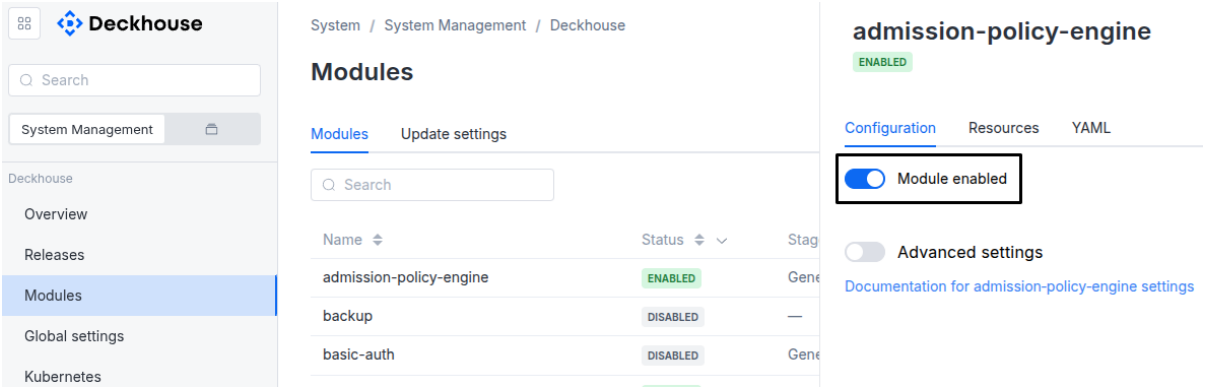
- Registering with `node-manager` so that DVPInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

> **⚠** If the cluster was installed with the DVPClusterConfiguration schema, migrate to configuration via ModuleConfig. Until the migration is complete, the `D8CloudProviderDVPMigrationPending` alert may fire and Deckhouse updates may be blocked.
>
> See How to migrate a cloud provider to ModuleConfig.

Configuration



> **i** The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in DVP.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-dvp` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

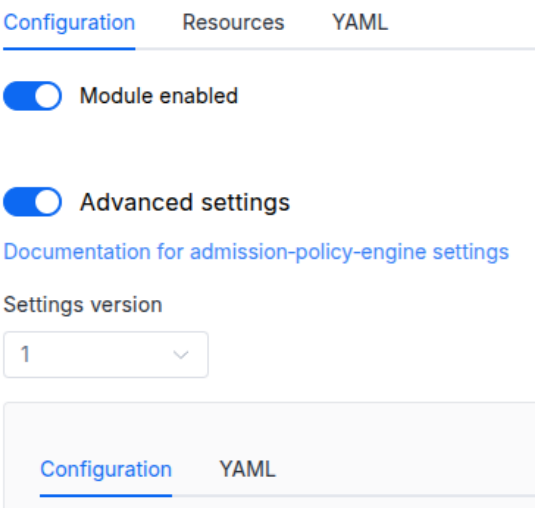
  ```
  d8 system module enable cloud-provider-dvp
  ```

- **Using ModuleConfig `cloud-provider-dvp`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-dvp` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-dvp`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-dvp
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-dvp` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-dvp` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-dvp`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

Edit the existing ModuleConfig `cloud-provider-dvp` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc cloud-provider-dvp
```

Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `cloud-provider-dvp` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-dvp`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-dvp
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.provider**
    object

    Contains settings to connect to the Deckhouse Kubernetes Platform API.

    - **settings.provider.kubeconfigDataBase64**
      string

      Required value

      Kubeconfig to connect to Deckhouse Kubernetes Platform API base64 encoded.

      Example:

      ```
      kubeconfigDataBase64: ZXhhbXBsZQo=
      ```

    - **settings.provider.namespace**
      string

      Required value

      Namespace in which DKP cluster resources will be created.

      > **i** Caution! If not explicitly specified, the default namespace for kubeconfig will be used.

      Example:

      ```
      namespace: default
      ```

  - **settings.zones**
    array of strings

    A set of zones in which nodes can be created. To use this setting, the `topology.kubernetes.io/zone` label must be set on DVP nodes. Read more about topological labels.

    > **i** Caution! To set the required label for a DVP node, follow the NodeGroup documentation.

    Example:

```
zones:
- zone-a
- zone-b
```

Provider configuration

> **i** The module lifecycle stage: General Availability

DVPClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in Deckhouse Virtualization Platform (DVP).

Used by the cloud provider if a cluster’s control plane is hosted in the DVP cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> **i** Once you modify the node configuration, run `dhctl converge` for changes to take effect.

Example:

```
apiVersion: deckhouse.io/v1
kind: DVPClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
zones:
- zone-a
- zone-b
- zone-c
region: r1
masterNodeGroup:
  replicas: 3
  zones:
  - zone-a
  - zone-b
  - zone-c
  instanceClass:
    virtualMachine:
      cpu:
        cores: 1
        coreFraction: 100%
      memory:
        size: 4Gi
      virtualMachineClassName: generic
      ipAddresses:
      - 10.66.30.100
      - 10.66.30.101
      - 10.66.30.102
      additionalLabels:
        additional-vm-label: label-value
      additionalAnnotations:
        additional-vm-annotation: annotation-value
      tolerations:
      - key: dedicated.deckhouse.io
        operator: Equal
        value: system
      nodeSelector:
        beta.kubernetes.io/os: linux
    rootDisk:
      size: 10Gi
      storageClass: linstor-thin-r1
      image:
```

```
      kind: ClusterVirtualImage
      name: ubuntu-2204
   etcdDisk:
     size: 10Gi
     storageClass: linstor-thin-r1
   additionalDisks:
   - size: 10Gi
     storageClass: linstor-thin-r1
   - size: 1Gi
     storageClass: linstor-thin-r1
nodeGroups:
- name: worker
  zones:
  - zone-a
  - zone-b
  - zone-c
  replicas: 1
  instanceClass:
    virtualMachine:
      cpu:
        cores: 4
        coreFraction: 100%
      memory:
        size: 8Gi
      virtualMachineClassName: generic
    rootDisk:
      size: 10Gi
      image:
        kind: ClusterVirtualImage
        name: ubuntu-2204
    additionalDisks:
    - size: 10Gi
      storageClass: linstor-thin-r1
    - size: 1Gi
      storageClass: linstor-thin-r1
provider:
  kubeconfigDataBase64: ZXhhbXBsZQo=
  namespace: default
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **kind**
  string

  Required value

  Allowed values: `DVPClusterConfiguration`

- **layout**
  string

  Required value

  Layout name.

  Read more about possible provider layouts.

  Allowed values: `Standard`

- **masterNodeGroup**
  object

  Required value

  The definition of the master’s NodeGroup.

  > **i** Once you modify the `masterNodeGroup` configuration, run [`dhctl converge`] for changes to take effect.

- **masterNodeGroup.instanceClass**
  object

  Required value

  Configuration for the virtual machine’s root disk.

  - **masterNodeGroup.instanceClass.additionalDisks**
    array of objects

    Parameters for additional virtual machine disks.

    Each item in the array describes one additional disk. Both `size` and `storageClass` parameters must be specified for each disk.

    - **masterNodeGroup.instanceClass.additionalDisks.size**
      string

      Required value

      Size of the additional disk.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

      Example:

      ```
      size: 10Gi
      ```

    - **masterNodeGroup.instanceClass.additionalDisks.storageClass**
      string

      Required value

      Name of the existing StorageClass that will be used to create the additional disk.

      Example:

      ```
      storageClass: ceph-pool-r2-csi-rbd-immediate
      ```

  - **masterNodeGroup.instanceClass.additionalLabels**
    object

    Additional labels.

    Example:

    ```
    project: cms-production
    severity: critical
    ```

  - **masterNodeGroup.instanceClass.etcdDisk**
    object

    Required value

    Specifies settings for the etcd data disk.

    - **masterNodeGroup.instanceClass.etcdDisk.size**
      string

      Required value

      Etcd disk size.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

      Example:

      ```
      size: 10Gi
      ```

    - **masterNodeGroup.instanceClass.etcdDisk.storageClass**
      string

      Name of the existing StorageClass will be used to create the etcd data disk.

      If the value is not specified, the StorageClass will be used according to the global storageClass parameter setting.

  - **masterNodeGroup.instanceClass.rootDisk**
    object

Required value

Specifies settings for the root disk of the virtual machine.

- **masterNodeGroup.instanceClass.rootDisk.image**
  object

  Required value

  Image parameters that will be used to create the virtual machine's root disk.

  - **masterNodeGroup.instanceClass.rootDisk.image.kind**
    string

    Required value

    The kind of the image source.

    Allowed values: `ClusterVirtualImage`, `VirtualImage`

  - **masterNodeGroup.instanceClass.rootDisk.image.name**
    string

    Required value

    The name of the image that will be used to create the root disk.

    > **i** The installation requires Linux OS images with cloud-init pre-installed.

- **masterNodeGroup.instanceClass.rootDisk.size**
  string

  Required value

  Root disk size.

  Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

  Example:

  ```
  size: 10Gi
  ```

- **masterNodeGroup.instanceClass.rootDisk.storageClass**
  string

  Name of the existing StorageClass will be used to create the virtual machine's root disk.

  If the value is not specified, the StorageClass will be used according to the global storageClass parameter setting.

- **masterNodeGroup.instanceClass.virtualMachine**
  object

  Required value

  Virtual machine settings for the created master node.

  > **i** The `runPolicy: AlwaysOnUnlessStoppedManually` policy is used for virtual machines of nodes. This allows the virtual machine to be stopped manually (for example, for maintenance) without triggering an automatic restart.

  - **masterNodeGroup.instanceClass.virtualMachine.additionalAnnotations**
    object

    Additional annotations for a virtual machine resource.

    Example:

    ```
    cluster-owner: user
    ```

  - **masterNodeGroup.instanceClass.virtualMachine.additionalLabels**
    object

    Additional labels for a virtual machine resource.

    Example:

```
cluster-owner: user
```

- **masterNodeGroup.instanceClass.virtualMachine.bootloader**
  string

  Defines a bootloader for the virtual machine.

  - `BIOS`: Use BIOS.
  - `EFI`: Use Unified Extensible Firmware (EFI/UEFI).
  - `EFIWithSecureBoot`: Use UEFI/EFI with Secure Boot support.

  Default: `EFI`

  Allowed values: `BIOS`, `EFI`, `EFIWithSecureBoot`

- **masterNodeGroup.instanceClass.virtualMachine.cpu**
  object

  Required value

  CPU settings for the virtual machine.

  - **masterNodeGroup.instanceClass.virtualMachine.cpu.coreFraction**
    string

    Guaranteed share of CPU that will be allocated to the virtual machine.

    Default: `100%`

    Pattern: `^100%$|^[1-9][0-9]?%$`

    Example:

    ```
    coreFraction: 100%
    ```

  - **masterNodeGroup.instanceClass.virtualMachine.cpu.cores**
    integer

    Required value

    Number of CPU cores for the virtual machine.

    Allowed values: `1 <= X`

- **masterNodeGroup.instanceClass.virtualMachine.ipAddresses**
  array of strings

  Static IP addresses to be assigned to the network interfaces of the virtual machines. The number of addresses must match the number of replicas being created — each IP address will be assigned to a specific virtual machine replica. For example, if 3 replicas are specified and the IP addresses provided are: ip1, ip2, and ip3, then ip1 will be assigned to the first replica, ip2 to the second, and ip3 to the third.

  > **i** These addresses must belong to the address range specified in the virtualization module configuration in the `virtualMachineCIDRs` parameter.

  - **Element of the array**
    string

    Pattern: `^([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})|(Auto)$`

- **masterNodeGroup.instanceClass.virtualMachine.liveMigrationPolicy**
  string

  Live migration policy for the virtual machine.

  - `Manual`: Migration is controlled manually.
  - `Never`: Migration is disabled.
  - `AlwaysSafe`: Always use safe migration (may fail if VM has a high rate of memory changes).
  - `PreferSafe`: Prefer safe migration, fallback to forced if needed.
  - `AlwaysForced`: Always use forced migration with VM slowdown.
  - `PreferForced`: Prefer forced migration (recommended for master nodes due to high memory activity).

  Default: `PreferForced`

  Allowed values: `Manual`, `Never`, `AlwaysSafe`, `PreferSafe`, `AlwaysForced`, `PreferForced`

- **masterNodeGroup.instanceClass.virtualMachine.memory**

object

Required value

Specifies the memory settings for the virtual machine.

- **masterNodeGroup.instanceClass.virtualMachine.memory.size**
  string

  Required value

  Amount of memory resources allowed for the virtual machine.

  Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

  Example:

  ```
  size: 4Gi
  ```

- **masterNodeGroup.instanceClass.virtualMachine.nodeSelector**
  object

  Allows a virtual machine to be assigned to specified DVP nodes. The same as in the `spec.nodeSelector` parameter for Kubernetes Pods.

- **masterNodeGroup.instanceClass.virtualMachine.priorityClassName**
  string

  The same as in the `spec.priorityClassName` parameter for Kubernetes Pods.

- **masterNodeGroup.instanceClass.virtualMachine.runPolicy**
  string

  Virtual machine run policy.

  - `AlwaysOn`: The virtual machine should always be running.
  - `AlwaysOff`: The virtual machine should always be stopped.
  - `Manual`: The virtual machine state is controlled manually.
  - `AlwaysOnUnlessStoppedManually`: The virtual machine can be stopped manually (for example, for maintenance), but it will automatically start after a host reboot.

  Default: `AlwaysOnUnlessStoppedManually`

  Allowed values: `AlwaysOn`, `AlwaysOff`, `Manual`, `AlwaysOnUnlessStoppedManually`

- **masterNodeGroup.instanceClass.virtualMachine.tolerations**
  array of objects

  Allows setting tolerations for virtual machines for a DVP node. The same as in the `spec.tolerations` parameter in Kubernetes Pods.

  - **masterNodeGroup.instanceClass.virtualMachine.tolerations.effect**
    string
  - **masterNodeGroup.instanceClass.virtualMachine.tolerations.key**
    string
  - **masterNodeGroup.instanceClass.virtualMachine.tolerations.operator**
    string
  - **masterNodeGroup.instanceClass.virtualMachine.tolerations.tolerationSeconds**
    integer
  - **masterNodeGroup.instanceClass.virtualMachine.tolerations.value**
    string

- **masterNodeGroup.instanceClass.virtualMachine.virtualMachineClassName**
  string

  Required value

  The name of the VirtualMachineClass.

  Intended for centralized configuration of preferred virtual machine parameters. It allows you to specify CPU instruction sets, resource configuration policies for CPU and memory, and define the ratio between these resources.

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create.

  It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  A set of zones in which nodes can be created.

  To use this setting, the `topology.kubernetes.io/zone` label must be set on DVP nodes. Read more about topological labels.

  > **i** To set the required label for a DVP node, follow the NodeGroup documentation.

- **nodeGroups**
  array of objects

  Array of additional NodeGroups for creating static nodes (for example, for dedicated frontend nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Configuration of the virtual machine and its disk for the created static node.

    - **nodeGroups.instanceClass.additionalDisks**
      array of objects

      Parameters for additional virtual machine disks.

      Each item in the array describes one additional disk. Both `size` and `storageClass` parameters must be specified for each disk.

      - **nodeGroups.instanceClass.additionalDisks.size**
        string

        Required value

        Size of the additional disk.

        Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

        Example:

        ```
        size: 10Gi
        ```

      - **nodeGroups.instanceClass.additionalDisks.storageClass**
        string

        Required value

        Name of the existing StorageClass that will be used to create the additional disk.

        Example:

        ```
        storageClass: ceph-pool-r2-csi-rbd-immediate
        ```

    - **nodeGroups.instanceClass.rootDisk**
      object

      Required value

      Specifies settings for the root disk of the virtual machine.

      - **nodeGroups.instanceClass.rootDisk.image**
        object

        Required value

        Image parameters that will be used to create the virtual machine’s root disk.

        - **nodeGroups.instanceClass.rootDisk.image.kind**
          string

          Required value

          The kind of the image source.

          Allowed values: `ClusterVirtualImage`, `VirtualImage`

        - **nodeGroups.instanceClass.rootDisk.image.name**
          string

Required value

The name of the image that will be used to create the root disk.

> **i** The installation requires Linux OS images with cloud-init pre-installed.

- **nodeGroups.instanceClass.rootDisk.size**
  string

  Required value

  Root disk size.

  Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

  Example:

  ```
  size: 10Gi
  ```

- **nodeGroups.instanceClass.rootDisk.storageClass**
  string

  Name of the existing StorageClass will be used to create the virtual machine's root disk.

  If the value is not specified, the StorageClass will be used according to the global storageClass parameter setting.

- **nodeGroups.instanceClass.virtualMachine**
  object

  Required value

  Virtual machine settings for the created master node.

  > **i** The `runPolicy: AlwaysOnUnlessStoppedManually` policy is used for virtual machines of nodes. This allows the virtual machine to be stopped manually (for example, for maintenance) without triggering an automatic restart.

  - **nodeGroups.instanceClass.virtualMachine.additionalAnnotations**
    object

    Additional annotations for a virtual machine resource.

    Example:

    ```
    cluster-owner: user
    ```

  - **nodeGroups.instanceClass.virtualMachine.additionalLabels**
    object

    Additional labels for a virtual machine resource.

    Example:

    ```
    cluster-owner: user
    ```

  - **nodeGroups.instanceClass.virtualMachine.bootloader**
    string

    Defines a bootloader for the virtual machine.

    - `BIOS`: Use BIOS.
    - `EFI`: Use Unified Extensible Firmware (EFI/UEFI).
    - `EFIWithSecureBoot`: Use UEFI/EFI with Secure Boot support.

    Default: `EFI`

    Allowed values: `BIOS`, `EFI`, `EFIWithSecureBoot`

  - **nodeGroups.instanceClass.virtualMachine.cpu**
    object

    Required value

    CPU settings for the virtual machine.

    - **nodeGroups.instanceClass.virtualMachine.cpu.coreFraction**

string

Guaranteed share of CPU that will be allocated to the virtual machine.

Default: `100%`

Pattern: `^100%$|^[1-9][0-9]?%$`

Example:

```
coreFraction: 100%
```

- **nodeGroups.instanceClass.virtualMachine.cpu.cores**
  integer

  Required value

  Number of CPU cores for the virtual machine.

  Allowed values: `1 <= X`

- **nodeGroups.instanceClass.virtualMachine.ipAddresses**
  array of strings

  Static IP addresses to be assigned to the network interfaces of the virtual machines. The number of addresses must match the number of replicas being created — each IP address will be assigned to a specific virtual machine replica. For example, if 3 replicas are specified and the IP addresses provided are: ip1, ip2, and ip3, then ip1 will be assigned to the first replica, ip2 to the second, and ip3 to the third.

  > **i** These addresses must belong to the address range specified in the virtualization module configuration in the `virtualMachineCIDRs` parameter.

  - **Element of the array**
    string

    Pattern: `^([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})|(Auto)$`

- **nodeGroups.instanceClass.virtualMachine.liveMigrationPolicy**
  string

  Live migration policy for the virtual machine.

  - `Manual`: Migration is controlled manually.
  - `Never`: Migration is disabled.
  - `AlwaysSafe`: Always use safe migration (may fail if VM has a high rate of memory changes).
  - `PreferSafe`: Prefer safe migration, fallback to forced if needed.
  - `AlwaysForced`: Always use forced migration with VM slowdown.
  - `PreferForced`: Prefer forced migration (recommended for master nodes due to high memory activity).

  Default: `PreferForced`

  Allowed values: `Manual`, `Never`, `AlwaysSafe`, `PreferSafe`, `AlwaysForced`, `PreferForced`

- **nodeGroups.instanceClass.virtualMachine.memory**
  object

  Required value

  Specifies the memory settings for the virtual machine.

  - **nodeGroups.instanceClass.virtualMachine.memory.size**
    string

    Required value

    Amount of memory resources allowed for the virtual machine.

    Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

    Example:

    ```
    size: 4Gi
    ```

- **nodeGroups.instanceClass.virtualMachine.nodeSelector**
  object

Allows a virtual machine to be assigned to specified DVP nodes. The same as in the `spec.nodeSelector` parameter for Kubernetes Pods.

- **nodeGroups.instanceClass.virtualMachine.priorityClassName**
  string

  The same as in the `spec.priorityClassName` parameter for Kubernetes Pods.

- **nodeGroups.instanceClass.virtualMachine.runPolicy**
  string

  Virtual machine run policy.

  - `AlwaysOn`: The virtual machine should always be running.
  - `AlwaysOff`: The virtual machine should always be stopped.
  - `Manual`: The virtual machine state is controlled manually.
  - `AlwaysOnUnlessStoppedManually`: The virtual machine can be stopped manually (for example, for maintenance), but it will automatically start after a host reboot.

  Default: `AlwaysOnUnlessStoppedManually`

  Allowed values: `AlwaysOn`, `AlwaysOff`, `Manual`, `AlwaysOnUnlessStoppedManually`

- **nodeGroups.instanceClass.virtualMachine.tolerations**
  array of objects

  Allows setting tolerations for virtual machines for a DVP node. The same as in the `spec.tolerations` parameter in Kubernetes Pods.

  - **nodeGroups.instanceClass.virtualMachine.tolerations.effect**
    string
  - **nodeGroups.instanceClass.virtualMachine.tolerations.key**
    string
  - **nodeGroups.instanceClass.virtualMachine.tolerations.operator**
    string
  - **nodeGroups.instanceClass.virtualMachine.tolerations.tolerationSeconds**
    integer
  - **nodeGroups.instanceClass.virtualMachine.tolerations.value**
    string

- **nodeGroups.instanceClass.virtualMachine.virtualMachineClassName**
  string

  Required value

  The name of the VirtualMachineClass.

  Intended for centralized configuration of preferred virtual machine parameters. It allows you to specify CPU instruction sets, resource configuration policies for CPU and memory, and define the ratio between these resources.

- **nodeGroups.name**
  string

  Required value

  Name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the standard `metadata.annotations` field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: "true"
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to all cluster resources (if supported by the resources).

    The same as the standard `metadata.labels` field.

    When modifying labels in the running cluster, make sure re-create all the machines to apply the new labels.

    Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Only the `effect`, `key`, and `values` fields are available.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  Required value

  Number of nodes to create.

- **nodeGroups.zones**
  array of strings

  A set of zones in which nodes can be created.

  To use this setting, the `topology.kubernetes.io/zone` label must be set on DVP nodes. Read more about topological labels.

  > **i** To set the required label for a DVP node, follow the NodeGroup documentation.

- **provider**
  object

  Required value

  Contains settings to connect to the Deckhouse Kubernetes Platform API.

  - **provider.kubeconfigDataBase64**
    string

    Required value

    Kubeconfig to connect to Deckhouse Kubernetes Platform API, Base64-encoded.

    Pattern: `^[A-Za-z0-9+/]+[=]{0,2}$`
  - **provider.namespace**
    string

    Required value

    Namespace in which DKP cluster resources will be created.

    > **i** If not explicitly specified, the default namespace for kubeconfig will be used.

  - **provider.networkPolicy**
    string

    Control rules for network traffic to and from workloads running in the Project resource.

    - `Isolated`: Applies a restrictive NetworkPolicy that allows only network traffic required for

platform system components to function. All other traffic is denied.
  - `None`: The cluster does not request any network policies. Existing project-level restrictions still apply.

Default: `Isolated`

Allowed values: `Isolated`, `None`

- **region**
  string

  Region name.

  To use this setting, the `topology.kubernetes.io/region` label must be set on DVP nodes. Read more about topological labels.

  > **i** To set the required label for a DVP node, follow the NodeGroup documentation.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **zones**
  array of strings

  A set of zones in which nodes can be created.

  To use this setting, the `topology.kubernetes.io/zone` label must be set on DVP nodes. Read more about topological labels.

  > **i** To set the required label for a DVP node, follow the NodeGroup documentation.

Preparing environment

> **i** The module lifecycle stage: General Availability

Deckhouse Kubernetes Platform components interact with DVP resources through the DVP API. To configure this connection, create a new user (ServiceAccount), assign the necessary permissions, and generate a kubeconfig.

> ⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

> ⚠ If the `update-hostname` module of the `cloud-init` package is not disabled, it is recommended to change its run frequency from `always` to `once-per-instance`.
>
> To do this, modify the `update-hostname` module configuration in the `/etc/cloud/cloud.cfg` file:
>
> ```
> cloud_init_modules:
>   ...
>   - [update-hostname, once-per-instance]
>   ...
> ```
>
> The `update-hostname` module can also be disabled completely by removing it from the `cloud_init_modules` module list in the `/etc/cloud/cloud.cfg` file.

Creating a user

Create a new user in the DVP cluster using the following command:

```
d8 k create -f -<<EOF
apiVersion: v1
kind: ServiceAccount
metadata:
  name: sa-demo
  namespace: default
---
apiVersion: v1
kind: Secret
metadata:
  name: sa-demo-token
  namespace: default
  annotations:
    kubernetes.io/service-account.name: sa-demo
type: kubernetes.io/service-account-token
EOF
```

Adding a role

Add a role to the created user in the DVP cluster using the following command:

```
d8 k create -f -<<EOF
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: sa-demo-rb
  namespace: default
subjects:
  - kind: ServiceAccount
    name: sa-demo
    namespace: default
roleRef:
  kind: ClusterRole
  name: d8:use:role:manager
  apiGroup: rbac.authorization.k8s.io
EOF
```

Generating a kubeconfig

Generate a kubeconfig to be used in the cluster initial configuration file:

```
cat <<EOF > kubeconfig
apiVersion: v1
clusters:
- cluster:
    server: https://<KUBE-APISERVER-URL>   # Replace this with the actual API server address
for the cluster.
  name: <CLUSTER-NAME>                     # Replace with the cluster name.
contexts:
- context:
    cluster: <CLUSTER-NAME>                # Replace with the cluster name.
    user: sa-demo
    namespace: default
  name: sa-demo-context
current-context: sa-demo-context
kind: Config
preferences: {}
users:
- name: sa-demo
  user:
    token: $(d8 k get secret sa-demo-token -n default -o json | jq -rc .data.token | base64 -d)
EOF
```

Encode the generated kubeconfig file using Base64 encoding (it appears in the initial configuration file as follows):

```
base64 kubeconfig | tr -d '\n'
```

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

DVPInstanceClass

Scope: Cluster
Version: v1alpha1

- **spec**
  object

  Required value

  - **spec.additionalDisks**
    array of objects

    Parameters for additional virtual machine disks.

    - **spec.additionalDisks.size**
      string

      Required value

      Size of the additional disk.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

      Example:

      ```
      size: 10Gi
      ```

    - **spec.additionalDisks.storageClass**
      string

      Required value

      Name of the existing StorageClass that will be used to create the additional disk.

  - **spec.rootDisk**
    object

    Required value

    Specifies settings for the root disk of the virtual machine.

    - **spec.rootDisk.image**
      object

      Required value

      Image parameters that will be used to create the virtual machine’s root disk.

      - **spec.rootDisk.image.kind**
        string

        Required value

        The kind of the image source.

        Allowed values: `ClusterVirtualImage`, `VirtualImage`, `VirtualDisk`

      - **spec.rootDisk.image.name**
        string

        Required value

        The name of the image that will be used to create the root disk.

        > **i** The installation requires Linux OS images with cloud-init pre-installed.

    - **spec.rootDisk.size**
      string

      Required value

      Root disk size.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

Example:

```
size: 10Gi
```

- **spec.rootDisk.storageClass**
  string

  The name of the existing StorageClass will be used to create the virtual machine's root disk.

  If the value is not specified, the StorageClass will be used according to the global storageClass parameter setting.

- **spec.virtualMachine**
  object

  Required value

  Virtual machine settings for the created node.

  > **i** The `runPolicy: AlwaysOnUnlessStoppedManually` policy is used for virtual machines of nodes. This allows the virtual machine to be stopped manually (for example, for maintenance) without triggering an automatic restart.

  - **spec.virtualMachine.bootloader**
    string

    Defines a bootloader for the virtual machine.

    - `BIOS`: Use BIOS.
    - `EFI`: Use Unified Extensible Firmware (EFI/UEFI).
    - `EFIWithSecureBoot`: Use UEFI/EFI with the Secure Boot support.

    Default: `EFI`

    Allowed values: `BIOS`, `EFI`, `EFIWithSecureBoot`

  - **spec.virtualMachine.cpu**
    object

    Required value

    CPU settings for the virtual machine.

    - **spec.virtualMachine.cpu.coreFraction**
      string

      Guaranteed share of CPU fraction that will be allocated to the virtual machine.

      Default: `100%`

      Pattern: `^100%$|^[1-9][0-9]?%$`

      Example:

      ```
      coreFraction: 100%
      ```

    - **spec.virtualMachine.cpu.cores**
      integer

      Required value

      Number of CPU cores for the virtual machine.

      Allowed values: `1 <= X`

      Example:

      ```
      cores: 4
      ```

  - **spec.virtualMachine.liveMigrationPolicy**
    string

    Live migration policy for the virtual machine.

    - `Manual`: Migration is controlled manually.
    - `Never`: Migration is disabled.
    - `AlwaysSafe`: Always use safe migration (may fail if VM has a high rate of memory changes).
    - `PreferSafe`: Prefer safe migration, fallback to forced if needed.
    - `AlwaysForced`: Always use forced migration with VM slowdown.
    - `PreferForced`: Prefer forced migration (recommended for master nodes due to high memory activity).

    Default: `PreferForced`

    Allowed values: `Manual`, `Never`, `AlwaysSafe`, `PreferSafe`, `AlwaysForced`, `PreferForced`

    Example:

```
liveMigrationPolicy: PreferForced
```

- **spec.virtualMachine.memory**
  object

  Required value

  Specifies the memory settings for the virtual machine.

  - **spec.virtualMachine.memory.size**
    string

    Required value

    Amount of memory resources allowed for the virtual machine.

    Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

    Example:

    ```
    size: 4Gi
    ```

- **spec.virtualMachine.runPolicy**
  string

  Virtual machine run policy.

  - `AlwaysOn`: The virtual machine should always be running.
  - `AlwaysOff`: The virtual machine should always be stopped.
  - `Manual`: The virtual machine state is controlled manually.
  - `AlwaysOnUnlessStoppedManually`: The virtual machine can be stopped manually (for example, for maintenance), but it will automatically start after a host reboot.

  Default: `AlwaysOnUnlessStoppedManually`

  Allowed values: `AlwaysOn`, `AlwaysOff`, `Manual`, `AlwaysOnUnlessStoppedManually`

  Example:

  ```
  runPolicy: AlwaysOnUnlessStoppedManually
  ```

- **spec.virtualMachine.virtualMachineClassName**
  string

  Required value

  The name of the VirtualMachineClass.

  Intended for centralized configuration of preferred virtual machine parameters. It allows you to specify CPU instruction sets, resource configuration policies for CPU and memory, and define the ratio between these resources.

Layouts

> **i** The module lifecycle stage: General Availability

Standard

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1
kind: DVPClusterConfiguration
layout: Standard
sshPublicKey: <SSH_PUBLIC_KEY>
masterNodeGroup:
  replicas: 1
  instanceClass:
    virtualMachine:
      cpu:
        cores: 4
        coreFraction: 100%
      memory:
        size: 8Gi
      ipAddresses:
        - Auto
      virtualMachineClassName: generic
    rootDisk:
      size: 50Gi
      storageClass: ceph-pool-r2-csi-rbd-immediate
      image:
        kind: ClusterVirtualImage
        name: ubuntu-2204
    etcdDisk:
      size: 15Gi
      storageClass: ceph-pool-r2-csi-rbd-immediate
provider:
  kubeconfigDataBase64: <KUBE_CONFIG>
  namespace: demo
```

Cloud provider — Basis Dynamix

⚠ The module lifecycle stage: Preview

The `cloud-provider-dynamix` module integrates Deckhouse Kubernetes Platform with the Basis Dynamix platform. It allows the `node-manager` module to use Dynamix resources when provisioning nodes for a NodeGroup.

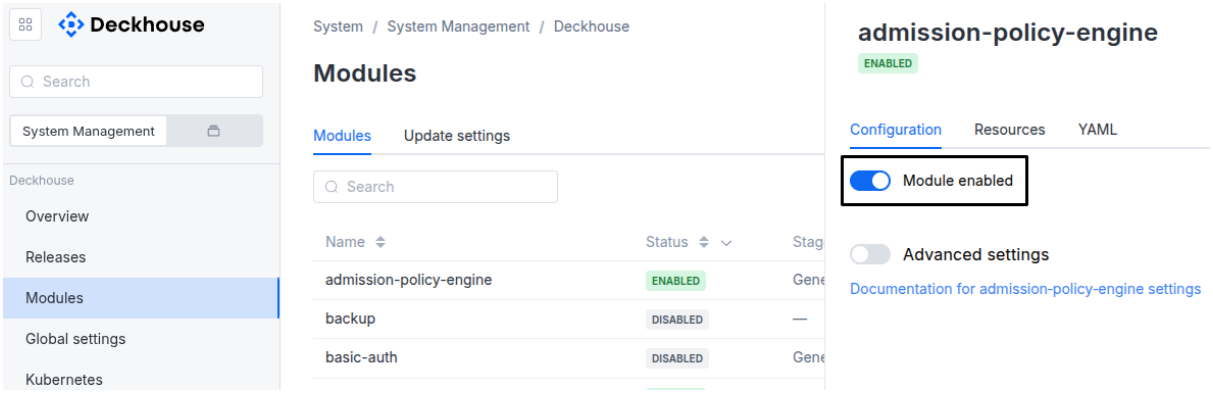
Features of the `cloud-provider-dynamix` module:

- Managing Dynamix resources via `cloud-controller-manager`:
  - updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in Dynamix;
  - creates load balancers for Services of the LoadBalancer type. The Service must include annotations with the names of the internal and external networks.
- Provisioning disks via the Dynamix CSI driver (`dynamix.deckhouse.io`) so that PersistentVolumes can be requested from the cluster.
- Provisioning CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-decort`.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the DynamixInstanceClass resource.
- Registering with `node-manager` so that DynamixInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

> **i** The module is in the Preview stage.

Configuration

> **⚠** The module lifecycle stage: Preview



The module is automatically enabled for all cloud clusters deployed in Basis Dynamix.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-dynamix` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

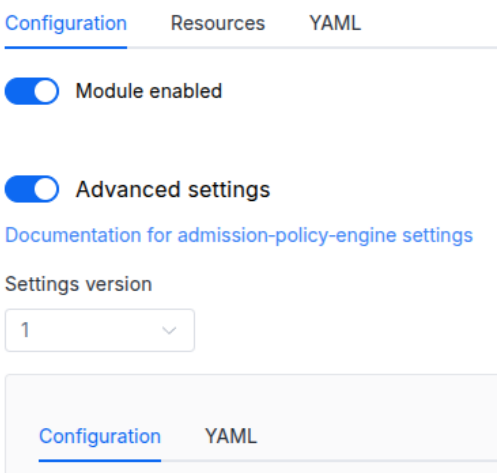
```
d8 system module enable cloud-provider-dynamix
```

- **Using ModuleConfig `cloud-provider-dynamix`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-dynamix` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-dynamix`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-dynamix
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-dynamix` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `cloud-provider-dynamix` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-dynamix`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-dynamix` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-dynamix
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-dynamix` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-dynamix`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-dynamix
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

The module does not have any settings.

Provider configuration

⚠ The module lifecycle stage: Preview

i If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-dynamix` module in the Deckhouse configuration. If the cluster control plane is hosted in a cloud, the cloud provider uses the DynamixClusterConfiguration structure for configuration.

DynamixClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in Dynamix.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> **i** After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: DynamixClusterConfiguration
layout: StandardWithInternalNetwork
sshPublicKey: ssh-rsa AAAA
location: dynamix
account: acc_user
nodeNetworkCIDR: 10.241.32.0/24
nameservers:
- 10.0.0.10
provider:
  controllerUrl: "<controller url>"
  oAuth2Url: "<oAuth2 url>"
  appId: "<app id>"
  appSecret: "<app secret>"
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    storageEndpoint: "<storage endpoint>"
    pool: "<pool>"
    externalNetwork: "<external network>"
nodeGroups:
- name: worker
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    externalNetwork: "<external network>"
```

- **account**
  string

  Required value

  Account name.

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **kind**
  string

  Required value

  Allowed values: `DynamixClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **location**
  string

  Required value

  The name of the location to install the cluster.

- **masterNodeGroup**
  object

Required value

The definition of the master’s NodeGroup.

> **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

- **masterNodeGroup.instanceClass**
  object

  Required value

  Partial contents of the fields of the DynamixInstanceClass.

  - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
    integer

    Etcd disk size in GiB.

    Default: `15`

    Example:

    ```
    etcdDiskSizeGb: 15
    ```

  - **masterNodeGroup.instanceClass.externalNetwork**
    string

    Required value

    External network name.

    Example:

    ```
    externalNetwork: extnet_vlan_1700
    ```

  - **masterNodeGroup.instanceClass.imageName**
    string

    Required value

    OS image name to use for VM deployment.

    Example:

    ```
    imageName: '1'
    ```

  - **masterNodeGroup.instanceClass.memory**
    integer

    Required value

    Memory in MiB to allocate to the VM.

    Allowed values: `1 <= X`

    Example:

    ```
    memory: 8192
    ```

  - **masterNodeGroup.instanceClass.numCPUs**
    integer

    Required value

    Number of vCPUs to allocate to the VM.

    Allowed values: `1 <= X`

    Example:

    ```
    numCPUs: 2
    ```

  - **masterNodeGroup.instanceClass.pool**
    string

    Required value

    Storage pool name.

    Example:

    ```
    pool: pool_a
    ```

  - **masterNodeGroup.instanceClass.rootDiskSizeGb**

integer

Root disk size in GiB to use in Dynamix VirtualMachines.

Default: `50`

Example:

```
rootDiskSizeGb: 50
```

- **masterNodeGroup.instanceClass.storageEndpoint**
  string

  Required value

  Storage name.

  Example:

  ```
  storageEndpoint: SharedTatlin_G1_SEP
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **nameservers**
  array of strings

  A list of IP addresses of the DNS servers.

  Default: `[]`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the.

    - **nodeGroups.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in GiB.

      Default: `15`

      Example:

      ```
      etcdDiskSizeGb: 15
      ```

    - **nodeGroups.instanceClass.externalNetwork**
      string

      Required value

      External network name.

      Example:

      ```
      externalNetwork: extnet_vlan_1700
      ```

    - **nodeGroups.instanceClass.imageName**
      string

      Required value

      OS image name to use for VM deployment.

      Example:

      ```
      imageName: '1'
      ```

    - **nodeGroups.instanceClass.memory**
      integer

      Required value

      Memory in MiB to allocate to the VM.

Allowed values: `1 <= X`

Example:

```
memory: 8192
```

- **nodeGroups.instanceClass.numCPUs**
integer

  Required value

  Number of vCPUs to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

```
numCPUs: 2
```

- **nodeGroups.instanceClass.pool**
string

  Storage pool name.

  Example:

```
pool: pool_a
```

- **nodeGroups.instanceClass.rootDiskSizeGb**
integer

  Root disk size in GiB to use in Dynamix VirtualMachines.

  Default: `50`

  Example:

```
rootDiskSizeGb: 50
```

- **nodeGroups.instanceClass.storageEndpoint**
string

  Storage name.

  Example:

```
storageEndpoint: SharedTatlin_G1_SEP
```

- **nodeGroups.name**
string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
object

    The same as the `metadata.annotations` standard field.

    Example:

```
annotations:
  ai.fleet.com/discombobulate: 'true'
```

  - **nodeGroups.nodeTemplate.labels**
object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

  - **nodeGroups.nodeTemplate.taints**
array of objects

The same as the `.spec.taints` field of the Node object.

> **i** Available fields: `effect`, `key`, and `values`.

Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

- **nodeGroups.nodeTemplate.taints.effect**
  string

  Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
- **nodeGroups.nodeTemplate.taints.key**
  string
- **nodeGroups.nodeTemplate.taints.value**
  string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeNetworkCIDR**
  string

  IP CIDR to be assigned to the internal segment of this ViNS.

- **provider**
  object

  Required value

  Parameters for connecting to the Dynamix.

  - **provider.appId**
    string

    Required value

    App ID.

  - **provider.appSecret**
    string

    Required value

    App Secret.

  - **provider.controllerUrl**
    string

    Required value

    The URL to the Dynamix API endpoint.

  - **provider.insecure**
    boolean

    Set to `true` if Dynamix has a self-signed certificate.

    Default: `false`

  - **provider.oAuth2Url**
    string

    Required value

    The URL to the SSO Dynamix API endpoint.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

Preparing environment

> **⚠** The module lifecycle stage: Preview

Prepare an operating system image

Operating system vendors typically provide special cloud builds of their operating systems for use in virtualization environments. These builds typically contain virtual hardware drivers, cloud-init, virtualization guest agents, and are distributed as IMG or QCOW2 disk images. We recommend that you use these cloud images as the OS on the nodes in your clusters.

The cloud image of the operating system must be placed in the “Images” → “Template Images” section of the Basis Dynamix portal. Follow these steps to upload the OS image to the storage:

If the infrastructure does not have a DNS server, access to the Basis Dynamix portal from the cluster. Basis Dynamix portal from the cluster can be organized by adding the IP address and domains associated with the Basis Dynamix portal to the `cloud-init` template for generating the hosts file. This template is located in the `/etc/cloud/templates/` folder. The name of the template depends on the OS.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

⚠ After adding data to hosts and before creating the template from the virtual machine, you must run the `cloud-init clean` command.

Custom Resources

ℹ The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

⚠ The module lifecycle stage: Preview

DynamixInstanceClass

Scope: Cluster
Version: v1

Parameters of a group of Dynamix VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.externalNetwork**
    string

    External network name.

    Example:

    ```
    externalNetwork: extnet_vlan_1700
    ```

  - **spec.imageName**
    string

    Required value

    Name of the OS image to base this VM on.

    Example:

    ```
    imageName: alt-p10-cloud-x86_64.img
    ```

  - **spec.memory**
    integer

    Required value

    Memory in MiB to allocate to Dynamix VirtualMachines.

    Example:

    ```
    memory: 8192
    ```

  - **spec.numCPUs**
    integer

    Required value

Count of vCPUs to allocate to Dynamix VirtualMachines.

Example:

```
numCPUs: 2
```

- **spec.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in Dynamix VirtualMachines.

  The disk will be automatically resized if its size in the template differs from specified.

  Default: `30`

  Example:

  ```
  rootDiskSizeGb: 30
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

FAQ

⚠ The module lifecycle stage: Preview

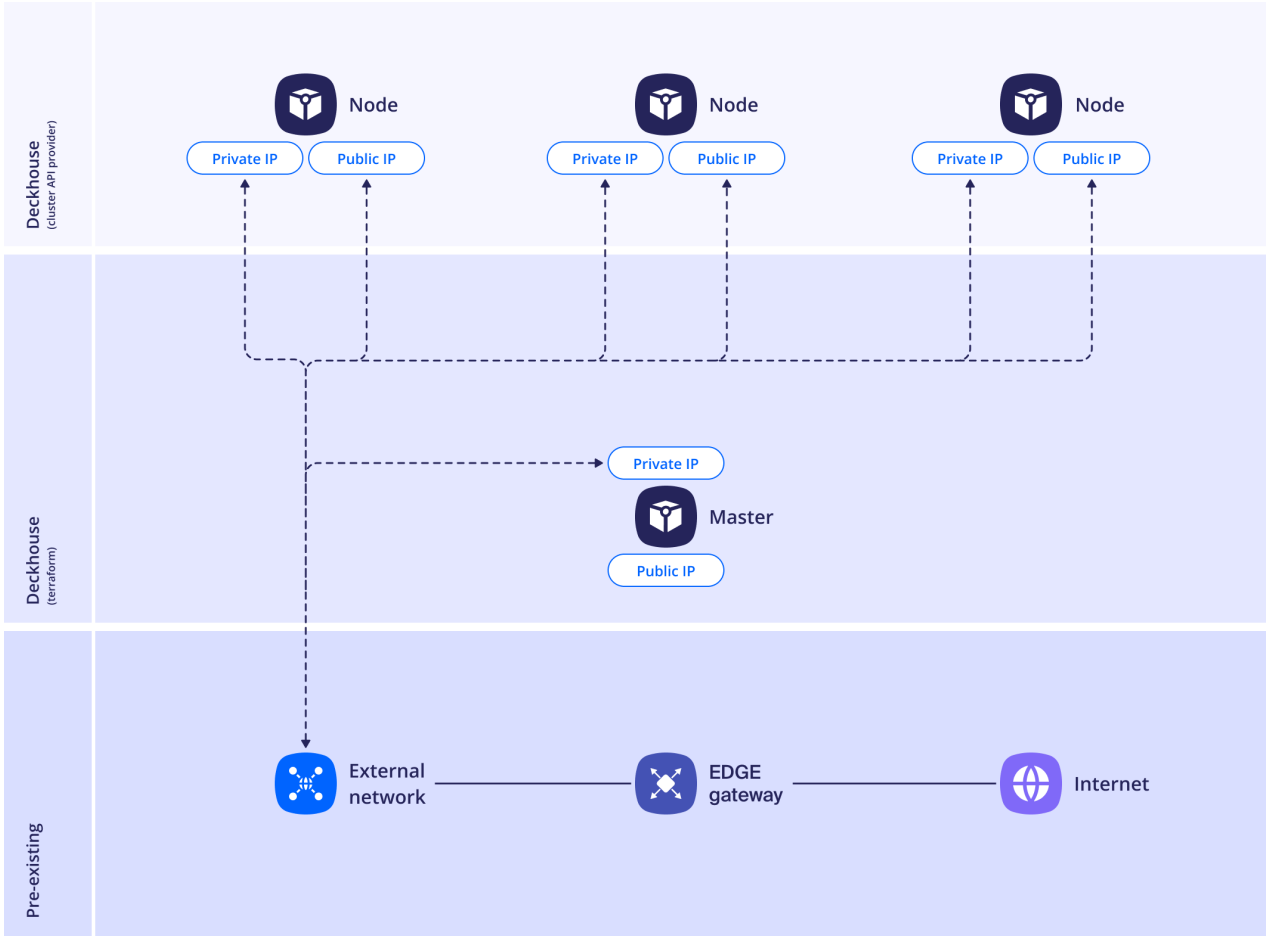
How to configure a LoadBalancer?

o configure a Service of the LoadBalancer type, add the following annotations to the Service manifest:

```
metadata:
  annotations:
    dynamix.cpi.flant.com/internal-network-name: <internal_name>
    dynamix.cpi.flant.com/external-network-name: <external_name>
```

Both annotations are required:

- `dynamix.cpi.flant.com/internal-network-name` — the name of the internal network in Basis Dynamix
- `dynamix.cpi.flant.com/external-network-name` — the name of the external network in Basis Dynamix



The terms “internal network” and “external network” are used in the context of Basis Dynamix. The external network does not have to be public and may use private IP addresses.

