: the report discloses the full permission map of the subject, including other namespaces. A report about oneself is available to every authenticated user and requires no extra permissions.

The managers of the `iam` and `security` subsystems have this right as well. It comes with the `d8:subsystem-capability:iam:inspect_access` capability of `d8:subsystem:iam:manager` and `d8:subsystem:security:manager`, and so the roles above them have it too (`d8:subsystem:iam:superadmin`, `d8:subsystem:security:superadmin`, `d8:system:manager` and `d8:system:superadmin`).

How does a user see the list of namespaces available to them?

With the multitenancy mode enabled (`enableMultiTenancy`), the namespace list is filtered automatically: the `d8 k get namespaces` command returns to a user only the namespaces they have access to — via any of the mechanisms (role bindings, ProjectRoleBinding/ClusterProjectRoleBinding, ClusterAuthorizationRule/AuthorizationRule). A user does not see foreign namespaces and cannot learn about their existence from the list.

If the `console` module older than 1.44.0 is enabled, the list is not filtered: the access levels of ClusterAuthorizationRule and AuthorizationRule and the namespace roles keep the permission to list every namespace.

The same list is served by the read-only `accessiblenamespaces` resource — any authenticated user can query it **for themselves**:

```
d8 k get accessiblenamespaces
```

This is convenient for scripts and interfaces: there is no need to iterate over namespaces checking access to each one.

How does an interface find out where a user may perform an action?

With the multitenancy mode enabled (`enableMultiTenancy`), the SelfScopedAccessReview resource gives the user who creates it with information about the namespaces in which they are allowed to perform actions within the filtering scope: in the whole cluster, in how many namespaces of the scope and, on request, in which ones. One query replaces an access check per namespace. The namespaces are counted by the rule that filters a list sent with the same scope, so a section built on the answer opens exactly when its list has objects to return.

Any authenticated user can create the resource, and it answers only about the caller. A query with the `spec.user`, `spec.groups`, `spec.uid` or `spec.extra` fields is refused.

Example query from a Deckhouse web interface page that shows deployments of all projects, offers to create one and shows pod logs:

```
d8 k create -o yaml -f - <<EOF
apiVersion: authorization.deckhouse.io/v1alpha1
kind: SelfScopedAccessReview
spec:
  scope: projects
  requests:
  - group: apps
    resource: deployments
    verbs: [list, watch]
  - group: apps
    resource: deployments
    verbs: [create]
    includeNamespaces: true
  - group: ""
    resource: pods
    subresource: log
    verbs: [get]
    includeNamespaces: true
EOF
```

Example answer for a user who administers the `shop-dev` and `shop-stage` namespaces of a project and has read access without pod logs in `shop-prod`:

```
status:
  results:
  - allowed: true
    cluster: false
    count: 3
  - allowed: true
    cluster: false
    count: 2
    namespaces: [shop-dev, shop-stage]
  - allowed: true
    cluster: false
    count: 2
    namespaces: [shop-dev, shop-stage]
```

Example answer for a cluster administrator. The namespaces are neither counted nor listed, even with `includeNamespaces: true`:

```
status:
  results:
  - allowed: true
    cluster: true
  - allowed: true
    cluster: true
  - allowed: true
    cluster: true
```

Example answer for a user who can only read deployments in the `billing-prod` namespace of another project:

```
status:
  results:
  - allowed: true
    cluster: false
    count: 1
  - allowed: false
    cluster: false
    count: 0
    namespaces: []
  - allowed: false
    cluster: false
    count: 0
    namespaces: []
```

The query fields:

- `spec.scope`: Scope of the `X-Deckhouse-Scope` header (filtering scope): `accessible`, `projects`, `system` or `project`.
- `spec.project`: Project of the `project` scope.
- `spec.requests`: Actions to check. Each sets the API group (`group`, empty for the core group), the resource (`resource`), the subresource if any (`subresource`) and the verbs (`verbs`). `includeNamespaces: true` asks for the names of the namespaces.

The `status.results` list has an entry per request, in the same order as the requests in the SelfScopedAccessReview:

- `allowed`: The action is allowed in the whole cluster or in at least one namespace of the scope.
- `cluster`: The action is allowed in the whole cluster. The namespaces are then neither counted nor listed.
- `count`: Number of namespaces of the scope where the action is allowed.
- `namespaces`: Namespaces of the scope where the action is allowed, sorted alphabetically, when the request sets `includeNamespaces: true`. An empty list means none.
- `reason`: `NotFilterable` when the action on a namespaced resource cannot be answered by namespaces: the list of the resource is not filtered by scope. Only a permission in the whole cluster allows such an action.
- `evaluationError`: Reason why this request could not be checked. The other requests are answered.

The namespaces where the action is allowed are counted as follows:

- A namespace counts when every verb of the request is allowed in it. A request for `list` and `watch` counts the namespaces where both are allowed.
- Only the namespaces the user sees in the `accessiblenamespaces` list are counted and named, and the namespaces where a RoleBinding grants access to every authenticated user (the `system:authenticated` group): RBAC opens them to the user, and the filtered list returns their objects.
- For `get`, `list` and `watch` of a resource, the answer names the namespaces the list with the same scope returns objects from.
- Other verbs and subresources, for example `create` or `pods/log`, are checked in every namespace of the scope.
- `get`, `list` and `watch` of `namespaces` are answered with the accessible namespaces whatever the scope, as the list of namespaces is filtered.
- `get`, `list` and `watch` of `deckhouse.io/projects` are answered with every accessible namespace: each stands for its project, and a namespace without the `projects.deckhouse.io/project` label for the virtual project `multitenancy-manager` counts it in, `deckhouse` for `d8-*`, `kube-*`, `upmeter-*` and namespaces with the `heritage: deckhouse` or `heritage: upmeter` label, `default` for the rest. So `count` and `namespaces` list namespaces, not projects: a project with three accessible namespaces counts three. A user who may list namespaces in the whole cluster sees every project and gets `cluster: true`.
- `update`, `patch` and `delete` of `namespaces` and their subresources are checked for every namespace of the scope, with that namespace as the target: the `ClusterAuthorizationRule` limits apply to them.
- When a request for `namespaces` combines a read with a write, a namespace opened to every authenticated user but missing from `accessiblenamespaces` counts only if `get` is allowed in it and `list` and `watch` in the whole cluster, as the API server checks them.
- `create` and `deletecollection` of `namespaces`, every write of `deckhouse.io/projects`, and every action on another cluster-scoped resource, such as `nodes` or `ModuleConfig`, are allowed only by a permission in the whole cluster. Without one the answer is `allowed: false`, with no `count` and no `reason`.
- A read of a namespaced resource the scope does not filter gets `reason: NotFilterable` unless it