If one of the annotations is not specified, cloud-controller-manager will fail to process the Service.

Cloud provider - Basis Dynamix: Layouts

⚠ The module lifecycle stage: Preview

Standard

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1
kind: DynamixClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
location: dynamix
account: acc_user
provider:
  controllerUrl: "<controller url>"
  oAuth2Url: "<oAuth2 url>"
  appId: "<app id>"
  appSecret: "<app secret>"
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    storageEndpoint: "<storage endpoint>"
    pool: "<pool>"
    externalNetwork: "<external network>"
```

StandardWithInternalNetwork

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1
kind: DynamixClusterConfiguration
layout: StandardWithInternalNetwork
sshPublicKey: "<SSH_PUBLIC_KEY>"
location: dynamix
account: acc_user
nodeNetworkCIDR: "10.241.32.0/24"
nameservers: ["10.0.0.10"]
provider:
  controllerUrl: "<controller url>"
  oAuth2Url: "<oAuth2 url>"
  appId: "<app id>"
  appSecret: "<app secret>"
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 6
    memory: 16384
    rootDiskSizeGb: 50
    imageName: "<image name>"
    storageEndpoint: "<storage endpoint>"
    pool: "<pool>"
    externalNetwork: "<external network>"
```

Cloud provider — GCP

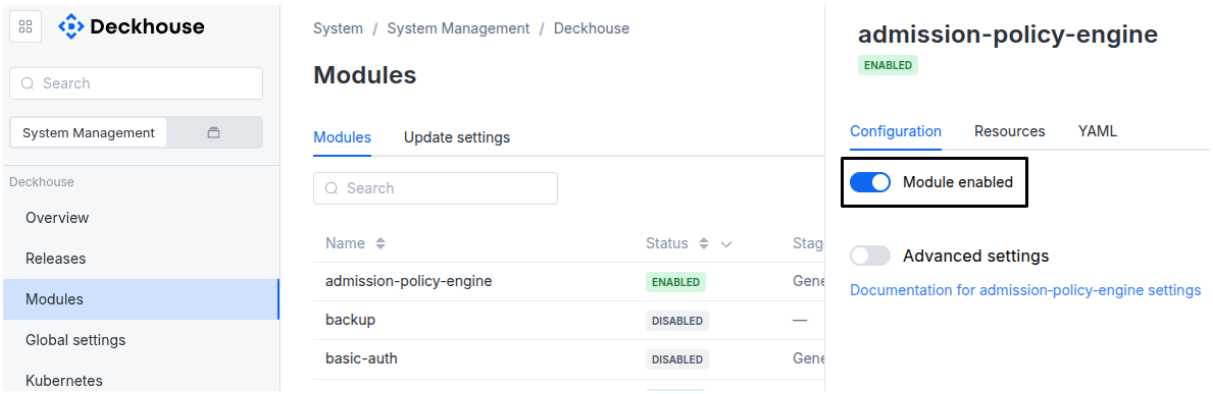
> **i** The module lifecycle stage: General Availability

The `cloud-provider-gcp` module integrates Deckhouse Kubernetes Platform with Google Cloud Platform (GCP). It allows the `node-manager` module to use GCP resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-gcp` module:

- Managing GCP resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the GCP side;
  - creates load balancers for Services of the LoadBalancer type;
  - updates cluster node metadata and removes from Kubernetes nodes that no longer exist in GCP.
- Provisioning disks via the Persistent Disk CSI driver (`pd.csi.storage.gke.io`) and creating StorageClasses for GCP disk types so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-google`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM). Virtual machine parameters are set in the GCPInstanceClass resource.
- Registering with `node-manager` so that GCPInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Configuration



> **i** The module lifecycle stage: General Availability

The module is configured automatically based on the chosen placement strategy defined in the GCPClusterConfiguration struct. In most cases, you do not have to configure the module manually.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-gcp` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

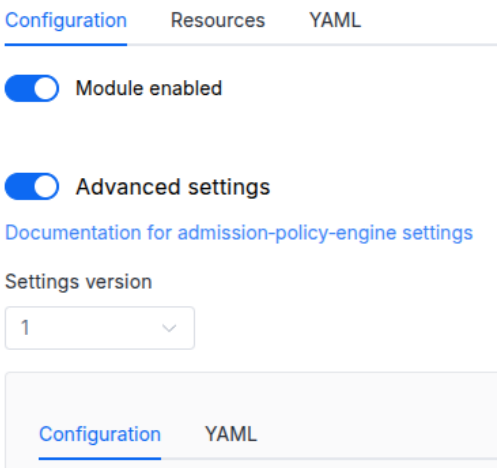
  ```
  d8 system module enable cloud-provider-gcp
  ```

- **Using ModuleConfig `cloud-provider-gcp`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-gcp` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-gcp`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-gcp
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-gcp` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-gcp` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-gcp`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-gcp` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-gcp
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the

`spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `cloud-provider-gcp` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-gcp`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-gcp
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

You can configure the number and parameters of provisioning machines in the cloud via the `NodeGroup` custom resource of the node-manager module. Also, in this custom resource, you can specify the instance class's name for the above group of nodes (the `cloudInstances.ClassReference` parameter of NodeGroup). In the case of the GCP cloud provider, the instance class is the `GCPInstanceClass` custom resource that stores specific parameters of the machines.

The module automatically creates StorageClasses that cover all the available disk types in GCP:

Type	Replication	StorageClass Name
standard	none	pd-standard-not-replicated
standard	regional	pd-standard-replicated
balanced	none	pd-balanced-not-replicated
balanced	regional	pd-balanced-replicated
ssd	none	pd-ssd-not-replicated
ssd	regional	pd-ssd-replicated

Also, it can filter out the unnecessary StorageClasses (you can do this via the `exclude` parameter).

Parameters

Schema version: 1

- **settings**
  object
  - **settings.storageClass**
    object
    - **settings.storageClass.default**
      Deprecated
      string

      The name of StorageClass that will be used in the cluster by default.

      If the parameter is omitted, the default StorageClass is either:

      - existing StorageClass present in the cluster that has the default annotation;
      - the first (in lexicographic order) StorageClass created by the module (in accordance with the order listed in the table above).

      > **i** **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

      Example:

      ```
      default: pd-ssd-not-replicated
      ```

    - **settings.storageClass.exclude**
      array of strings

      A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster;

      Example:

      ```
      exclude:
      - pd-standard.*
      - pd-ssd-replicated
      ```

Provider configuration

> **i** The module lifecycle stage: General Availability

GCPClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in GCP.

Used by the cloud provider if a cluster's control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> **i** After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: GCPClusterConfiguration
layout: WithoutNAT
sshKey: "<SSH_PUBLIC_KEY>"
subnetworkCIDR: 10.36.0.0/24
masterNodeGroup:
  replicas: 1
  zones:
  - europe-west3-b
  instanceClass:
    machineType: n1-standard-4
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
    diskSizeGb: 50
nodeGroups:
- name: static
  replicas: 1
  zones:
  - europe-west3-b
  instanceClass:
    machineType: n1-standard-4
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
    diskSizeGb: 50
    additionalNetworkTags:
    - tag1
    additionalLabels:
      kube-node: static
provider:
  region: europe-west3
  serviceAccountJSON: "<SERVICE_ACCOUNT_JSON>"
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`
- **kind**
  string

  Required value

  Allowed values: `GCPClusterConfiguration`
- **labels**
  object

  A list of labels to attach to cluster resources.

  Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

  You can learn more about the labels in the official documentation.

  Format — `key: value`.
- **layout**

string

Required value

The way resources are located in the cloud.

`Standard` - set Cloud NAT mode. More info...

`WithoutNAT` - a dedicated VPC is created for the cluster. All cluster nodes have public IP addresses. More info...

Allowed values: `Standard`, `WithoutNAT`

- **masterNodeGroup**
  object

  Required value

  Parameters of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the GCPInstanceClass fields.

    - **masterNodeGroup.instanceClass.additionalLabels**
      object

      Additional labels.

      For details on labels, refer to the Google Cloud documentation.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **masterNodeGroup.instanceClass.additionalNetworkTags**
      array of strings

      The list of additional network tags.

      You can use network tags to apply firewall rules to instances. The detailed description of network tags is available in the Google Cloud documentation.

    - **masterNodeGroup.instanceClass.disableExternalIP**
      boolean

      Defines whether to disable external IP for an instance or not.

      This parameter is only available for the `Standard` layout.

      True means that nodes do not have public addresses and connect to the Internet over `CloudNAT`;

      False means that static public addresses are created for nodes, they are also used for One-to-one NAT.;

      Default: `true`

      Allowed values: `true`, `false`

    - **masterNodeGroup.instanceClass.diskSizeGb**
      integer

      Instance disk size in gibibytes.

      Example:

      ```
      diskSizeGb: 50
      ```

    - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in gibibytes.

      Default: `20`

      Example:

      ```
      etcdDiskSizeGb: 20
      ```

    - **masterNodeGroup.instanceClass.image**
      string

      Required value

Image to use while provisioning GCP servers.

You can find a list of available images in the provider documentation.

The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

Example:

```
image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
```

- **masterNodeGroup.instanceClass.machineType**
  string

  Required value

  Machine type of GCP instance.

  > **Caution!** Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

  ```
  machineType: n1-standard-4
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create.

  It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the GCPInstanceClass fields.

    - **nodeGroups.instanceClass.additionalLabels**
      object

      Additional labels.

      For details on labels, refer to the Google Cloud documentation.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **nodeGroups.instanceClass.additionalNetworkTags**
      array of strings

      The list of additional network tags.

      You can use network tags to apply firewall rules to instances. The detailed description of network tags is available in the Google Cloud documentation.

    - **nodeGroups.instanceClass.disableExternalIP**
      boolean

      Defines whether to disable external IP for an instance or not.

      This parameter is only available for the `Standard` layout.

True means that nodes do not have public addresses and connect to the Internet over `CloudNAT`;

False means that static public addresses are created for nodes, they are also used for One-to-one NAT.;

Default: `true`

Allowed values: `true`, `false`

- **nodeGroups.instanceClass.diskSizeGb**
  integer

  Instance disk size in gibibytes.

  Example:

  ```
  diskSizeGb: 50
  ```

- **nodeGroups.instanceClass.image**
  string

  Required value

  Image to use while provisioning GCP servers.

  You can find a list of available images in the provider documentation.

  The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

  Example:

  ```
  image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
  ```

- **nodeGroups.instanceClass.machineType**
  string

  Required value

  Machine type of GCP instance.

  > **Caution!** Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

  ```
  machineType: n1-standard-4
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**
  object

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` (https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.25/#objectmeta-v1-meta).

  - **nodeGroups.nodeTemplate.labels**
    object

    The same as the `metadata.labels` standard (https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.25/#objectmeta-v1-meta).

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object(https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.25/#taint-v1-core).

    > Available fields: `effect`, `key`, and `values`.

    - **nodeGroups.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

        - **nodeGroups.nodeTemplate.taints.key**
          string
        - **nodeGroups.nodeTemplate.taints.value**
          string
    - **nodeGroups.replicas**
      integer

      Required value

      The number of nodes to create.

    - **nodeGroups.zones**
      array of strings

      A limited set of zones in which master nodes can be created.

      The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **peeredVPCs**
  array of strings

  A list of GCP VPC networks to peer with the cluster network.

  The service account must have access to all the VPCs listed. You have to configure the peering connection manually if no access is available.

- **provider**
  object

  Required value

  Parameters for connecting to the GCP API.

    - **provider.region**
      string

      Required value

      The name of the region where instances will be provisioned.

    - **provider.serviceAccountJSON**
      string

      Required value

      A key to the Service Account with Project Admin privileges (`service account key`) in the JSON format.

      How to create it a `service account key`.

- **sshAllowList**
  array of strings

  A list of CIDR’s allowed to connect to nodes via SSH.

  By default, from any.

- **sshKey**
  string

  Required value

  A public key to access nodes as `user`.

- **standard**
  object

  Settings for the `Standard` layout.

    - **standard.cloudNATAddresses**
      array of strings

      A list of public static IP addresses for `Cloud NAT`.

- **subnetworkCIDR**
  string

  A subnet to use for cluster nodes.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **withoutNAT**
  object

  Settings for the `WithoutNAT` layout.

- **zones**
  array of strings

  A limited set of zones in which master nodes can be created.

The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

Preparing environment

ℹ The module lifecycle stage: General Availability

⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

For more information, see the documentation.

⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:

- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

You need to create a service account so that Deckhouse Kubernetes Platform can manage resources in the Google Cloud. Below is a brief sequence of steps to create a service account. If you need detailed instructions, you can find them in the provider's documentation.

⚠ **Note!** The created `service account key` cannot be restored, you can only delete and create a new one.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Setup using Google Cloud Console

Follow this link, select your project and create a new service account or select an existing one.

The account must be assigned several necessary roles:

```
Compute Admin
Service Account User
Network Management Admin
```

You can add roles when creating a service account or edit them here.

To create a `service account key` in JSON format, click on three vertical dots in the Actions column and select `Manage keys`. Next, click on `Add key` -> `Create new key` -> `Key type` -> `JSON`.

Setup using gcloud CLI

To configure via the command line interface, follow these steps:

1. Export environment variables:

   ```
   export PROJECT_ID=sandbox
   export SERVICE_ACCOUNT_NAME=deckhouse
   ```

2. Select a project:

   ```
   gcloud config set project $PROJECT_ID
   ```

3. Create a service account:

   ```
   gcloud iam service-accounts create $SERVICE_ACCOUNT_NAME
   ```

4. Connect roles to the service account:

```
for role in roles/compute.admin roles/iam.serviceAccountUser roles/networkmanagement.admin;
do gcloud projects add-iam-policy-binding ${PROJECT_ID} --
member=serviceAccount:${SERVICE_ACCOUNT_NAME}@${PROJECT_ID}.iam.gserviceaccount.com \
   --role=${role}; done
```

List of roles required:

```
roles/compute.admin
roles/iam.serviceAccountUser
roles/networkmanagement.admin
```

5. Verify service account roles:

```
gcloud projects get-iam-policy ${PROJECT_ID} --flatten="bindings[].members" --
format='table(bindings.role)' \
     --filter="bindings.members:${SERVICE_ACCOUNT_NAME}@${PROJECT_ID}.iam.gserviceaccount.com"
```

6. Create a `service account key`:

```
gcloud iam service-accounts keys create --iam-account
${SERVICE_ACCOUNT_NAME}@${PROJECT_ID}.iam.gserviceaccount.com \
     ~/service-account-key-${PROJECT_ID}-${SERVICE_ACCOUNT_NAME}.json
```

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

GCPInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of GCP Instances used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalDisks**
    array of objects

    A list of additional disks to attach to the instance.

    Useful for storage workloads such as LINSTOR, Ceph, NFS, and similar.

    Example:

    ```
    additionalDisks:
    - size: 100
      type: pd-ssd
    ```

    - **spec.additionalDisks.autoDelete**
      boolean

      Automatically delete the disk when the instance is deleted.

      Default: `true`

    - **spec.additionalDisks.provisionedIops**
      integer

      Provisioned IOPS for the disk.

      Required for `pd-extreme` and `hyperdisk-extreme` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.provisionedThroughput**
      integer

Provisioned throughput in MiB/s for the disk.

Applicable for `hyperdisk-balanced` and `hyperdisk-throughput` disk types.

Allowed values: `1 <= X`

- **spec.additionalDisks.size**
  integer

  Required value

  Disk size in gigabytes (GB).

  Allowed values: `1 <= X`

  Example:

  ```
  size: 100
  ```

- **spec.additionalDisks.type**
  string

  Required value

  Disk type.

  - `pd-standard` — standard Persistent Disk (HDD).
  - `pd-balanced` — balanced Persistent Disk (SSD).
  - `pd-ssd` — SSD Persistent Disk.
  - `pd-extreme` — extreme Persistent Disk; requires `provisionedIops`.
  - `hyperdisk-balanced` — Hyperdisk with balanced performance.
  - `hyperdisk-throughput` — Hyperdisk optimized for throughput.
  - `hyperdisk-extreme` — Hyperdisk with maximum performance; requires `provisionedIops`.

  Allowed values: `pd-standard`, `pd-balanced`, `pd-ssd`, `pd-extreme`, `hyperdisk-balanced`, `hyperdisk-throughput`, `hyperdisk-extreme`

  Example:

  ```
  type: pd-ssd
  ```

- **spec.additionalLabels**
  object

  Additional labels.

  More info...

  Example:

  ```
  additionalLabels:
    project: cms-production
    severity: critical
  ```

- **spec.additionalNetworkTags**
  array of strings

  The list of additional tags.

  For example, you can use tags to apply firewall rules to instances. The detailed description of network tags is available in the official documentation.

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `machineType` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`a2-highgpu-8g`, `c2-standard-8`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

```
cpu: 1000m
```

- **spec.capacity.memory**
  integer or string

  Required value

  Node memory resources.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

  ```
  memory: 1500Mi
  ```

- **spec.disableExternalIP**
  boolean

  Defines whether to disable external ip for an instance or not. True means that an instance is created without external ip

- **spec.diskSizeGb**
  integer

  Instance’s root disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGb: 20
  ```

- **spec.diskType**
  string

  Instance’s disk type.

  Default: `pd-standard`

  Allowed values: `pd-standard`, `pd-ssd`

  Example:

  ```
  diskType: pd-ssd
  ```

- **spec.enableNestedVirtualization**
  boolean

  Enables nested virtualization on the instance.

  Required for running virtual machine workloads (e.g., KVM-based VMs) inside GCP instances.

  Warning. Only supported on specific machine types. See the GCP documentation for the list of compatible types.

  Default: `false`

- **spec.image**
  string

  Not required value.

  Image to use while provisioning GCP servers.

  You can find a list of available images in the provider documentation.

  The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

  Example:

  ```
  image: https://www.googleapis.com/compute/v1/projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
  ```

- **spec.machineType**
  string

  Required value

  Machine type of GCP instance.

  Caution! Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

```
machineType: n1-standard-4
```

  - **spec.preemptible**
    boolean

    Should instances be preemptible.

    Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of GCP Instances used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalDisks**
    array of objects

    A list of additional disks to attach to the instance.

    Useful for storage workloads such as LINSTOR, Ceph, NFS, and similar.

    Example:

    ```
    additionalDisks:
    - size: 100
      type: pd-ssd
    ```

    - **spec.additionalDisks.autoDelete**
      boolean

      Automatically delete the disk when the instance is deleted.

      Default: `true`

    - **spec.additionalDisks.provisionedIops**
      integer

      Provisioned IOPS for the disk.

      Required for `pd-extreme` and `hyperdisk-extreme` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.provisionedThroughput**
      integer

      Provisioned throughput in MiB/s for the disk.

      Applicable for `hyperdisk-balanced` and `hyperdisk-throughput` disk types.

      Allowed values: `1 <= X`

    - **spec.additionalDisks.size**
      integer

      Required value

      Disk size in gigabytes (GB).

      Allowed values: `1 <= X`

      Example:

      ```
      size: 100
      ```

    - **spec.additionalDisks.type**
      string

      Required value

      Disk type.

      - `pd-standard` — standard Persistent Disk (HDD).
      - `pd-balanced` — balanced Persistent Disk (SSD).
      - `pd-ssd` — SSD Persistent Disk.
      - `pd-extreme` — extreme Persistent Disk; requires `provisionedIops`.
      - `hyperdisk-balanced` — Hyperdisk with balanced performance.
      - `hyperdisk-throughput` — Hyperdisk optimized for throughput.
      - `hyperdisk-extreme` — Hyperdisk with maximum performance; requires `provisionedIops`.

Allowed values: `pd-standard`, `pd-balanced`, `pd-ssd`, `pd-extreme`, `hyperdisk-balanced`, `hyperdisk-throughput`, `hyperdisk-extreme`

Example:

```
type: pd-ssd
```

- **spec.additionalLabels**
  object

  Additional labels.

  More info...

  Example:

  ```
  additionalLabels:
    project: cms-production
    severity: critical
  ```

- **spec.additionalNetworkTags**
  array of strings

  The list of additional tags.

  For example, you can use tags to apply firewall rules to instances. The detailed description of network tags is available in the official documentation.

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `machineType` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`a2-highgpu-8g`, `c2-standard-8`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

    Node memory resources.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    memory: 1500Mi
    ```

- **spec.disableExternalIP**
  boolean

  Defines whether to disable external ip for an instance or not. True means that an instance is created without external ip

- **spec.diskSizeGb**
  integer

  Instance’s root disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGb: 20
  ```

- **spec.diskType**
  string

  Instance’s disk type.

  Default: `pd-standard`

  Allowed values: `pd-standard`, `pd-ssd`

  Example:

  ```
  diskType: pd-ssd
  ```

- **spec.enableNestedVirtualization**
  boolean

  Enables nested virtualization on the instance.

  Required for running virtual machine workloads (e.g., KVM-based VMs) inside GCP instances.

  Warning. Only supported on specific machine types. See the GCP documentation for the list of compatible types.

  Default: `false`

- **spec.image**
  string

  Not required value.

  Image to use while provisioning GCP servers.

  You can find a list of available images in the provider documentation.

  The list of OS and their versions supported by Deckhouse can be found in the Deckhouse documentation (take into account the Deckhouse version used).

  Example:

  ```
  image: https://www.googleapis.com/compute/v1/projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128
  ```

- **spec.machineType**
  string

  Required value

  Machine type of GCP instance.

  Caution! Make sure that this type is present in all zones specified in the `zones` parameter.

  GCP lets you specify a custom amount of resources (CPU and RAM), e.g., `custom-8-40960` or `n2-custom-8-40960`.

  Example:

  ```
  machineType: n1-standard-4
  ```

- **spec.preemptible**
  boolean

  Should instances be preemptible.

  Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

FAQ

> **i** The module lifecycle stage: General Availability

How do I create a cluster?

1. Set up a cloud environment.
2. Enable the module or pass the `--extra-config-map-data base64_encoding_of_custom_config` flag with the module parameters to the `install.sh` script.
3. Create one or more GCPInstanceClass custom resources.
4. Create one or more NodeGroup custom resources for managing the number and the process of provisioning machines in the cloud.

Adding CloudStatic nodes to a cluster

For the VMs, you want to add to a cluster as nodes, add a `Network Tag` similar to the cluster prefix.

You can find out `prefix` using the command:

```
d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r '.data."cluster-configuration.yaml"' \
  | base64 -d | grep prefix
```

Examples

> **i** The module lifecycle stage: General Availability

An example of the `GCPInstanceClass` custom resource

Below is a simple example of custom resource `GCPInstanceClass` configuration:

```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: test
spec:
  machineType: n1-standard-1
```

Enabling nested virtualization

To run virtual machine workloads (e.g., KVM-based VMs) inside GCP instances, enable nested virtualization.

> **i** Only specific machine types support nested virtualization. See the GCP documentation for the list of compatible types.

```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: vm-nodes
spec:
  machineType: n2-standard-8
  enableNestedVirtualization: true
```

Adding additional disks

To attach additional disks to instances (for example, for LINSTOR, Ceph, NFS storage nodes, and similar solutions), specify them in the `additionalDisks` parameter:

```
apiVersion: deckhouse.io/v1
kind: GCPInstanceClass
metadata:
  name: storage-nodes
spec:
  machineType: n1-standard-8
  additionalDisks:
  - size: 200
    type: pd-ssd
  - size: 500
    type: pd-standard
    autoDelete: true
```

Configuring security policies on nodes

For cluster virtual machines in GCP, you may need to limit or expand incoming and outgoing traffic for various reasons. Some of these may include:

- Allowing connections to cluster nodes from virtual machines from a different subnet.
- Allow connections to static node ports for application operation.
- Restricting access to external resources or other virtual machines in the cloud at the request of the security service.

For all this, additional network tags must be used.

Enabling additional network tags on static and master nodes

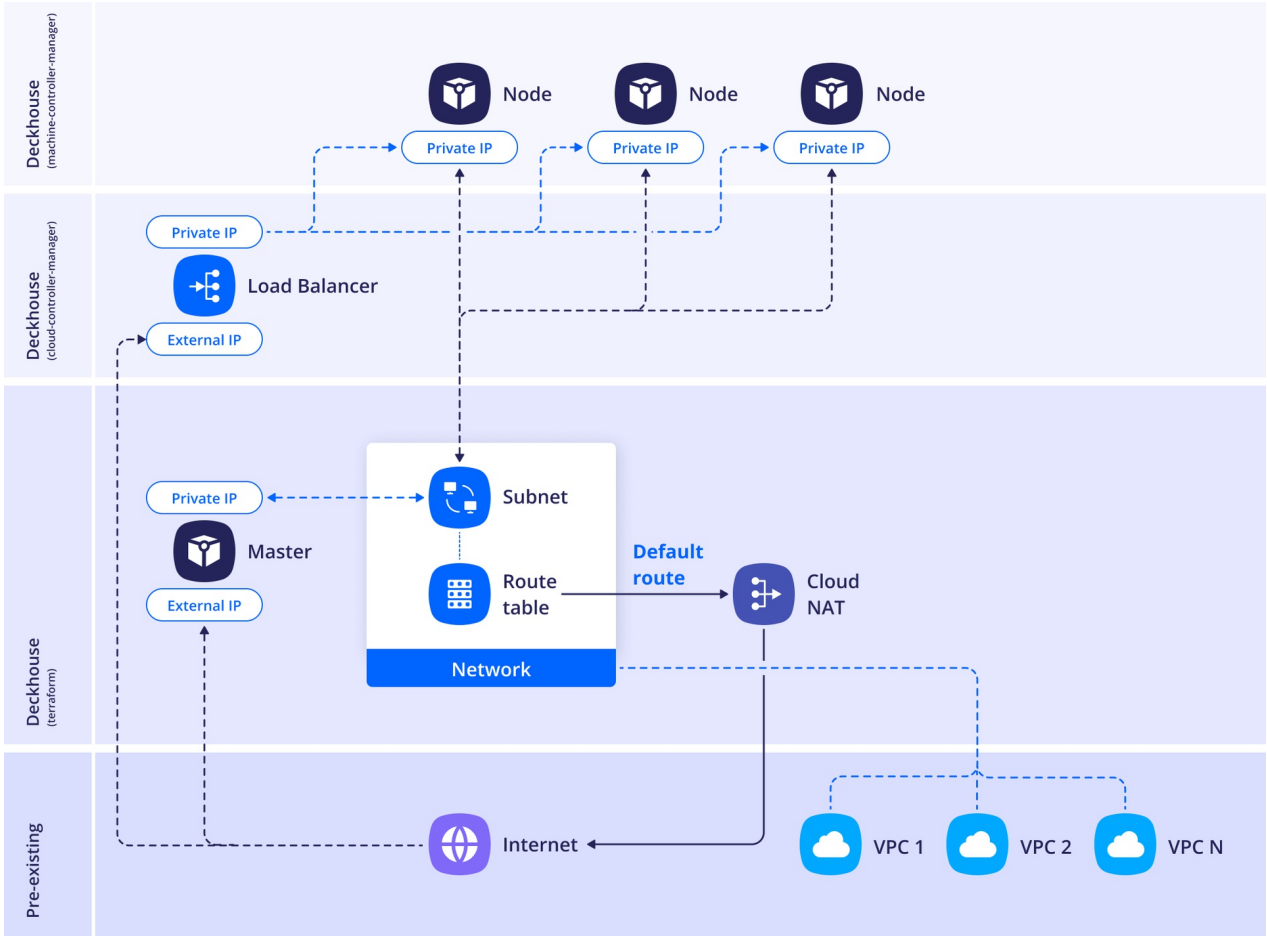
This parameter can be set either in an existing cluster or when creating one. In both cases, additional network tags are declared in the `GCPClusterConfiguration`:

- for master nodes, in the `additionalNetworkTags` field of the `masterNodeGroup` section;
- for static nodes, in the `additionalNetworkTags` field of the `nodeGroups` subsection that corresponds to the target nodeGroup.

The `additionalNetworkTags` field contains an array of strings with network tags names.

Enabling additional network tags on ephemeral nodes

You have to set the `additionalNetworkTags` parameter for all `GCPInstanceClass` that require additional network tags.



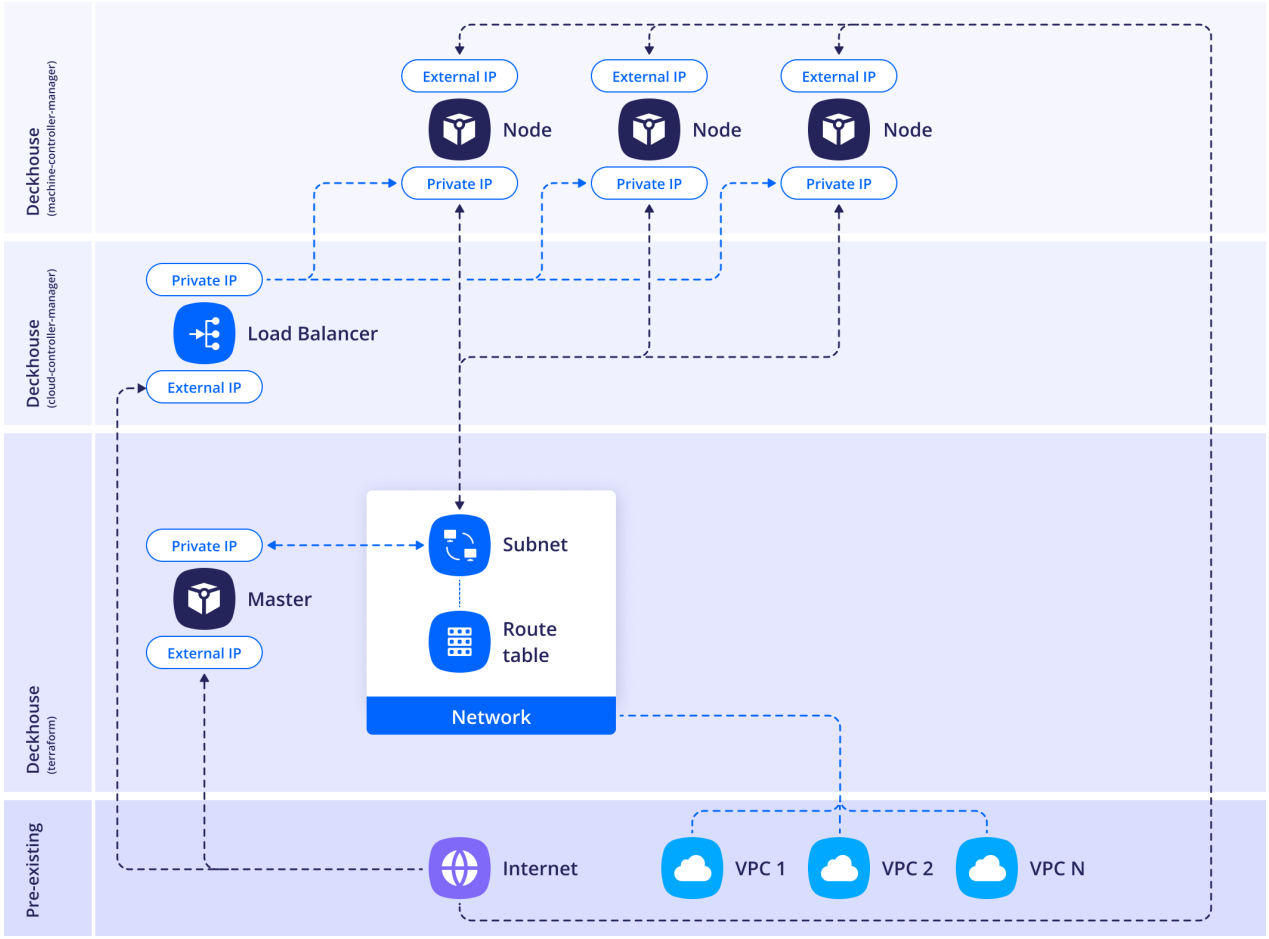
Layouts

> **i** The module lifecycle stage: General Availability

Two layouts are supported. Below is more information about each of them.

Standard

- A separate VPC with Cloud NAT is created for the cluster.
- Nodes in the cluster do not have public IP addresses.
- Public IP addresses can be allocated to master and static nodes:
  - In this case, one-to-one NAT is used to translate the public IP address to the node's IP address (note that CloudNAT is not used in such a case).
- If the master does not have a public IP, then an additional instance with a public IP (aka bastion host) is required for installation tasks and accessing the cluster.
- Peering can also be configured between the cluster VPC and other VPCs.



Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: GCPClusterConfiguration
layout: Standard
standard:
  # Optional, compute address names from this list are used as addresses for Cloud NAT.
  cloudNATAddresses:
  - example-address-1
  - example-address-2
subnetworkCIDR: 10.0.0.0/24       # Required.
peeredVPCs:
# Optional, list of GCP VPC Networks with which Kubernetes VPC Network will be peered.
- default
sshKey: "<SSH_PUBLIC_KEY>"  # Required.
labels:
  kube: example
masterNodeGroup:
  replicas: 1
  zones:                       # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128 # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    disableExternalIP: false       # Optional, by default master has externalIP.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:            # Optional.
      kube-node: master
nodeGroups:
- name: static
  replicas: 1
  zones:                       # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128 # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    disableExternalIP: true        # Optional, by default nodes do not have externalIP.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:            # Optional.
      kube-node: static
provider:
  region: europe-west4           # Required.
  serviceAccountJSON: |          # Required.
    {
      "type": "service_account",
      "project_id": "sandbox",
      "private_key_id": "98sdcj5e8c7asd98j4j3n9csakn",
      "private_key": "-----BEGIN PRIVATE KEY-----",
      "client_id": "342975658279248",
      "auth_uri": "https://accounts.google.com/o/oauth2/auth",
      "token_uri": "https://oauth2.googleapis.com/token",
      "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
      "client_x509_cert_url": "https://www.googleapis.com/robot/v1/metadata/x509/k8s-
test%40sandbox.iam.gserviceaccount.com"
    }
```

WithoutNAT

- A dedicated VPC is created for the cluster; all cluster nodes have public IP addresses.
- Peering can be configured between the cluster VPC and other VPCs.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: GCPClusterConfiguration
layout: WithoutNAT
subnetworkCIDR: 10.0.0.0/24       # Required.
# Optional, list of GCP VPC Networks with which Kubernetes VPC Network will be peered.
peeredVPCs:
- default
labels:
  kube: example
masterNodeGroup:
  replicas: 1
  zones:                        # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128  # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:             # Optional.
      kube-node: master
nodeGroups:
- name: static
  replicas: 1
  zones:                        # Optional.
  - europe-west4-b
  instanceClass:
    machineType: n1-standard-4     # Required.
    image: projects/ubuntu-os-cloud/global/images/ubuntu-2404-noble-amd64-v20260128  # Required.
    diskSizeGb: 20               # Optional, local disk is used if not specified.
    additionalNetworkTags:         # Optional.
    - tag1
    additionalLabels:             # Optional.
      kube-node: static
provider:
  region: europe-west4            # Required.
  serviceAccountJSON: |           # Required.
    {
      "type": "service_account",
      "project_id": "sandbox",
      "private_key_id": "98sdcj5e8c7asd98j4j3n9csakn",
      "private_key": "-----BEGIN PRIVATE KEY-----",
      "client_id": "342975658279248",
      "auth_uri": "https://accounts.google.com/o/oauth2/auth",
      "token_uri": "https://oauth2.googleapis.com/token",
      "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
      "client_x509_cert_url": "https://www.googleapis.com/robot/v1/metadata/x509/k8s-
test%40sandbox.iam.gserviceaccount.com"
    }
```

Cloud provider — Huawei Cloud

> **i** The module lifecycle stage: General Availability

The `cloud-provider-huaweicloud` module integrates Deckhouse Kubernetes Platform with Huawei Cloud. It allows the `node-manager` module to use Huawei Cloud resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-huaweicloud` module:

- Managing Huawei Cloud resources via `cloud-controller-manager`:
  - updates instance and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in the cloud;
  - creates load balancers (ELB) for Services of the LoadBalancer type.
- Provisioning disks via the EVS CSI driver (`evs.csi.huaweicloud.com`) so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-huaweicloud`.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the HuaweiCloudInstanceClass resource.
- Registering with `node-manager` so that HuaweiCloudInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Configuration

> **i** The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in Huawei Cloud.

The module has 1 alert.

The module does not have any settings.

Provider configuration

> **i** The module lifecycle stage: General Availability

HuaweiCloudClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in Huawei Cloud.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

Example:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
zones:
- eu-3a
standard:
  externalNetworkName: external-network
provider:
  domainName: "<DOMAIN_NAME>"
  region: eu-3
  accessKey: "<USERNAME>"
  secretKey: "<PASSWORD>"
masterNodeGroup:
  replicas: 1
  instanceClass:
    flavorName: m1.large
    rootDiskSize: 50
    imageName: debian-11-genericcloud-amd64-20220911-1135
  volumeTypeMap:
    eu-1a: fast-eu-1a
    eu-1b: fast-eu-1b
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.large
    imageName: debian-11-genericcloud-amd64-20220911-1135
    rootDiskSize: 50
  volumeTypeMap:
    eu-1a: fast-eu-1a
    eu-1b: fast-eu-1b
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`
- **kind**
  string

  Required value

  Allowed values: `HuaweiCloudClusterConfiguration`
- **layout**
  string

Required value

The layout name.

For details about possible provider layouts, refer to Layouts.

- **masterNodeGroup**

  Required value

  The definition of a NodeGroup for master nodes.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the HuaweiCloudInstanceClass.

    - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in gigabytes.

      Default: `10`

      Example:

      ```
      etcdDiskSizeGb: 10
      ```

    - **masterNodeGroup.instanceClass.flavorName**
      string

      Required value

      The flavor of Huawei Cloud servers.

    - **masterNodeGroup.instanceClass.imageName**
      string

      Required value

      The image to use while provisioning Huawei Cloud servers.

      For the list of operating systems and specific versions supported by Deckhouse, refer to Supported Kubernetes and OS versions (take into account the Deckhouse version you use).

    - **masterNodeGroup.instanceClass.rootDiskSize**
      integer

      The size of a root disk in gigabytes.

      This parameter also affects the type of a root disk.

      Default: `50`

      Example:

      ```
      rootDiskSize: 50
      ```

  - **masterNodeGroup.replicas**
    integer

    Required value

    The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

    Allowed values: `1 <= X`

  - **masterNodeGroup.serverGroup**
    object

    The ServerGroup object groups instances together. The instances in the group are placed on the same hypervisor (affinity) or different hypervisors (anti-affinity). This allows you to increase the fault tolerance of the cluster.

    - **masterNodeGroup.serverGroup.policy**
      string

      Required value

      The policy that determines how instances are distributed among hypervisors.

      - `AntiAffinity`: Instances are placed on different hypervisors. This policy is managed by Deckhouse.

      Allowed values: `AntiAffinity`

- **masterNodeGroup.volumeTypeMap**
  object

  Required value

  A dictionary of disk types for storing etcd data and Kubernetes configuration files.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <DISK TYPE>` (see the example).

  If the `rootDiskSize` parameter is specified, the same disk type will be used for the VM's boot drive.

  We recommend using the fastest disks provided by the provider in all cases.

  If the value specified in `replicas` exceeds the number of elements in the dictionary, the master nodes whose number exceeds the length of the dictionary get the values starting from the beginning of the dictionary. For example, if `replicas: 5`, then master-0, master-2, master-4 will have the `fast-eu-1a` disk type, while master-1, master-3 will have the `fast-eu-1b` disk type.

  Example:

  ```
  volumeTypeMap:
    eu-1a: fast-eu-1a
    eu-1b: fast-eu-1b
  ```

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields.

    - **nodeGroups.instanceClass.additionalNetworks**
      array of strings

      Not required value.

      List of network IDs (subnets) for secondary NICs.

    - **nodeGroups.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in gigabytes.

      Default: `10`

      Example:

      ```
      etcdDiskSizeGb: 10
      ```

    - **nodeGroups.instanceClass.flavorName**
      string

      Required value

      The flavor of Huawei Cloud servers.

    - **nodeGroups.instanceClass.imageName**
      string

      Required value

      The image to use while provisioning Huawei Cloud servers.

      For the list of operating systems and specific versions supported by Deckhouse, refer to Supported Kubernetes and OS versions (take into account the Deckhouse version you use).

    - **nodeGroups.instanceClass.mainNetwork**
      string

      Not required value.

      Primary network ID for the VM's main NIC. **By default**, the value from 'HuaweiCloudDiscoverData' is used.

    - **nodeGroups.instanceClass.rootDiskSize**
      integer

      The size of a root disk in gigabytes.

      This parameter also affects the type of a root disk.

      Default: `50`

      Example:

      ```
      rootDiskSize: 50
      ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to all cluster resources, if they support it.

    The same as the `metadata.labels` standard field.

    If you change a label on a running cluster, recreate all virtual machines after the changes come into effect.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **nodeGroups.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **nodeGroups.nodeTemplate.taints.key**
      string
    - **nodeGroups.nodeTemplate.taints.value**
      string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeGroups.volumeTypeMap**
  object

  A dictionary mapping availability zones to disk types for the group's worker nodes.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <DISK TYPE>` (see the example).

  If the `rootDiskSize` parameter is specified, the same disk type is used for the VM's boot disk.

  We recommend using the fastest disk type offered by the provider whenever possible.

  If `volumeTypeMap` is not specified for a node group, the `masterNodeGroup`'s `volumeTypeMap` is used as a fallback for that group.

  If the replicas value exceeds the number of entries in the dictionary, assignment wraps around from the beginning. For example, if `replicas: 5` for the `front` group and the dictionary lists `fast-eu-1a` first and `fast-eu-1b` second, then front-0, front-2, front-4 will use `fast-eu-1a`, while front-1, front-3 will use `fast-eu-1b`.

  Example:

```
volumeTypeMap:
  eu-1a: fast-eu-1a
  eu-1b: fast-eu-1b
```

- **provider**
  object

  Required value

  Huawei Cloud API connection settings.

  These settings match the ones in the `connection` field of the cloud-provider-huaweicloud module.

  - **provider.accessKey**
    string

    Required value

    The Huawei Cloud access key.

  - **provider.authURL**
    string

    The identity authentication URL.

  - **provider.cloud**
    string

    Required value

    The endpoint of the cloud provider.

  - **provider.domainName**
    string

    The account name of IAM to scope to.

  - **provider.enterpriseProjectID**
    string

    The enterprise project ID.

  - **provider.insecure**
    boolean

    Trust self-signed SSL certificates.

  - **provider.projectID**
    string

    The project ID.

  - **provider.region**
    string

    Required value

    The Huawei Cloud region where the cluster will be deployed.

  - **provider.secretKey**
    string

    Required value

    The Huawei Cloud secret key.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **standard**
  object

  Settings for the `Standard` layout.

  - **standard.enableEIP**
    boolean

    Enable Elastic IP for the master nodes.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **standard.internalNetworkCIDR**
    string

    Required value

    Routing for the internal cluster node network.

Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **standard.internalNetworkDNSServers**
  array of strings

  A list of addresses of the recursive DNSs for the internal cluster node network.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **standard.internalNetworkSecurity**
  boolean

  Defines whether SecurityGroups must be configured for the internal network ports.

  Default: `true`

- **vpcPeering**
  object

  Settings for the `VpcPeering` layout.

  - **vpcPeering.internalNetworkCIDR**
    string

    Required value

    Routing for the internal cluster node network.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **vpcPeering.internalNetworkDNSServers**
    array of strings

    A list of addresses of the recursive DNSs for the internal cluster node network.

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

  - **vpcPeering.internalNetworkSecurity**
    boolean

    Defines whether SecurityGroups must be configured for the internal network ports.

    Default: `true`

  - **vpcPeering.subnet**
    string

    The name of the subnet in the VPC.

- **zones**
  array of strings

  Not required value.

  The globally restricted set of zones that this cloud provider works with.

Preparing environment

> **i** The module lifecycle stage: General Availability

> ⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:
>
> - Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
> - `CgroupsV2` support.
> - Systemd version `244` or newer.
> - `erofs` kernel module support.
>
> For more information, see the documentation.

⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:

- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Deckhouse Kubernetes Platform components interact with Huawei Cloud resources through the Huawei Cloud API. To configure this connection, you need to create a user in the Huawei Cloud IAM service and provide it with the necessary permissions.

Configuring IAM via the web interface

To configure IAM via the web interface, first create a new user group and assign the necessary permissions. Follow these steps:

1. Go to the “Identity and Access Management (IAM)” section.
2. Open the “User Groups” page and click “Create User Group”.
3. In the “Name” field, enter the group name (e.g., `deckhouse`).
4. Click “OK” to create the group.
5. Select the newly created group from the list.
6. On the “Permissions” tab, click “Authorize”.
7. Assign the following policies: “ECS Admin”, “VPC Administrator”, “NAT Admin”, “ELB FullAccess”, “DEW KeypairFullAccess”.
8. Click “Next”, then “OK”, and complete the setup by clicking “Finish”.

Then add a new user. Follow these steps:

1. Go to the “Users” page in the IAM section and click “Create User”.
2. In the “Username” field, enter the username (e.g., `deckhouse`).
3. Set “Access type” to “Programmatic access” and make sure “Management console access” is disabled.
4. Select “Access key” as the “Credential Type”.
5. Click “Next”.
6. Select the previously created user group.
7. Click “Create” to complete the user creation process.
8. Click “OK” to download the `Access Key ID` and `Secret Access Key`. Make sure to save these credentials in a secure location, as they will be needed to access the API.

JSON policies

Below are the contents of the policies in JSON format:

ECS Admin policy

```
{
"Version": "1.1",
"Statement": [
{
    "Action": [
    "ecs:*:*",
    "evs:*:get",
    "evs:*:list",
    "evs:volumes:create",
    "evs:volumes:delete",
    "evs:volumes:attach",
    "evs:volumes:detach",

                "vpc:vpns:*",
                "ecs:*:get",
                "ecs:*:list",
                "elb:*:get",
                "elb:*:list"
            ],
            "Effect": "Allow"
        }
    ]
}
```

NAT Admin policy

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Action": [
                "nat:*:*",
                "vpc:*:*"
            ],
            "Effect": "Allow"
        }
    ]
}
```

DEW KeypairFullAccess policy

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Action": [
                "kps:domainKeypairs:*",
                "ecs:serverKeypairs:*"
            ],
            "Effect": "Allow"
        }
    ]
}
```

ELB FullAccess policy

```
{
  "Version": "1.1",
  "Statement": [
      {
          "Action": [
              "elb:*:*",
              "vpc:*:get*",
              "vpc:*:list*",
              "ecs:*:get*",
              "ecs:*:list*"
          ],
          "Effect": "Allow"
      }
  ]
}
```

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

HuaweiCloudInstanceClass

Scope: Cluster
Version: v1

Huawei Cloud server group parameters used by `machine-controller-manager` (the node-manager module).

The CloudInstanceClass resource of the `node-manager` module refers to this resource.

Example:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudInstanceClass
metadata:
  name: worker
spec:
  imageName: alt-p11
  flavorName: s7n.xlarge.2
  rootDiskSize: 50
  rootDiskType: SSD
```

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Not required value.

    List of networks IDs (subnets) for secondary NICs.

  - **spec.flavorName**
    string

    Required value

    Flavor of Huawei Cloud servers.

    To get a list of all available flavors, run the following command: `cloud ECS ListFlavors`.

    For all non-master nodes, it’s recommended that you use a flavor that includes a local disk. If the cloud provider supports local disks, they’re usually faster and cheaper. The disadvantage of using such a flavor is the inability to migrate nodes between hypervisors.

    Example:

    ```
    flavorName: m1.medium
    ```

  - **spec.imageName**
    string

    Not required value.

    Image to use while provisioning HuaweiCloud servers.

    Use this command to get a list of available images: `cloud IMS ListImages`.

    For the list of operating systems and specific versions supported by Deckhouse, refer to Supported Kubernetes and OS versions (take into account the Deckhouse version you use).

    By default, either the `HuaweiCloudDiscoveryData` value or `instances.imageName` is used.

    Example:

    ```
    imageName: ubuntu-18-04-cloud-amd64
    ```

  - **spec.mainNetwork**
    string

    Not required value.

    ID of the primary network for the VM’s main NIC.

    By default, the value from ‘HuaweiCloudDiscoverData’ is used.

  - **spec.rootDiskSize**
    integer

    Not required value.

    The size of a root disk in gigabytes.

    This parameter also affects the type of a root disk.

    Example:

    ```
    rootDiskSize: 20
    ```

  - **spec.rootDiskType**
    string

    Not required value.

    The type of a root disk.

    The parameter is used to specify the type of a volume that will be used for the root disk.

By default, the value from `HuaweiCloudDiscoveryData` is used.

Example:

```
rootDiskType: GPSSD
```

- **spec.securityGroups**
  array of strings

  Not required value.

  Security groups that will be applied to VM’s network ports in addition to security groups set in a cloud provider configuration.

  These security groups allow you to set firewall rules for provisioned instances.

  The `SecurityGroups` group may not be supported by the cloud provider.

  Example:

  ```
  securityGroups:
  - security-group-1
  - security-group-2
  ```

- **spec.serverGroupID**
  string

  Not required value.

  The server group to assign the machine to.

  Example:

  ```
  serverGroupID: server-group-1
  ```

- **spec.subnets**
  Deprecated
  array of strings

  Not required value.

  > **i** Use the additionalNetworks field instead.

  Paths to networks that the secondary VirtualMachines NICs will connect to.

  Example:

  ```
  subnets:
  - BGP-network-VLAN-3894
  - External-VLAN-3699
  ```

- **spec.vipAddress**
  string

  Not required value.

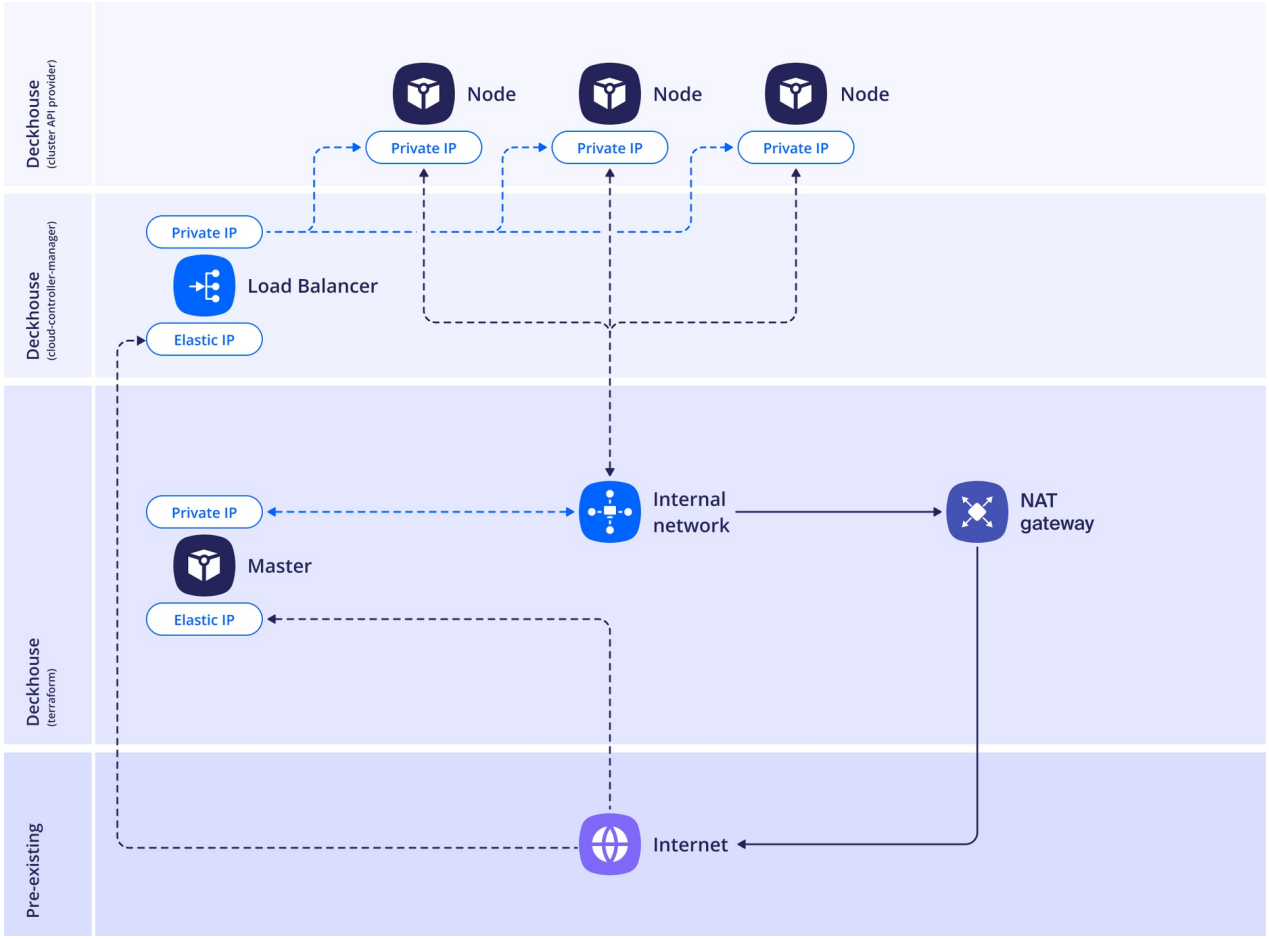
  If filled, enables Virtual IP for all nodes in this instance class.

  `Auto` or IPv4 address are expected.

  Pattern: `^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$|^Auto$`

  Example:

  ```
  vipAddress: Auto
  ```

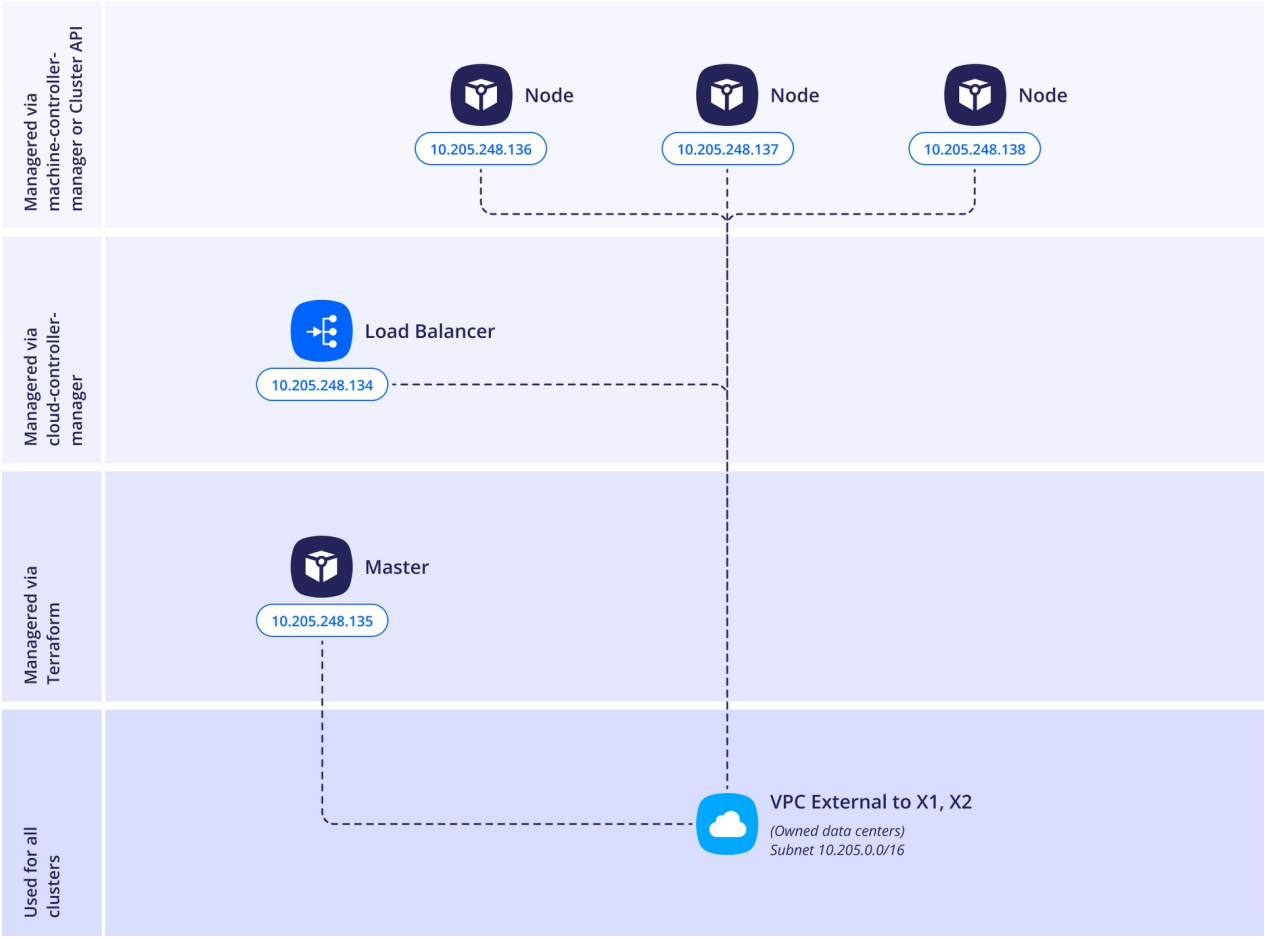


- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Cloud provider - HuaweiCloud: Layouts

> **i** The module lifecycle stage: General Availability

Standard



- An internal cluster network is created with a gateway to the public network.
- The elastic IP can be assigned to the master node.
- Nodes managed by the Cluster API do not have public IP addresses.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
standard:
  internalNetworkDNSServers:
    - 8.8.8.8
  internalNetworkCIDR: 192.168.199.0/24
  internalNetworkSecurity: true
  enableEIP: true
provider:
  cloud: hc.sbercloud.ru
  region: ru-moscow-1
  accessKey: "<Access key>"
  secretKey: "<Secret key>"
  projectID: "<Project ID>"
masterNodeGroup:
  replicas: 1
  instanceClass:
    imageName: alt-p11
    flavorName: s7n.xlarge.2
    rootDiskSize: 50
  serverGroup:
    policy: AntiAffinity
  volumeTypeMap:
    ru-moscow-1a: SSD
```

VpcPeering

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: HuaweiCloudClusterConfiguration
layout: VpcPeering
sshPublicKey: "<SSH_PUBLIC_KEY>"
vpcPeering:
  internalNetworkDNSServers:
    - 8.8.8.8
  internalNetworkCIDR: 10.221.128.0/24
  internalNetworkSecurity: true
  subnet: subnet-43b4
```

Cloud provider — OpenStack

> **i** The module lifecycle stage: General Availability

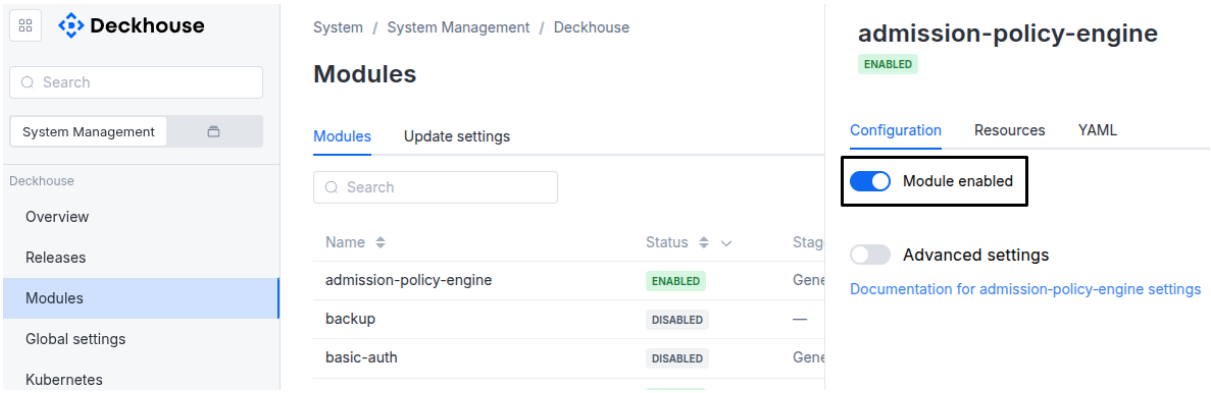
The `cloud-provider-openstack` module integrates Deckhouse Kubernetes Platform with OpenStack-based clouds. It allows the `node-manager` module to use OpenStack resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-openstack` module:

- Managing OpenStack resources via `cloud-controller-manager`:
  - updates OpenStack server and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in OpenStack;
  - creates load balancers (Octavia) for Services of the LoadBalancer type.
- Provisioning block disks via the Cinder CSI driver (`cinder.csi.openstack.org`). Manila (filesystem) is not supported. The Cinder CSI driver supports re-authentication in OpenStack with service catalog refresh, which improves resilience for long-running pods with volumes.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-openstack`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM) or Cluster API (CAPI). Virtual machine parameters are set in the OpenStackInstanceClass resource.
- Registering with `node-manager` so that OpenStackInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used. The network mode depends on the `podNetworkMode` parameter.

⚠ The module is migrating CloudEphemeral node management from Machine Controller Manager (MCM) to Cluster API (CAPI). Existing NodeGroups continue to use MCM, while new ones are created with CAPI by default. For migrating existing groups, see How to migrate node groups to Cluster API (CAPI).

Configuration



ℹ The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in OpenStack.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-openstack` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

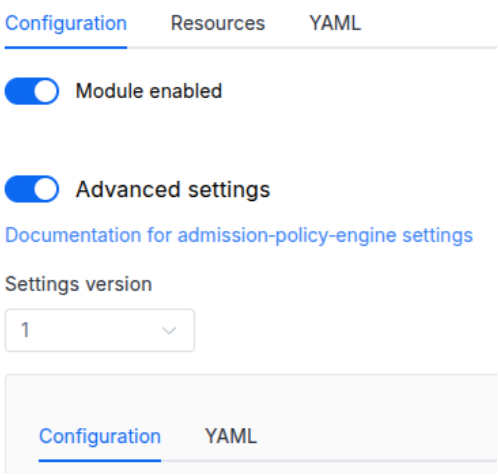
```
d8 system module enable cloud-provider-openstack
```

- **Using ModuleConfig `cloud-provider-openstack`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-openstack` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-openstack`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-openstack
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-openstack` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cloud-provider-openstack` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-openstack`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-openstack` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-openstack
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-openstack` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-openstack`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-openstack
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

You can configure the number and parameters of ordering machines in the cloud via the `NodeGroup` custom resource of the node-manager module. Also, in this custom resource, you can specify the instance class’s name for the above group of nodes (the `cloudInstances.ClassReference` NodeGroup parameter). In the case of the OpenStack-based cloud provider, the instance class is the `OpenStackInstanceClass` custom resource that stores specific parameters of the machines.

> **i** An OpenStack cluster is deployed in a single region (`provider.region` in OpenStackClusterConfiguration). Zones from other regions cannot be used. See How do I create NodeGroups in availability zones? .

The module settings are set automatically based on the placement strategy chosen. In most cases, you do not have to configure the module manually.

If you need to configure a module because, say, you have a bare metal cluster and you need to enable additional instances from vSphere, then refer to the How to configure a Hybrid cluster in vSphere section.

> **i** **Note!** If the parameters provided below are changed, the **existing `Machines` are NOT redeployed** (new `Machines` will be created with the updated parameters). Redeployment is only performed when `NodeGroup` and `OpenStackInstanceClass` parameters are changed. You can learn more in the node-manager module’s documentation. To authenticate using the `user-authn` module, you need to create a new `Generic` application in the project’s Crowd.

List of required OpenStack services

A list of OpenStack services required for Deckhouse Kubernetes Platform to work in OpenStack:

Service	API Version
Identity (Keystone)	v3
Compute (Nova)	v2
Network (Neutron)	v2
Block Storage (Cinder)	v3
Load Balancing (Octavia) *	v2

* If you need to order a Load Balancer.

To ensure proper integration and functionality, the OpenStack user associated with the Deckhouse Kubernetes Platform should be granted the “member” role. This role assignment is essential to provide the necessary permissions for interacting with the listed services and managing resources within the OpenStack environment.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.additionalExternalNetworkNames**
    array of strings

    Specifies additional networks that can be connected to the VM. `cloud-controller-manager` uses them to insert `ExternalIP` to `.status.addresses` field in the Node API object.

    If you have instances in the cluster that use External Networks (other than those set out in the placement strategy), you must pass them via the `additionalExternalNetworkNames` parameter.

    Example:

    ```
    additionalExternalNetworkNames:
    - some-bgp-network
    ```

  - **settings.connection**
    object

    This section contains parameters required to connect to the cloud provider’s API.

    - **settings.connection.authURL**
      string

      An OpenStack Identity API URL.

    - **settings.connection.caCert**
      string

      Specify the CA x509 certificate used for signing if the OpenStack API has a self-signed certificate; The certificate must have a PEM format.

    - **settings.connection.domainName**
      string

      The domain name.

    - **settings.connection.password**
      string

      The user’s password.

    - **settings.connection.region**
      string

      The OpenStack region where the cluster will be deployed.

    - **settings.connection.tenantID**
      string

      The project ID. Cannot be used together with `tenantName`.

    - **settings.connection.tenantName**
      string

      The project name.

      Cannot be used together with `tenantID`.

    - **settings.connection.username**
      string

      The name of the user that has full project privileges.

  - **settings.csiDriver**
    object

    Parameters for configuring the Cinder CSI Driver.

- **settings.csiDriver.fsGroupPolicy**
  string

  Defines if the underlying volume supports changing ownership and permission of the volume before being mounted.

  - `ReadWriteOnceWithFSType`: Apply fsGroup only for ReadWriteOnce volumes (Kubernetes default behavior).
  - `File`: Always apply fsGroup. Use this for RWX volumes with Ceph backend.
  - `None`: Never change permissions.

  Default: `ReadWriteOnceWithFSType`

  Allowed values: `ReadWriteOnceWithFSType`, `File`, `None`

- **settings.externalNetworkNames**
  array of strings

  Additional networks that are connected to the VM. cloud-controller-manager uses them to insert ExternalIPs into `.status.addresses` in the Node API object.

  Example:

  ```
  externalNetworkNames:
  - KUBE-3
  - devops-internal
  ```

- **settings.ignoreVolumeMicroversion**
  boolean

  Setting for backwards compatibility. Enable if the cloud OpenStack version is less than 3.34 and you get error “Version 3.34 is not supported by the API. Minimum is 3.0 and maximum is 3.x” when ordering a PV. This will disable volumes online resize, but will restore ability to order new PVs. (original PR https://github.com/kubernetes/cloud-provider-openstack/pull/1986/)

  Default: `false`

- **settings.instances**
  object

  Instance parameters that are used when creating virtual machines.

  - **settings.instances.additionalNetworks**
    array of strings

    A list of networks to connect to the instance.

  - **settings.instances.imageName**
    string

    The name of the image.

  - **settings.instances.mainNetwork**
    string

    The path to the network that will serve as the primary network (the default gateway) for connecting to the VM.

  - **settings.instances.securityGroups**
    array of strings

    A list of securityGroups to assign to the provisioned instances. Defines firewall rules for the provisioned instances.

  - **settings.instances.sshKeyPairName**
    string

    The name of the OpenStack `keypair` resource; it is used for provisioning instances.

- **settings.internalNetworkNames**
  array of strings

  Additional networks that are connected to the VM. cloud-controller-manager uses them to insert InternalIPs into `.status.addresses` in the Node API object.

  Example:

  ```
  internalNetworkNames:
  - KUBE-3
  - devops-internal
  ```

- **settings.loadBalancer**
  object

  Load Balancer parameters.

  - **settings.loadBalancer.disabled**
    boolean

Set to `true` to disable LoadBalancer support if the OpenStack cloud doesn't have Octavia (LBaaS) service available.

Default: `false`

- **settings.loadBalancer.floatingNetworkID**
  string

  An ID of the external network for floating IPs.

- **settings.loadBalancer.subnetID**
  string

  An ID of the Neutron subnet to create the load balancer virtual IP in.

- **settings.podNetworkMode**
  string

  Sets the traffic mode for the network that the pods use to communicate with each other (usually, it is an internal network; however, there can be exceptions):

  - `DirectRouting` — means that there is a direct routing between the nodes.
  - `DirectRoutingWithPortSecurityEnabled` — direct routing is enabled between the nodes, but only if the range of addresses of the internal network is explicitly allowed in OpenStack for Ports.
    - **Caution!** Make sure that the `username` can edit AllowedAddressPairs on Ports connected to the `internalNetworkName` network. Generally, an OpenStack user doesn't have such a privilege if the network has the `shared` flag set.
  - `VXLAN` — direct routing between the nodes isn't available; VXLAN should be used.

  Allowed values: `DirectRouting`, `DirectRoutingWithPortSecurityEnabled`, `VXLAN`

- **settings.storageClass**
  object

  The module automatically creates StorageClasses that are available in OpenStack.

  - **settings.storageClass.default**
    Deprecated
    string

    The name of StorageClass that will be used in the cluster by default.

    If the parameter is omitted, the default StorageClass is either:

    - an arbitrary StorageClass present in the cluster that has the default annotation;
    - the first (in lexicographic order) StorageClass created by the module (in accordance with the order in OpenStack).

    > **Parameter is deprecated**. Instead, use the global parameter global.defaultClusterStorageClass.

    Example:

    ```
    default: ceph-ssd
    ```

  - **settings.storageClass.exclude**
    array of strings

    A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

    Example:

    ```
    exclude:
    - ".*-hdd"
    - iscsi-fast
    ```

  - **settings.storageClass.topologyEnabled**
    boolean

    This feature enables driver to consider the topology constraints while creating the volume. It is used only during volume provisioning, existing PersistentVolumes are not affected.

    > **Warning.** If it is set to `false` all-new PersistentVolumes are provisioned without topology constraints.

    Default: `true`

- **settings.tags**
  object

  A dictionary of tags that will be available on all provisioned instances.

- **settings.zones**
  array of strings

  The default list of zones for provisioning instances. Can be redefined for each NodeGroup individually.

Provider configuration

> **i** The module lifecycle stage: General Availability

OpenStackClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in OpenStack.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> **i** After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
zones:
- eu-3a
- eu-3b
standard:
  internalNetworkDNSServers:
  - 8.8.8.8
  internalNetworkCIDR: 192.168.195.0/24
  internalNetworkSecurity: false
  externalNetworkName: external-network
provider:
  authURL: "<AUTH_URL>"
  domainName: "<DOMAIN_NAME>"
  tenantID: "<TENANT_ID>"
  username: "<USERNAME>"
  password: "<PASSWORD>"
  region: eu-3
masterNodeGroup:
  replicas: 1
  instanceClass:
    rootDiskSize: 50
    flavorName: m1.large
    imageName: debian-11-genericcloud-amd64-20220911-1135
  volumeTypeMap:
    eu-3a: fast.eu-3a
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.large
    imageName: debian-11-genericcloud-amd64-20220911-1135
    rootDiskSize: 50
    configDrive: false
    floatingIPPools:
    - public
    - shared
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  zones:
  - eu-3a
  - eu-3b
```

- **apiVersion**
  string

  Required value

Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **kind**
  string

  Required value

  Allowed values: `OpenStackClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **masterNodeGroup**

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the OpenStackInstanceClass.

    - **masterNodeGroup.instanceClass.additionalSecurityGroups**
      array of strings

      Security groups that will be applied to VM's network ports. Default group should also be added to this list.

      They allow you to set firewall rules for provisioned instances.

      The `SecurityGroups` may not be supported by the cloud provider.

    - **masterNodeGroup.instanceClass.additionalTags**
      object

      The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

      Example:

      ```
      additionalTags:
        project: cms-production
        severity: critical
      ```

    - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in gigabytes.

      Default: `10`

      Example:

      ```
      etcdDiskSizeGb: 10
      ```

    - **masterNodeGroup.instanceClass.flavorName**
      string

      Required value

      Flavor of OpenStack servers.

      To get a list of all available flavors, run the command: `openstack flavor list`.

      For all non-master nodes it is advisable to use flavor's with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

      Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

    - **masterNodeGroup.instanceClass.imageName**
      string

      Required value

      Image to use while provisioning OpenStack servers.

      Use this command to get a list of available images: `openstack image list`.

The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

- **masterNodeGroup.instanceClass.rootDiskSize**
  integer

  The size of a root disk (in gigabytes).

  This parameter also has influence on type of volume that will be used for root disk; the “How to use rootDiskSize and when it is preferred” section describes how to use it.

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.serverGroup**
  object

  Object groups instances together. The instances in the group are placed on the same hypervisor (affinity) or different hypervisors (anti-affinity). This allows you to increase the fault tolerance of the cluster.

  - **masterNodeGroup.serverGroup.manuallyManaged**
    object
    - **masterNodeGroup.serverGroup.manuallyManaged.id**
      string

      Required value

      The id of the existing `ServerGroup` object managed outside of Deckhouse.
  - **masterNodeGroup.serverGroup.policy**
    string

    Required value

    The policy that determines how instances are distributed among hypervisors.

    - `AntiAffinity` — instances are placed on different hypervisors. This policy is managed by Deckhouse.
    - `ManuallyManaged` — instances are placed on different hypervisors. This policy is managed outside of Deckhouse.

    Allowed values: `AntiAffinity`, `ManuallyManaged`

- **masterNodeGroup.volumeTypeMap**
  object

  Required value

  A dictionary of disk types for storing etcd data and Kubernetes configuration files.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <VOLUME TYPE>` (see the example).

  If the `rootDiskSize` parameter is specified, the same disk type will be used for the VM’s boot drive.

  We recommend using the fastest disks provided by the provider in all cases.

  If the value specified in `replicas` exceeds the number of elements in the dictionary, the master nodes whose number exceeds the length of the dictionary get the values starting from the beginning of the dictionary. For example, if `replicas: 5`, then master-0, master-2, master-4 will have the `fast-eu-1a` disk type, while master-1, master-3 will have the `fast-eu-1b` disk type.

  Master nodes will be created in zones specified at this param following by alphabetical order. Based on the example below, `master-0` will be created in zone `eu-1a`, `master-1` will be created in zone `eu-1b`, and `master-2` will be created in zone `eu-1a`.

  Useful commands:

  - `openstack availability zone list` — get list of availability zones.
  - `openstack volume type list` — get list of volume types.

  Example:

  ```
  volumeTypeMap:
    eu-1a: fast-eu-1a
    eu-1b: fast-eu-1b
  ```

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating CloudPermanent nodes (for example, dedicated front nodes or gateways).

  For CloudEphemeral nodes, use a separate NodeGroup resource and an OpenStackInstanceClass.

  - **nodeGroups.instanceClass**

object

Partial contents of the fields of the OpenStackInstanceClass.

- **nodeGroups.instanceClass.additionalNetworks**
  array of strings

  Paths to networks that VirtualMachines secondary NICs will connect to. To get a list of all available networks, run the command: `openstack network list`.

  Example:

  ```
  additionalNetworks:
  - BGP-network-VLAN-3894
  - External-VLAN-3699
  ```

- **nodeGroups.instanceClass.additionalSecurityGroups**
  array of strings

  Security groups that will be applied to VM’s network ports. Default group should also be added to this list.

  They allow you to set firewall rules for provisioned instances.

  The `SecurityGroups` may not be supported by the cloud provider.

- **nodeGroups.instanceClass.additionalTags**
  object

  The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

  Example:

  ```
  additionalTags:
    project: cms-production
    severity: critical
  ```

- **nodeGroups.instanceClass.configDrive**
  boolean

  Not required value.

  Specifies whether an additional disk containing the bootstrapping configuration will be mounted to the node.

  You must set it if DHCP is disabled in the `mainNetwork`.

  Default: `false`

- **nodeGroups.instanceClass.flavorName**
  string

  Required value

  Flavor of OpenStack servers.

  To get a list of all available flavors, run the command: `openstack flavor list`.

  For all non-master nodes it is advisable to use flavor’s with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

  Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

- **nodeGroups.instanceClass.floatingIPPools**
  array of strings

  A list of networks to assign Floating IPs to nodes.

- **nodeGroups.instanceClass.imageName**
  string

  Required value

  Image to use while provisioning OpenStack servers.

  Use this command to get a list of available images: `openstack image list`.

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

- **nodeGroups.instanceClass.mainNetwork**
  string

  Required value

  Path to the network that VirtualMachines primary NICs will connect to (default gateway). To get a list of all available networks, run the command: `openstack network list`.

- **nodeGroups.instanceClass.networksWithSecurityDisabled**

array of strings

A list of `mainNetwork` and `additionalNetworks` in which `SecurityGroups` and `AllowedAddressPairs` on ports **cannot be configured**.

- **nodeGroups.instanceClass.rootDiskSize**
  integer

  The size of a root disk (in gigabytes).

  This parameter also has influence on type of volume that will be used for root disk; the “How to use rootDiskSize and when it is preferred” section describes how to use it.

- **nodeGroups.name**
  string

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **nodeGroups.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **nodeGroups.nodeTemplate.taints.key**
      string
    - **nodeGroups.nodeTemplate.taints.value**
      string

- **nodeGroups.replicas**
  integer

  The number of nodes to create.

- **nodeGroups.volumeTypeMap**
  object

  A dictionary of disk types for root drive.

  Format of dictionary elements: `<AVAILABILITY ZONE>: <VOLUME TYPE>` (see the example).

  If the value specified in `replicas` exceeds the number of elements in the dictionary, the nodes whose number exceeds the length of the dictionary get the values starting from the beginning of the dictionary. For example, if

`replicas: 5`, then worker-0, worker-2, worker-4 will have the `fast-eu-1a` disk type, while worker-1, worker-3 will have the `fast-eu-1b` disk type.

> **Caution.** Limits by availability zones works only when using the `zones` parameter (`nodeGroups.zones`). If `zones` parameter is not specified, all availability zones will be used.

Useful commands:

- `openstack availability zone list` — get list of availability zones.
- `openstack volume type list` — get list of volume types.

Example:

```
volumeTypeMap:
  eu-1a: fast-eu-1a
  eu-1b: fast-eu-1b
```

- **nodeGroups.zones**
  array of strings

  Not required value.

  A limited set of zones in which nodes can be created.

  The zones must belong to the `provider.region` region. If the `zones` parameter is set, only zones from that parameter can be used.

- **provider**
  object

  Required value

  Contains settings to connect to the OpenStack API.

  These settings are the same as those in the `connection` field of the cloud-provider-openstack module.

  - **provider.authURL**
    string

    An OpenStack Identity API URL.

  - **provider.caCert**
    string

    Specify the CA x509 certificate used for signing if the OpenStack API has a self-signed certificate. Certificate should be passed in PEM format as multiline string.

    Example:

    ```
    caCert: |
      -----BEGIN CERTIFICATE-----
      MIIFyDCCBLCgAwIBAgIQBwDIWH1asdaKNaALUa4NUzANBgkqhkiG9w0BAQsFADBc
      ...
      -----END CERTIFICATE-----
    ```

  - **provider.domainName**
    string

    The domain name.

    `OS_USER_DOMAIN_NAME` variable from the openrc file.

  - **provider.password**
    string

    The user’s password.

  - **provider.region**
    string

    The OpenStack region where the cluster will be deployed.

    The cluster runs in a single region. Master nodes, as well as CloudPermanent and CloudEphemeral nodes, can be created only in zones of this region.

  - **provider.tenantID**
    string

    The project id.

    Cannot be used together with `tenantName`.

  - **provider.tenantName**
    string

    The project name.

Cannot be used together with `tenantID`.

- **provider.username**
  string

  The name of the user that has full project privileges.

- **simple**
  object

  Settings for the `Simple` layout.

  - **simple.externalNetworkDHCP**
    boolean

    This parameter defines if DHCP is enabled in the external network.

    Default: `true`

  - **simple.externalNetworkName**
    string

    Required value

    The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

  - **simple.podNetworkMode**
    string

    Sets the traffic mode for the network that the pods use to communicate with each other (usually, it is an internal network; however, there can be exceptions):

    - `DirectRouting` — nodes are directly routed (SecurityGroups are disabled in this mode).
    - `VXLAN` — direct routing does NOT work between nodes, VXLAN must be used (SecurityGroups are disabled in this mode).

    > **Caution.** After changing this parameter, you need to run `dhctl converge` command for the changes to take effect.

    > **Caution.** All cluster nodes must be rebooted after switching work mode from/to VXLAN.

    Default: `VXLAN`

    Allowed values: `VXLAN`, `DirectRouting`

- **simpleWithInternalNetwork**
  object

  Settings for the `SimpleWithInternalNetwork` layout.

  - **simpleWithInternalNetwork.externalNetworkDHCP**
    boolean

    This parameter defines if DHCP is enabled in the external network.

    Default: `true`

  - **simpleWithInternalNetwork.externalNetworkName**
    string

    The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

  - **simpleWithInternalNetwork.internalSubnetName**
    string

    Required value

    The name of the subnet in which the cluster nodes will run.

  - **simpleWithInternalNetwork.masterWithExternalFloatingIP**
    boolean

    Defines if Floating IP must be assigned to master nodes.

    Default: `true`

  - **simpleWithInternalNetwork.podNetworkMode**
    string

    Sets the traffic mode for the network that the pods use to communicate with each other (usually, it is an internal network; however, there can be exceptions):

    - `DirectRouting` — nodes are directly routed (SecurityGroups are disabled in this mode).
    - `DirectRoutingWithPortSecurityEnabled` — direct routing is enabled between the nodes, but only if the range of addresses of the internal network is explicitly allowed in OpenStack for Ports:
      - **Caution.** Make sure that the `username` can edit `AllowedAddressPairs` on Ports connected to the

`internalNetworkName` network. Usually, an OpenStack user doesn’t have such a privilege if the network has the `shared` flag set.

- `VXLAN` — direct routing does NOT work between nodes, VXLAN must be used (`SecurityGroups` are disabled in this mode).

> **Caution.** After changing this parameter, you need to run `dhctl converge` command for the changes to take effect.

> **Caution.** All cluster nodes must be rebooted after switching work mode from/to VXLAN.

Default: `DirectRoutingWithPortSecurityEnabled`

Allowed values: `VXLAN`, `DirectRouting`, `DirectRoutingWithPortSecurityEnabled`

- **sshAllowList**
  array of strings

  A list of CIDR’s allowed to connect to nodes via SSH.

  By default, `0.0.0.0/0`.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **standard**
  object

  Settings for the `Standard` layout.

  - **standard.bastion**
    object

    The definition of the bastion instance.

    - **standard.bastion.instanceClass**
      object

      Partial contents of the fields of the OpenStackInstanceClass.

      - **standard.bastion.instanceClass.additionalTags**
        object

        The additional tags to attach to the instance created (in addition to those specified in the cloud provider configuration).

        Example:

        ```
        additionalTags:
          project: cms-production
          severity: critical
        ```

      - **standard.bastion.instanceClass.flavorName**
        string

        Required value

        Flavor of OpenStack servers.

        To get a list of all available flavors, run the command: `openstack flavor list`.

      - **standard.bastion.instanceClass.imageName**
        string

        Required value

        Image to use while provisioning OpenStack servers.

        Use this command to get a list of available images: `openstack image list`.

        The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

      - **standard.bastion.instanceClass.rootDiskSize**
        integer

        The size of a root disk (in gigabytes).

        This parameter also has influence on type of volume that will be used for root disk; the “How to use rootDiskSize and when it is preferred” section describes how to use it.

        Default: `50`

    - **standard.bastion.volumeType**

string

Root disk type.

- **standard.bastion.zone**
  string

  The zone to create an instance for the bastion node.

- **standard.externalNetworkName**
  string

  Required value

  The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

- **standard.internalNetworkCIDR**
  string

  Required value

  Routing for the internal cluster network.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **standard.internalNetworkDNSServers**
  array of strings

  Required value

  A list of addresses of the recursive DNSs of the internal cluster network.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **standard.internalNetworkSecurity**
  boolean

  Defines whether SecurityGroups and AllowedAddressPairs must be configured for ports of the internal network.

  Default: `true`

- **standardWithNoRouter**
  object

  Settings for the `StandardWithNoRouter` layout.

  - **standardWithNoRouter.externalNetworkDHCP**
    boolean

    This parameter defines if DHCP is enabled in the external network.

    Default: `true`

  - **standardWithNoRouter.externalNetworkName**
    string

    Required value

    The name of the network for external connections. To get a list of all available networks, run the command: `openstack network list`.

  - **standardWithNoRouter.internalNetworkCIDR**
    string

    Required value

    Routing for the internal cluster network.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **standardWithNoRouter.internalNetworkSecurity**
    boolean

    Defines whether SecurityGroups and AllowedAddressPairs must be configured for ports of the internal network.

    Default: `true`

- **tags**
  object

  Not required value.

  A dictionary of tags to create on all resources that support this feature.

  You have to re-create all the machines to add new tags if tags were modified in the running cluster.

- **zones**

array of strings

Not required value.

The globally restricted set of availability zones that this cloud provider works with.

Specify only zones of the `provider.region` region. The cluster is deployed in a single OpenStack region — zones from other regions cannot be used.

To get the list of zones in the region, run: `openstack availability zone list --compute`.

Preparing environment

> **i** The module lifecycle stage: General Availability

> ⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:
>
> - Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
> - `CgroupsV2` support.
> - Systemd version `244` or newer.
> - `erofs` kernel module support.
>
> For more information, see the documentation.

> ⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:
>
> - `cloud-config.service`;
> - `cloud-final.service`;
> - `cloud-init.service`.

> ⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

To manage resources in an OpenStack cloud, Deckhouse connects to the OpenStack API.
The list of OpenStack API services that need to be accessed for deployment is available in the settings section.
The user credentials required to connect to the OpenStack API are located in the openrc file (OpenStack RC file).