is allowed in the whole cluster. These are resources without `list`, resources of aggregated APIs such as `metrics.k8s.io`, and resources the cluster does not serve, `deckhouse.io/projects` without the `multitenancy-manager` module included: their lists with a scope are refused.
- In the `projects` and `project` scopes, a namespace with an empty `projects.deckhouse.io/project` label belongs to no project. The answer for `deckhouse.io/projects` counts it for its virtual project, as described above.
- The `accessible` and `system` scopes include the `default`, `kube-*` and `d8-*` namespaces, as their lists do. The `system` and `projects` scopes can overlap: the namespaces of a project named `d8`, such as `d8-x`, belong to both.

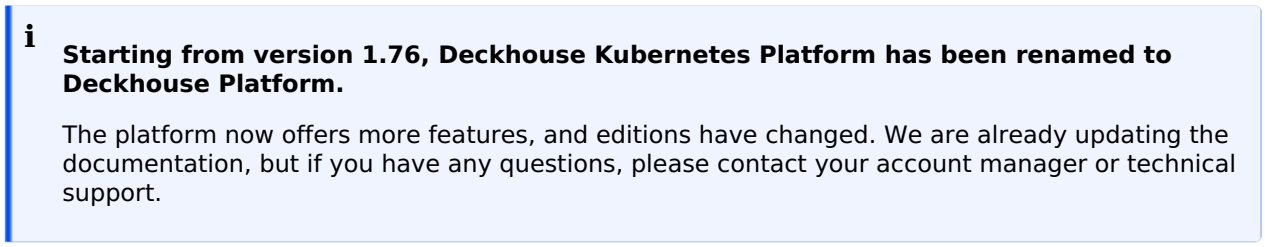
The answer describes authorization, the decision whether the user may perform the action on the resource. Admission can still refuse a write of a particular object:

- creation, update and delete of objects with the `heritage: deckhouse` label, for everyone except platform components;
- update and delete of objects that `multitenancy-manager` creates in project namespaces, and deletion of a project namespace;
- creation of a namespace while the `allowNamespacesWithoutProjects` parameter of the `multitenancy-manager` module is `false`;
- creation of a ProjectRoleBinding or a ProjectNamespace outside the main namespace of the project;
- creation of users, groups and `ClusterAuthorizationRule` objects with rights beyond the user's own.

The answer cannot express a permission for named objects only (`resourceNames` in a role): it asks about a resource without an object name, so such a permission is not counted. A change of rules or bindings reaches the answer within seconds, while the API server can keep its previous decision for a repeated request for up to 30 seconds.

While the `ClusterAuthorizationRules` are not yet loaded or no longer tracked, the whole query is answered with `503` and the `Retry-After` header: the API server refuses requests in that state too, and an answer computed without the rules would read as a refusal.

The answer applies the `ClusterAuthorizationRule` limits whenever the authorization webhook of `user-authz` is enabled through the `controlPlaneConfigurator.enabled` parameter and the `control-plane-manager` module, which puts it into the API server configuration, is enabled. If a third-party authorization webhook is set by hand in the `apiserver.authz.webhookURL` parameter of the `control-plane-manager` module, the API server may not apply these limits, while the answer still does.



To keep an interface consistent with the data it shows, follow these rules:

1. Ask with the scope of the list the page shows.
2. Show a section when `allowed` is `true`.
3. Cache answers per scope and project.
4. Treat an empty list returned with a scope as the absence of objects, not as missing permissions.
5. Take the namespaces of a creation form from `namespaces` of a request with `includeNamespaces: true`.

The `projects` and `project` scopes require the `multitenancy-manager` module to be enabled in the cluster. Without it, a query with these scopes is refused with `400`, and the `accessible` and `system` scopes work as usual. The cluster then serves no projects, and requests for `deckhouse.io/projects` get `reason: NotFilterable` unless they are allowed in the whole cluster.

The server answers with an error in the following cases:

- `400`: The query is invalid. Examples are an unknown scope, more than 1000 requests, more than five requests with `includeNamespaces: true`, more than 16 verbs in one request, or more than 10,000,000 checks of a verb in a namespace. A user with 10,000 namespaces reaches the last bound with 1000 requests of one verb, or 500 requests of two: split such a query into several.
- `429`: The same user has 30 queries in progress.
- `504`: The query was not answered within 10 seconds.
- `503`: `permission-browser-apiserver` is unavailable, or it has not loaded the `ClusterAuthorizationRules` yet (with `Retry-After`).

Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

The vertical-pod-autoscaler module

> **i** The module lifecycle stage: General Availability
>
> The module has requirements for installation

Vertical Pod Autoscaler (VPA) is an infrastructure service that allows you to avoid setting exact resource requests for a container if their values are not known in advance. VPA can automatically adjust the CPU and memory reservations (providing that the corresponding mode is enabled) based on the actual resource consumption (as shown by the Prometheus data). Also, VPA can recommend values for resource requests and limits without updating them automatically.

VPA has the following operating modes:

- `InPlaceOrRecreate`: A default mode. Available in Kubernetes 1.33 and later. VPA attempts to update Pod resources without recreating the Pod. If in-place resource updates are not possible, VPA recreates the Pod similarly to the `Recreate` mode.
- `Recreate`: The mode allows VPA to change resources of running pods (restart them while running). In case of one pod running (`replicas: 1`), this will lead to the service being unavailable during the restart. In this mode, VPA does not recreate pods that were created without a controller.
- `Initial`: VPA modifies Pod resources only when Pods are started (but not during operation).
- `Off`: VPA does not take any action to update the resource requests for the running containers. In this case, if VPA is running in this mode, you can see what resource values it recommends (`d8 k describe vpa <vpa-name>`).

> **⚠** The `Auto` mode is deprecated. It will no longer be supported in future DP versions. Switch to one of the supported operating modes.

VPA limitations:

- When using modes that allow Pod recreation, VPA may recreate a Pod if its `resource requests` cannot be updated in place. The new Pod can be scheduled to another node.
- VPA **should not be used concurrently with CPU and memory-based HPA**. However, you can use VPA together with HPA for custom/external metrics.
- VPA notices almost all `out-of-memory` events, but that does not guarantee its response.
- VPA performance has not been tested for huge clusters.
- VPA recommendations may exceed the available resources in the cluster. That can lead to **Pods becoming Pending**.
- Using multiple VPAs for the same Pod can lead to undefined behavior.
- If VPA is deleted or “turned off” (the `Off` mode), the changes made by VPA earlier are not reset (the most recent value set is kept). It may lead to confusion due to the difference between resource values in Helm/controller and the actual resources of Pods (it may be perceived as if they “came from out of nowhere”).

> **i** We highly recommend using Pod Disruption Budget with VPA.

Grafana dashboard

Displayed on dashboards:

- `Main / Namespace`, `Main / Namespace / Controller`, `Main / Namespace / Controller / Pod` — the `VPA type` column shows the value of `updatePolicy.updateMode`;
- `Main / Namespaces` — the `VPA %` column shows the percentage of VPA-enabled Pods.

Vertical Pod Autoscaler Architecture

VPA consists of 3 components:

- `Recommender` — this component monitors the current resource consumption (by making requests to the Metrics API implemented in the `prometheus-metrics-adapter` module) as well as consumption history (by making requests to Trickster caching proxy). As its name suggests, the component provides CPU and memory recommendations for containers.
- `Updater` — this component checks if the Pods have correct resources set and, if not, kills them so that they can be recreated by their controllers with the updated resource requests.
- `Admission Plugin` — this component sets the correct resource requests on new Pods (either just

created or recreated by their controller due to Updater's activity).

When the Updater component changes resource values, Pods are evicted using the Eviction API. Thus, the `Pod Disruption Budget` is taken into account for the Pods being updated.

Third-party components

List of third-party software used in the `vertical-pod-autoscaler` module:

- Kubernetes Autoscaler 1.8.1

  License: Apache License 2.0

  A autoscaling-related components for Kubernetes.

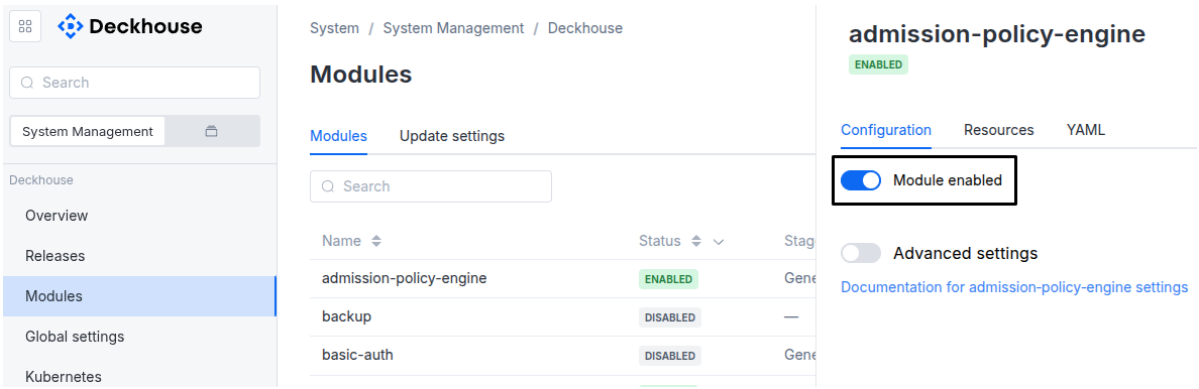
The vertical-pod-autoscaler: configuration

> The module lifecycle stage: General Availability
>
> The module has requirements for installation

VPA works directly with the Pod (instead of the Pod controller) by measuring and changing its containers' parameters. Configuring is performed using the `VerticalPodAutoscaler` Custom Resource.

The module generally requires no configuration and only has the `nodeSelector/tolerations` and `logLevel` settings.



The module has 1 alert.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `vertical-pod-autoscaler` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

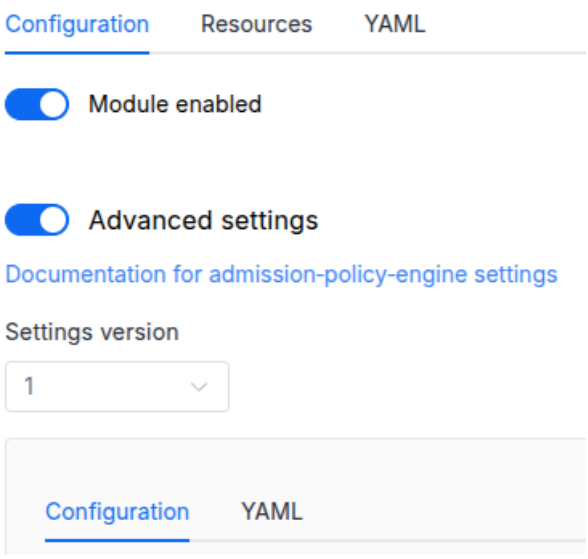
```
d8 system module enable vertical-pod-autoscaler
```

- **Using ModuleConfig `vertical-pod-autoscaler`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `vertical-pod-autoscaler` (create it if necessary);

  Example of a manifest to enable module `vertical-pod-autoscaler`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: vertical-pod-autoscaler
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `vertical-pod-autoscaler` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `vertical-pod-autoscaler` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `vertical-pod-autoscaler`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `vertical-pod-autoscaler` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc vertical-pod-autoscaler
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `vertical-pod-autoscaler` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `vertical-pod-autoscaler`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: vertical-pod-autoscaler
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Requirements

To the versions of other modules:

- `prometheus`: any version.
- `prometheus-metrics-adapter`: any version.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.logLevel**
    string

    Logging level of the VPA components: recommender, updater, and admission-controller.