You can read the OpenStack documentation to get information about getting and using an openrc file with the standard OpenStack web interface.

The interface for getting an openrc file may differ if you use an OpenStack API of a cloud provider.

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

OpenStackInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of OpenStack servers used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines' secondary NICs will connect to.

    By default: the value from `OpenStackCloudDiscoveryData` is used.

    Example:

```
additionalNetworks:
- BGP-network-VLAN-3894
- External-VLAN-3699
```

- **spec.additionalSecurityGroups**
  array of strings

  Security groups that will be applied to VM’s network ports. Default group should also be added to this list.

  They allow you to set firewall rules for provisioned instances.

  The `SecurityGroups` may not be supported by the cloud provider.

  Example:

  ```
  additionalSecurityGroups:
  - security-group-1
  - security-group-2
  ```

- **spec.additionalTags**
  object

  The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

  Example:

  ```
  additionalTags:
    project: cms-production
    severity: critical
  ```

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `flavorName` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`m1.medium`, `m1.large`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

    Node memory resources.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    memory: 1500Mi
    ```

- **spec.flavorName**
  string

  Required value

  Flavor of OpenStack servers.

  Get a list of all available flavors: `openstack flavor list`.

  For all non-master nodes it is advisable to use flavor’s with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

Example:

```
flavorName: m1.medium
```

- **spec.imageName**
  string

  Not required value.

  Image to use while provisioning OpenStack servers.

  Use this command to get a list of available images: `openstack image list`.

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account the Deckhouse version used).

  By default: either `OpenStackCloudDiscoveryData` value or `instances.imageName` is used.

  Example:

  ```
  imageName: ubuntu-18-04-cloud-amd64
  ```

- **spec.mainNetwork**
  string

  Not required value.

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  By default: the value from `OpenStackCloudDiscoveryData` is used.

  Example:

  ```
  mainNetwork: k8s-msk-178
  ```

- **spec.rootDiskSize**
  integer

  Not required value.

  The size of a root disk (in gigabytes). This parameter also has influence on type of volume that will be used for root disk; the "How to use rootDiskSize and when it is preferred" section describes how to use it.

  Example:

  ```
  rootDiskSize: 20
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of OpenStack servers used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines' secondary NICs will connect to.

    By default: the value from `OpenStackCloudDiscoveryData` is used.

    Example:

    ```
    additionalNetworks:
    - BGP-network-VLAN-3894
    - External-VLAN-3699
    ```

  - **spec.additionalSecurityGroups**
    array of strings

    Security groups that will be applied to VM's network ports. Default group should also be added to this list.

    They allow you to set firewall rules for provisioned instances.

    The `SecurityGroups` may not be supported by the cloud provider.

    Example:

```
additionalSecurityGroups:
- security-group-1
- security-group-2
```

- **spec.additionalTags**
  object

  The additional tags to attach to the instances created (in addition to those specified in the cloud provider configuration).

  Example:

  ```
  additionalTags:
    project: cms-production
    severity: critical
  ```

- **spec.capacity**
  Deprecated
  object

  Deprecated: the parameter is no longer used. Deckhouse is using parameters from the cloud for passed instance type.

  Instance capacity for *non-standard* instance types (the `flavorName` parameter).

  Cluster-autoscaler uses the parameter for scheduling only when there are no nodes in NodeGroup yet (if `minPerZone` equal to 0). If there are already nodes in the NodeGroup, then cluster-autoscaler uses the actual node capacity (CPU, memory) when planning, and does not use the `capacity` parameter.

  The parameter must be specified only for *non-standard* instance types. Info about the capacity of *standard* instance types (`m1.medium`, `m1.large`, etc.) is embedded in Deckhouse.

  - **spec.capacity.cpu**
    integer or string

    Required value

    Node vCPU resources.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    cpu: 1000m
    ```

  - **spec.capacity.memory**
    integer or string

    Required value

    Node memory resources.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    memory: 1500Mi
    ```

- **spec.flavorName**
  string

  Required value

  Flavor of OpenStack servers.

  Get a list of all available flavors: `openstack flavor list`.

  For all non-master nodes it is advisable to use flavor’s with a local disk. If cloud provider supports local disks they are usually faster and cheaper. The disadvantage of using such flavors is the inability to migrate nodes between hypervisors.

  Flavor create example: `openstack flavor create c4m8d50 --ram 8192 --disk 50 --vcpus 4`

  Example:

  ```
  flavorName: m1.medium
  ```

- **spec.imageName**
  string

  Not required value.

  Image to use while provisioning OpenStack servers.

  Use this command to get a list of available images: `openstack image list`.

  The list of OS and their versions supported by Deckhouse can be found in the documentation (take into account

the Deckhouse version used).

By default: either `OpenStackCloudDiscoveryData` value or `instances.imageName` is used.

Example:

```
imageName: ubuntu-18-04-cloud-amd64
```

- **spec.mainNetwork**
  string

  Not required value.

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  By default: the value from `OpenStackCloudDiscoveryData` is used.

  Example:

  ```
  mainNetwork: k8s-msk-178
  ```

- **spec.rootDiskSize**
  integer

  Not required value.

  The size of a root disk (in gigabytes). This parameter also has influence on type of volume that will be used for root disk; the "How to use rootDiskSize and when it is preferred" section describes how to use it.

  Example:

  ```
  rootDiskSize: 20
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

FAQ

> **i** The module lifecycle stage: General Availability

How do I set up LoadBalancer?

> **⚠** To correctly determine the client IP address, use a LoadBalancer with Proxy Protocol support.

It is recommended to limit the list of nodes added to the load balancer pool using the `loadbalancer.openstack.org/node-selector` annotation.

Without a `node-selector` restriction, cloud-controller-manager may use all suitable cluster nodes as load balancer targets. As a result, adding or removing nodes that are not related to the workload served by the load balancer may trigger an update of the load balancer pool membership. In large or frequently changing clusters, such updates may occur regularly and, in some configurations, may cause brief disruptions to existing connections.

It is recommended to use `loadbalancer.openstack.org/node-selector` to select only the nodes that should be used as targets for the corresponding LoadBalancer.

IngressNginxController example

In this example, the Ingress controller pods are scheduled on frontend nodes, while the `loadbalancer.openstack.org/node-selector` annotation limits the load balancer pool to the same nodes:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: LoadBalancerWithProxyProtocol
  loadBalancerWithProxyProtocol:
    annotations:
      loadbalancer.openstack.org/node-selector: "node-role.deckhouse.io/frontend="
      loadbalancer.openstack.org/proxy-protocol: "true"
      loadbalancer.openstack.org/timeout-member-connect: "2000"
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
  - effect: NoExecute
    key: dedicated.deckhouse.io
    operator: Equal
    value: frontend
```

How do I set up security policies on cluster nodes?

There may be many reasons why you may need to restrict or expand incoming/outgoing traffic on cluster VMs in OpenStack:

- Allow VMs on a different subnet to connect to cluster nodes.
- Allow connecting to the ports of the static node so that the application can work.
- Restrict access to external resources or other VMs in the cloud for security reasons.

For all this, additional security groups should be used. You can only use security groups that are created in the cloud tentatively.

Enabling additional security groups on static and master nodes

This parameter can be set either in an existing cluster or when creating one. In both cases, additional security groups are declared in the `OpenStackClusterConfiguration`:

- for master nodes, in the `additionalSecurityGroups` of the `masterNodeGroup` section;
- for static nodes, in the `additionalSecurityGroups` field of the `nodeGroups` subsection that corresponds to the target nodeGroup.

The `additionalSecurityGroups` field contains an array of strings with security group names.

Enabling additional security groups on ephemeral nodes

You have to set the `additionalSecurityGroups` parameter for all OpenStackInstanceClasses in the cluster that require additional security groups. See the parameters of the cloud-provider-openstack module.

How do I create NodeGroups in availability zones?

An OpenStack cluster is deployed in a single region, which is set by the `provider.region` parameter of the OpenStackClusterConfiguration resource. Nodes can be created only in availability zones of this region. Using zones from other regions is not supported.

To get the list of availability zones in the region, run:

```
openstack --os-region-name <REGION> availability zone list --compute
```

CloudPermanent node groups are defined in the `nodeGroups` section of the OpenStackClusterConfiguration resource. To limit availability zones, use the `nodeGroups[].zones` parameter.

CloudEphemeral nodes are created with a separate NodeGroup resource with `nodeType: CloudEphemeral`. Availability zones for them are set in the `spec.cloudInstances.zones` parameter. If the `zones` parameter is specified in OpenStackClusterConfiguration, the required zones must also be added to it.

> **i** If the admission webhook returns the `unknown zone` error when creating a NodeGroup, make sure that the specified zone belongs to the `provider.region` region and, when using the `zones` parameter, is included in the OpenStackClusterConfiguration zones list.

Nodes from another region can be added to the cluster only manually as Static nodes. The `cloud-provider-openstack` module does not create such nodes.

> **⚠** After changing OpenStackClusterConfiguration, run the `dhctl converge` command. For details, see Adding and managing cloud nodes.

Example NodeGroup for CloudEphemeral nodes:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: workers
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    classReference:
      kind: OpenStackInstanceClass
      name: workers
    minPerZone: 1
    maxPerZone: 1
    zones:
    - eu-3a
    - eu-3b
```

How do I create a hybrid cluster?

A hybrid cluster combines bare metal and OpenStack nodes. To create such a cluster, you need an L2 network between all nodes of the cluster.

> **i** The Deckhouse Kubernetes Platform allows to set a prefix for the names of CloudEphemeral nodes added to a hybrid cluster with Static master nodes. To do this, use the `instancePrefix` parameter of the `node-manager` module. The prefix specified in the parameter will be added to the name of all CloudEphemeral nodes added to the cluster. It is not possible to set a prefix for a specific NodeGroup.

To set up a hybrid cluster, follow these steps:

1. Delete flannel from kube-system: `d8 k -n kube-system delete ds flannel-ds`.
2. Enable and configure the module.
3. Create one or more OpenStackInstanceClass custom resources.
4. Create one or more NodeManager custom resources for specifying the number of machines and managing the provisioning process in the cloud.

> **i** **Caution!** Cloud-controller-manager synchronizes OpenStack and Kubernetes states by deleting Kubernetes nodes that are not in OpenStack. In a hybrid cluster, such behavior does not always make sense. That is why cloud-controller-manager automatically skips Kubernetes nodes that do not have the `--cloud-provider=external` parameter (Deckhouse inserts `static://` into nodes in `.spec.providerID`, and cloud-controller-manager ignores them).

Attaching storage devices to instances in a hybrid cluster

To use PersistentVolumes on OpenStack nodes, you must create StorageClass with the appropriate OpenStack volume type. The `openstack volume type list` command lists all available types.

Here is the example config for the `ceph-ssd` volume type:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: ceph-ssd
provisioner: csi-cinderplugin # have to be like this
parameters:
  type: ceph-ssd
volumeBindingMode: WaitForFirstConsumer
```

How do I create an image in OpenStack?

1. Download the latest stable Ubuntu 18.04 image:

   ```
   curl -L https://cloud-images.ubuntu.com/bionic/current/bionic-server-cloudimg-amd64.img --output ~/ubuntu-18-04-cloud-amd64
   ```

2. Prepare an OpenStack RC (openrc) file containing credentials for accessing the OpenStack API:

   > **i** The interface for getting an openrc file may differ depending on the OpenStack provider. If the provider has a standard interface for OpenStack, you can download the openrc file using the following instruction.

3. Otherwise, install the OpenStack client using this instruction.

Also, you can run the container and mount an openrc file and a downloaded Ubuntu image in it:

```
docker run -ti --rm -v ~/ubuntu-18-04-cloud-amd64:/ubuntu-18-04-cloud-amd64 -v ~/.openrc:/openrc jmcvea/openstack-client
```

4. Initialize the environment variables from the openrc file:

```
source /openrc
```

5. Get a list of available disk types:

```
/ # openstack volume type list
+--------------------------------------+--------------+-----------+
| ID                                   | Name         | Is Public |
+--------------------------------------+--------------+-----------+
| 8d39c9db-0293-48c0-8d44-015a2f6788ff | ko1-high-iops | True      |
| bf800b7c-9ae0-4cda-b9c5-fae283b3e9fd | dp1-high-iops | True      |
| 74101409-a462-4f03-872a-7de727a178b8 | ko1-ssd       | True      |
| eadd8860-f5a4-45e1-ae27-8c58094257e0 | dp1-ssd       | True      |
| 48372c05-c842-4f6e-89ca-09af3868b2c4 | ssd           | True      |
| a75c3502-4de6-4876-a457-a6c4594c067a | ms1           | True      |
| ebf5922e-42af-4f97-8f23-716340290de2 | dp1           | True      |
| a6e853c1-78ad-4c18-93f9-2bba317a1d13 | ceph          | True      |
+--------------------------------------+--------------+-----------+
```

6. Create an image, pass the disk format to use (if OpenStack does not support local disks or these disks don’t fit):

```
openstack image create --private --disk-format qcow2 --container-format bare \
  --file /ubuntu-18-04-cloud-amd64 --property cinder_img_volume_type=dp1-high-iops ubuntu-18-04-cloud-amd64
```

7. Check that the image was created successfully:

```
/ # openstack image show ubuntu-18-04-cloud-amd64
+------------------+------------------------------------
```

are supported.

How to set up online disk resize

The OpenStack API states that the resize is completed successfully. However, Nova does not get any information about the resize from Cinder. As a result, the size of the disk in the guest OS remains the same.

To get rid of this problem, you need to insert the Nova API access parameters into the `cinder.conf` file, e.g., as follows:

```
[nova]
interface = admin
insecure = {{ keystone_service_internaluri_insecure | bool }}
auth_type = {{ cinder_keystone_auth_plugin }}
auth_url = {{ keystone_service_internaluri }}/v3
password = {{ nova_service_password }}
project_domain_id = default
project_name = service
region_name = {{ nova_service_region }}
user_domain_id = default
username = {{ nova_service_user_name }}
```

Source...

How to use `rootDiskSize` and when it is preferred?

Disks in OpenStack

The node disk can be local or network. A local disk in OpenStack, is an ephemeral disk, and a network disk is a persistent disk (cinder storage). Nodes with local disks cannot migrate between hypervisors.

- A network disk is preferred for the master node so that the node can migrate between hypervisors.
- A local disk is preffered for the ephemeral node to save on cost. Not all cloud providers support the use of local disks. If local disks are not supported, you have to use network disks for ephemeral nodes.

Local disk (ephemeral)	Network disk (persistent)
Cheaper	More expensive
Suitable for ephemeral nodes	Suitable for master nodes

The `rootDiskSize` parameter

The `OpenStackInstanceClass` has a `rootDiskSize` parameter, and OpenStack flavor has a disk size parameter. Which disk will be ordered depending on the combination of parameters is shown in the table:

	flavor disk size = 0	flavor disk size > 0
`rootDiskSize` is not specified	*You need to set the size*. Without specifying the size, there will be an error creating a VM.	Local disk with size according to the flavor
`rootDiskSize` is specified	Network disk with the `rootDiskSize` size	Network disk (rootDiskSize) and local disk (according to the flavor). Avoid using this option, as the cloud provider will charge for both disks.

> **i** Please note, that to create a node with the `CloudEphemeral` type in a zone other than zone A, you must first create a flavor with a disk of the required size. The rootDiskSize parameter does not need to be specified.

Network disk is recommended for master nodes and bastion host

- Use flavor with a zero disk size.
- Set the `rootDiskSize` in the `OpenStackInstanceClass`.
- Check the disk type. The disk type will be taken from the OS image if it is set. If it is not set, the disk type will be taken from volumeTypeMap.

Local disk is recommended for ephemeral nodes

- Use flavor with the specified disk size.
- Do not use the `rootDiskSize` parameter in the `OpenStackInstanceClass`.
- Check the disk type. The disk type will be taken from the OS image if it is set. If it is not set, the default disk type of the cloud provider will be used.

How do I check the disk volume in a flavor?

```
# openstack flavor show m1.medium-50g -c disk
+-------+-------+
| Field | Value |
+-------+-------+
| disk  | 50    |
+-------+-------+
```

How to override a default volume type of cloud provider?

If there are several types of disks in a *cloud provider*, you can set a default disk type for the image in order to select a specific VM's disk type. To do this, specify the name of a disk type in the image metadata.

Also, you may need to create a custom OpenStack image; the "How do I create an image in OpenStack" section describes how to do it

Example:

```
openstack volume type list
openstack image set ubuntu-18-04-cloud-amd64 --property cinder_img_volume_type=VOLUME_NAME
```

OFFLINE disk resize

Some cloud providers may not support ONLINE disk resizing. If you get the following error, then you need to reduce the number of StatefulSet replicas to 0, wait for disk resizing and return the number of replicas that was before the start of the operation.

```
Warning  VolumeResizeFailed     5s (x11 over 41s)  external-resizer cinder.csi.openstack.org
resize volume "pvc-555555-ab66-4f8d-947c-296520bae4c1" by resizer "cinder.csi.openstack.org" failed:
rpc error: code = Internal desc = Could not resize volume "bb5a275b-3f30-4916-9480-9efe4b6dfba5" to size 2:
Expected HTTP response code [202] when accessing
[POST https://public.infra.myfavourite-cloud-provider.ru:8776/v3/555555555555/volumes/bb5a275b-3f30-4916-9480-
9efe4b6dfba5/action], but got 406 instead
{"computeFault": {"message": "Version 3.42 is not supported by the API. Minimum is 3.0 and maximum is 3.27.", "code": 406}}
```

What to do if switching to nodes in lower-priority groups takes a long time?

If switching to nodes in lower-priority groups takes a long time, follow the instructions.

Examples

> **i** The module lifecycle stage: General Availability

Below are two simple examples of OpenStack cloud provider configuration.

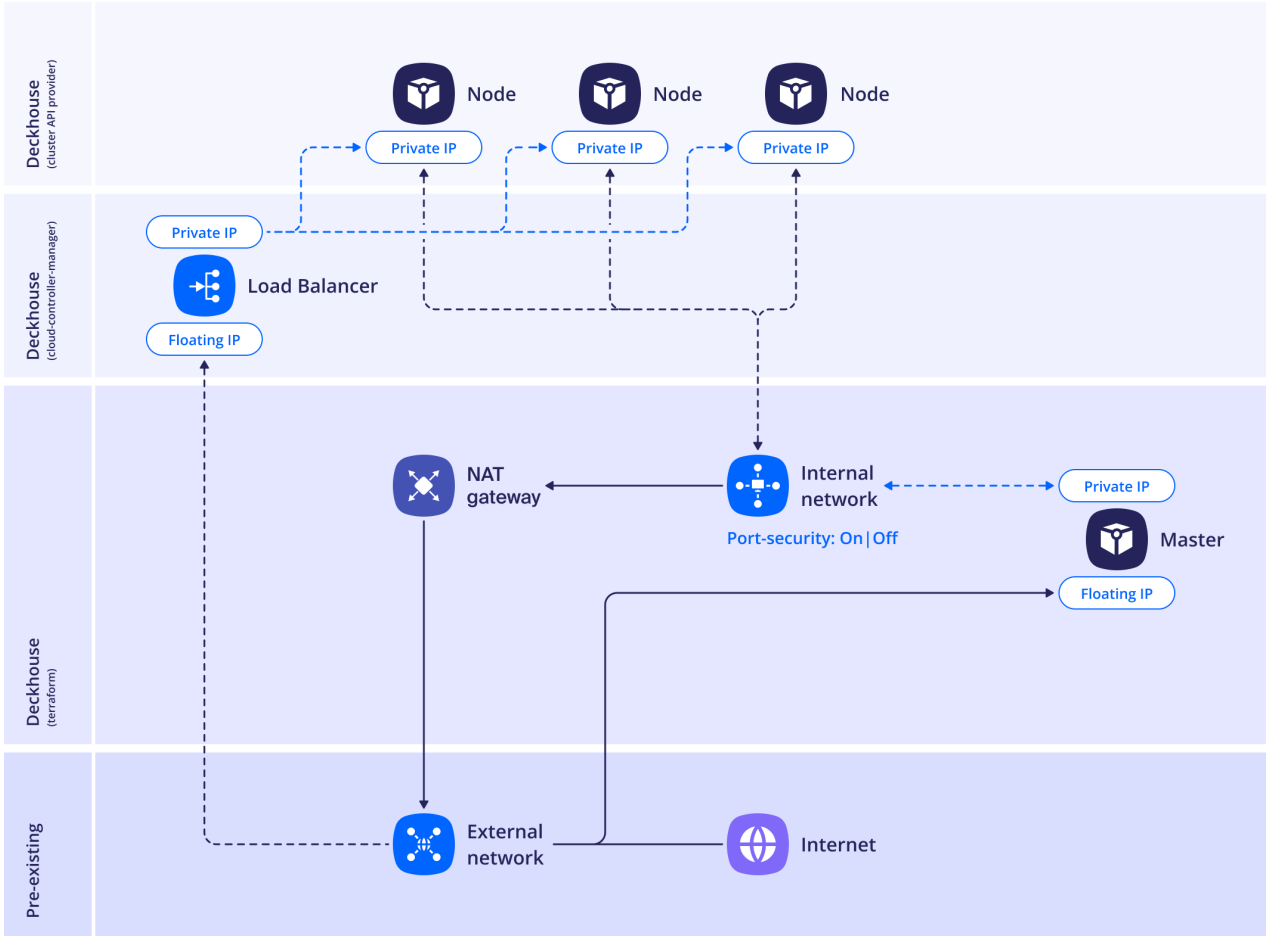
Example 1

```
apiVersion: deckhouse.io/v1
kind: OpenStackInstanceClass
metadata:
  name: test
spec:
  flavorName: m1.large
```

Example 2

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-openstack
spec:
  version: 1
  enabled: true
  settings:
    connection:
      authURL: https://test.tests.com:5000/v3/
      domainName: default
      tenantName: default
      username: jamie
      password: nein
      region: SomeRegion
    externalNetworkNames:
    - public
    internalNetworkNames:
    - kube
    instances:
      sshKeyPairName: my-ssh-keypair
      securityGroups:
      - default
      - allow-ssh-and-icmp
    zones:
    - zone-a
    - zone-b
    tags:
      project: cms
      owner: default
```

Cloud provider - OpenStack: Layouts



> **i** The module lifecycle stage: General Availability

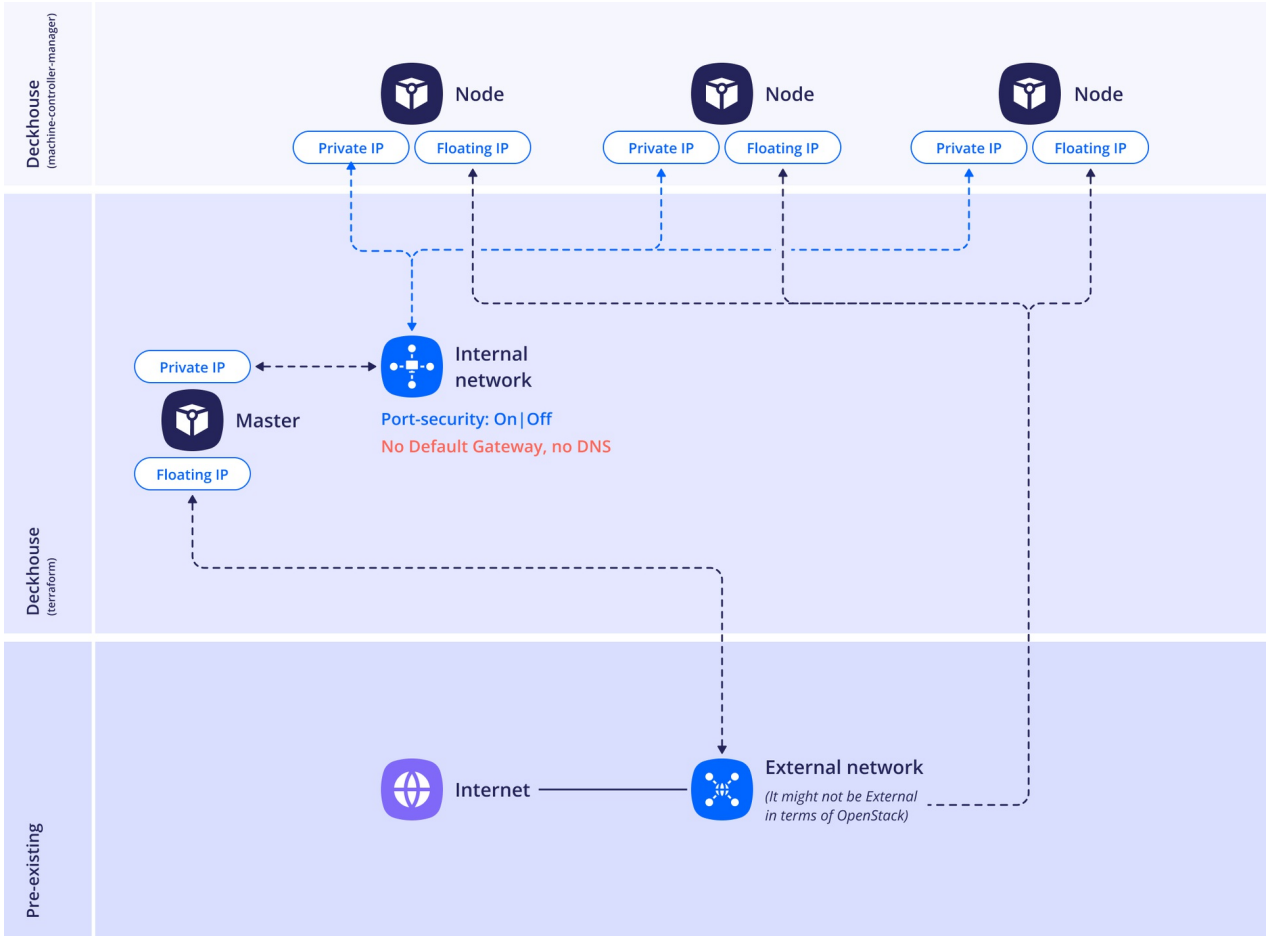
Four layouts are supported. Below is more information about each of them.

Standard

In this scheme, an internal cluster network is created with a gateway to the public network; the nodes do not have public IP addresses. Note that the floating IP is assigned to the master node.

> **i** **Caution!** If the provider does not support SecurityGroups, all applications running on nodes with Floating IPs assigned will be available at a public IP. For example, `kube-apiserver` on master nodes will be available on port 6443. To avoid this, we recommend using the SimpleWithInternalNetwork placement strategy or Standard strategy with bastion host.

Example of the layout configuration:



```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: Standard
standard:
  internalNetworkCIDR: 192.168.199.0/24       # Required.
  internalNetworkDNSServers:                 # Required.
  - 8.8.8.8
  - 4.2.2.2
  internalNetworkSecurity: true|false         # Optional, default true.
  externalNetworkName: shared                # Required.
  bastion:
    zone: ru2-b                             # Optional.
    volumeType: fast-ru-2b                   # Optional.
    instanceClass:
      flavorName: m1.large                   # Required.
      imageName: ubuntu-20-04-cloud-amd64      # Required.
      rootDiskSize: 50                      # Optional, default 50 gigabytes.
      additionalTags:

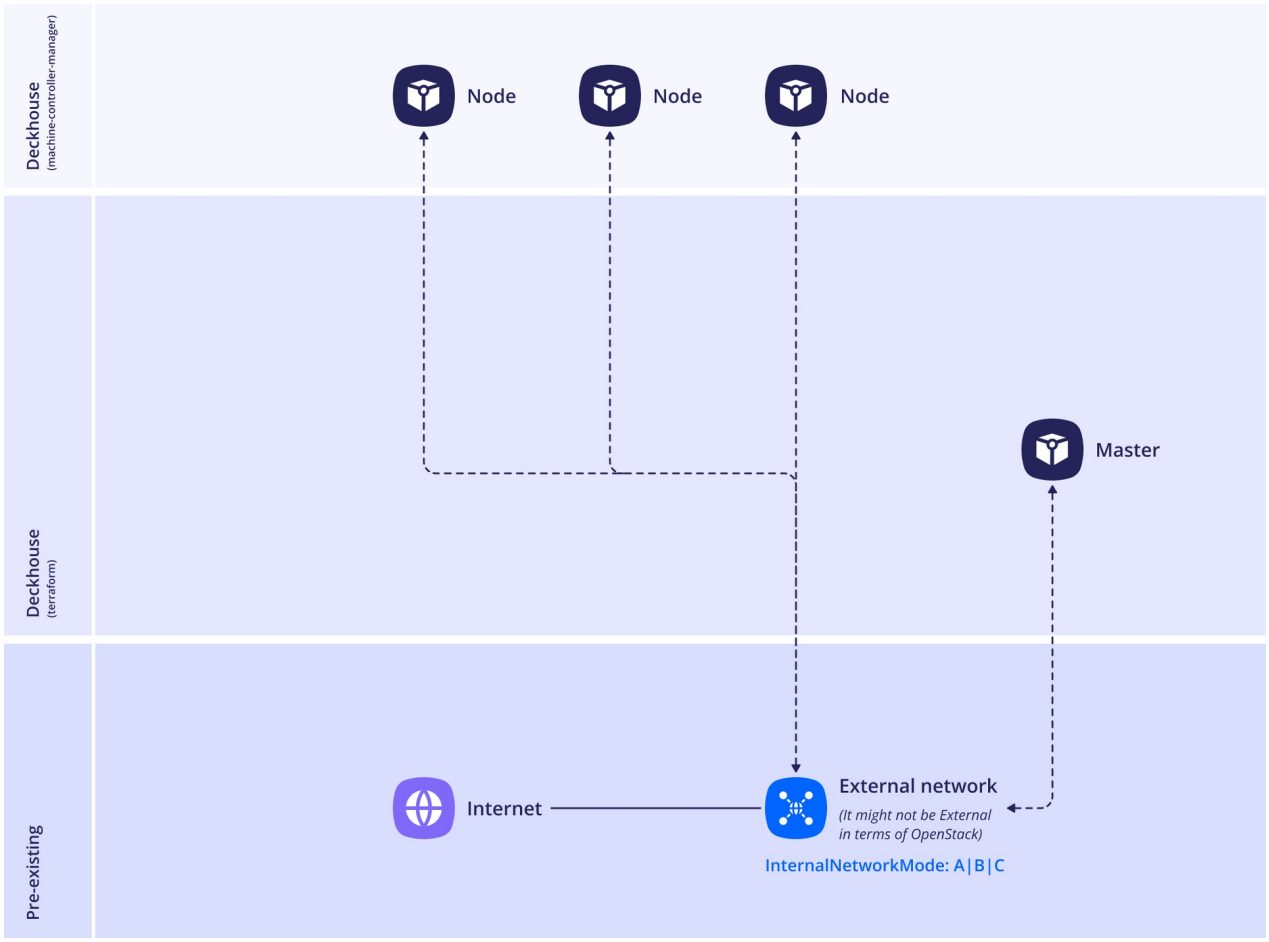
StandardWithNoRouter

An internal cluster network is created that does not have access to the public network. All nodes (including master ones) have two interfaces: the first one to the public network, the second one to the internal network. This layout should be used if you want all nodes in the cluster to be directly accessible.

> **i**
>
> **Caution!** This strategy does not support a LoadBalancer since a Floating IP is not available for the router-less network. Thus, you cannot provision a load balancer with the Floating IP. An internal load balancer with the virtual IP in the public network is only accessible to cluster nodes.
>
> **Caution!** In this strategy, it is necessary to explicitly specify the name of the internal network in `additionalNetworks` when creating an `OpenStackInstanceClass` in the cluster.



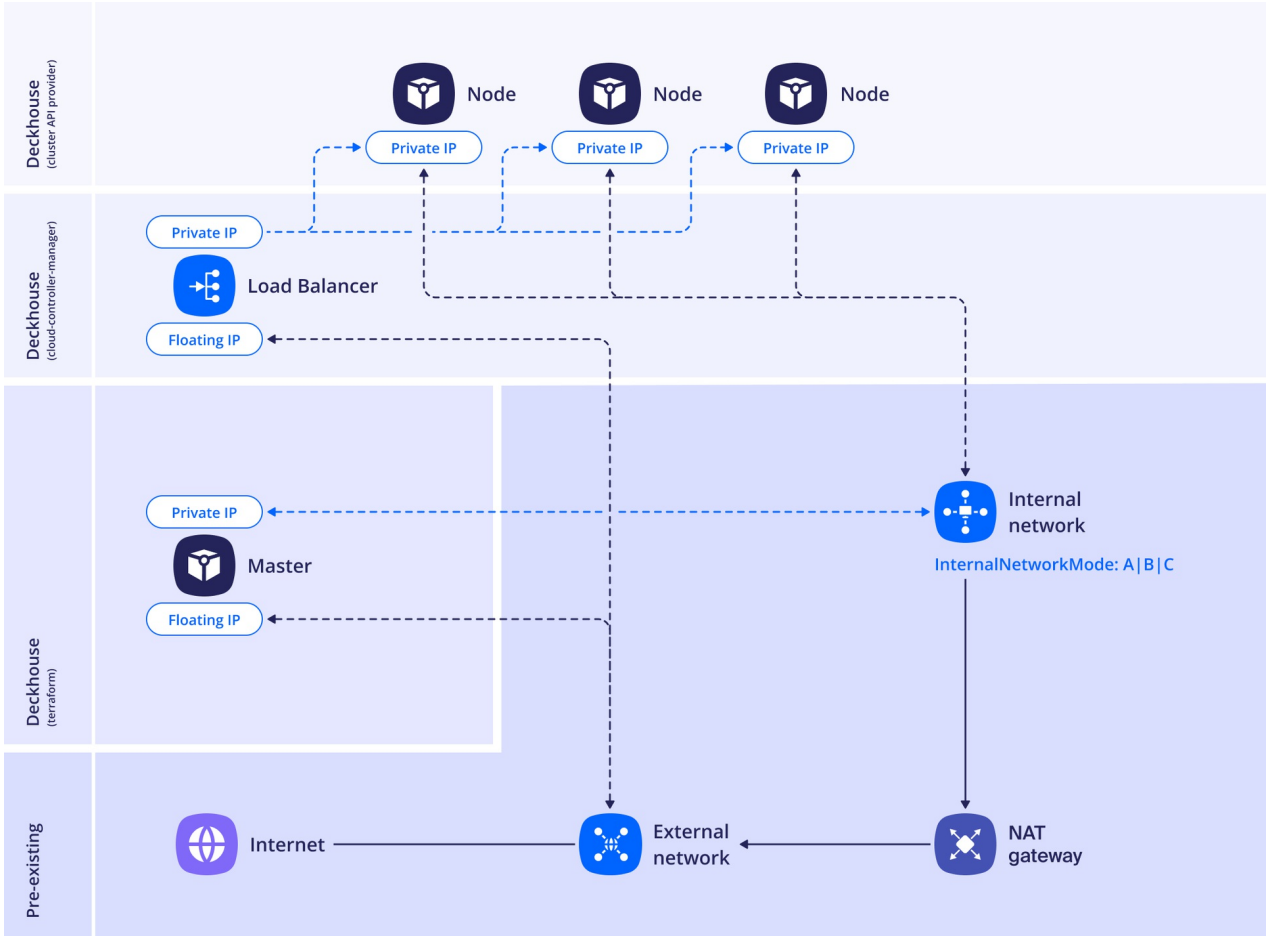
Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: StandardWithNoRouter
standardWithNoRouter:
  internalNetworkCIDR: 192.168.199.0/24        # Required.
  externalNetworkName: ext-net                # Required.
  # Optional, whether dhcp is enabled in specified external
  # network (default true).
  externalNetworkDHCP: false
  internalNetworkSecurity: true|false          # Optional, default true.
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                     # Required.
    imageName: ubuntu-18-04-cloud-amd64        # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    nova: ceph-ssd
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                     # Required.
    imageName: ubuntu-18-04-cloud-amd64        # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive
    # is required during vm bootstrap process. It's needed
    # if there is no dhcp in network that is used as default
    # gateway.
    configDrive: false
    # Required, the gateway of the network will be used as the default gateway.
    # Matches the cloud.prefix in the ClusterConfiguration resource.
    mainNetwork: kube
    additionalNetworks:                      # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required if rootDiskSize is specified. Volume type map for node's root volume
  volumeTypeMap:
    nova: ceph-ssd
sshPublicKey: "<SSH_PUBLIC_KEY>"
provider:
  ...
```

Simple

The master node and cluster nodes are connected to the existing network. This placement strategy might come in handy if you need to merge a Kubernetes cluster with existing VMs.

> **Caution!** This strategy does not support a LoadBalancer since a Floating IP is not available for the router-less network. Thus, you cannot provision a load balancer with the Floating IP. An internal load balancer with the virtual IP in the public network is only accessible to cluster nodes.



Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: Simple
simple:
  externalNetworkName: ext-net              # Required.
  externalNetworkDHCP: false                # Optional, default true.
  # Optional, by default VXLAN, may also be DirectRouting
  # or DirectRoutingWithPortSecurityEnabled.
  podNetworkMode: VXLAN
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    nova: ceph-ssd
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive
    # is required during vm bootstrap process. It's needed
    # if there is no dhcp in network that is used as default
    # gateway.
    configDrive: false
    # Required, network will be used as default gateway.
    # Matches the name of the pre-created network.
    mainNetwork: kube
    additionalNetworks:                     # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
sshPublicKey: "<SSH_PUBLIC_KEY>"
provider:
  ...
```

SimpleWithInternalNetwork

The master node and cluster nodes are connected to the existing network. This placement strategy might come in handy if you need to merge a Kubernetes cluster with existing VMs.

> **i** **Caution!** This placement strategy does not involve the management of `SecurityGroups` (it is assumed they were created beforehand). To configure security policies, you must explicitly specify both `additionalSecurityGroups` in the `OpenStackClusterConfiguration` for the masterNodeGroup and other nodeGroups, and `additionalSecurityGroups` when creating `OpenStackInstanceClass` in the cluster.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: OpenStackClusterConfiguration
layout: SimpleWithInternalNetwork
simpleWithInternalNetwork:
  # Required, all cluster nodes have to be in the same subnet.
  internalSubnetName: pivot-standard
  # Optional, by default DirectRoutingWithPortSecurityEnabled,
  # may also be DirectRouting or VXLAN.
  podNetworkMode: DirectRoutingWithPortSecurityEnabled
  # Optional, if set will be used for load balancer default
  # configuration and ordering master floating IP.
  externalNetworkName: ext-net
  # Optional, default value is true.
  masterWithExternalFloatingIP: false
masterNodeGroup:
  replicas: 3
  instanceClass:
    flavorName: m1.large                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 50
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
  # Required, volume type map for etcd and kubernetes certs
  # (always use fastest disk supplied by provider).
  volumeTypeMap:
    # If rootDiskSize specified than this volume type will
    # be also used for master root volume.
    nova: ceph-ssd
nodeGroups:
- name: front
  replicas: 2
  instanceClass:
    flavorName: m1.small                    # Required.
    imageName: ubuntu-18-04-cloud-amd64       # Required.
    # Optional, local disk is used if not specified.
    rootDiskSize: 20
    # Optional, default false, determines if config drive
    # is required during vm bootstrap process. It's needed
    # if there is no dhcp in network that is used as default
    # gateway.
    configDrive: false
    # Required, network will be used as default gateway.
    # Matches the name of the pre-created network.
    mainNetwork: kube
    additionalNetworks:                     # Optional.
    - office
    - shared
    # Optional, if there are networks with disabled port
    # security their names must be specified.
    networksWithSecurityDisabled:
    - office
    # Optional, list of network pools where to order floating IPs.
    floatingIPPools:
    - public
    - shared
    # Optional, additional security groups.
    additionalSecurityGroups:
    - sec_group_1
    - sec_group_2
sshPublicKey: "<SSH_PUBLIC_KEY>"
provider:
  ...
```

Cloud provider — VMware Cloud Director

> **i** The module lifecycle stage: General Availability

The `cloud-provider-vcd` module integrates Deckhouse Kubernetes Platform with VMware Cloud Director. It allows the

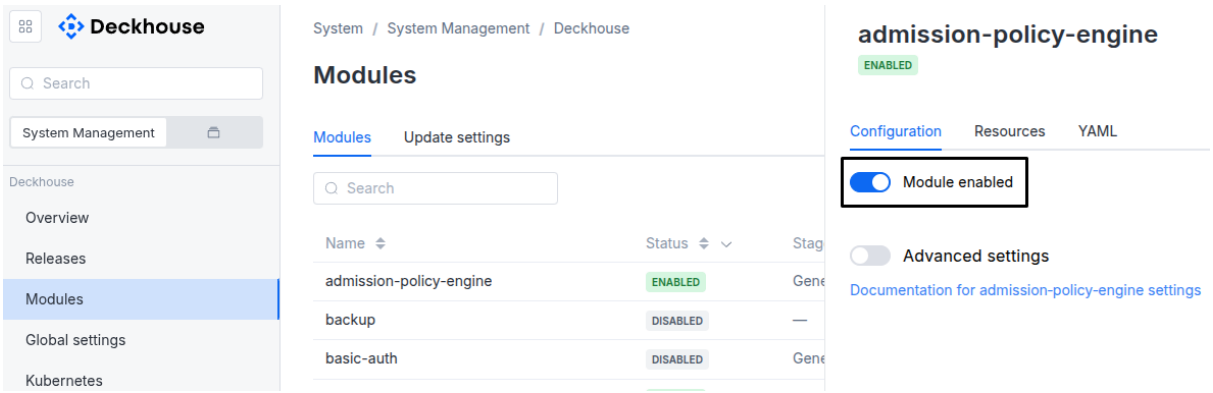
`node-manager` module to use VCD resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-vcd` module:

- Managing VCD resources via `cloud-controller-manager`:
  - updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in VCD;
  - creates load balancers for Services of the LoadBalancer type. This uses VMware NSX Advanced Load Balancer (Avi); support is available with NSX-T.
- Provisioning disks via the Named Disk CSI driver (`named-disk.csi.cloud-director.vmware.com`) so that PersistentVolumes can be requested from the cluster.
- Provisioning CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-vcd`. Base infrastructure is provisioned depending on the layout.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the VCDInstanceClass resource.
- Registering with `node-manager` so that VCDInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

> **i** For VCD API versions earlier than 37.2, the module uses compatibility mode (legacy components).

Configuration



> **i** The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in VMware Cloud Director.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vcd` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

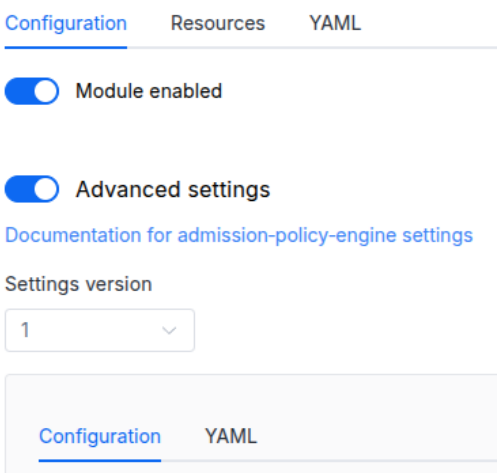
```
d8 system module enable cloud-provider-vcd
```

- **Using ModuleConfig `cloud-provider-vcd`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-vcd` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-vcd`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vcd
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vcd` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `cloud-provider-vcd` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-vcd`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-vcd` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-vcd
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-vcd` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-vcd`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-vcd
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.storageClass**
    object

    The module automatically creates StorageClasses that are available in VCD (VMware Cloud Director).

    - **settings.storageClass.default**
      Deprecated
      string

      The name of StorageClass that will be used in the cluster by default.

      If the parameter is omitted, the default StorageClass is either:

      - an arbitrary StorageClass present in the cluster that has the default annotation;
      - StorageClass for `default StorageProfile`;
      - the first (in lexicographic order) StorageClass created by the module.

      > **i** **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

Example:

```
default: ceph-ssd
```

- **settings.storageClass.exclude**
  array of strings

  A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

  Example:

```
exclude:
- ".*-hdd"
- iscsi-fast
```

Provider configuration

> **i** The module lifecycle stage: General Availability

> **i** If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-vcd` module in the Deckhouse configuration. Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the VCDClusterConfiguration structure for configuration.

VCDClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in VCD.

Used by the cloud provider if a cluster's control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> **i** After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: VCDClusterConfiguration
sshPublicKey: "<SSH_PUBLIC_KEY>"
organization: My_Org
virtualDataCenter: My_Org
virtualApplicationName: Cloud
mainNetwork: internal
layout: Standard
internalNetworkCIDR: 172.16.2.0/24
masterNodeGroup:
  replicas: 1
  instanceClass:
    template: Templates/ubuntu-focal-20.04
    sizingPolicy: 4cpu8ram
    rootDiskSizeGb: 20
    etcdDiskSizeGb: 20
    storageProfile: nvme
nodeGroups:
- name: worker
  replicas: 1
  instanceClass:
    template: Org/Templates/ubuntu-focal-20.04
    sizingPolicy: 16cpu32ram
    storageProfile: ssd
provider:
  server: "<SERVER>"
  username: "<USERNAME>"
  password: "<PASSWORD>"
  insecure: true
```

- **apiVersion**

string

Required value

Allowed values: `deckhouse.io/v1`

- **bastion**
  object

  Parameters for the bastion host, which is used to access the cluster’s nodes.

  - **bastion.instanceClass**
    object

    Required value

    Partial contents of the fields of the VCDInstanceClass.

    - **bastion.instanceClass.additionalMetadata**
      object

      Custom string key-value pairs to be stored in the Metadata of the bastion, useful for organizing and categorizing your virtualization inventory.

      The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the spec. This field will take precedence over the existing metadata in cases of duplicate keys.

    - **bastion.instanceClass.mainNetworkIPAddress**
      string

      The IP address of the bastion host in the `mainNetwork`. If not set, the DHCP client will be enabled.

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

    - **bastion.instanceClass.placementPolicy**
      string

      Placement policy to be used on this machine.

      If no placement policy is specified, the default placement policy will be used to create the bastion host.

      Length: `1..128`

    - **bastion.instanceClass.rootDiskSizeGb**
      integer

      Root disk size in gigabytes.

      Default: `50`

      Allowed values: `0 <= X`

      Example:

      ```
      rootDiskSizeGb: 50
      ```

    - **bastion.instanceClass.sizingPolicy**
      string

      Required value

      Sizing policy to be used on this machine.

      If no sizing policy is specified, the default sizing policy will be used to create the bastion host.

      Length: `1..128`

    - **bastion.instanceClass.storageProfile**
      string

      Required value

      Storage profile to be used on this machine.

      Length: `1..128`

    - **bastion.instanceClass.template**

      Required value

      Path of the template OVA that is to be used.

      Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

      If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

      You can find the template identifier in the URL when you open the template in the VCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

Length: `1..128`

- **createDefaultFirewallRules**
  boolean

  If enabled, configures the following default firewall rules for the cluster’s main network (mainNetwork):

  - Allows all outgoing connections from mainNetwork.
  - Allows all incoming ICMP packets to mainNetwork.
  - Allows all incoming TCP connections to mainNetwork on port 22 (SSH).
  - Allows all incoming TCP and UDP connections to mainNetwork for NodePorts in the range 30000–32767.

  Attention! Using this option together with an Edge Gateway of type NSX-T implies that only one cluster should be deployed per Edge Gateway, because in this case all existing firewall rules will be overwritten.

  Default: `false`

- **edgeGateway**
  object

  VMware Cloud Director Edge Gateway parameters (belongs to Virtual Data Center).

  - **edgeGateway.NSX-V**
    object

    Additional parameters required if `type` is NSX-V.

    - **edgeGateway.NSX-V.externalNetworkName**
      string

      External network name for build DNAT rule for master node. The external network is the one connected to the Edge Gateway in `Gateway Interface` and has an external IP address.

      Length: `1..128`

    - **edgeGateway.NSX-V.externalNetworkType**
      string

      External network type for build DNAT rule for master node (one of “org” or “ext”).

      Allowed values: `org`, `ext`

  - **edgeGateway.externalIP**
    string

    Required value

    The IP address accessible from external networks through which incoming SSH connections are forwarded to the master node using DNAT.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **edgeGateway.externalPort**
    integer

    The external port mapped by the DNAT rule to forward incoming SSH connections to the master node.

    Default: `22`

    Allowed values: `1 <= X <= 65535`

    Example:

    ```
    externalPort: 22
    ```

  - **edgeGateway.name**
    string

    Required value

    VMware Cloud Director Edge Gateway name.

    Length: `1..128`

  - **edgeGateway.type**
    string

    Required value

    Network virtualization platform type providing the VMware Cloud Director Edge Gateway (one of “NSX-V” or “NSX-T”). The type can be obtained from your administrator.

    Allowed values: `NSX-V`, `NSX-T`

- **internalNetworkCIDR**
  string

  Subnet for master nodes in the internal network.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **internalNetworkDHCPPoolStartAddress**
  integer

  Specifies the starting address number in the internal network from which the DHCP address pool will begin. Addresses below this number will not be assigned automatically by DHCP and are available for manual allocation. If not set, the default start address is 30.

  For example, in a network 192.168.100.128/27, a value of 10 means the DHCP pool will start with the IP address 192.168.100.138. The pool will end at the address immediately before the broadcast address (192.168.100.159), i.e., the last assignable host address.

  Allowed values: `2 <= X`

- **internalNetworkDNSServers**
  array of strings

  A list of addresses of the recursive DNSs servers.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **kind**
  string

  Required value

  Allowed values: `VCDClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **legacyMode**
  boolean

  Support for outdated versions of the VCD API.

  If set to `true`, the API version below `37.2` will be used.

  The parameter has an effect only when installing a cluster. In the working cluster, the need to enable the support for outdated versions of the VCD API is determined automatically.

  Default: `false`

- **mainNetwork**
  string

  Required value

  Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

  Example:

  ```
  mainNetwork: internal
  ```

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the VCDInstanceClass.

    - **masterNodeGroup.instanceClass.additionalMetadata**
      object

      Custom string key-value pairs to be stored in the Metadata of every master node VM, useful for organizing and categorizing your virtualization inventory.

      The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the spec. This field will take precedence over the existing metadata in cases of duplicate keys.

    - **masterNodeGroup.instanceClass.affinityRule**

object

Specifies the affinity rule applied to virtual machines of the master nodes within the cluster. Affinity rules determine how nodes are scheduled in relation to each other at the hypervisor level, which can help improve fault tolerance, and control the distribution of workloads. If not specified, no affinity rule will be applied by default.

- **masterNodeGroup.instanceClass.affinityRule.polarity**
  string

  Required value

  The polarity of the affinity rule. Must be either `Affinity` or `AntiAffinity`. `Affinity` means that nodes should be placed on the same host, while `AntiAffinity` means they should be placed on different hosts.

  Allowed values: `Affinity`, `AntiAffinity`

- **masterNodeGroup.instanceClass.affinityRule.required**
  boolean

  Indicates whether the affinity rule is mandatory (`true`) or only preferred (`false`). If set to `true`, the rule must be enforced; if `false`, the rule is applied if possible but not strictly required.

  Default: `false`

- **masterNodeGroup.instanceClass.etcdDiskSizeGb**
  integer

  Etcd disk size in gigabytes.

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **masterNodeGroup.instanceClass.mainNetworkIPAddresses**
  array of strings

  A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

  By default, the DHCP client is enabled.

  Example:

  ```
  mainNetworkIPAddresses:
  - 10.1.14.20
  - 10.1.4.21
  ```

  - **Element of the array**
    string

    An IP address with a CIDR prefix.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **masterNodeGroup.instanceClass.placementPolicy**
  string

  PlacementPolicy is the placement policy to be used on this machine.

  If no placement policy is specified, default placement policy will be used to create the nodes.

  Example:

  ```
  placementPolicy: Hypervisor1
  ```

- **masterNodeGroup.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in gigabytes.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **masterNodeGroup.instanceClass.sizingPolicy**
  string

  Required value

  SizingPolicy is the sizing policy to be used on this machine.

  If no sizing policy is specified, default sizing policy will be used to create the nodes.

  Example:

```
sizingPolicy: 4Cpu8Memory
```

- **masterNodeGroup.instanceClass.storageProfile**
  string

  Required value

  StorageProfile is the storage profile to be used on this machine.

  Example:

  ```
  storageProfile: ssd
  ```

- **masterNodeGroup.instanceClass.template**
  string

  Required value

  Path of the template OVA that is to be used.

  Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

  If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

  You can find the template identifier in the URL when you open the template in the VCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

  Examples:

  ```
  template: Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: MyOrg/Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

  ```
  template: MyOrg/Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **metadata**
  object

  Custom metadata entries to be stored in cluster objects such as virtual machines, disks and network.

  Clearing the `metadata` and `additionalMetadata` fields, if they contain any keys, will result in all metadata no longer being tracked except for nodes of the CloudEphemeral type. This means that if you need to remove metadata entirely, you will have to do it manually.

  > **Warning.** Changing the metadata will cause the recreation of CloudEphemeral nodes.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the VCDInstanceClass.

    - **nodeGroups.instanceClass.additionalMetadata**
      object

      Custom string key-value pairs to be stored in the Metadata of every node VM, useful for organizing and categorizing your virtualization inventory.

      The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the spec. This field will take precedence over the existing metadata in cases of duplicate keys.

    - **nodeGroups.instanceClass.affinityRule**
      object

Specifies the affinity rule applied to virtual machines of nodes of the NodeGroup within the cluster. Affinity rules determine how nodes are scheduled in relation to each other at the hypervisor level, which can help improve fault tolerance, and control the distribution of workloads. If not specified, no affinity rule will be applied by default.

- **nodeGroups.instanceClass.affinityRule.polarity**
  string

  Required value

  The polarity of the affinity rule. Must be either `Affinity` or `AntiAffinity`. `Affinity` means that nodes should be placed on the same host, while `AntiAffinity` means they should be placed on different hosts.

  Allowed values: `Affinity`, `AntiAffinity`

- **nodeGroups.instanceClass.affinityRule.required**
  boolean

  Indicates whether the affinity rule is mandatory (`true`) or only preferred (`false`). If set to `true`, the rule must be enforced; if `false`, the rule is applied if possible but not strictly required.

  Default: `false`

- **nodeGroups.instanceClass.mainNetworkIPAddresses**
  array of strings

  A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

  By default, the DHCP client is enabled.

  Example:

  ```
  mainNetworkIPAddresses:
  - 10.1.14.20
  - 10.1.4.21
  ```

  - **Element of the array**
    string

    An IP address with a CIDR prefix.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **nodeGroups.instanceClass.placementPolicy**
  string

  PlacementPolicy is the placement policy to be used on this machine.

  If no placement policy is specified, default placement policy will be used to create the nodes.

  Example:

  ```
  placementPolicy: Hypervisor1
  ```

- **nodeGroups.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in gigabytes.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **nodeGroups.instanceClass.sizingPolicy**
  string

  Required value

  SizingPolicy is the sizing policy to be used on this machine.

  If no sizing policy is specified, default sizing policy will be used to create the nodes.

  Example:

  ```
  sizingPolicy: 4Cpu8Memory
  ```

- **nodeGroups.instanceClass.storageProfile**
  string

  Required value

  StorageProfile is the storage profile to be used on this machine.

  Example:

```
storageProfile: ssd
```

- **nodeGroups.instanceClass.template**
  string

  Required value

  Path of the template OVA that is to be used.

  Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

  If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

  You can find the template identifier in the URL when you open the template in the VCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

  Examples:

  ```
  template: Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: MyOrg/Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

  ```
  template: MyOrg/Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **nodeGroups.nodeTemplate.taints.effect**
      string

Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

- **nodeGroups.nodeTemplate.taints.key**
  string
- **nodeGroups.nodeTemplate.taints.value**
  string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **organization**
  string

  Required value

  VMware Cloud Director Organization name.

- **provider**
  object

  Required value

  Parameters for connecting to the VCD.

  - **provider.apiToken**
    string

    The token for authentication.

    > **Caution!** When using `apiToken`, leave `username` and `password` empty.

  - **provider.insecure**
    boolean

    Set to `true` if VCD has a self-signed certificate.

    Default: `false`

  - **provider.password**
    string

    The user’s password.

  - **provider.server**
    string

    Required value

    The host or the IP address of the VCD server.

  - **provider.username**
    string

    The login ID.

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **virtualApplicationName**
  string

  Required value

  VMware Cloud Director Virtual Application name (belongs to Virtual Data Center).

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **virtualDataCenter**
  string

  Required value

  VMware Cloud Director Virtual Data Center name (belongs to Organization).

Preparing environment

> The module lifecycle stage: General Availability

List of required VCD resources

- Organization
- VirtualDataCenter
- vApp
- StoragePolicy
- SizingPolicy
- Network
- EdgeRouter
- Catalog

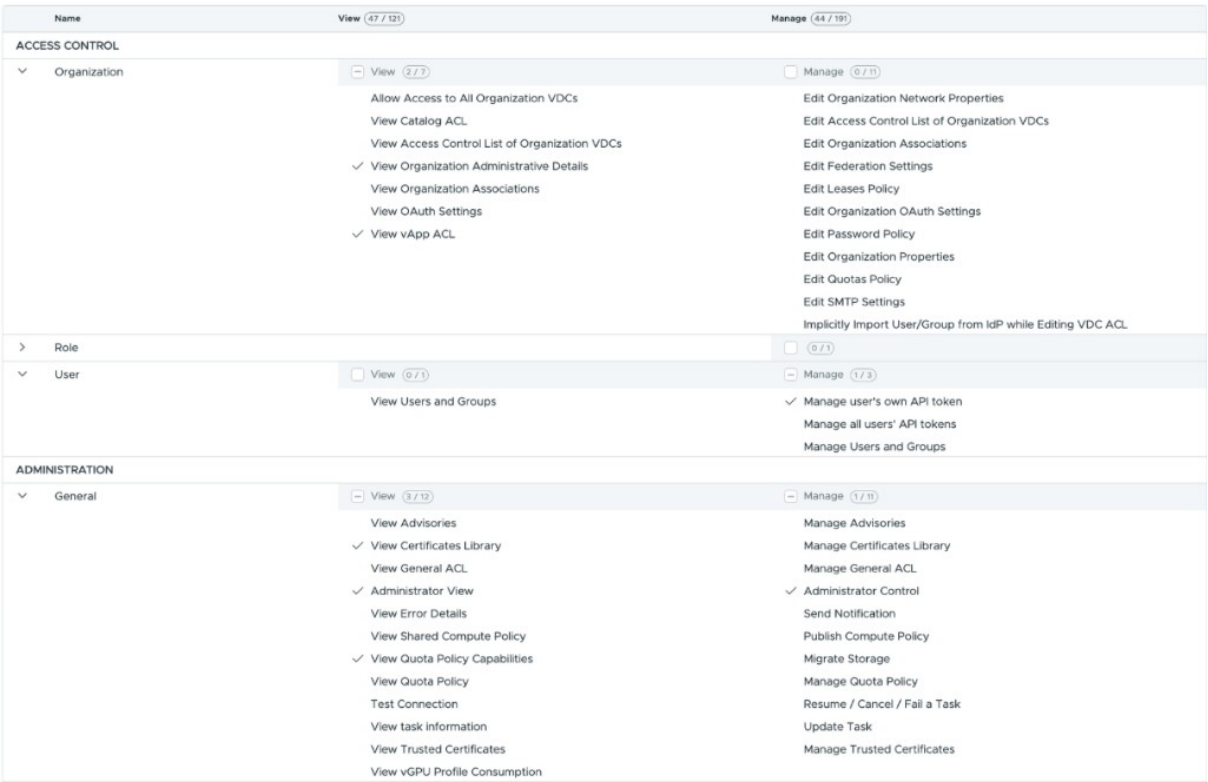
The Organization, VirtualDataCenter, StoragePolicy, SizingPolicy, EdgeRouter, and Catalog resources must be provided by your VMware Cloud Director service provider.

⚠ Each VDC (Virtual Data Center) must have an Edge Gateway configured, and the cluster network must be connected to it.

Network (internal network) can be configured either by your VMware Cloud Director service provider or manually by you. If you choose the `WithNAT` placement scheme, the network will be created automatically. The following section describes how to configure the internal network manually.

User permissions

For access to the VMware Cloud Director API, one of the following options is sufficient:

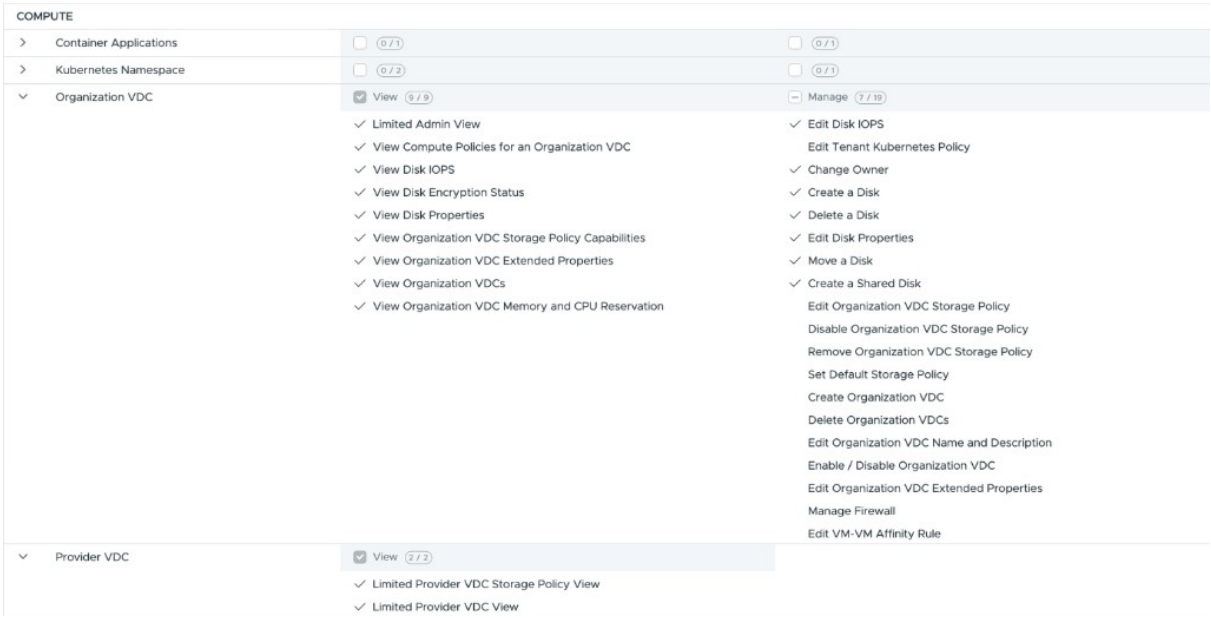


- The `Organization Administrator` role with the `Preserve All ExtraConfig Elements During OVF Import and Export` right. This option does not require configuring a separate role, but grants the user full administrative access to the organization.
- A custom role with the set of rights listed below. This set is sufficient to create a cluster, provision nodes (including CloudEphemeral with static addressing and DHCP), and work with CSI disks and StorageClass without granting additional administrative rights.

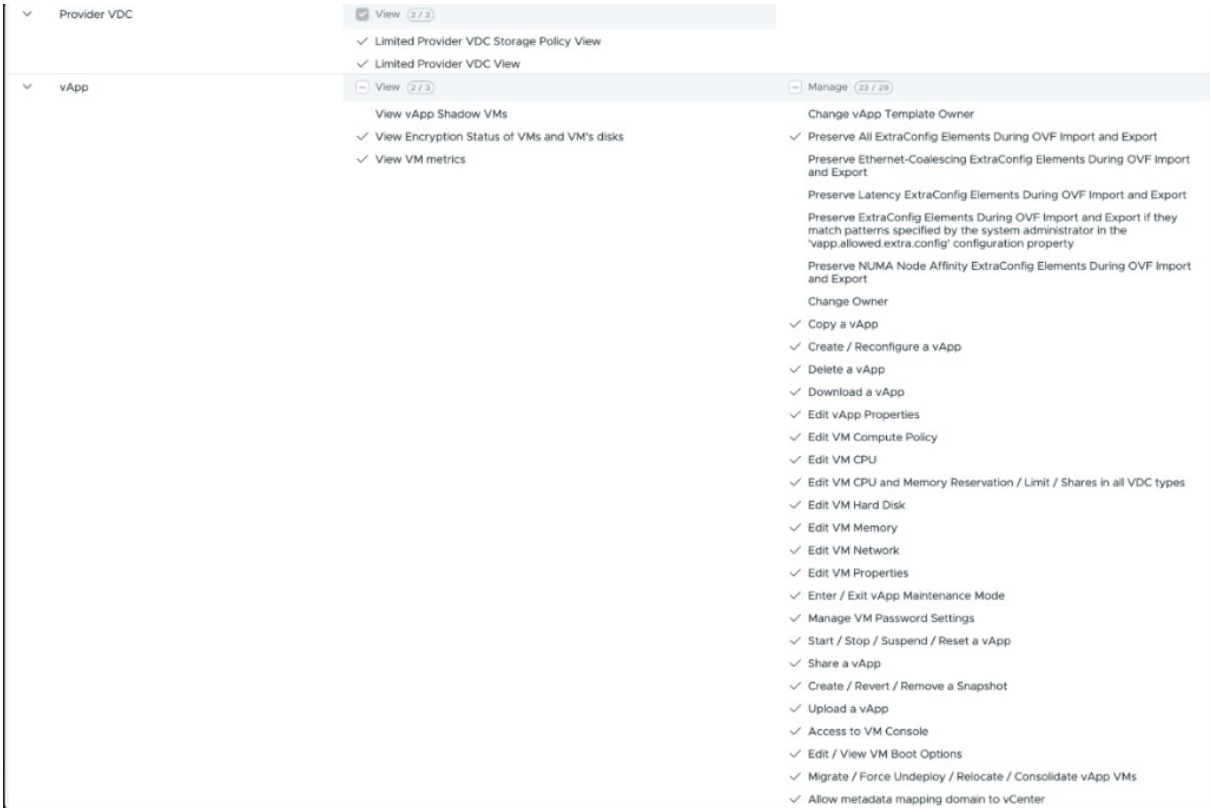
In VMware Cloud Director, user permissions come from the role and from a **Rights Bundle** — a set of rights published to the organization. Add the `Preserve All ExtraConfig Elements During OVF Import and Export` right both to the role and to the organization's Rights Bundle.

⚠ Without the `Preserve All ExtraConfig Elements During OVF Import and Export` right in both the role and the organization's Rights Bundle, `userdata` is not passed to the virtual machines of ephemeral nodes.

To create a custom role, enable the rights as shown below. Right names match the VCD UI.



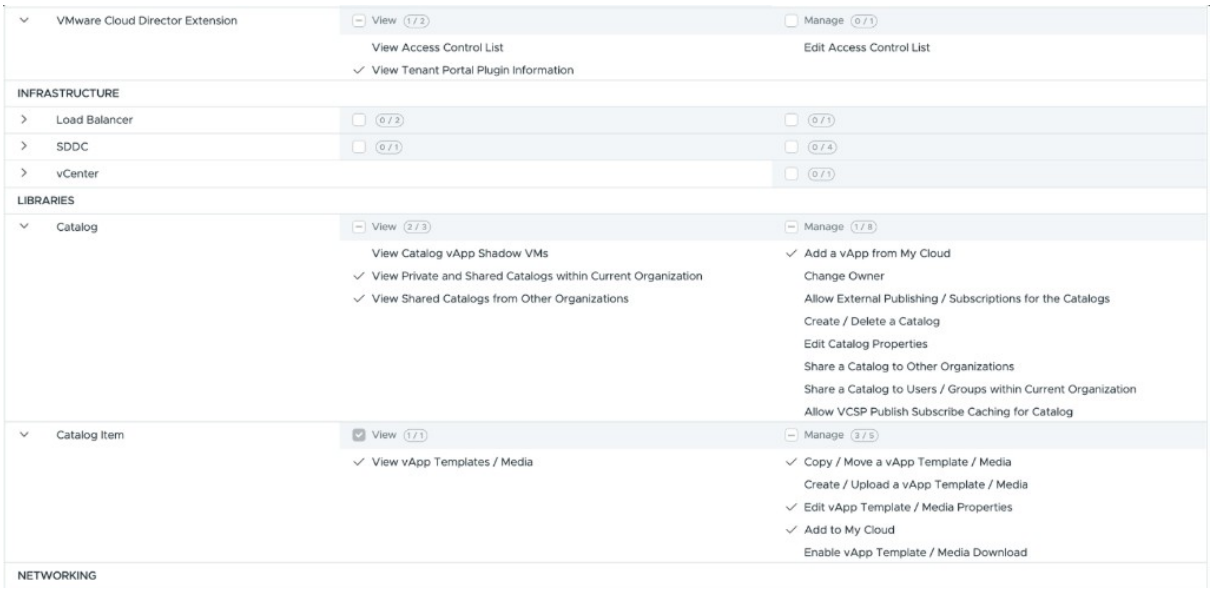
1. In the "ACCESS CONTROL" and "ADMINISTRATION" sections, enable the following rights:
   - Organization → View: `View Organization Administrative Details`, `View vApp ACL`
   - User → Manage: `Manage user's own API token`
   - General → View: `View Certificates Library`, `Administrator View`, `View Quota Policy Capabilities`
   - General → Manage: `Administrator Control`



2. In the "COMPUTE" → "Organization VDC" section, enable all View rights and the following Manage rights:
   - `Edit Disk IOPS`

- `Edit Tenant Kubernetes Policy`
- `Change Owner`
- `Create a Disk`
- `Delete a Disk`
- `Edit Disk Properties`
- `Move a Disk`
- `Create a Shared Disk`

In the “Provider VDC” → View section, enable `Limited Provider VDC Storage Policy View` and `Limited Provider VDC View`:

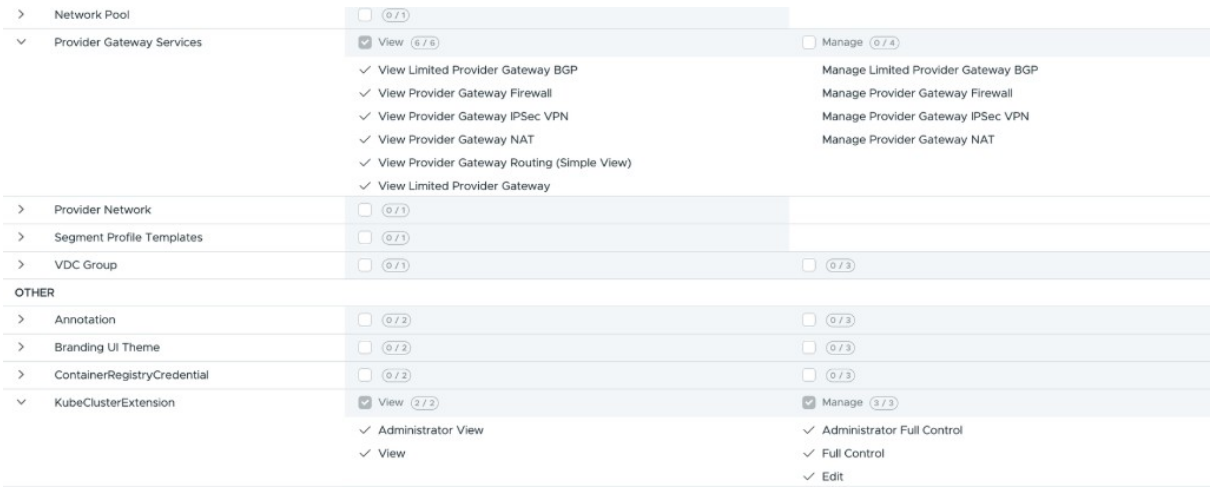


3. In the “COMPUTE” → “vApp” section, enable the rights as shown in the screenshot. Make sure that `Preserve All ExtraConfig Elements During OVF Import and Export` is enabled. In the verified role, View includes `View Encryption Status of VMs and VM's disks` and `View VM metrics`; `View vApp Shadow VMs` and the other Preserve ExtraConfig options are not enabled:

4. In the “LIBRARIES” section, enable the following rights:

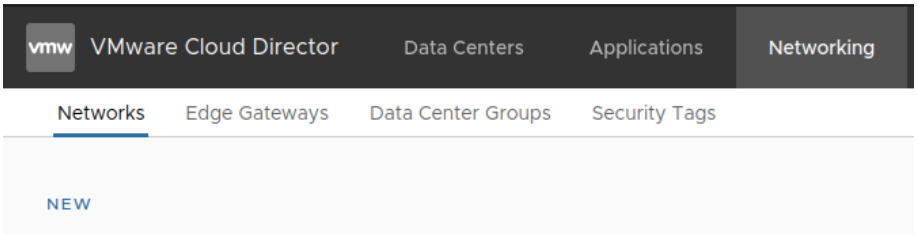
   - Catalog → View: `View Private and Shared Catalogs within Current Organization`, `View Shared Catalogs from Other Organizations` (to use images from shared catalogs)
   - Catalog → Manage: `Add a vApp from My Cloud`
   - Catalog Item → View: `View vApp Templates / Media`
   - Catalog Item → Manage: `Copy / Move a vApp Template / Media`, `Edit vApp Template / Media Properties`, `Add to My Cloud`

   In the “VMware Cloud Director Extension” → View section, enable `View Tenant Portal Plugin Information`:

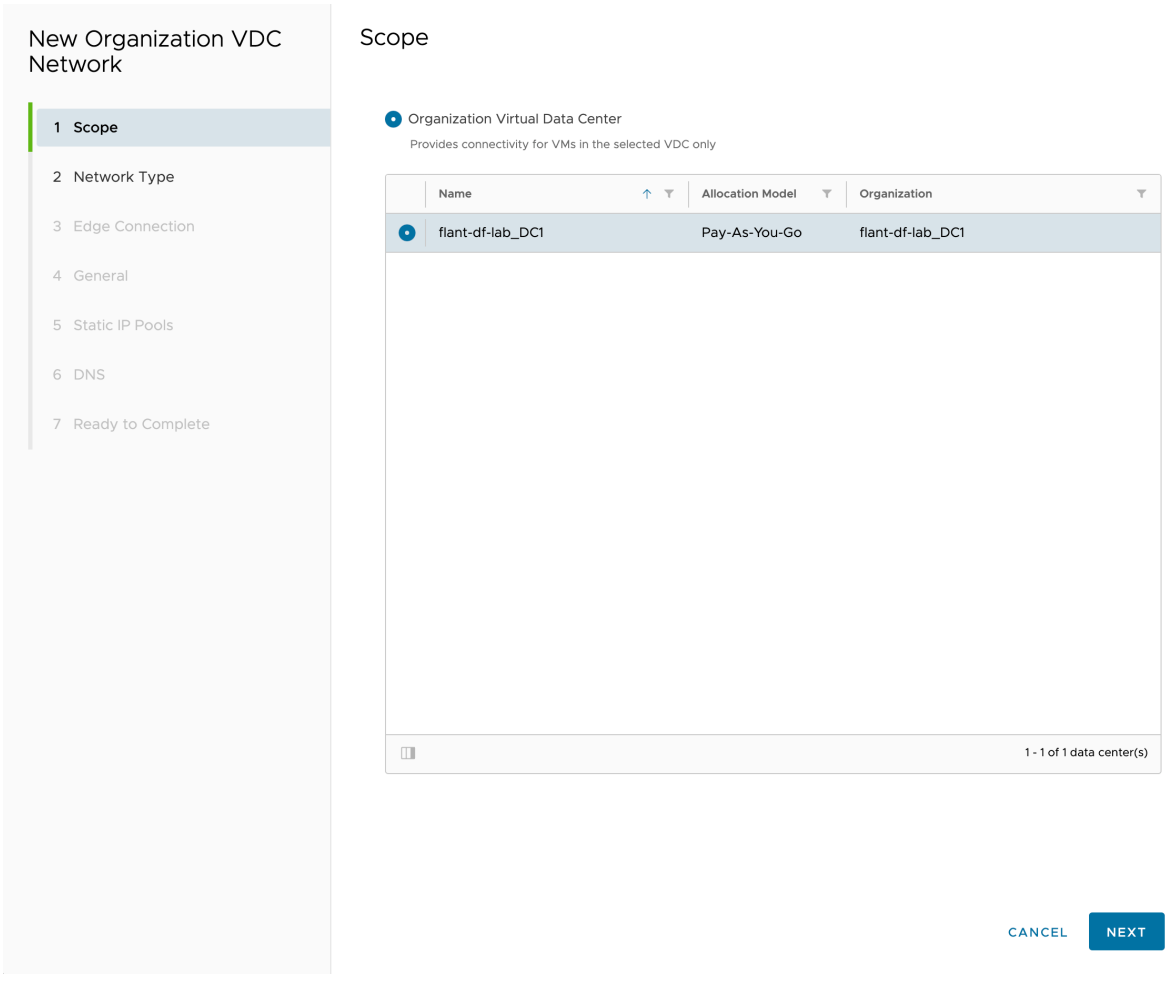


5. In the “NETWORKING” section, enable the following rights:

   - Edge Gateway → View: `View Gateway`
   - Edge Gateway Services → View: all items
   - Edge Gateway Services → Manage: `Load Balancer Configure`, `NAT Configure`
   - IP Spaces → View: `View IP Spaces`
   - IP Spaces → Manage: `Allocate IP Spaces`, `Manage IP Spaces`
   - Organization VDC Network → View: `View Properties`
   - Organization VDC Network → Manage: `Edit Properties` (required to create networks in the organization)

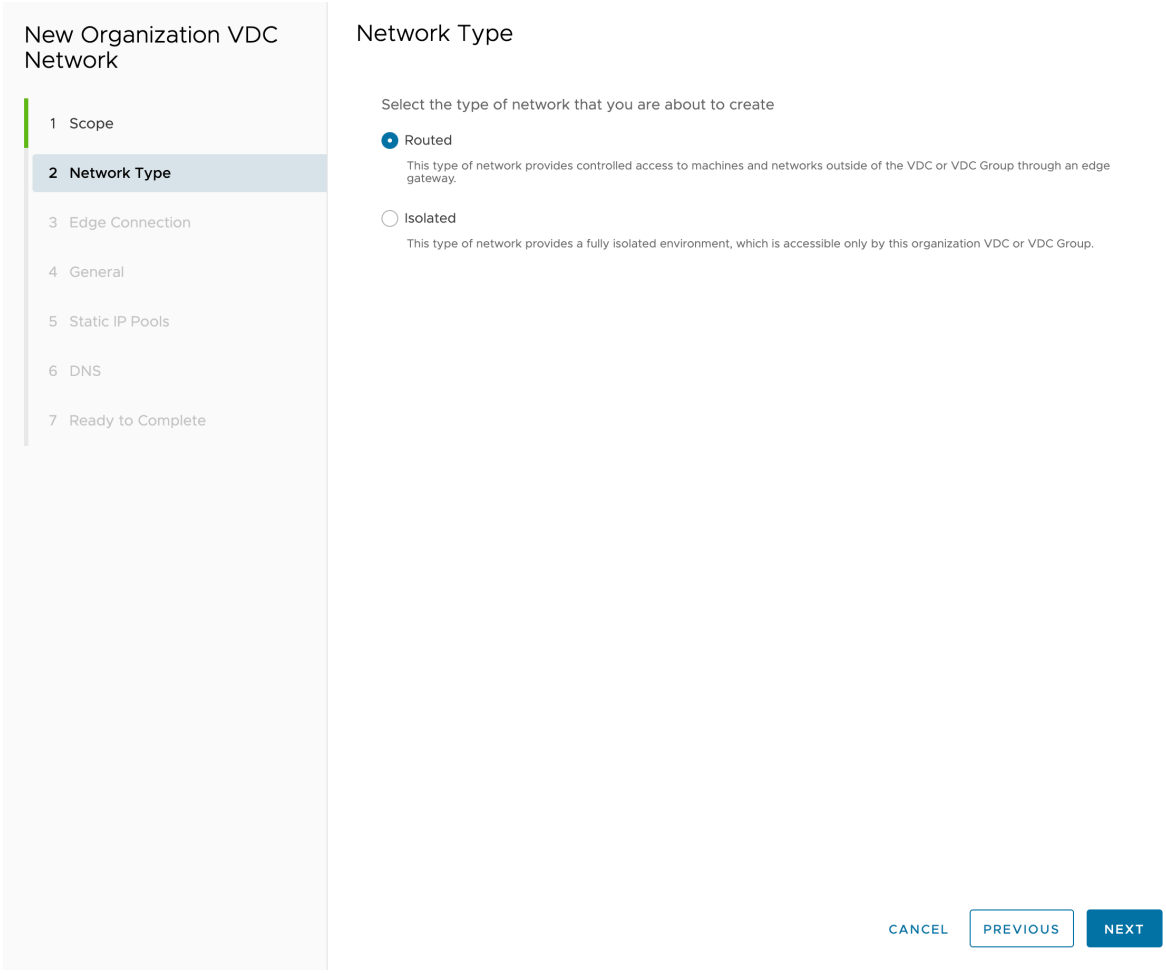


6. In the “Provider Gateway Services” section, enable all View rights. In the “KubeClusterExtension” section, enable all View and Manage rights:

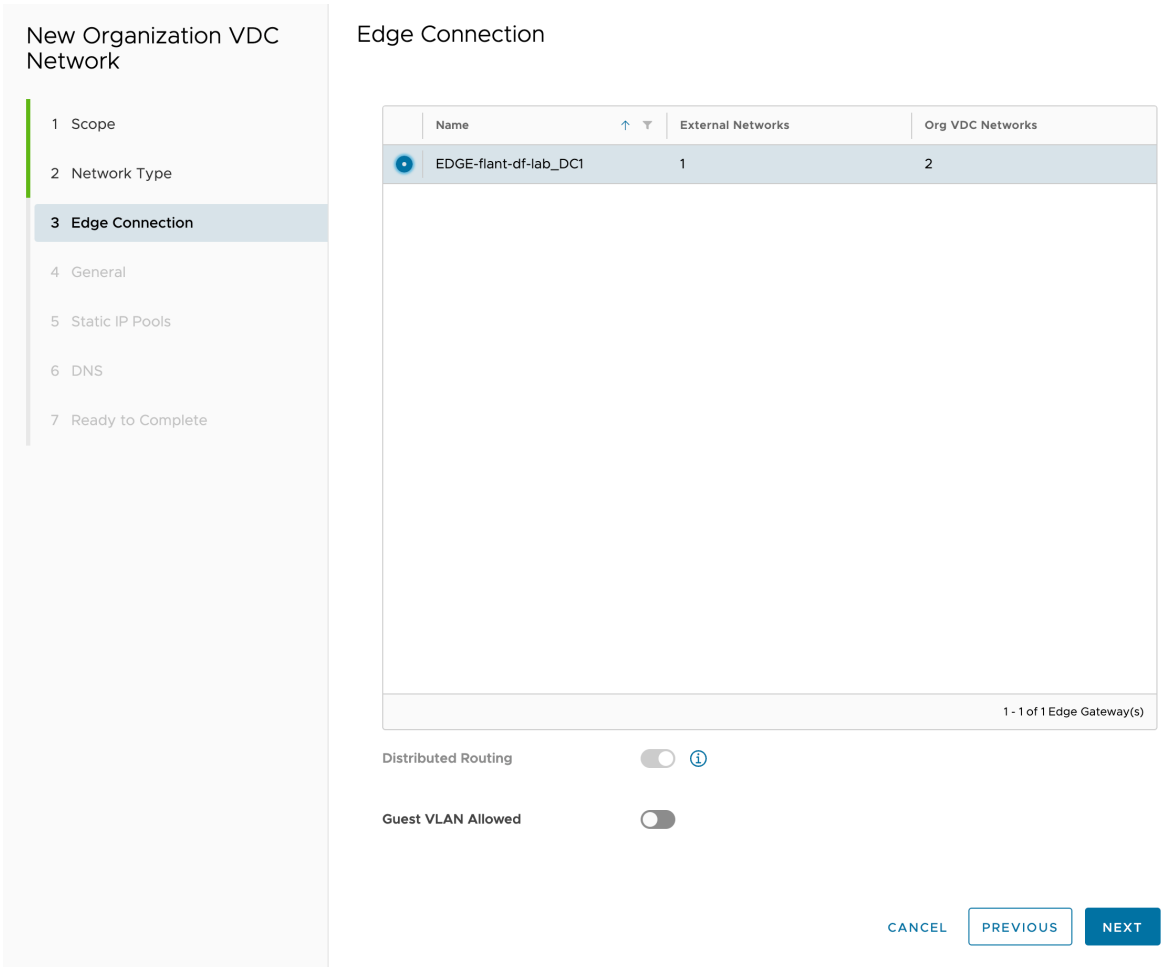


Adding a network

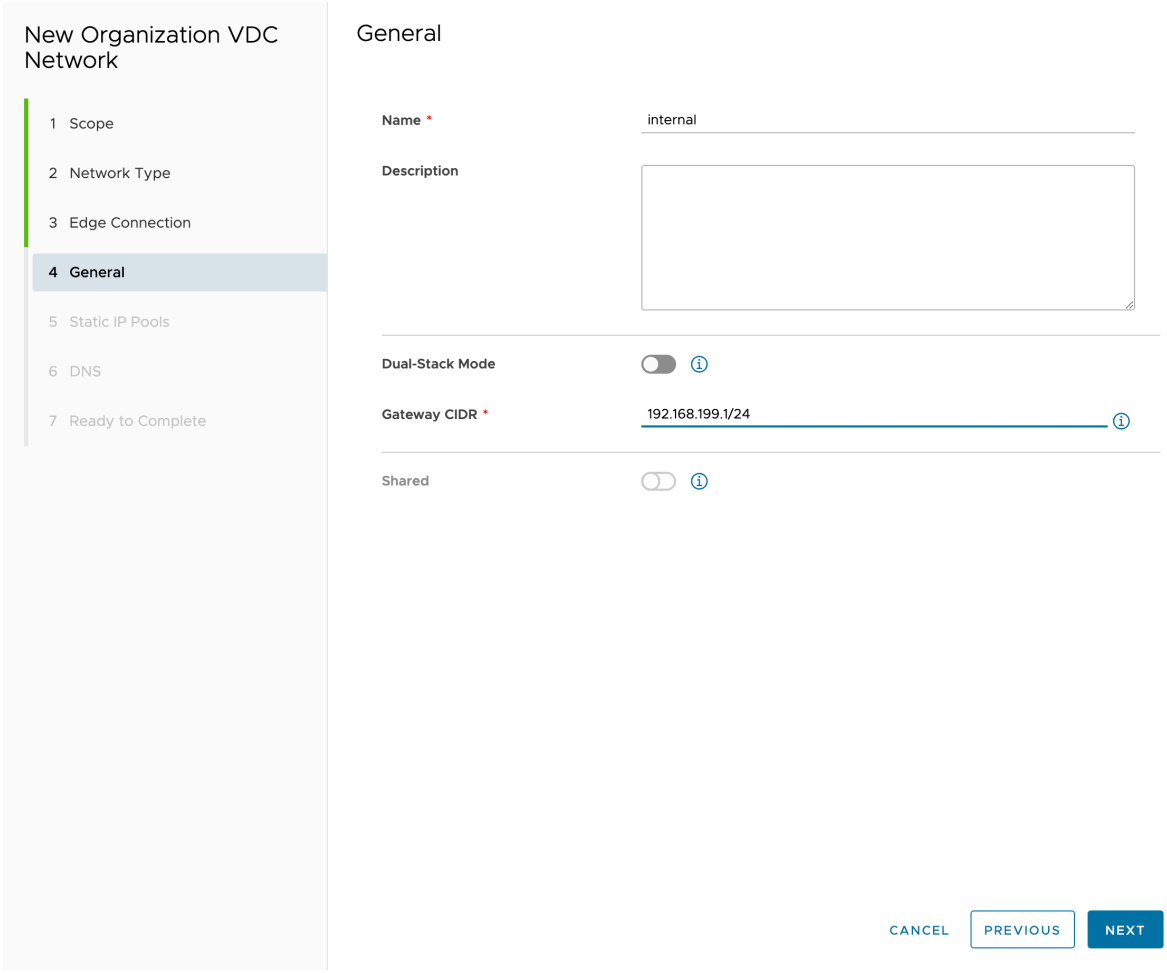
> **i** This instruction is applicable only for the `Standard` layout.



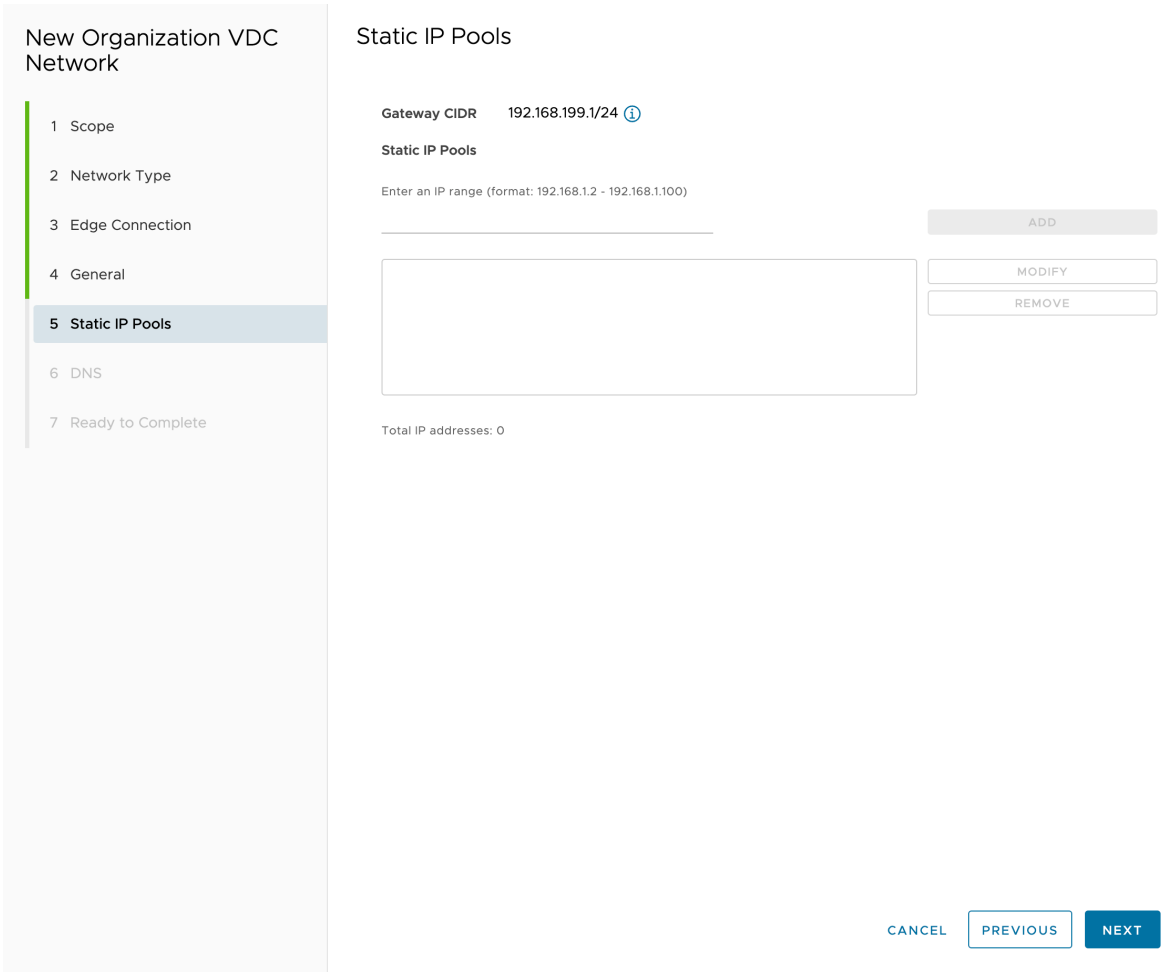
1. Go to the “Networking” tab and click “NEW”:



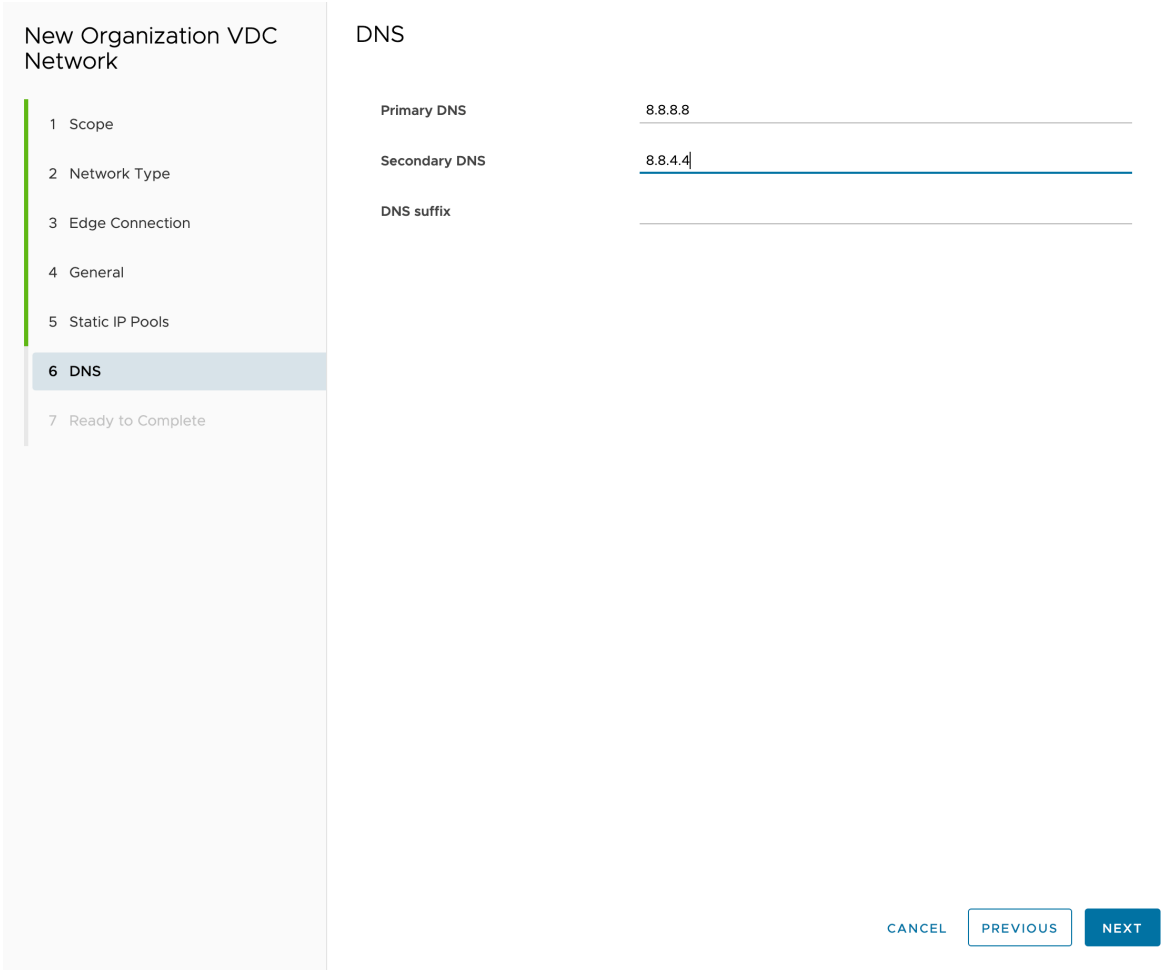
2. Select the Data Center:



3. At the “Network type” step, select “Routed”:



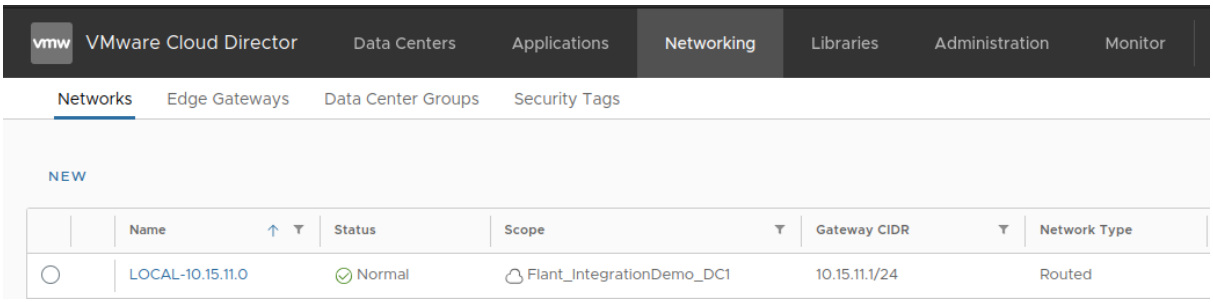
4. Connect `EdgeRouter` to the network:



5. Specify the network name and CIDR:

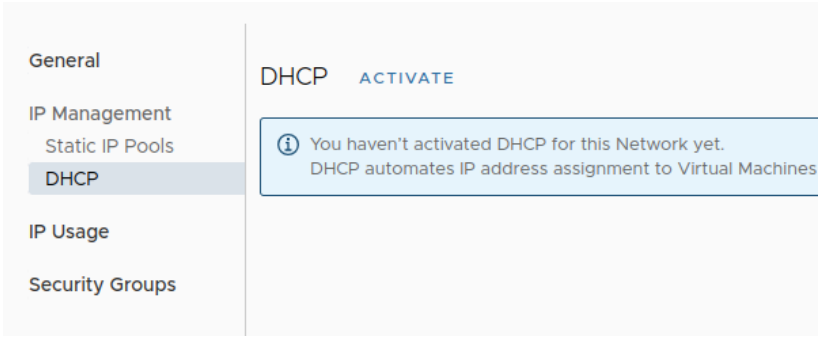
6. Do not add “Static IP Pools” because DHCP will be used:

7. Specify the DNS server addresses:



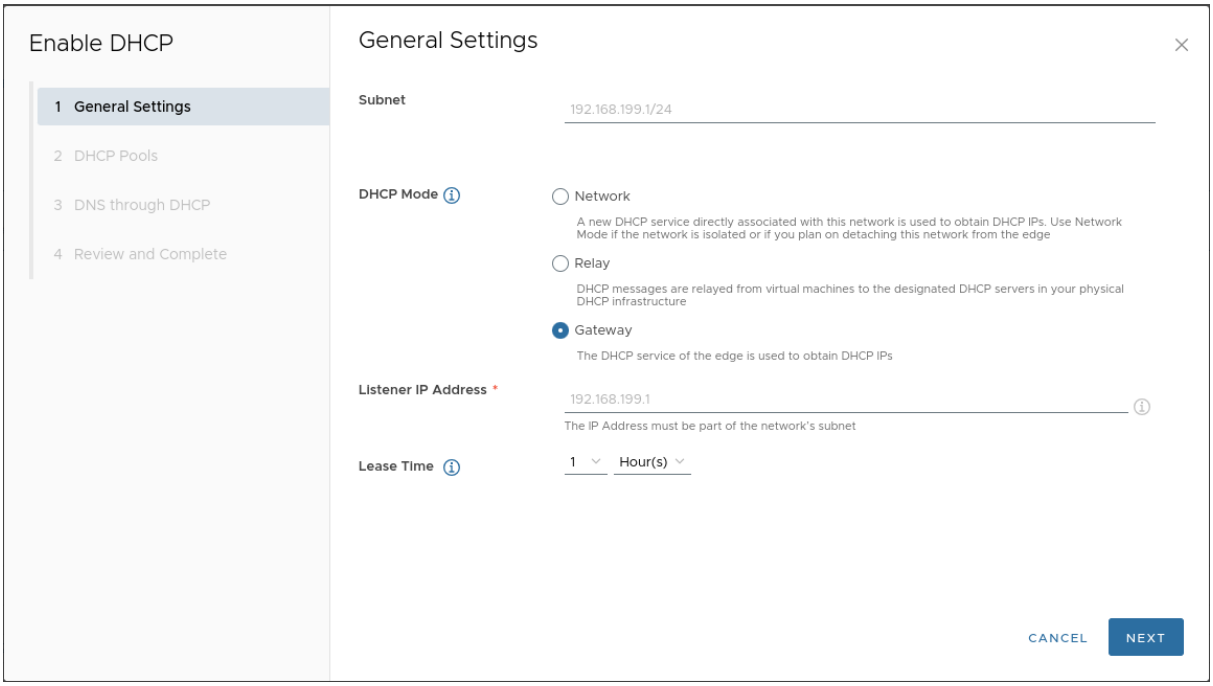
Configuring DHCP

> **i** This instruction is applicable only for the `Standard` layout.

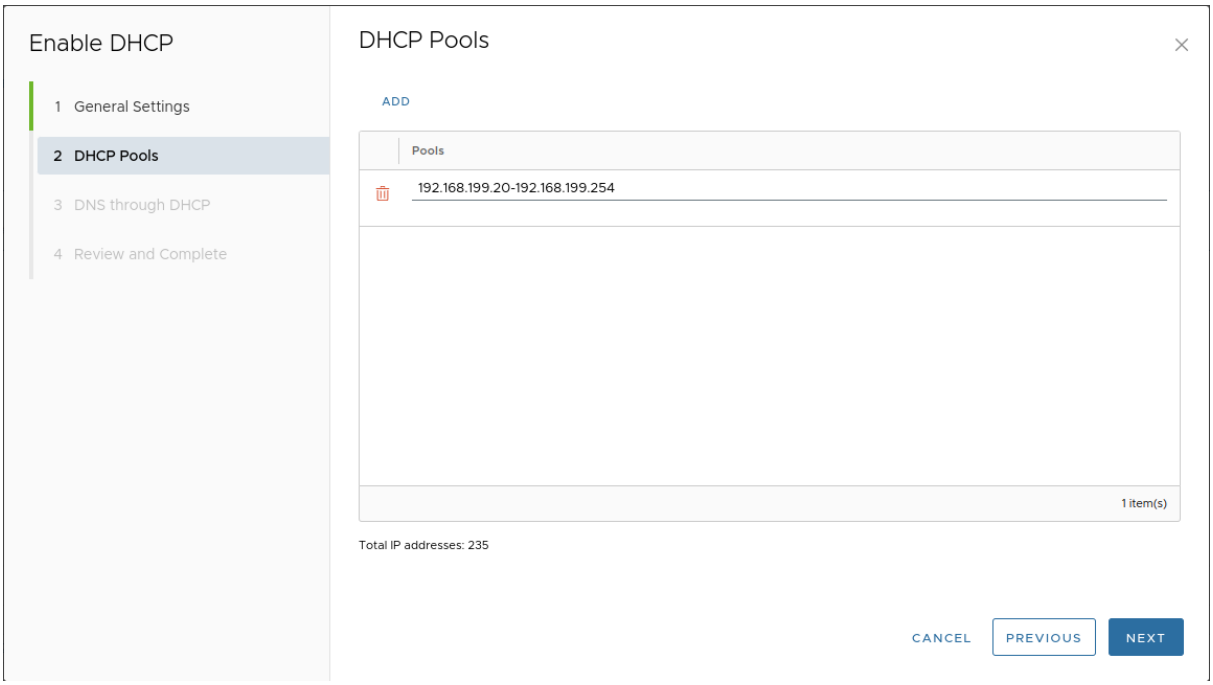


To provision nodes dynamically, enable the DHCP server for the internal network.

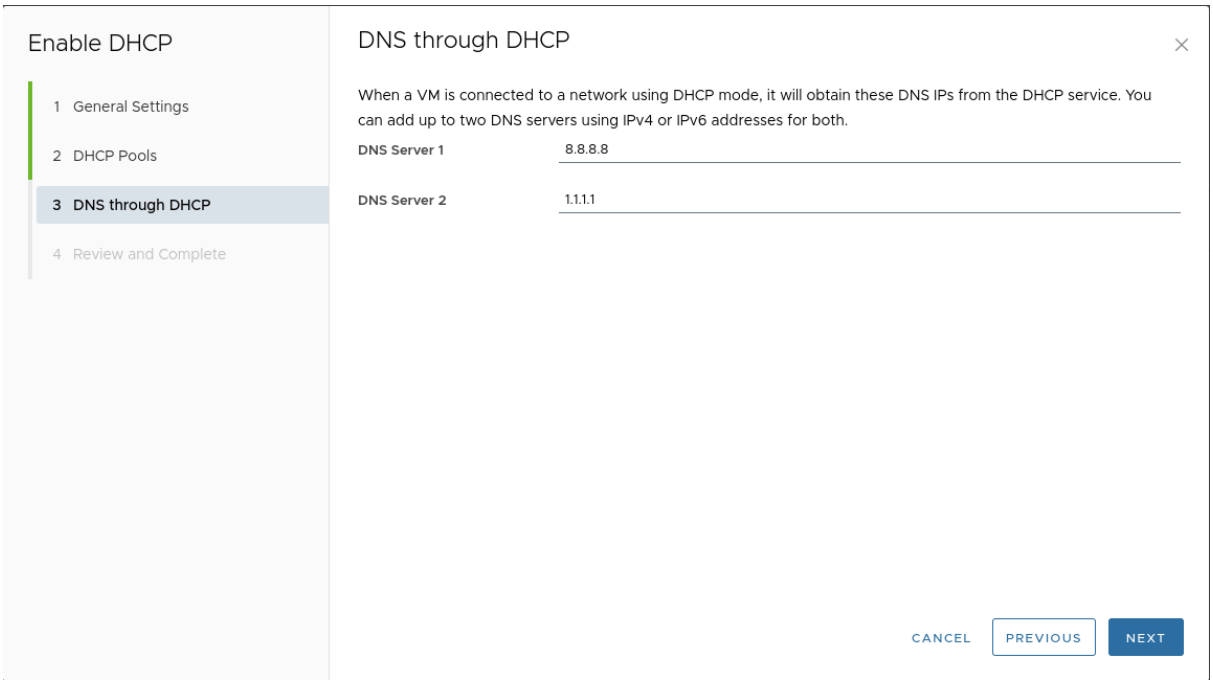
> **i** We recommend allocating the beginning of the network address range to system consumers (control plane, frontend nodes, system nodes) and the rest to the DHCP pool. For example, for a `/24` mask network it would be enough to allocate 20 addresses to system consumers.



1. Click the “Networking” tab and open the network you created:

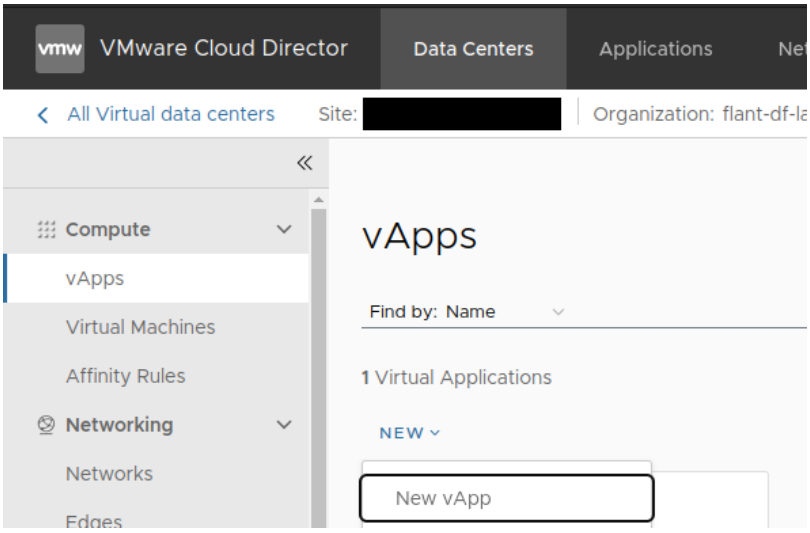


2. In the opened window, select “IP Management” → “DHCP” → “Activate”:

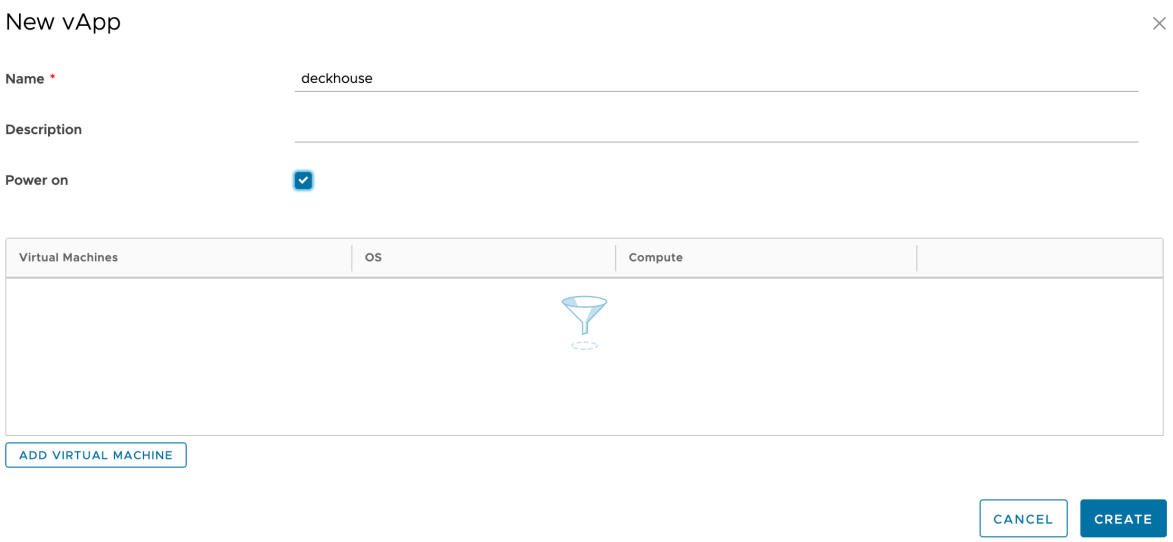


3. In the “General settings” tab, set the parameters as shown in the example:

4. Add a pool:



5. Set the DNS server addresses:

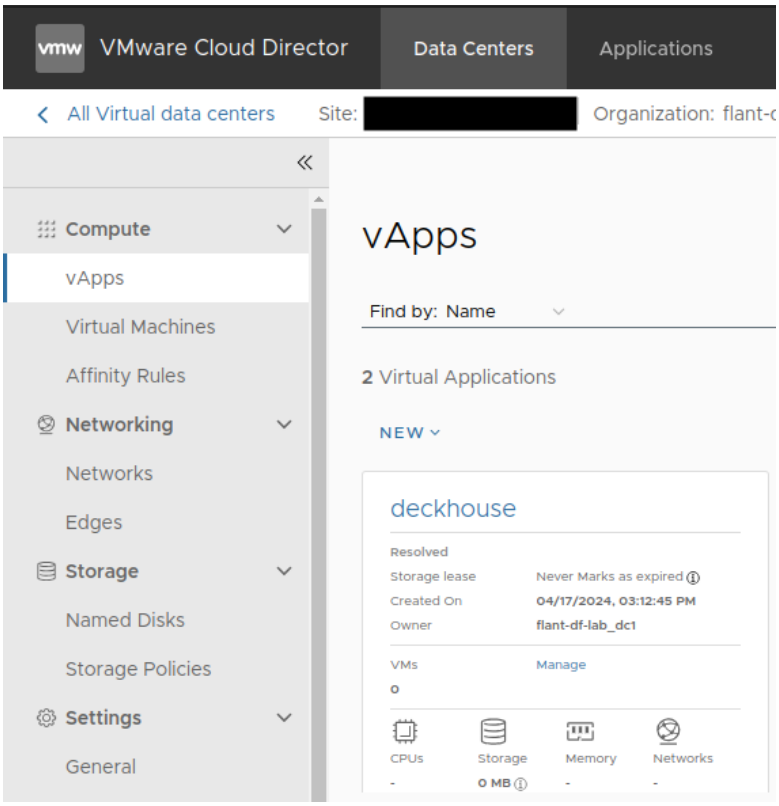


Adding a vApp

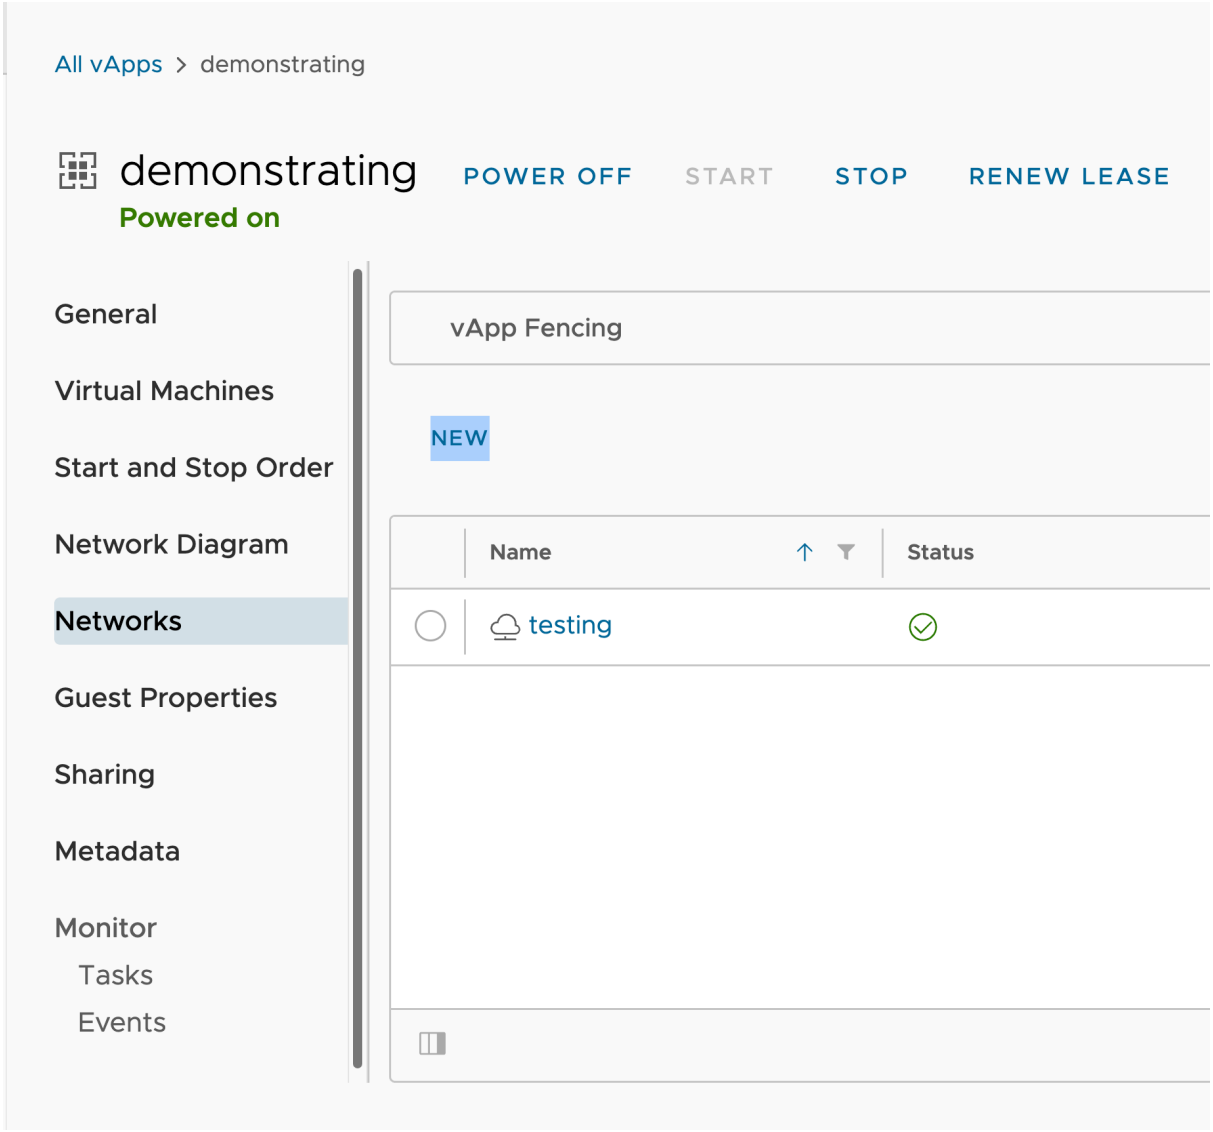
> **i** This instruction is applicable only for the `Standard` deployment layout.

1. Switch to the “Data Centers” tab → “vApps” → “NEW” → “New vApp”:

2. Specify a name and enable the vApp:

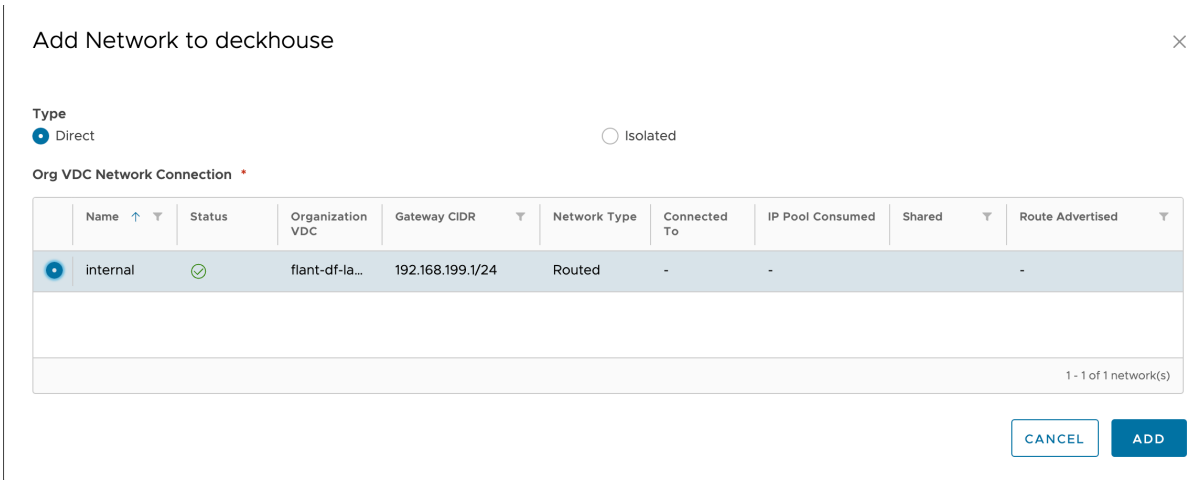


Adding a network to the vApp



> **i** This instruction is applicable only for the `Standard` deployment layout.

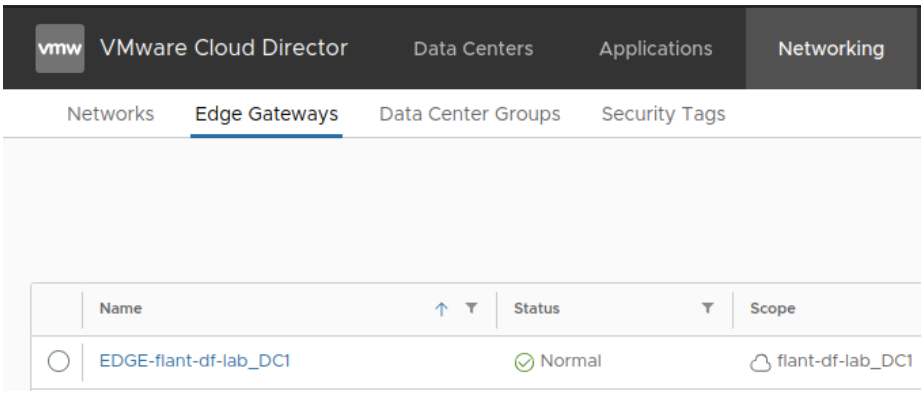
Once the vApp is created, connect the created internal network to it.



1. Switch to the “Data Centers” tab → “vApps” and open the target vApp:

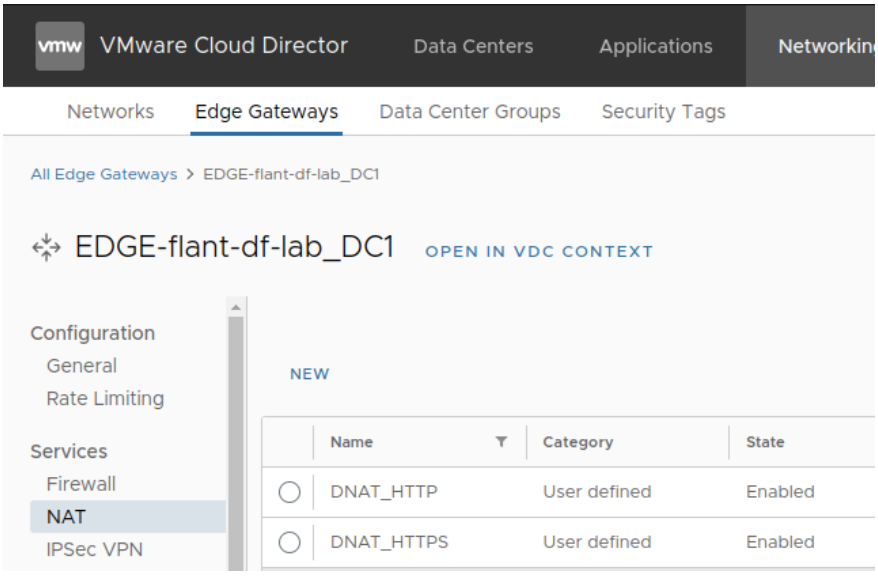
2. Go to the “Networks” tab and click “NEW”:

3. In the opened window, click the “Direct” type and select the network:



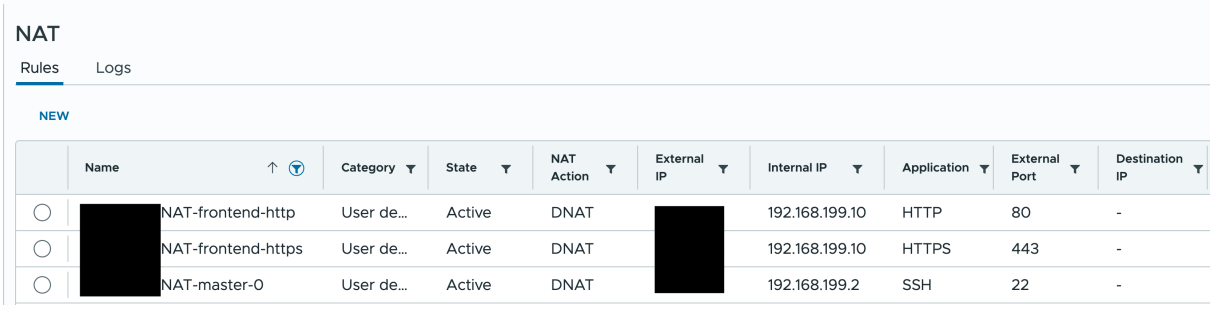
Incoming traffic

Incoming traffic should be routed to the edge router (ports `80`, `443`) using DNAT rules to be forwarded to a dedicated address on the internal network.
This address can be created by running MetalLB in L2 mode for dedicated frontend nodes.



Configuring DNAT/SNAT rules on the edge gateway

> **i** This instruction is applicable only for the `Standard` deployment layout.



1. Navigate to the “Networking” tab → “Edge Gateways” and open the edge gateway:

2. Switch to the “Services” tab → “NAT”:

3. Add the following rules:

   The first two rules are used for incoming traffic, while the third rule is used for SSH access to the control plane host (without this rule the installation will not be possible).

4. To allow virtual machines to access the Internet, configure SNAT rules following the example:

   This rule will allow virtual machines from the `192.168.199.0/24` subnet to access the Internet.

Let’s Encrypt certificate issuance

> **i** This instruction is applicable only for the `Standard` deployment layout.

When using `cert-manager` with the HTTP-01 ACME challenge type, you may need to configure Hairpin NAT (NAT loopback) on the Edge Gateway.

This is required when the Ingress domain name resolves to the external IP address of the Edge Gateway, while requests to

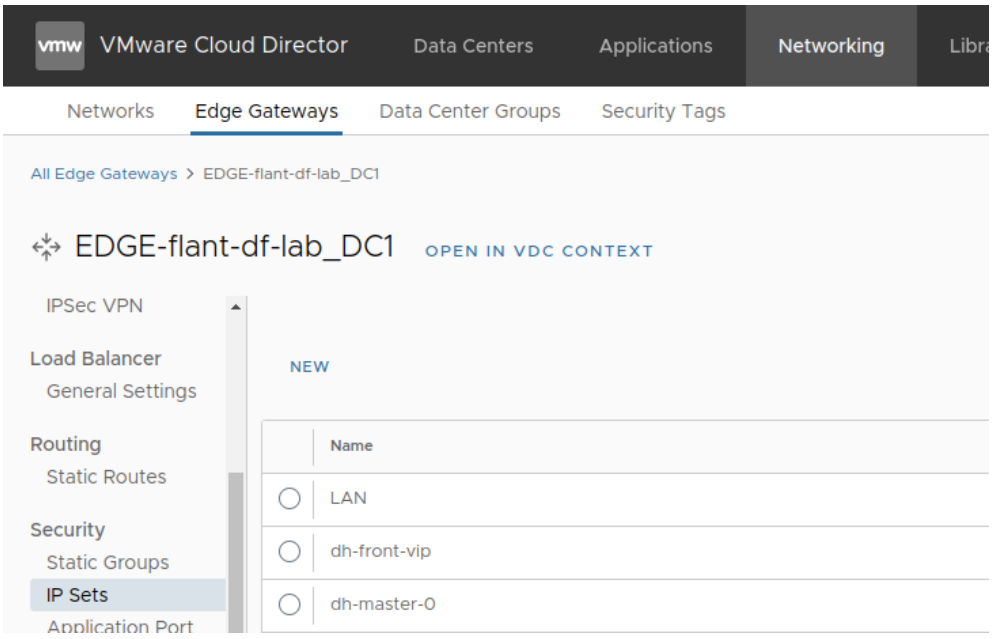
that address are made from **inside** the cluster (from the node network). In this case, the traffic must be correctly routed back to the internal network to the Ingress address (for example, the MetalLB address).

This is important for issuing Let's Encrypt certificates because cert-manager performs a preliminary self-check of the challenge URL before sending a request to the ACME provider. If the URL is not reachable from inside the cluster, certificate issuance will not start, even if the address is accessible from outside.

Example (cluster network `192.168.199.0/24`):

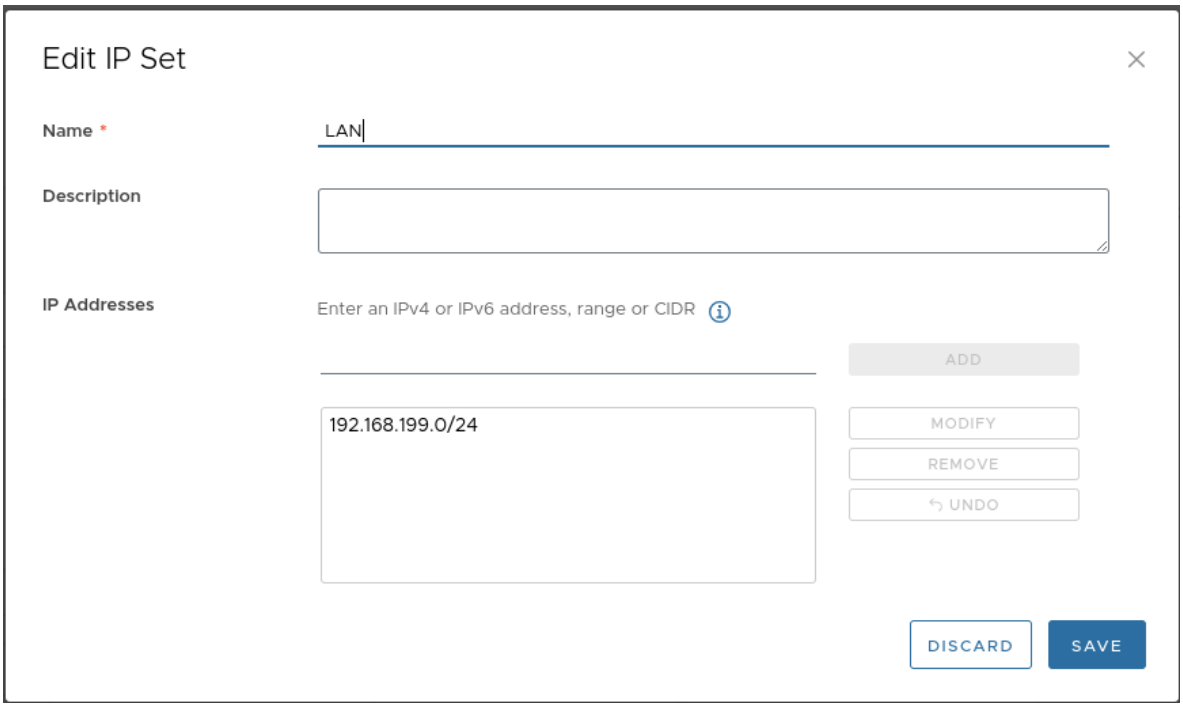
- internal node network: `192.168.199.0/24`
- external Edge Gateway IP address: `194.117.83.19`
- internal Ingress address (for example, MetalLB): `192.168.199.251`.

In this case, you must configure Hairpin NAT for traffic from the `192.168.199.0/24` network that is sent to the external IP `194.117.83.19`, with translation to the internal Ingress address `192.168.199.251`.

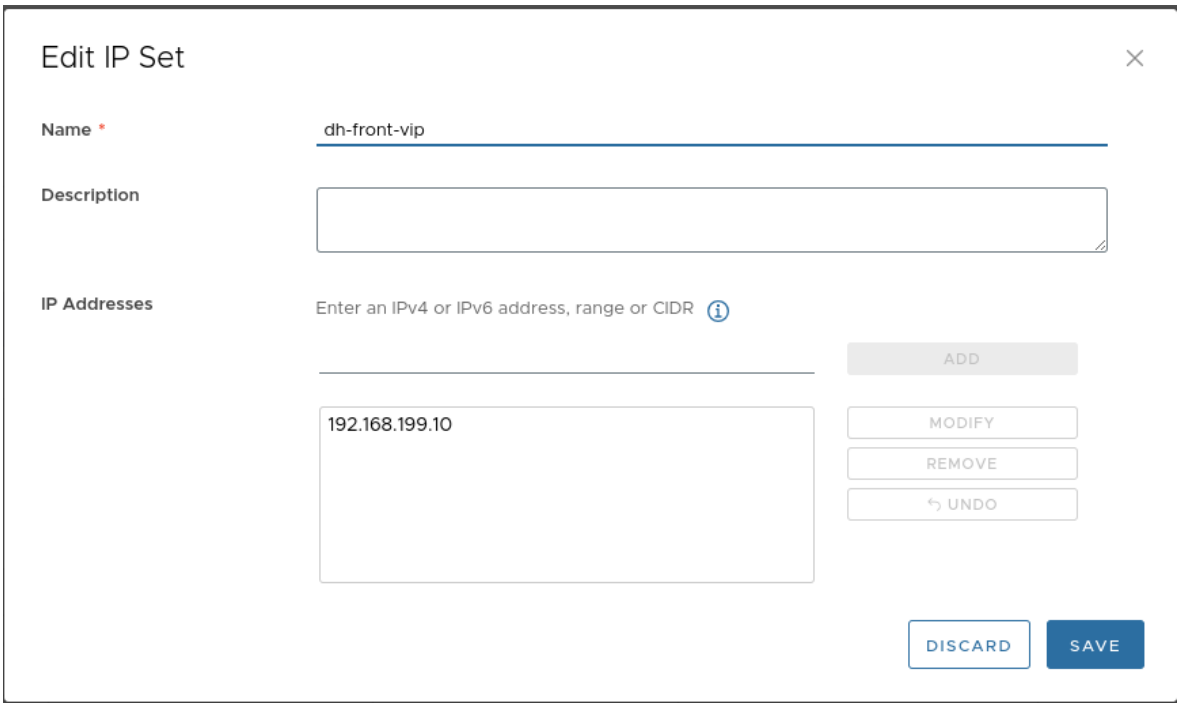


> **i**
>
> Hairpin NAT configuration may be required for Edge Gateway based on NSX-V.
>
> For NSX-T, the loopback scenario is often supported by default, but the actual behavior depends on the VMware Cloud Director provider configuration.

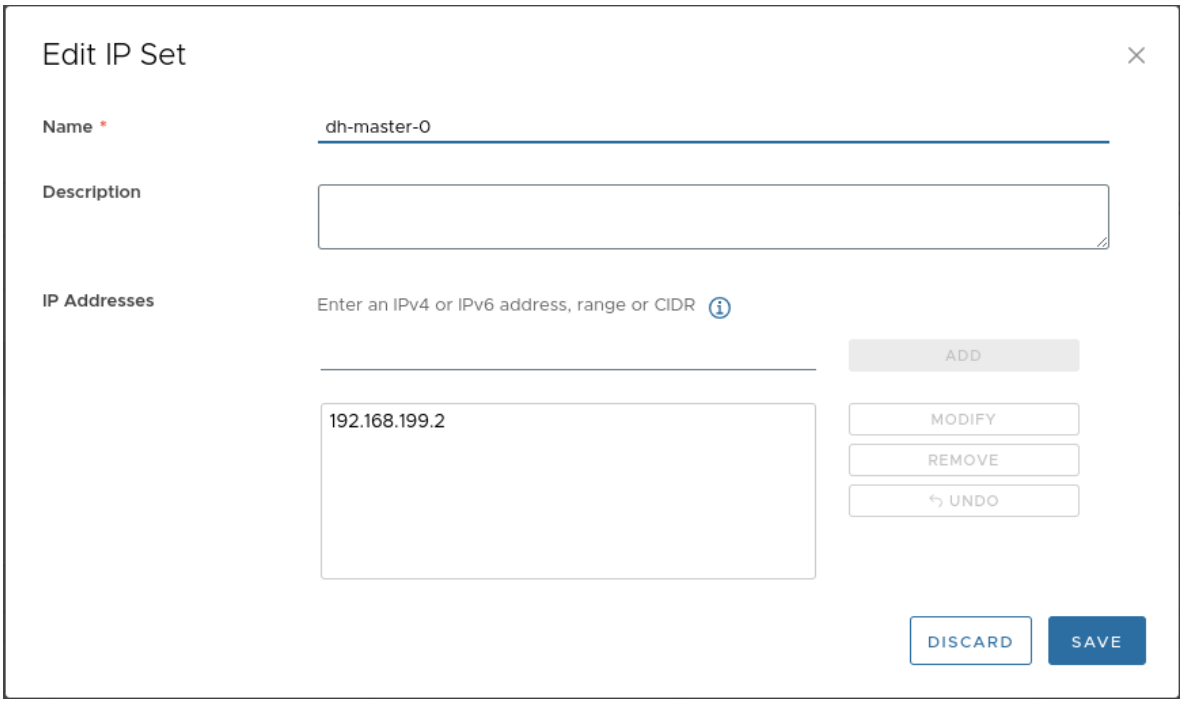
Configuring a firewall



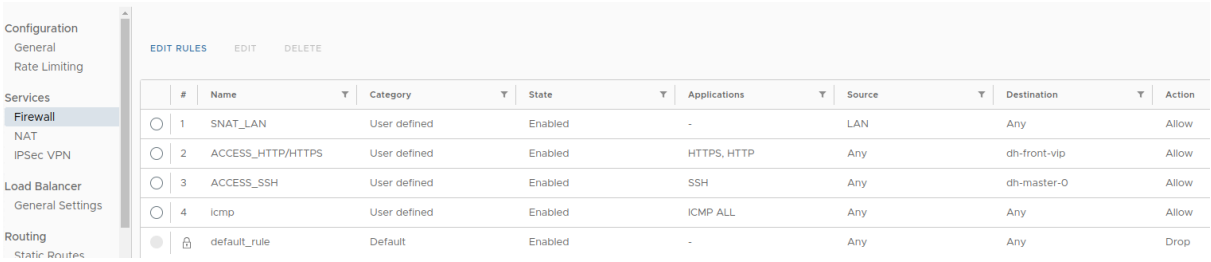
> **i**
>
> This instruction is applicable only for the `Standard` deployment layout.



Once DNAT is configured, set up the firewall. Start by configuring the IP sets.



1. Switch to the "Security" tab → "IP Sets":



2. Create the following set of IPs (the MetalLB address here is `.10` and the control plane node address is `.2`):

Edit IP Set
Name *
LAN
Description
IP Addresses
Enter an IPv4 or IPv6 address, range or CIDR
ADD
192.168.199.0/24
MODIFY
REMOVE
UNDO
DISCARD
SAVE

Edit IP Set

dh-front-vip
Description
IP Addresses
Enter an IPv4 or IPv6 address, range or CIDR
ADD
192.168.199.10
MODIFY
REMOVE
UNDO
DISCARD
SAVE

3. Add the following firewall rules:

Virtual machine template

⚠ The provider is confirmed to work with Ubuntu 22.04-based virtual machine templates only.

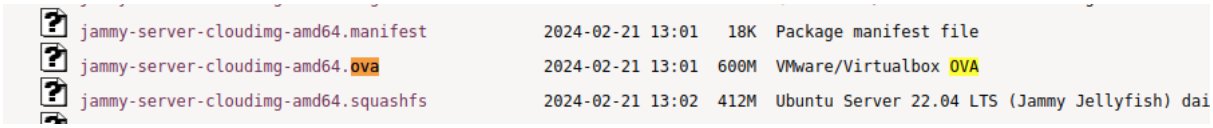
⚠ Disable vApp/Guest OS Customization (Guest Customization, vApp Customization, and similar mechanisms) for the cluster template and virtual machines in VMware Cloud Director. DKP performs the initial node provisioning via `cloud-init` (OVF/VMware GuestInfo datasource). If customization is enabled, it may conflict with `cloud-init` and result in incorrect node initialization.

⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

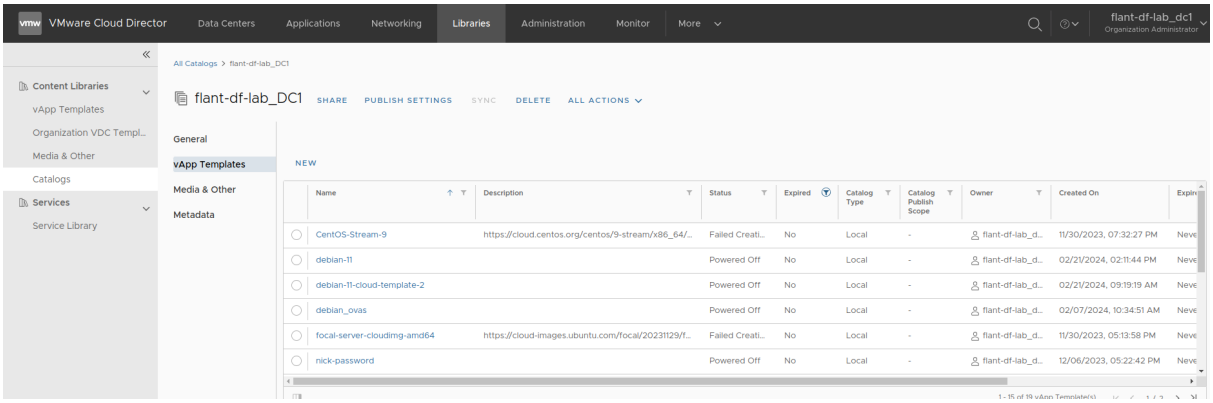
For more information, see the documentation.

⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:



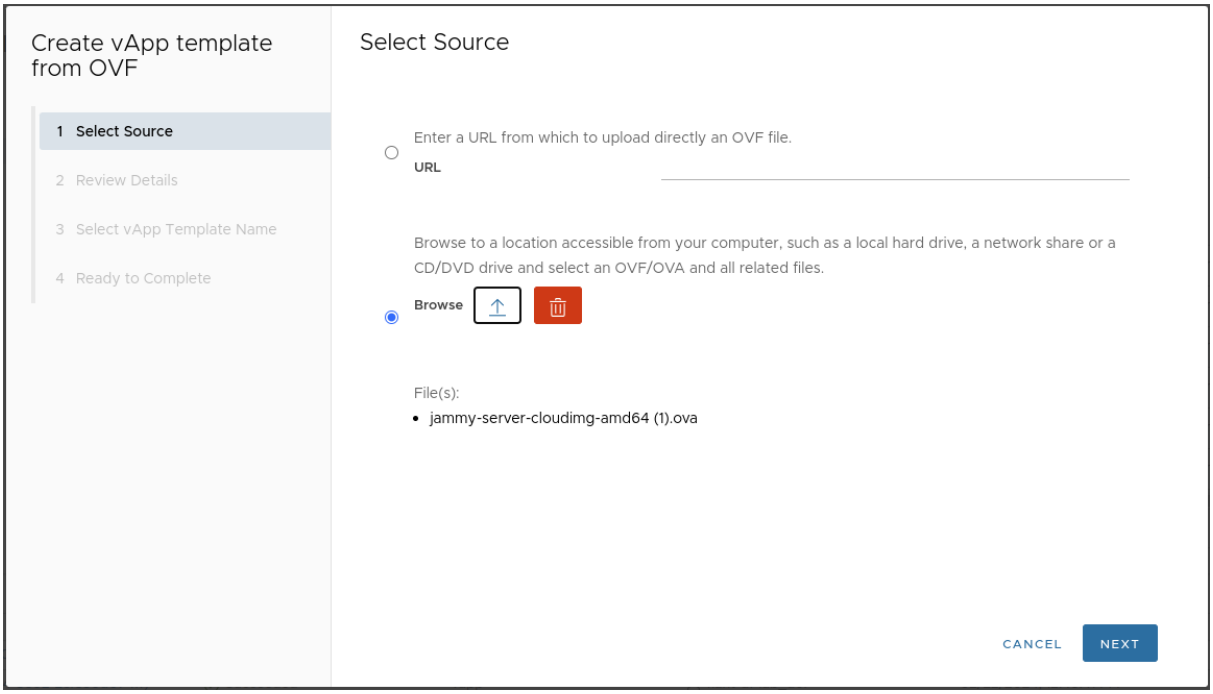
- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

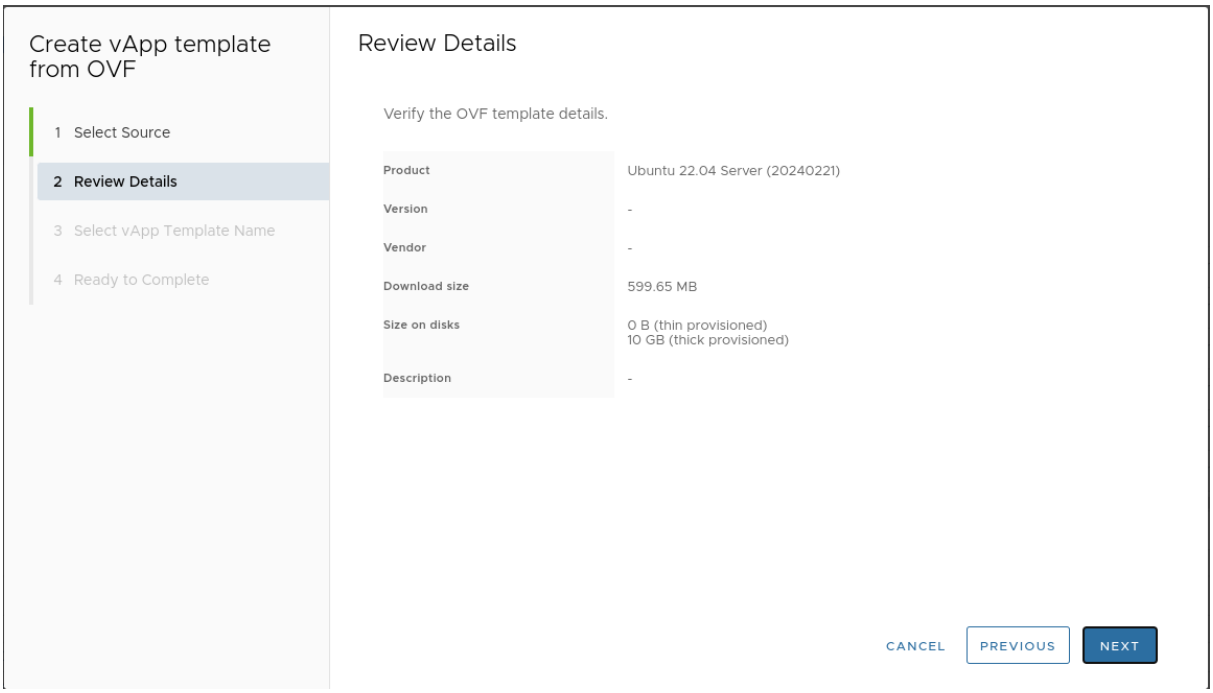


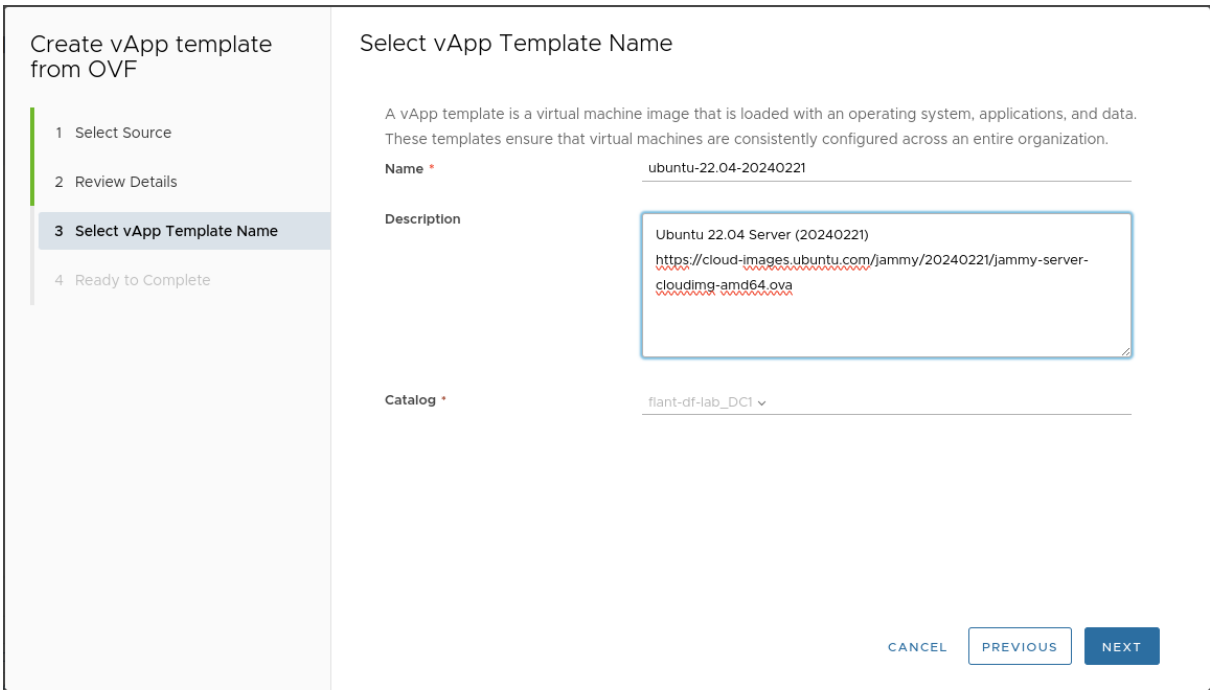
The example below uses the OVA file provided by Ubuntu, updated to include two fixes. Those fixes are essential for CloudPermanent nodes to be provisioned correctly and to be able to mount CSI-created disks.

Making a template from an OVA file

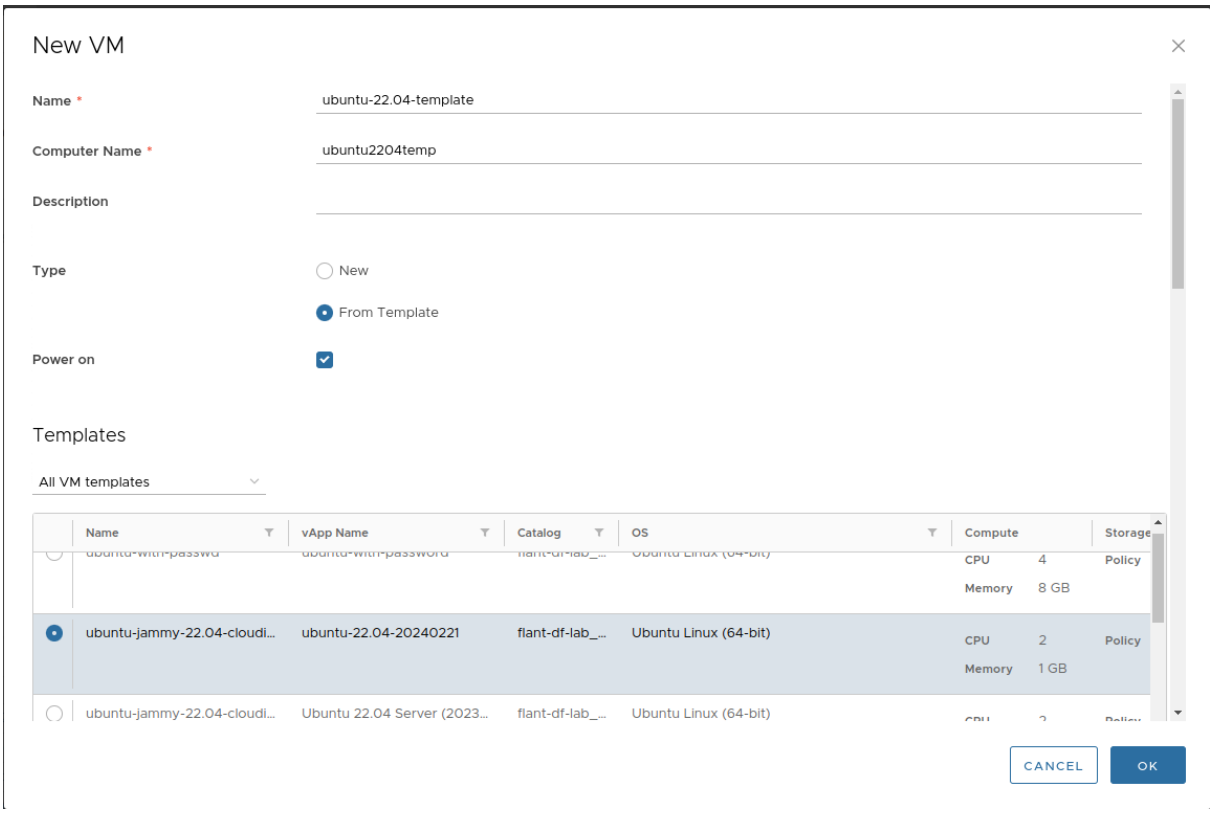


1. Download the OVA file:

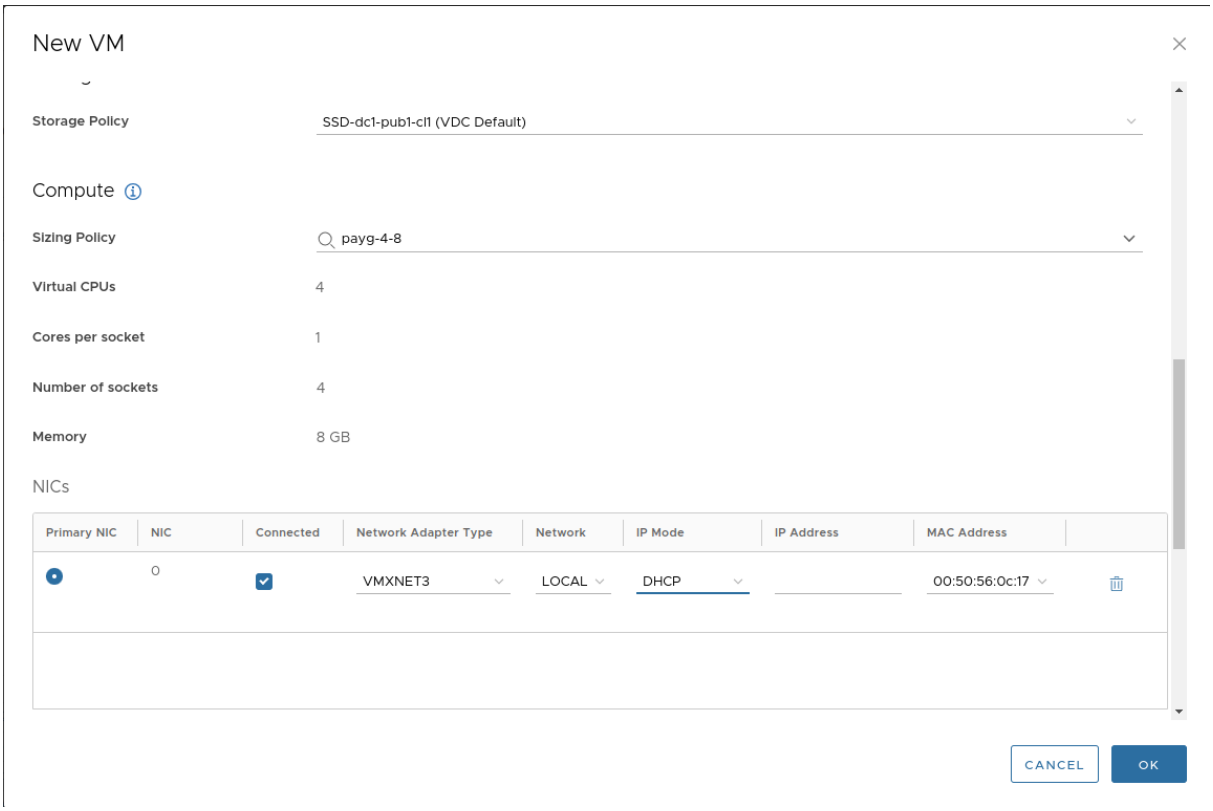


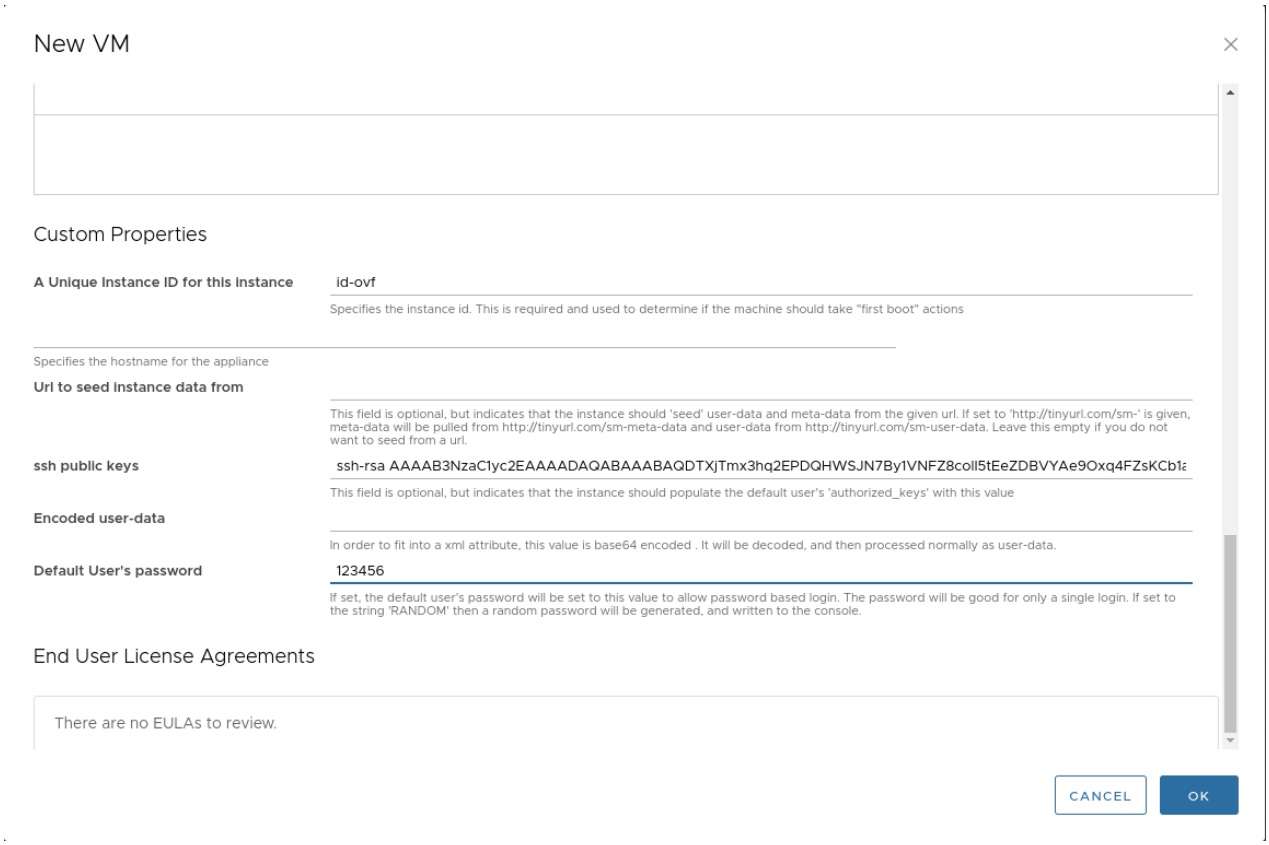


2. Switch to the “Libraries” tab → “Catalogs” → “Organization Catalog”:

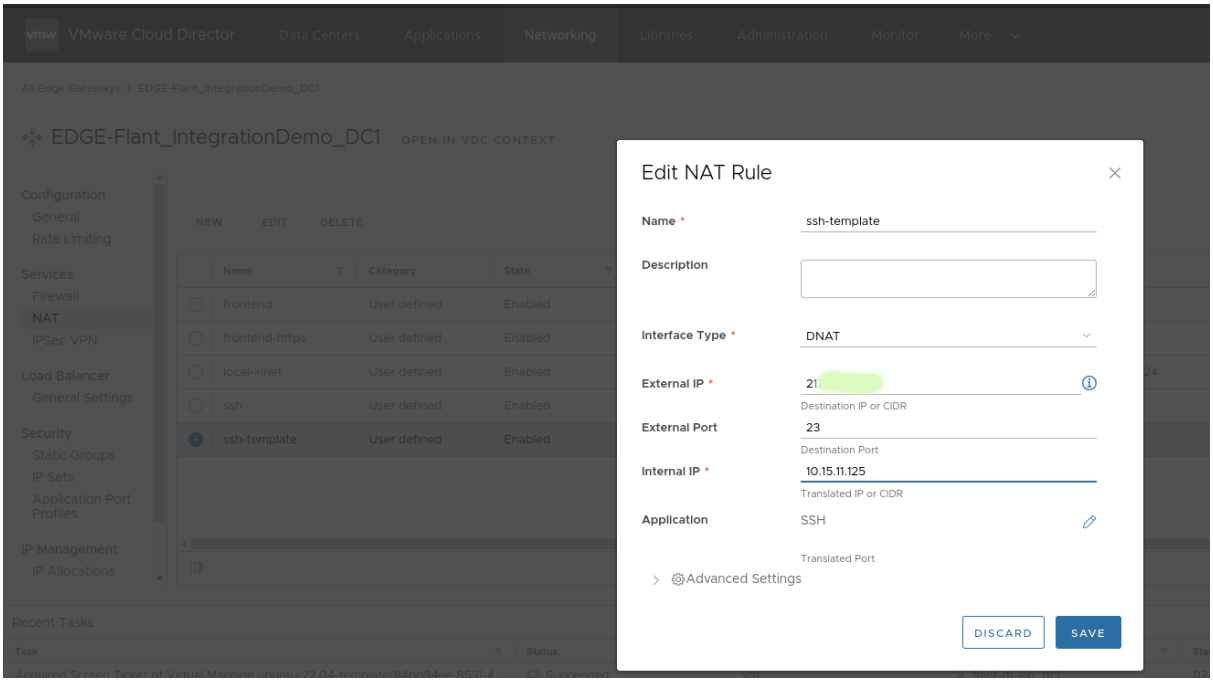


3. Select the template you downloaded and add it to the catalog:



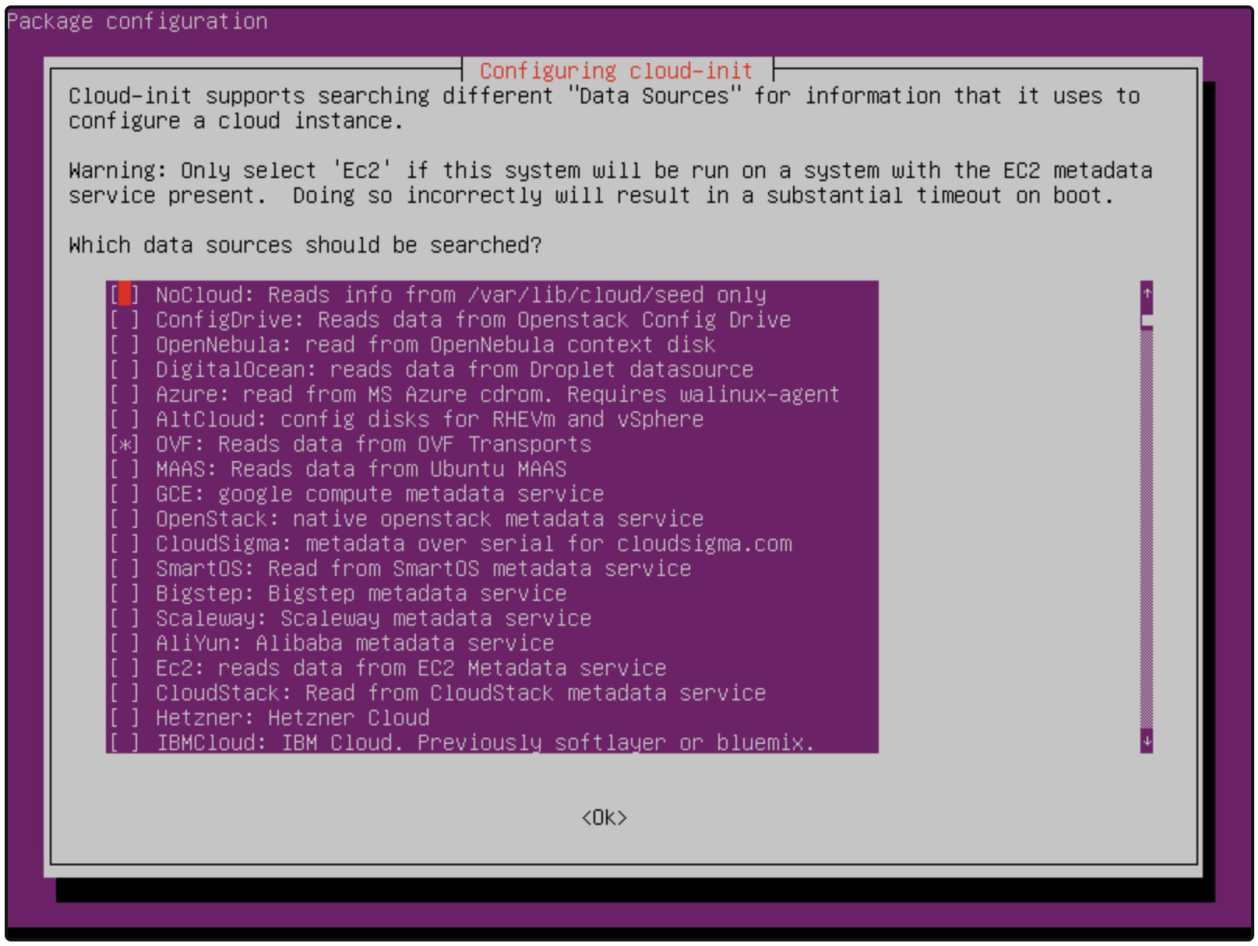


4. Create a virtual machine from the template:



⚠ Enter the default password and public key. You will need them to log in to the VM console.

Follow these steps to be able to connect to the virtual machine:



1. Start the virtual machine.
2. Wait for the IP address to be set.
3. Forward port `22` to the virtual machine:

Log on to the virtual machine over SSH and run the following commands:

```
rm /etc/netplan/99-netcfg-vmware.yaml
echo -e '\n[deployPkg]\nwait-cloudinit-timeout=1800\n' >> /etc/vmware-tools/tools.conf
echo 'disable_vmware_customization: true' > /etc/cloud/cloud.cfg.d/91_vmware_cust.cfg
dpkg-reconfigure cloud-init
```

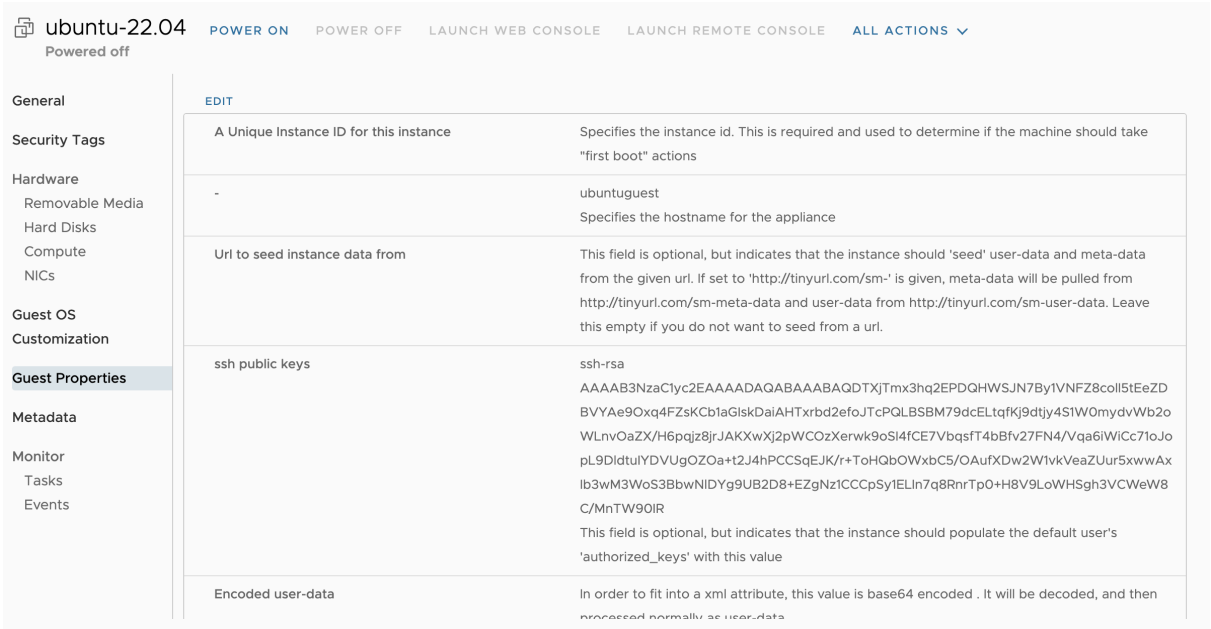
In the dialog box that appears, leave the checkmark only on `OVF: Reads data from OVF transports`, and make sure to scroll down and remove checkmarks from other options:

Make sure that the `datasource_list` parameter is specified in the `cloud-init` configuration. You can verify this using the following command:

```
cat /etc/cloud/cloud.cfg.d/90_dpkg.cfg
```

If the output is empty, execute the following command:

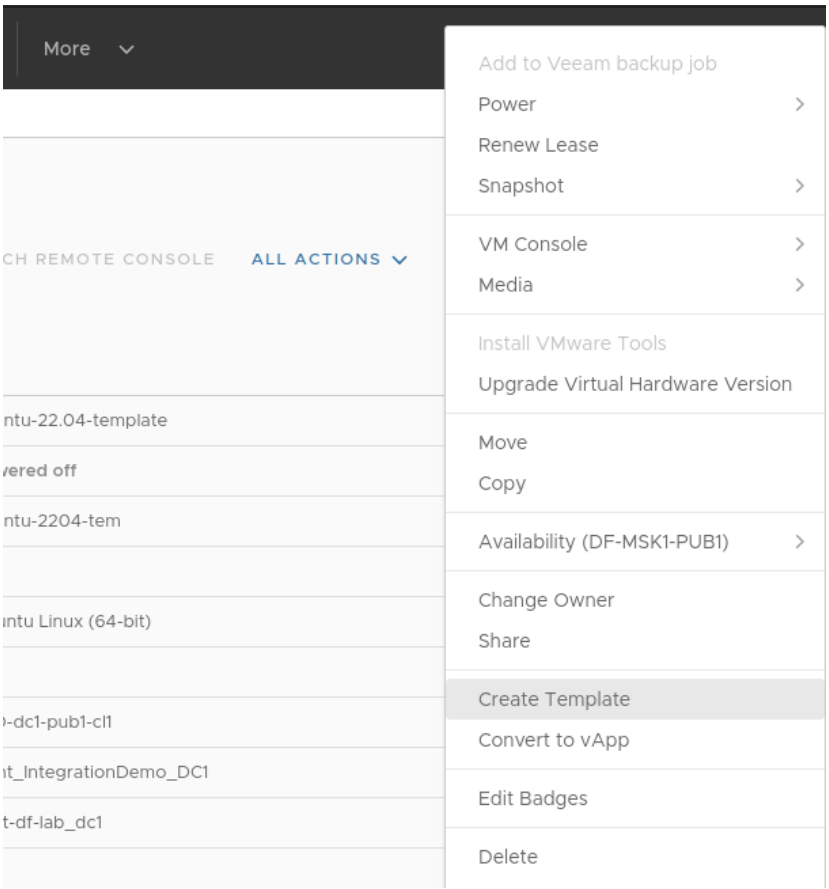
```
echo "datasource_list: [ OVF, VMware, None ]" > /etc/cloud/cloud.cfg.d/90_dpkg.cfg
```



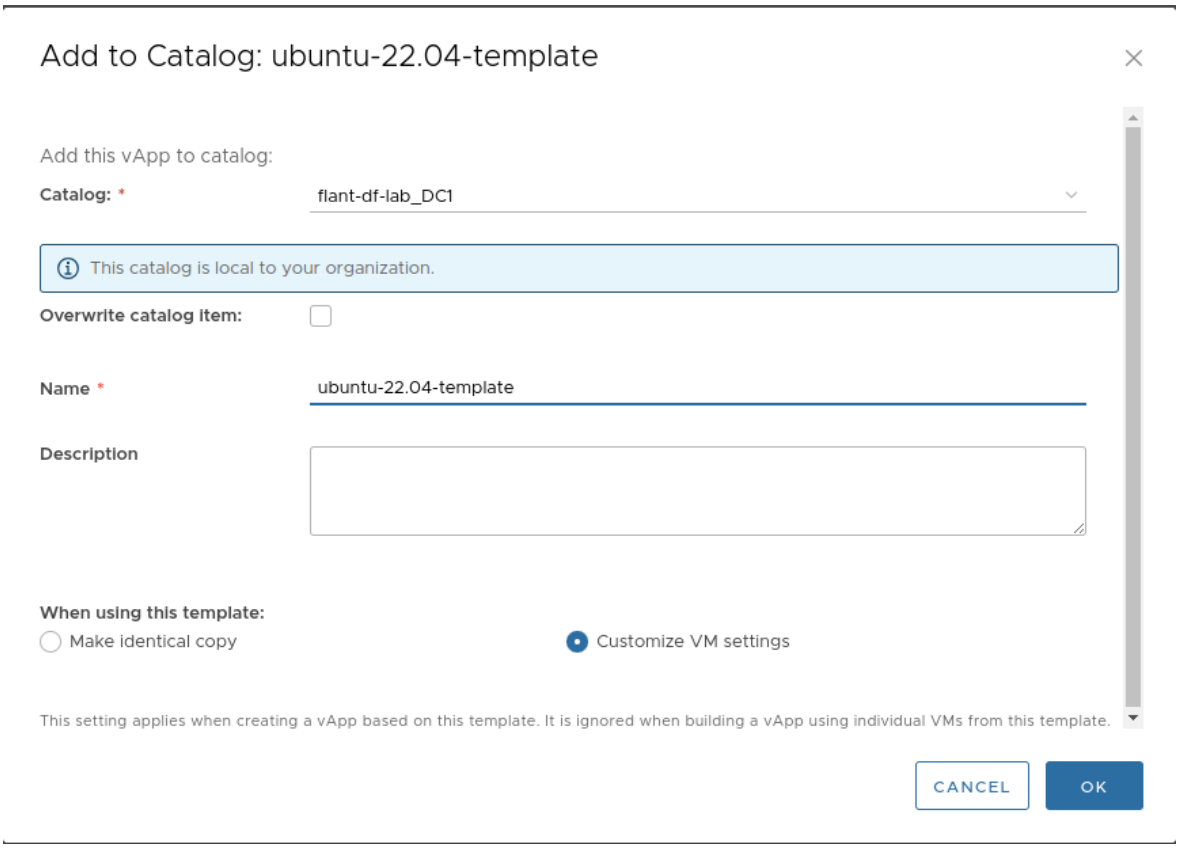
Execute the remaining commands:

```
truncate -s 0 /etc/machine-id
rm /var/lib/dbus/machine-id
ln -s /etc/machine-id /var/lib/dbus/machine-id
cloud-init clean --logs --seed
passwd -d ubuntu
passwd -d root
rm /home/ubuntu/.ssh/authorized_keys
history -c