    Each level includes the messages of the less detailed levels. Some informational messages and warnings, such as startup messages, are logged at any level.

    Supported values:

    - `Error`: Errors and important messages that VPA logs at the info level, such as failed evictions and failed in-place updates.
    - `Warning`: Warnings, the component version at startup, and the pod evictions caused by node resource pressure that the recommender processes (default).
    - `Info`: Actions on pods, such as evictions, in-place resource updates, and setting the resources of pods being created.
    - `Debug`: The progress of each recommender cycle and detailed information on decisions for each pod and container, such as why a pod was not updated. Produces a very large volume of logs, so use it for troubleshooting only.
    - `Trace`: Every request to the Kubernetes API. Use it only when `Debug` is not enough to find the problem.

    Default: `Warning`

    Allowed values: `Trace`, `Debug`, `Info`, `Warning`, `Error`

  - **settings.nodeSelector**
    object

    The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations**
    array of objects

    The same as in the pods' `spec.tolerations` parameter in Kubernetes;

    If the parameter is omitted or `false`, it will be determined automatically.

    - **settings.tolerations.effect**
      string
    - **settings.tolerations.key**
      string
    - **settings.tolerations.operator**

string
- **settings.tolerations.tolerationSeconds**
integer
- **settings.tolerations.value**
string

> **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**
>
> The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Custom resources

VerticalPodAutoscaler

Short names: vpa

Scope: Namespaced

- v1
- v1beta2

Configuration for a vertical pod autoscaler, which automatically manages pod resources based on historical and real time resource utilization.

- **apiVersion**
string

  Defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values.

  More information in the documentation.

- **kind**
string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase.

  More information in the documentation.

- **metadata**
object
- **spec**
object

  Required value

  Specification of the behavior of the autoscaler.

  More information in the documentation.

  - **spec.recommenders**
  array of objects

    Recommender responsible for generating recommendation for this object. List should be empty (then the default recommender will generate the recommendation) or contain exactly one recommender.

    VerticalPodAutoscalerRecommenderSelector points to a specific Vertical Pod Autoscaler

recommender. In the future it might pass parameters to the recommender.

- **spec.recommenders.name**
  string

  Required value

  Name of the recommender responsible for generating recommendation for this object.

- **spec.resourcePolicy**
  object

  Controls how the autoscaler computes recommended resources. The resource policy may be used to set constraints on the recommendations for individual containers.

  If any individual containers need to be excluded from getting the VPA recommendations, then it must be disabled explicitly by setting mode to `Off` under `containerPolicies`.

  If not specified, the autoscaler computes recommended resources for all containers in the pod, without additional constraints.

  - **spec.resourcePolicy.containerPolicies**
    array of objects

    Per-container resource policies.

    Controls how autoscaler computes the recommended resources for a specific container.

    - **spec.resourcePolicy.containerPolicies.containerName**
      string

      Name of the container or `DefaultContainerResourcePolicy`, in which case the policy is used by the containers that don’t have their own policy specified.

    - **spec.resourcePolicy.containerPolicies.controlledResources**
      array of strings

      Specifies the type of recommendations that will be computed (and possibly applied) by VPA. Only `cpu` and `memory` are supported. If not specified, the default of (`cpu`, `memory`) will be used.

      Default: `["cpu","memory"]`

      - **Element of the array**
        string

        ResourceName is the name identifying various resources in a ResourceList.

    - **spec.resourcePolicy.containerPolicies.controlledValues**
      string

      Specifies which resource values should be controlled.

      Default: `RequestsAndLimits`

      Allowed values: `RequestsAndLimits`, `RequestsOnly`

    - **spec.resourcePolicy.containerPolicies.maxAllowed**
      object

      Specifies the maximum amount of resources that will be recommended for the container. The default is no maximum.

    - **spec.resourcePolicy.containerPolicies.minAllowed**
      object

      Specifies the minimal amount of resources that will be recommended for the container. The default is no minimum.

    - **spec.resourcePolicy.containerPolicies.mode**
      string

      Whether autoscaler is enabled for the container.

      Default: `Auto`

      Allowed values: `Auto`, `Off`

    - **spec.resourcePolicy.containerPolicies.recommendationFactor**

object

Per-resource multiplier for the recommendation computed from usage. It is applied after the recommender's own safety margin and before `minAllowed` and `maxAllowed`. `1.2` increases the recommendation by 20%, `0.87` decreases it by 13%. The result never goes below the module-wide minimum recommendation.

Keys are `cpu` and `memory`. Values are quantities written as strings with at most two decimal places, for example `"1.25"`. The allowed range is greater than zero and up to `10` inclusive. A missing key means `1`.

The multiplier affects `target`, `lowerBound` and `upperBound`. `uncappedTarget` keeps the value computed without the multiplier. Limits follow requests proportionally, as usual.

- **spec.scope**
  string

  Scope controls additional recommendation partitioning for DaemonSet targets.

  The value must be a node label key (for example: `node.kubernetes.io/instance-type`).

- **spec.targetRef**
  object

  Required value

  Points to the controller managing the set of pods for the autoscaler to control — e.g. Deployment, StatefulSet.

  VerticalPodAutoscaler can be targeted at controller implementing scale subresource (the pod set is retrieved from the controller's `ScaleStatus`) or some well known controllers (e.g. for DaemonSet the pod set is read from the controller's spec).

  If VerticalPodAutoscaler cannot use specified target it will report `ConfigUnsupported` condition. Note that VerticalPodAutoscaler does not require full implementation of scale subresource — it will not use it to modify the replica count. The only thing retrieved is a label selector matching pods grouped by the target resource.

  - **spec.targetRef.apiVersion**
    string

    API version of the referent.

  - **spec.targetRef.kind**
    string

    Required value

    Kind of the referent.

    More info.

  - **spec.targetRef.name**
    string

    Required value

    Name of the referent.

    More info.

- **spec.updatePolicy**
  object

  Describes the rules on how changes are applied to the pods. If not specified, all fields in the `PodUpdatePolicy` are set to their default values.

  - **spec.updatePolicy.evictionRequirements**
    array of objects

    EvictionRequirements is a list of EvictionRequirements that need to evaluate to true in order for a Pod to be evicted. If more than one EvictionRequirement is specified, all of them need to be fulfilled to allow eviction.

    EvictionRequirement defines a single condition which needs to be true in order to evict a Pod.

- **spec.updatePolicy.evictionRequirements.changeRequirement**
  string

  Required value

  EvictionChangeRequirement refers to the relationship between the new target recommendation for a Pod and its current requests, what kind of change is necessary for the Pod to be evicted.

  Allowed values: `TargetHigherThanRequests`, `TargetLowerThanRequests`

- **spec.updatePolicy.evictionRequirements.resources**
  array of strings

  Required value

  Resources is a list of one or more resources that the condition applies to. If more than one resource is given, the EvictionRequirement is fulfilled if at least one resource meets `changeRequirement`.

  - **Element of the array**
    string

    ResourceName is the name identifying various resources in a ResourceList.

- **spec.updatePolicy.minReplicas**
  integer

  Minimal number of replicas which need to be alive for Updater to attempt pod eviction (pending other checks like PDB). Only positive values are allowed. Overrides global '–min-replicas' flag.

- **spec.updatePolicy.updateMode**
  string

  The operation mode of the VPA controller.

  - `InPlaceOrRecreate`: A default mode. Available in Kubernetes 1.33 and later. VPA attempts to update Pod resources without a restart; if that is not possible, it recreates the Pod.
  - `Recreate`: This mode allows VPA to modify resource requirements of the running pods (i.e., restart them during operation). This mode might result in temporary unavailability of the service (due to restart) if you have just one replica (`replicas: 1`). In this mode, VPA does not recreate pods that were not created by a controller.
  - `Initial`: VPA modifies pod resources only when pods are started (but not when pods are running).
  - `Auto`: A deprecated mode. It will no longer be supported in future DP versions. Use one of the supported operating modes instead.
  - `Off`: VPA does not take any action to update the resource requests for the running containers. Autoscaler calculates recommendations and stores them in the status field of the VPA object. You can browse VPA recommendations using the following command: `d8 k describe vpa <vpa-name>`.

  Default: `InPlaceOrRecreate`

  Allowed values: `Off`, `Initial`, `Recreate`, `Auto`, `InPlaceOrRecreate`

- **status**
  object

  Current information about the autoscaler.

  - **status.conditions**
    array of objects

    Set of conditions required for this autoscaler to scale its target, and indicates whether or not those conditions are met.

    Describes the state of a VerticalPodAutoscaler at a certain point.

    - **status.conditions.lastTransitionTime**
      string

      Last time the condition transitioned from one status to another.

    - **status.conditions.message**

string

A human-readable explanation containing details about the transition.

- **status.conditions.reason**
  string

  Reason for the condition’s last transition.

- **status.conditions.status**
  string

  Required value

  Status of the condition (`True`, `False`, Unknown).

- **status.conditions.type**
  string

  Required value

  Describes the current condition.

- **status.groups**
  array of objects

  Contains grouped recommendations by scope value when `spec.scope` is used.

  - **status.groups.containerRecommendations**
    array of objects

    Resources recommended by autoscaler for each container in this group.

    - **status.groups.containerRecommendations.containerName**
      string

      Name of the container.

    - **status.groups.containerRecommendations.lowerBound**
      object

      Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

    - **status.groups.containerRecommendations.scope**
      string

      Scope binds this recommendation to a specific scope value in form “ =".

    - **status.groups.containerRecommendations.target**
      object

      Required value

      Recommended amount of resources. Observes `ContainerResourcePolicy`.

    - **status.groups.containerRecommendations.uncappedTarget**
      object

      The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`, including `recommendationFactor`.

      May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

    - **status.groups.containerRecommendations.upperBound**
      object

      Maximum recommended amount of resources.

      Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

        - **status.groups.scopeValue**
          string

          Required value

          Scope value of `spec.scope` label key for this recommendation group.

    - **status.recommendation**
      object

      The most recently computed amount of resources recommended by the autoscaler for the controlled pods.

        - **status.recommendation.containerRecommendations**
          array of objects

          Resources recommended by the autoscaler for each container.

          Recommendation of resources computed by autoscaler for a specific container. Respects the container resource policy if present in the spec. In particular the recommendation is not produced for containers with `ContainerScalingMode` set to 'Off'.

            - **status.recommendation.containerRecommendations.containerName**
              string

              Name of the container.

            - **status.recommendation.containerRecommendations.lowerBound**
              object

              Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

            - **status.recommendation.containerRecommendations.scope**
              string

              Scope binds this recommendation to a specific scope value in form " =".

            - **status.recommendation.containerRecommendations.target**
              object

              Required value

              Recommended amount of resources. Observes `ContainerResourcePolicy`.

            - **status.recommendation.containerRecommendations.uncappedTarget**
              object

              The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`, including `recommendationFactor`. May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

            - **status.recommendation.containerRecommendations.upperBound**
              object

              Maximum recommended amount of resources. Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

Deprecated resource. Support for the resource might be removed in a later release.

Configuration for a vertical pod autoscaler, which automatically manages pod resources based on historical and real time resource utilization.

- **apiVersion**
  string

  Defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values.

More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase.

  More information in the documentation.

- **metadata**
  object
- **spec**
  object

  Required value

  Specification of the behavior of the autoscaler.

  More information in the documentation.

  - **spec.recommenders**
    array of objects

    Recommender responsible for generating recommendation for this object. List should be empty (then the default recommender will generate the recommendation) or contain exactly one recommender.

    VerticalPodAutoscalerRecommenderSelector points to a specific Vertical Pod Autoscaler recommender. In the future it might pass parameters to the recommender.

    - **spec.recommenders.name**
      string

      Required value

      Name of the recommender responsible for generating recommendation for this object.

  - **spec.resourcePolicy**
    object

    Controls how the autoscaler computes recommended resources. The resource policy may be used to set constraints on the recommendations for individual containers.

    If any individual containers need to be excluded from getting the VPA recommendations, then it must be disabled explicitly by setting mode to `Off` under `containerPolicies`.

    If not specified, the autoscaler computes recommended resources for all containers in the pod, without additional constraints.

    - **spec.resourcePolicy.containerPolicies**
      array of objects

      Per-container resource policies.

      Controls how autoscaler computes the recommended resources for a specific container.

      - **spec.resourcePolicy.containerPolicies.containerName**
        string

        Name of the container or `DefaultContainerResourcePolicy`, in which case the policy is used by the containers that don’t have their own policy specified.

      - **spec.resourcePolicy.containerPolicies.controlledResources**
        array of strings

        Specifies the type of recommendations that will be computed (and possibly applied) by VPA. Only `cpu` and `memory` are supported. If not specified, the default of (`cpu`, `memory`) will be used.

        Default: `["cpu","memory"]`

        - **Element of the array**
          string

          ResourceName is the name identifying various resources in a ResourceList.

      - **spec.resourcePolicy.containerPolicies.controlledValues**

string

Specifies which resource values should be controlled.

Default: `RequestsAndLimits`

Allowed values: `RequestsAndLimits`, `RequestsOnly`

- **spec.resourcePolicy.containerPolicies.maxAllowed**
  object

  Specifies the maximum amount of resources that will be recommended for the container. The default is no maximum.

- **spec.resourcePolicy.containerPolicies.minAllowed**
  object

  Specifies the minimal amount of resources that will be recommended for the container. The default is no minimum.

- **spec.resourcePolicy.containerPolicies.mode**
  string

  Whether autoscaler is enabled for the container.

  Default: `Auto`

  Allowed values: `Auto`, `Off`

- **spec.resourcePolicy.containerPolicies.recommendationFactor**
  object

  Per-resource multiplier for the recommendation computed from usage. It is applied after the recommender's own safety margin and before `minAllowed` and `maxAllowed`. `1.2` increases the recommendation by 20%, `0.87` decreases it by 13%. The result never goes below the module-wide minimum recommendation.

  Keys are `cpu` and `memory`. Values are quantities written as strings with at most two decimal places, for example `"1.25"`. The allowed range is greater than zero and up to `10` inclusive. A missing key means `1`.

  The multiplier affects `target`, `lowerBound` and `upperBound`. `uncappedTarget` keeps the value computed without the multiplier. Limits follow requests proportionally, as usual.

- **spec.scope**
  string

  Scope controls additional recommendation partitioning for DaemonSet targets.

  The value must be a node label key (for example: `node.kubernetes.io/instance-type`).

- **spec.targetRef**
  object

  Required value

  Points to the controller managing the set of pods for the autoscaler to control — e.g. Deployment, StatefulSet.

  VerticalPodAutoscaler can be targeted at controller implementing scale subresource (the pod set is retrieved from the controller's `ScaleStatus`) or some well known controllers (e.g. for DaemonSet the pod set is read from the controller's spec).

  If VerticalPodAutoscaler cannot use specified target it will report `ConfigUnsupported` condition. Note that VerticalPodAutoscaler does not require full implementation of scale subresource — it will not use it to modify the replica count. The only thing retrieved is a label selector matching pods grouped by the target resource.

  - **spec.targetRef.apiVersion**
    string

    API version of the referent.

  - **spec.targetRef.kind**
    string

    Required value

Kind of the referent.

More info.

- **spec.targetRef.name**
  string

  Required value

  Name of the referent.

  More info.

- **spec.updatePolicy**
  object

  Describes the rules on how changes are applied to the pods. If not specified, all fields in the `PodUpdatePolicy` are set to their default values.

  - **spec.updatePolicy.evictionRequirements**
    array of objects

    EvictionRequirements is a list of EvictionRequirements that need to evaluate to true in order for a Pod to be evicted. If more than one EvictionRequirement is specified, all of them need to be fulfilled to allow eviction.

    EvictionRequirement defines a single condition which needs to be true in order to evict a Pod.

    - **spec.updatePolicy.evictionRequirements.changeRequirement**
      string

      Required value

      EvictionChangeRequirement refers to the relationship between the new target recommendation for a Pod and its current requests, what kind of change is necessary for the Pod to be evicted.

      Allowed values: `TargetHigherThanRequests`, `TargetLowerThanRequests`

    - **spec.updatePolicy.evictionRequirements.resources**
      array of strings

      Required value

      Resources is a list of one or more resources that the condition applies to. If more than one resource is given, the EvictionRequirement is fulfilled if at least one resource meets `changeRequirement`.

      - **Element of the array**
        string

        ResourceName is the name identifying various resources in a ResourceList.

  - **spec.updatePolicy.minReplicas**
    integer

    Minimal number of replicas which need to be alive for Updater to attempt pod eviction (pending other checks like PDB). Only positive values are allowed. Overrides global ‘–min-replicas’ flag.

  - **spec.updatePolicy.updateMode**
    string

    The operation mode of the VPA controller.

    - `InPlaceOrRecreate`: A default mode. Available in Kubernetes 1.33 and later. VPA attempts to update Pod resources without a restart; if that is not possible, it recreates the Pod.
    - `Recreate`: This mode allows VPA to modify resource requirements of the running pods (i.e., restart them during operation). This mode might result in temporary unavailability of the service (due to restart) if you have just one replica (`replicas: 1`). In this mode, VPA does not recreate pods that were not created by a controller.
    - `Initial`: VPA modifies pod resources only when pods are started (but not when pods are running).
    - `Auto`: A deprecated mode. It will no longer be supported in future DP versions. Use one of the supported operating modes instead.

  - `Off`: VPA does not take any action to update the resource requests for the running containers. Autoscaler calculates recommendations and stores them in the status field of the VPA object. You can browse VPA recommendations using the following command: `d8 k describe vpa <vpa-name>`.

  Default: `InPlaceOrRecreate`

  Allowed values: `Off`, `Initial`, `Recreate`, `Auto`, `InPlaceOrRecreate`

- **status**
  object

  Current information about the autoscaler.

  - **status.conditions**
    array of objects

    Set of conditions required for this autoscaler to scale its target, and indicates whether or not those conditions are met.

    Describes the state of a VerticalPodAutoscaler at a certain point.

    - **status.conditions.lastTransitionTime**
      string

      Last time the condition transitioned from one status to another.

    - **status.conditions.message**
      string

      A human-readable explanation containing details about the transition.

    - **status.conditions.reason**
      string

      Reason for the condition’s last transition.

    - **status.conditions.status**
      string

      Required value

      Status of the condition (`True`, `False`, Unknown).

    - **status.conditions.type**
      string

      Required value

      Describes the current condition.

  - **status.groups**
    array of objects

    Contains grouped recommendations by scope value when `spec.scope` is used.

    - **status.groups.containerRecommendations**
      array of objects

      Resources recommended by autoscaler for each container in this group.

      - **status.groups.containerRecommendations.containerName**
        string

        Name of the container.

      - **status.groups.containerRecommendations.lowerBound**
        object

        Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

      - **status.groups.containerRecommendations.scope**
        string

        Scope binds this recommendation to a specific scope value in form “ =".

- **status.groups.containerRecommendations.target**
  object

  Required value

  Recommended amount of resources. Observes `ContainerResourcePolicy`.

- **status.groups.containerRecommendations.uncappedTarget**
  object

  The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`, including `recommendationFactor`.

  May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

- **status.groups.containerRecommendations.upperBound**
  object

  Maximum recommended amount of resources.

  Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

- **status.groups.scopeValue**
  string

  Required value

  Scope value of `spec.scope` label key for this recommendation group.

- **status.recommendation**
  object

  The most recently computed amount of resources recommended by the autoscaler for the controlled pods.

  - **status.recommendation.containerRecommendations**
    array of objects

    Resources recommended by the autoscaler for each container.

    Recommendation of resources computed by autoscaler for a specific container. Respects the container resource policy if present in the spec. In particular the recommendation is not produced for containers with `ContainerScalingMode` set to ‘Off’.

    - **status.recommendation.containerRecommendations.containerName**
      string

      Name of the container.

    - **status.recommendation.containerRecommendations.lowerBound**
      object

      Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

    - **status.recommendation.containerRecommendations.scope**
      string

      Scope binds this recommendation to a specific scope value in form “ =".

    - **status.recommendation.containerRecommendations.target**
      object

      Required value

      Recommended amount of resources. Observes `ContainerResourcePolicy`.

    - **status.recommendation.containerRecommendations.uncappedTarget**
      object

The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`, including `recommendationFactor`. May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

- **status.recommendation.containerRecommendations.upperBound**
  object

  Maximum recommended amount of resources. Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

VerticalPodAutoscalerCheckpoint

Short names: vpacheckpoint

Scope: Namespaced

- v1
- v1beta2

VerticalPodAutoscalerCheckpoint is the checkpoint of the internal state of VPA that is used for recovery after recommender's restart.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More information in the documentation.

- **metadata**
  object
- **spec**
  object

  Specification of the checkpoint. More information in the documentation.

  - **spec.containerName**
    string

    Name of the checkpointed container.

  - **spec.vpaObjectName**
    string

    Name of the VPA object that stored VerticalPodAutoscalerCheckpoint. object.

- **status**
  object

  Data of the checkpoint.

  - **status.cpuHistogram**
    object

    Checkpoint of histogram for consumption of CPU.

    - **status.cpuHistogram.bucketWeights**
      object

      Map from bucket index to bucket weight.

    - **status.cpuHistogram.referenceTimestamp**
      string

      Reference timestamp for samples collected within this histogram.

Reference timestamp for samples collected within this histogram.

- **status.cpuHistogram.totalWeight**
  number

  Sum of samples to be used as denominator for weights from BucketWeights.

- **status.firstSampleStart**
  string

  Timestamp of the fist sample from the histograms.

- **status.lastSampleStart**
  string

  Timestamp of the last sample from the histograms.

- **status.lastUpdateTime**
  string

  The time when the status was last refreshed.

- **status.memoryHistogram**
  object

  Checkpoint of histogram for consumption of memory.

  - **status.memoryHistogram.bucketWeights**
    object

    Map from bucket index to bucket weight.

  - **status.memoryHistogram.referenceTimestamp**
    string

    Reference timestamp for samples collected within this histogram.

  - **status.memoryHistogram.totalWeight**
    number

    Sum of samples to be used as denominator for weights from BucketWeights.

- **status.totalSamplesCount**
  integer

  Total number of samples in the histograms.

- **status.version**
  string

  Version of the format of the stored data.

Deprecated resource. Support for the resource might be removed in a later release.

VerticalPodAutoscalerCheckpoint is the checkpoint of the internal state of VPA that is used for recovery after recommender’s restart.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More information in the documentation.

- **metadata**
  object
- **spec**
  object

  Specification of the checkpoint. More information in the documentation.

  - **spec.containerName**

string

Name of the checkpointed container.

- **spec.vpaObjectName**
  string

  Name of the VPA object that stored VerticalPodAutoscalerCheckpoint. object.

- **status**
  object

  Data of the checkpoint.

  - **status.cpuHistogram**
    object

    Checkpoint of histogram for consumption of CPU.

    - **status.cpuHistogram.bucketWeights**
      object

      Map from bucket index to bucket weight.

    - **status.cpuHistogram.referenceTimestamp**
      string

      Reference timestamp for samples collected within this histogram.

    - **status.cpuHistogram.totalWeight**
      number

      Sum of samples to be used as denominator for weights from BucketWeights.

  - **status.firstSampleStart**
    string

    Timestamp of the fist sample from the histograms.

  - **status.lastSampleStart**
    string

    Timestamp of the last sample from the histograms.

  - **status.lastUpdateTime**
    string

    The time when the status was last refreshed.

  - **status.memoryHistogram**
    object

    Checkpoint of histogram for consumption of memory.

    - **status.memoryHistogram.bucketWeights**
      object

      Map from bucket index to bucket weight.

    - **status.memoryHistogram.referenceTimestamp**
      string

      Reference timestamp for samples collected within this histogram.

    - **status.memoryHistogram.totalWeight**
      number

      Sum of samples to be used as denominator for weights from BucketWeights.

  - **status.totalSamplesCount**
    integer

    Total number of samples in the histograms.

  - **status.version**
    string

    Version of the format of the stored data.

FAQ

> The module lifecycle stage: General Availability
>
> The module has requirements for installation

How do I view the Vertical Pod Autoscaler recommendations?

You can view the VPA recommendations after the VerticalPodAutoscaler custom resource is created using the following command:

```
d8 k describe vpa my-app-vpa
```

The `status` will have the following parameters:

- `Target` — the optimal amount of resources for the Pod (within the resourcePolicy).
- `Lower Bound` — the minimum recommended amount of resources for the regular operation of the application.
- `Upper Bound` — the maximum recommended amount of resources. Most likely, the resources above this upper bound will never be used by the application.
- `Uncapped Target` — the target computed from resource usage only, without the `resourcePolicy` constraints (`minAllowed`, `maxAllowed`) and without `recommendationFactor`.

How does Vertical Pod Autoscaler handle limits?

Example No. 1

The following example shows a VPA object:

```
---
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: test2
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: test2
  updatePolicy:
    updateMode: "Initial"
```

The VPA object contains a Pod with the following resources:

```
resources:
  limits:
    cpu: 2
  requests:
    cpu: 1
```

If a container uses all the CPU, and VPA recommends 1.168 CPU for that container, then the ratio between requests and limits will be 100%. In this case, when recreating the Pod, VPA will modify it and set the following resources:

```
resources:
  limits:
    cpu: 2336m
  requests:
    cpu: 1168m
```

Example No. 2

The following example shows a VPA object:

```
---
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: test2
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: test2
  updatePolicy:
    updateMode: "Initial"
```

The VPA object contains a pod with resources:

```
resources:
  limits:
    cpu: 1
  requests:
    cpu: 750m
```

If the request-to-limit ratio is 25% and VPA recommends 1.168 CPU for the container, VPA will change the container resources as follows:

```
resources:
  limits:
    cpu: 1557m
  requests:
    cpu: 1168m
```

If you need to limit the maximum number of resources that can be allocated to container constraints, you should use `maxAllowed` in the VPA object specification or use the Limit Range of the Kubernetes object.

How do I make VPA recommend more or less than it measured?

VPA computes the recommendation from the measured resource usage and adds its own safety margin. To make VPA recommend more or less, set the `recommendationFactor` field in the container policy of the VerticalPodAutoscaler object. VPA multiplies the computed recommendation by the specified value. For example, `1.2` increases the recommendation by 20%, and `0.87` decreases it by 13%.

Set the multipliers in the VerticalPodAutoscaler object. A policy with `containerName: "*"` applies to all containers that have no policy of their own:

```
---
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: my-app-vpa
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: my-app
  resourcePolicy:
    containerPolicies:
    - containerName: "*"
      recommendationFactor:
        cpu: "1.2"
        memory: "0.87"
```

The `cpu` and `memory` values are quantities written as strings with at most two decimal places, for example `"1.25"`. The allowed range is greater than zero and up to `10` inclusive. If you omit a key, the recommendation for that resource does not change.

VPA applies the multiplier after its own safety margin and before `minAllowed` and `maxAllowed`, so these constraints still limit the final recommendation. In the `status` of the VPA object, `target`, `lowerBound` and `upperBound` already include the multiplier. `uncappedTarget` shows the target computed without it.

Limits follow requests proportionally, as described in the section How does Vertical Pod Autoscaler handle limits?.

⚠ A `memory` multiplier below `1` increases the risk of OOM kills, because it reduces the headroom VPA keeps above the measured usage.

Changing a multiplier changes the recommendation, so the `Updater` component can update the Pods of the application according to its usual rules.

For a DaemonSet with `spec.scope`, VPA stores the recommendations in `status.groups` in a compact form that contains only `target` for each container. The value without the multiplier is not shown there.

i **Starting from version 1.76, Deckhouse Kubernetes Platform has been renamed to Deckhouse Platform.**

The platform now offers more features, and editions have changed. We are already updating the documentation, but if you have any questions, please contact your account manager or technical support.

Examples

i The module lifecycle stage: General Availability

The module has requirements for installation

The module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: vertical-pod-autoscaler
spec:
  version: 1
  enabled: true
  settings:
    nodeSelector:
      node-role/system: ""
    tolerations:
    - key: dedicated.deckhouse.io
      operator: Equal
      value: system
```

The basic `VerticalPodAutoscaler` custom resource example

```
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: my-app-vpa
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: StatefulSet
    name: my-app
```

The advanced `VerticalPodAutoscaler` custom resource example

```
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: my-app-vpa
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: my-app
  updatePolicy:
    updateMode: "InPlaceOrRecreate"
  resourcePolicy:
    containerPolicies:
    - containerName: hamster
      minAllowed:
        memory: 100Mi
        cpu: 120m
      maxAllowed:
        memory: 300Mi
        cpu: 350m
      mode: Auto
```