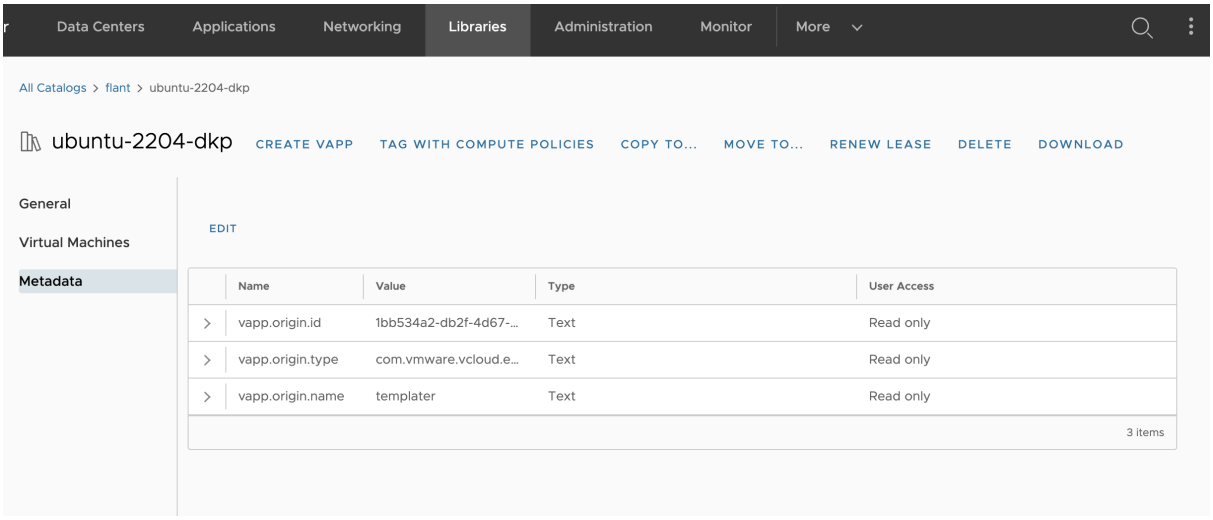
shutdown -P now
```



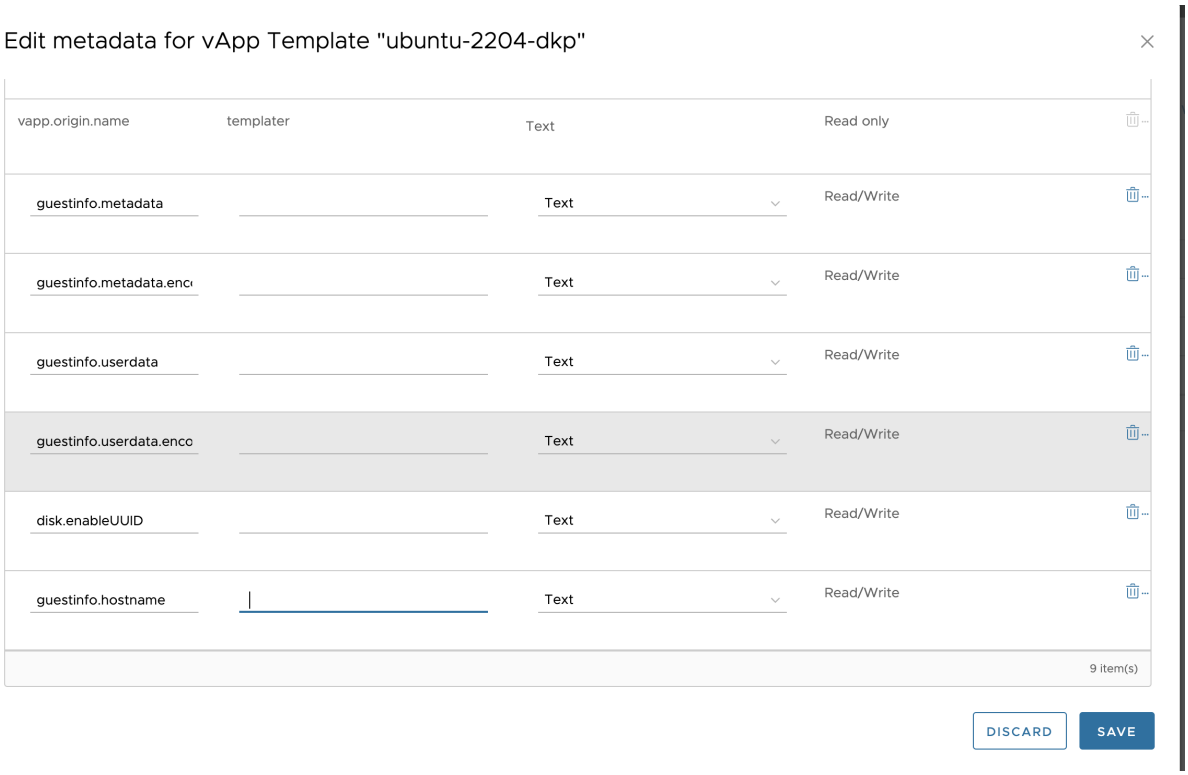
Setting up the template in VCD



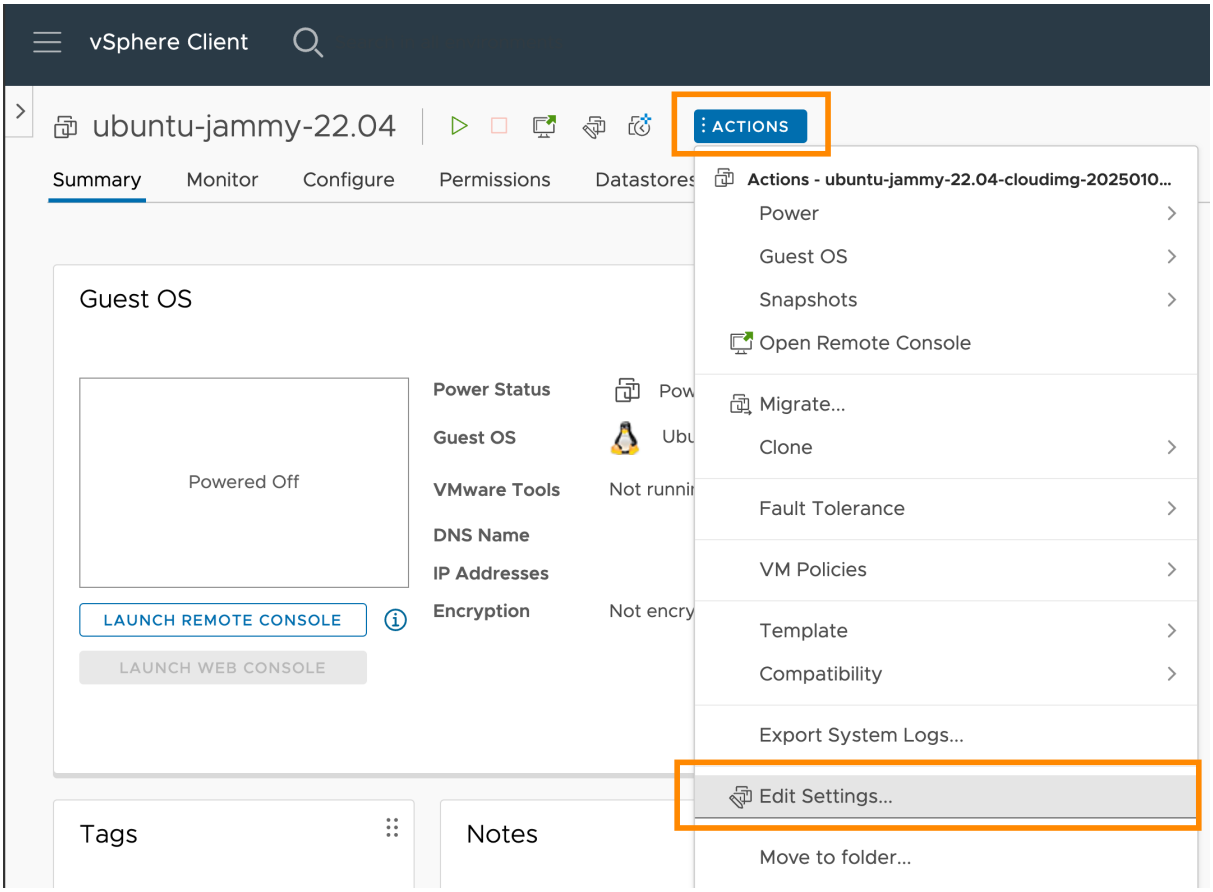
1. Shut down the virtual machine and clear all populated fields in “Guest Properties”:



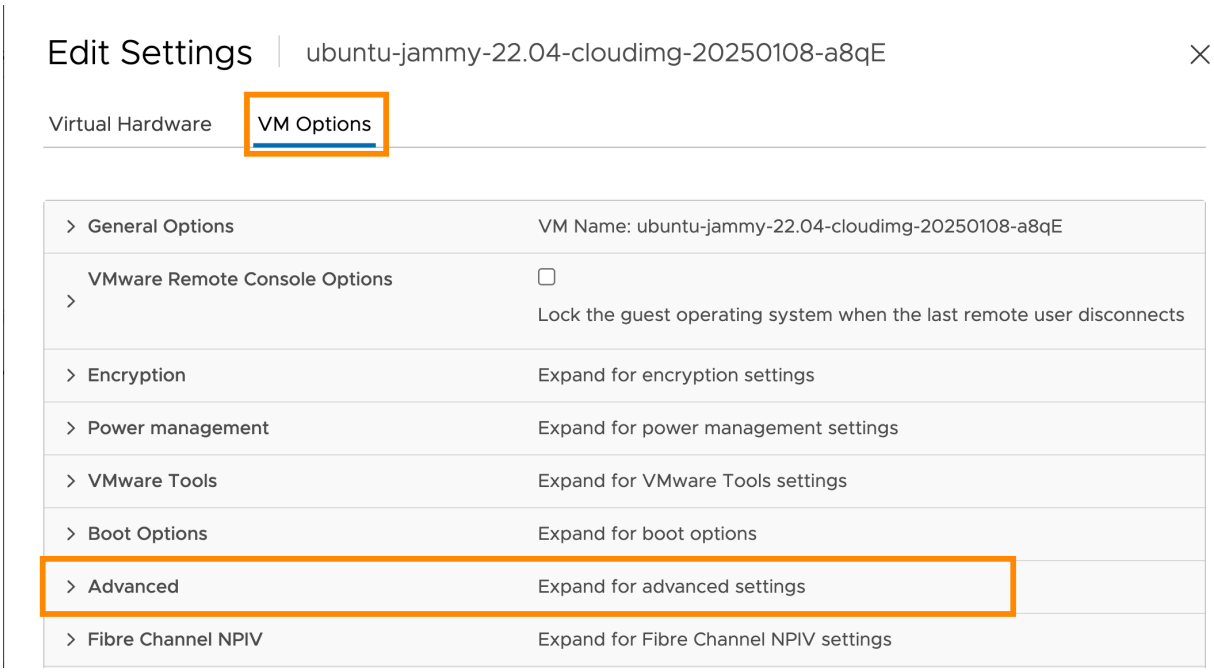
2. Create a virtual machine template:



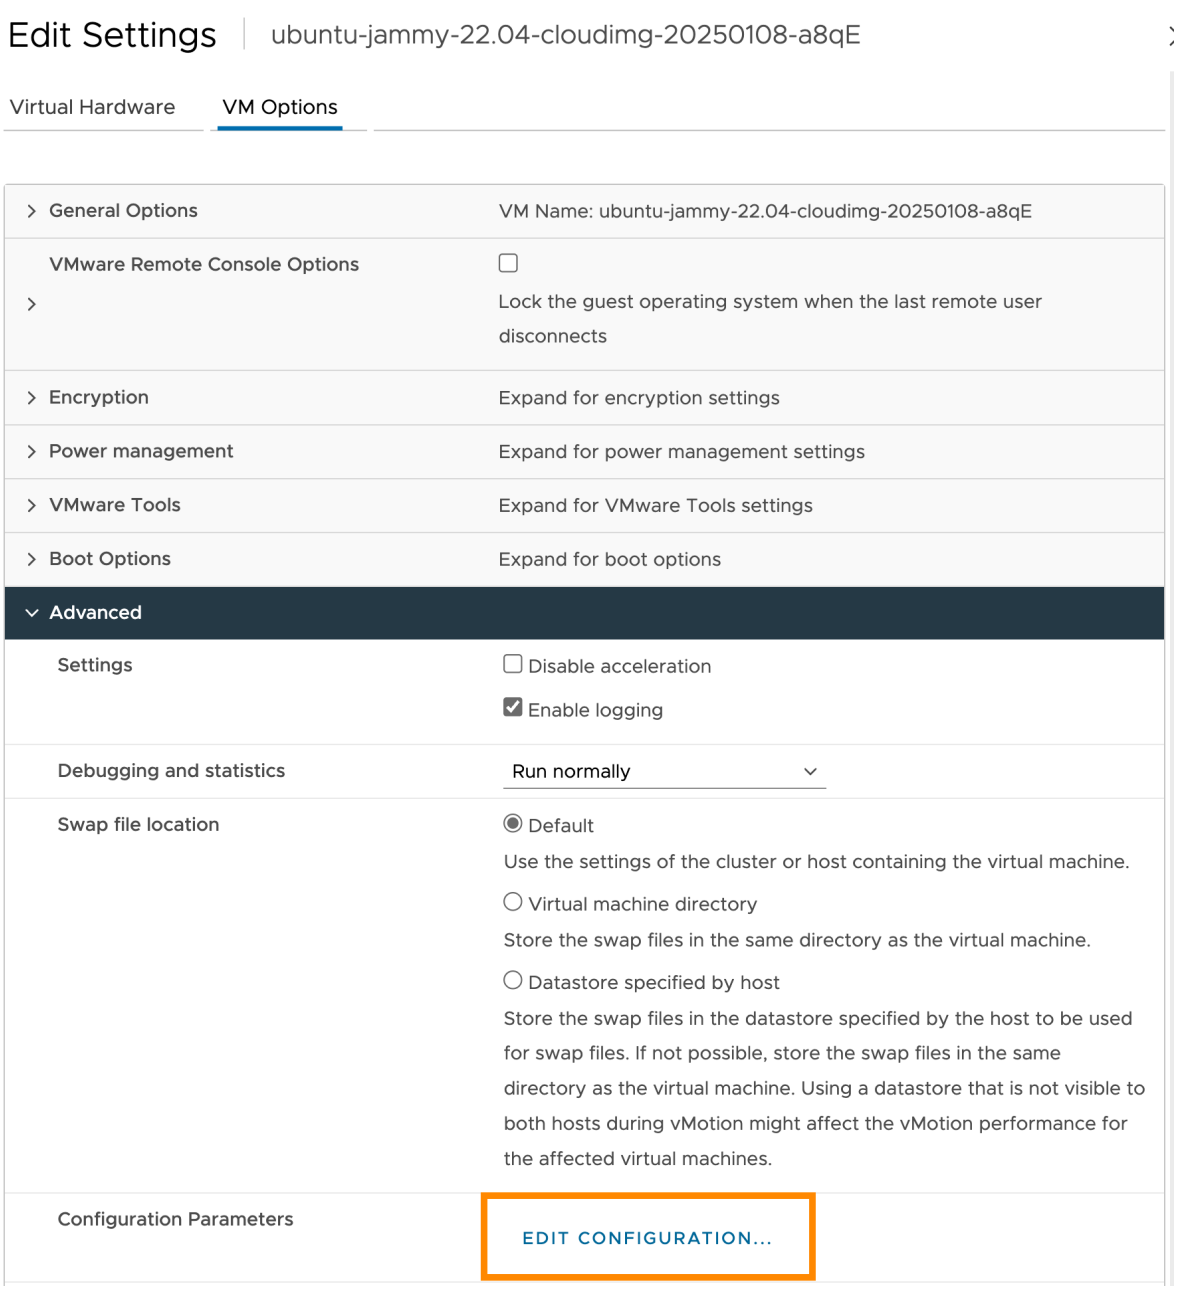
3. In the created template, navigate to the “Metadata” tab and add the following six fields:
   - `guestinfo.metadata`
   - `guestinfo.metadata.encoding`
   - `guestinfo.userdata`
   - `guestinfo.userdata.encoding`
   - `disk.enableUUID`
   - `guestinfo.hostname`



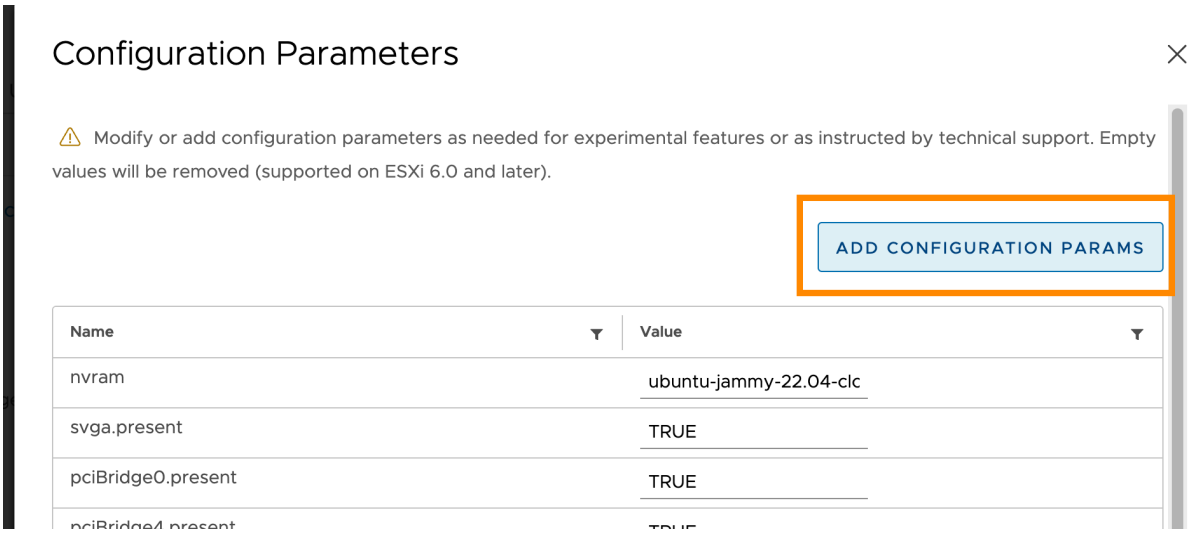
For **each** field in the add/edit form, set the following:

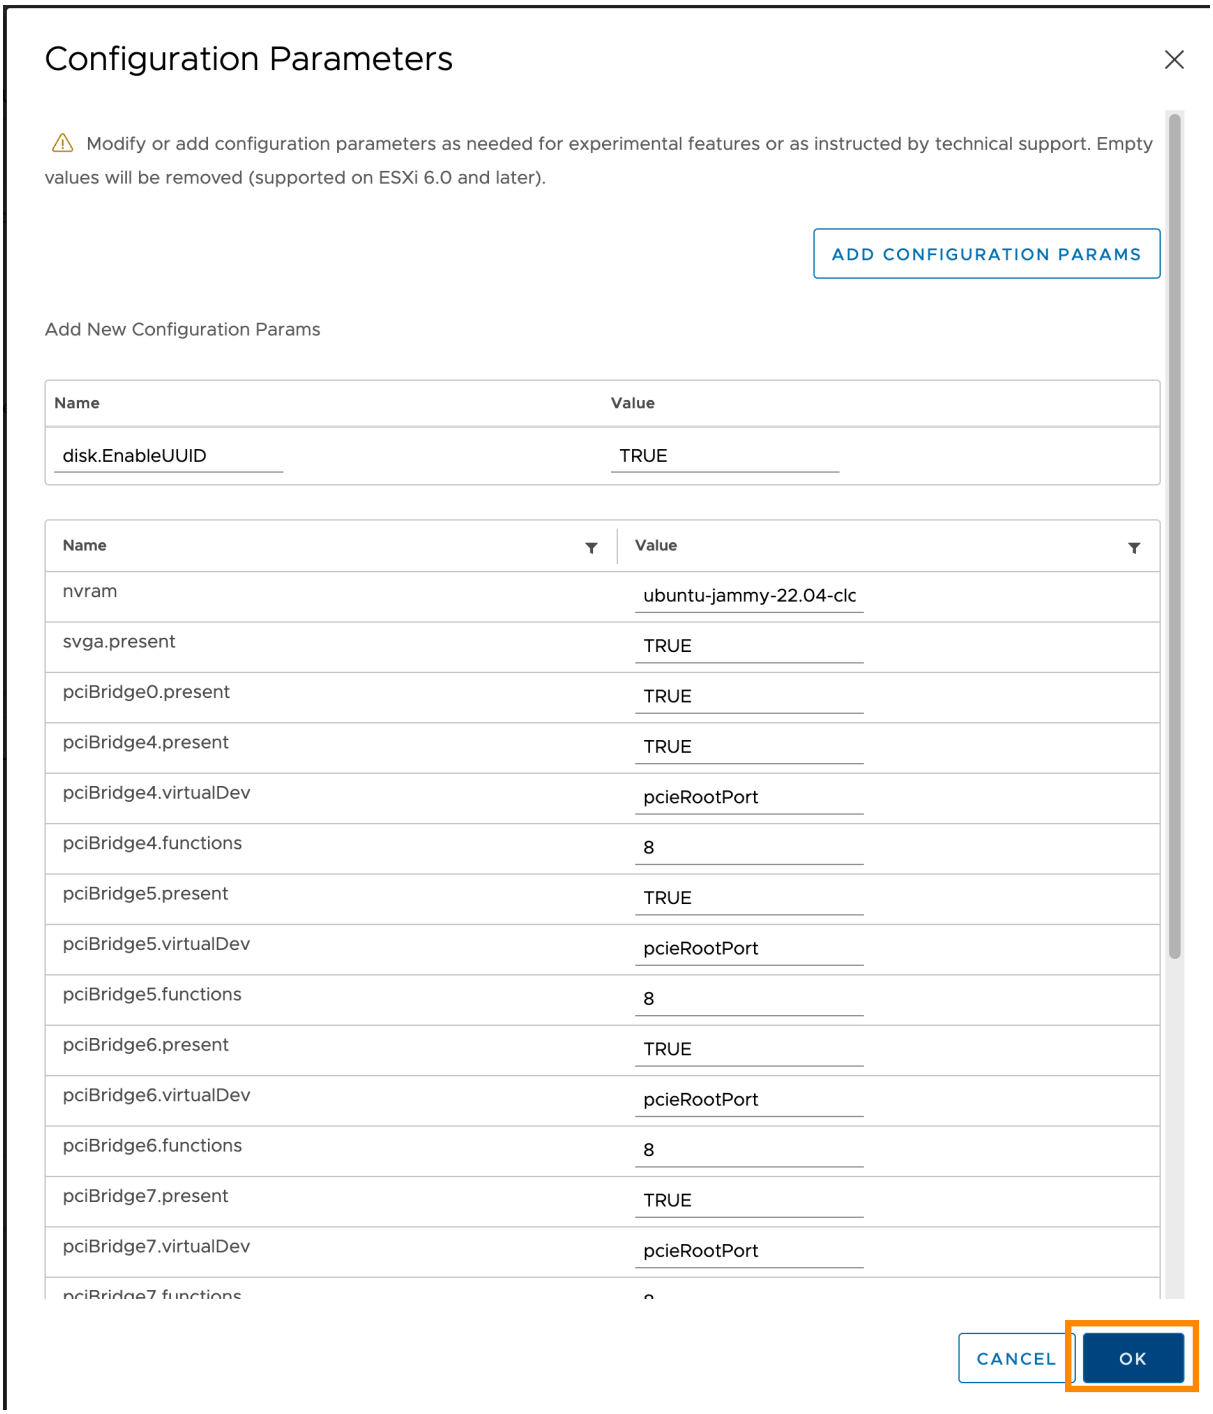


- “Type”: `Text` (text value)
- “User access”: `Read/Write`
- “Value”: A single space



> **i** The VCD UI may not save metadata with an empty value. A single space is used as a placeholder and does not affect functionality. The actual values will be populated automatically when virtual machines are created.





4. In the vCenter management panel for the template, enable the `disk.EnableUUID` parameter:

Swap file location
Default
Use the settings of the cluster or host containing the virtual machine.
Virtual machine directory
Store the swap files in the same directory as the virtual machine.
Datastore specified by host
Store the swap files in the datastore specified by the host to be used for swap files. If not possible, store the swap files in the same directory as the virtual machine. Using a datastore that is not visible to both hosts during vMotion might affect the vMotion performance for the affected virtual machines.
Configuration Parameters
EDIT CONFIGURATION...

Using the storage

- VCD supports CSI; disks are created as VCD Independent Disks.
- The `disk.EnableUUID` guest property must be set for the virtual machine templates in use.

- Deckhouse Kubernetes Platform supports disk resizing as of v1.59.1.

Using the LoadBalancer

- DKP components support `Service` resources of type `LoadBalancer` when deployed on VMware Cloud Director (VCD).
- VMware NSX Advanced Load Balancer (ALB or Avi Networks) is used as the load balancer.
- Support is available **only** when using the `NSX-T` network virtualization platform.
- The load balancer functionality must be enabled on the Edge Gateway by your VCD provider. You can verify this under **Edge Gateway → Load Balancer → General Settings** — the `State` parameter must be `Active`.
- If the load balancer was enabled after the DKP cluster was successfully created, the components will automatically pick up the changes within an hour (no additional actions are required).
- For each open port, a **Pool + Virtual Service** pair is created.
- If a firewall is in place, you must create an allow rule for the load balancer's external IP address and the corresponding ports.

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

VCDInstanceClass

Scope: Cluster
Version: v1

Parameters of a group of VCD VirtualMachines used by `cluster-api-controller-manager` (the cloud-provider-vcd module).

- **spec**
  object

  Required value

  - **spec.additionalMetadata**
    object

    Custom string key-value pairs to be stored in the Metadata of every node VM, useful for organizing and categorizing your virtualization inventory.

    The properties in this field will be merged with the existing metadata stored in the `metadata` field at the root of the VCDProviderClusterConfiguration spec. This field will take precedence over the existing metadata in cases of duplicate keys.

    > **i** **Warning.** Changing the `additionalMetadata` will cause the recreation of CloudEphemeral NodeGroups referring the VCDInstanceClass.

  - **spec.affinityRule**
    object

    Specifies the affinity rule applied only to virtual machines of node groups referencing this instance class within the cluster. Affinity rules determine how nodes are scheduled in relation to each other at the hypervisor level, which can help improve fault tolerance, and control the distribution of workloads. If not specified, no affinity rule will be applied by default.

    - **spec.affinityRule.polarity**
      string

      Required value

      The polarity of the affinity rule. Must be either `Affinity` or `AntiAffinity`. `Affinity` means that nodes should be placed on the same host, while `AntiAffinity` means they should be placed on different hosts.

      Allowed values: `Affinity`, `AntiAffinity`

    - **spec.affinityRule.required**
      boolean

      Indicates whether the affinity rule is mandatory (`true`) or only preferred (`false`). If set to `true`, the rule must be enforced; if `false`, the rule is applied if possible but not strictly required.

      Default: `false`

  - **spec.mainNetwork**
    string

    Path to the network that VirtualMachines' primary NICs will connect to (default gateway).

    Example:

```
mainNetwork: internal
```

- **spec.placementPolicy**
  string

  PlacementPolicy is the placement policy to be used on this machine. If no placement policy is specified, default placement policy will be used to create the nodes.

  Example:

  ```
  placementPolicy: Hypervisor1
  ```

- **spec.rootDiskSizeGb**
  integer

  root disk size in gigabytes.

  Default: `20`

  Example:

  ```
  rootDiskSizeGb: 20
  ```

- **spec.sizingPolicy**
  string

  SizingPolicy is the sizing policy to be used on this machine. If no sizing policy is specified, default sizing policy will be used to create the nodes.

  Example:

  ```
  sizingPolicy: 4Cpu8Memory
  ```

- **spec.storageProfile**
  string

  Required value

  StorageProfile is the storage profile to be used on this machine.

  Example:

  ```
  storageProfile: ssd
  ```

- **spec.template**
  string

  Required value

  Path of the template OVA that is to be used. Consists of organization (optional), catalog, template name or template identifier. If a shared catalog is used, the organization name must be specified (it may differ from the value of `provider.organization`).

  If you have templates with the same name in multiple catalogs with the same name, you should specify the identifier of the template.

  You can find the template identifier in the URL when you open the template in the vCD UI. For example, if the URL is `https://vcd.example.com/tenant/MyOrg/libraries/catalogs/1032506a-4555-43e1-8589-77b0c0522c75/catalog-vapp-templates/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7/general`, then the template identifier is `5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7`.

  Examples:

  ```
  template: Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: MyOrg/Linux/ubuntu2204-cloud-ova
  ```

  ```
  template: Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

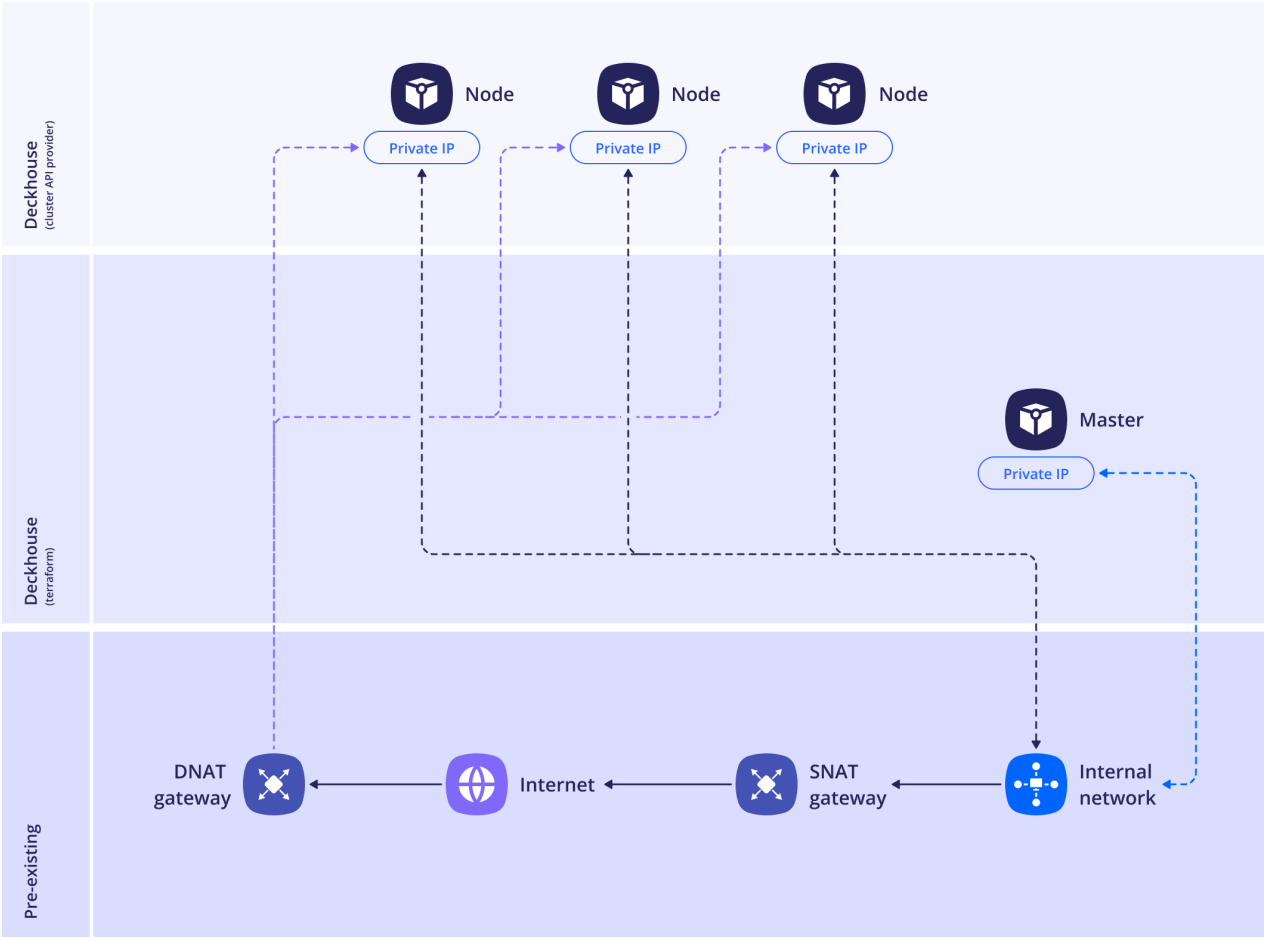
  ```
  template: MyOrg/Linux/5438c9f2-7e59-4eb3-b37c-cbd7f3e710c7
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Examples

> **i** The module lifecycle stage: General Availability

Below is an example VCDInstanceClass configuration for ephemeral nodes of VMware Cloud Director cloud provider.

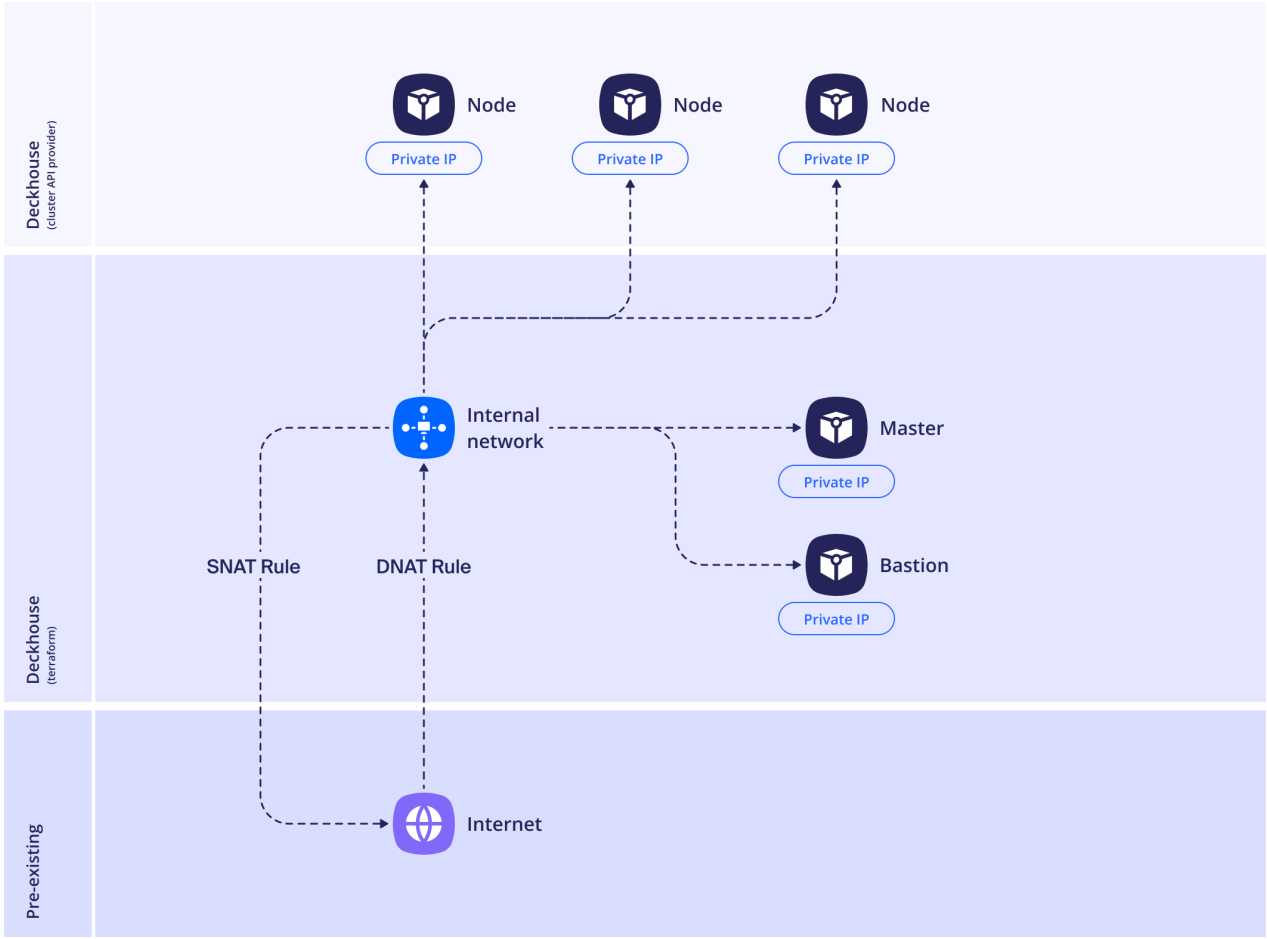


Example configuration of the VCDInstanceClass custom resource

```
apiVersion: deckhouse.io/v1
kind: VCDInstanceClass
metadata:
  name: test
spec:
  rootDiskSizeGb: 90
  sizingPolicy: payg-4-8
  storageProfile: SSD-dc1-pub1-cl1
  template: MyOrg/Linux/ubuntu2204-cloud-ova
```

Cloud provider - VMware Cloud Director: Layouts

> **i** The module lifecycle stage: General Availability



Standard

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1alpha1
kind: VCDClusterConfiguration
layout: Standard
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
sshPublicKey: <SSH_PUBLIC_KEY>
organization: deckhouse
virtualDataCenter: MSK-1
virtualApplicationName: deckhouse
internalNetworkCIDR: 192.168.199.0/24
masterNodeGroup:
  replicas: 1
  instanceClass:
    storageProfile: "Fast vHDD"
    sizingPolicy: 4cpu8mem
    template: "catalog/Ubuntu 22.04 Server"
    mainNetworkIPAddresses:
    - 192.168.199.2
```

WithNAT

When using this placement scheme, you must check with the administrator which network virtualization platform is in use and specify it in the `edgeGateway.type` parameter.
Two options are supported: `NSX-T` and `NSX-V`.

To ensure administrative access to the cluster nodes, a bastion is deployed. The parameters for its configuration are described in the `bastion` section.

If the Edge Gateway is based on `NSX-T`, a DHCP server will be automatically enabled in the created network for the nodes. It will assign IP addresses starting from the 30th address in the subnet up to the second-to-last (just before the broadcast address).
You can change the starting address of the DHCP pool using the `internalNetworkDHCPPoolStartAddress` parameter.

If `NSX-V` is used, DHCP must be configured manually. Otherwise, nodes that rely on dynamic IP assignment will not be able to obtain an address.

⚠ It is not recommended to use dynamic addressing for the first master node in combination with `NSX-V`.

The deployment scheme assumes automated creation of NAT rules:

- An SNAT rule for translating the addresses of the internal node network to the external address specified in the `edgeGateway.externalIP` property.
- A DNAT rule for translating the external address and port, specified in the `edgeGateway.externalIP` and `edgeGateway.externalPort` properties, respectively, to the internal address of the bastion instance on port 22 using the `TCP` protocol for administrative access to the nodes via SSH.

⚠ If the Edge Gateway is provided by `NSX-V`, you must specify the name and type of the network to which the rule will be bound in the `edgeGateway.NSX-V.externalNetworkName` and `edgeGateway.NSX-V.externalNetworkType` properties, respectively. Typically, this is a network connected to the Edge Gateway in `Gateway Interface` and having an external IP address.

Additionally, you can enable the creation of default firewall rules using the `createDefaultFirewallRules` property.

⚠ If the Edge Gateway is provided by `NSX-T`, existing rules on the Edge Gateway will be overwritten. It is assumed that using this option implies that only one cluster will be deployed per Edge Gateway.

The following rules will be created:

- Allow any outgoing traffic
- Allow incoming traffic over the `TCP` protocol on port 22 to enable SSH access to the cluster nodes
- Allow any incoming traffic over the `ICMP` protocol
- Allow incoming traffic over the `TCP` and `UDP` protocols on ports 30000–32767 for NodePort usage

Example of the layout configuration using `NSX-T`:

```
---
apiVersion: deckhouse.io/v1alpha1
kind: VCDClusterConfiguration
layout: WithNAT
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
sshPublicKey: <SSH_PUBLIC_KEY>
organization: deckhouse
virtualDataCenter: MSK-1
virtualApplicationName: deckhouse
internalNetworkCIDR: 192.168.199.0/24
internalNetworkDNSServers:
  - 77.88.8.8
  - 1.1.1.1
mainNetwork: internal
bastion:
  instanceClass:
    rootDiskSizeGb: 30
    sizingPolicy: 2cpu1mem
    template: "catalog/Ubuntu 22.04 Server"
    storageProfile: Fast vHDD
    mainNetworkIPAddress: 10.1.4.10
edgeGateway:
  name: "edge-gateway-01"
  type: "NSX-T"
  externalIP: 10.0.0.1
  externalPort: 10022
createDefaultFirewallRules: false
masterNodeGroup:
  replicas: 1
  instanceClass:
    storageProfile: "Fast vHDD"
    sizingPolicy: 4cpu8mem
    template: "catalog/Ubuntu 22.04 Server"
    mainNetworkIPAddresses:
    - 192.168.199.2
```

Example of the layout configuration using `NSX-V`:

```
---
apiVersion: deckhouse.io/v1alpha1
kind: VCDClusterConfiguration
layout: WithNAT
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
sshPublicKey: <SSH_PUBLIC_KEY>
organization: deckhouse
virtualDataCenter: MSK-1
virtualApplicationName: deckhouse
internalNetworkCIDR: 192.168.199.0/24
internalNetworkDNSServers:
  - 77.88.8.8
  - 1.1.1.1
mainNetwork: internal
bastion:
  instanceClass:
    rootDiskSizeGb: 30
    sizingPolicy: 2cpu1mem
    template: "catalog/Ubuntu 22.04 Server"
    storageProfile: Fast vHDD
    mainNetworkIPAddress: 10.1.4.10
edgeGateway:
  name: "edge-gateway-01"
  type: "NSX-V"
  externalIP: 10.0.0.1
  externalPort: 10022
  NSX-V:
    externalNetworkName: external
    externalNetworkType: ext
createDefaultFirewallRules: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    storageProfile: "Fast vHDD"
    sizingPolicy: 4cpu8mem
    template: "catalog/Ubuntu 22.04 Server"
    mainNetworkIPAddresses:
    - 192.168.199.2
```

Cloud provider — VMware vSphere

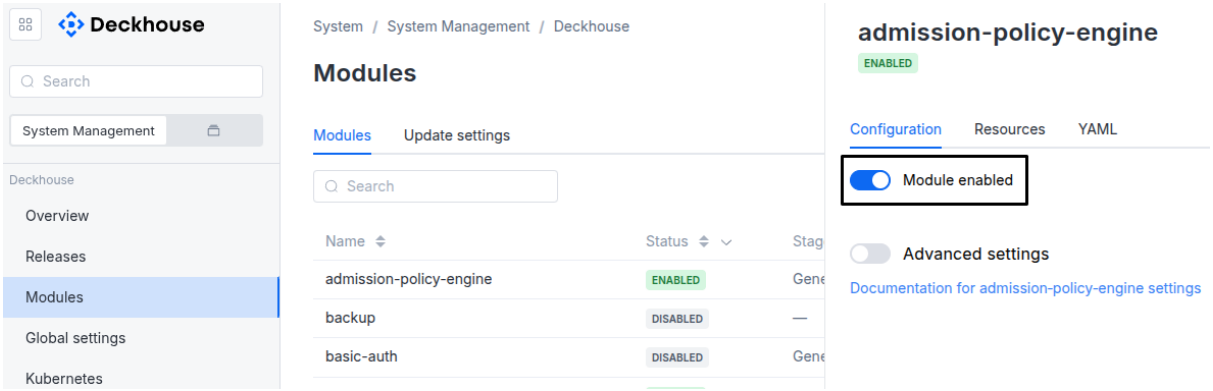
> **i** The module lifecycle stage: General Availability

The `cloud-provider-vsphere` module integrates Deckhouse Kubernetes Platform with VMware vSphere. It allows the `node-manager` module to use vSphere resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-vsphere` module:

- Managing vSphere resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the vSphere side;
  - updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in vSphere.
- Provisioning disks via CSI on datastore. By default, CNS volumes with online resize are used. First-Class Disk (FCD) mode is available as legacy and is configured with the `compatibilityFlag` parameter.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-vsphere`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM). Virtual machine parameters are set in the VsphereInstanceClass resource.
- Registering with `node-manager` so that VsphereInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Configuration



> **i** The module lifecycle stage: General Availability

The module is automatically enabled for all cloud clusters deployed in vSphere.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vsphere` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

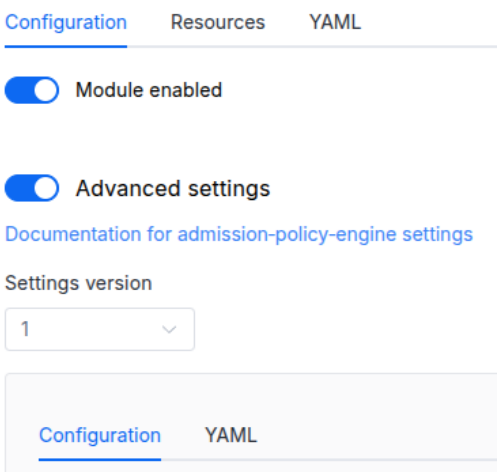
```
d8 system module enable cloud-provider-vsphere
```

- **Using ModuleConfig `cloud-provider-vsphere`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-vsphere` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-vsphere`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vsphere
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-vsphere` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cloud-provider-vsphere` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-vsphere`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-vsphere` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc cloud-provider-vsphere
```

Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `cloud-provider-vsphere` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `cloud-provider-vsphere`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vsphere
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  If the field `.storageClass.compatibilityFlag` exists, capitalize the field value.

If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-vsphere` module in the Deckhouse configuration (see below). Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the VsphereClusterConfiguration structure for configuration.

You can configure the number and parameters of ordering machines in the cloud via the `NodeGroup` custom resource of the `node-manager` module. Also, in this custom resource, you can specify the instance class's name for the above group of nodes (the `cloudInstances.ClassReference` parameter of NodeGroup). In the case of the vSphere cloud provider, the instance class is the `VsphereInstanceClass` custom resource that stores specific parameters of the machines.

Storage

The module automatically creates a StorageClass for each Datastore and DatastoreCluster in the zone (or zones).

Also, it can set the name of StorageClass that will be used in the cluster by default (the default parameter), and filter out the unnecessary StorageClasses (the exclude parameter).

CSI

By default, the storage subsystem uses CNS volumes with the ability of online-resize. FCD volumes are also supported, but only in the legacy or migration modes. You can set this via the compatibilityFlag parameter.

Important information concerning the increase of the PVC size

Due to the nature f volume-resizer, CSI, and vSphere API, you have to do the following after increasing the PVC size:

1. On the node where the Pod is located, run the `d8 k cordon <node_name>` command.
2. Delete the Pod.
3. Make sure that the resize was successful. The PVC object must *not have* the `Resizing` condition.

   > **i** The `FileSystemResizePending` state is OK.

4. On the node where the Pod is located, run the `d8 k uncordon <node_name>` command.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.disableTimesync**
    boolean

    Disable time synchronization on the vSphere side.

> **Caution!** This parameter will not disable the NTP daemons in the guest OS, but only disable the time correction on the part of ESXi.

- **settings.externalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert ExternalIP into the `.status.addresses` field in the Node API object.

- **settings.host**
  string

  The domain of the vCenter server.

- **settings.insecure**
  boolean

  Set to `true` if vCenter has a self-signed certificate.

- **settings.internalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert InternalIP into the `.status.addresses` field in the Node API object.

- **settings.nsxt**
  object

  Kubernetes load balancer support using NSX-T for the vSphere cloud controller manager.

  - **settings.nsxt.defaultIpPoolName**
    string

    Required value

    Name of the default IP pool used for the SVC's without `loadbalancer.vmware.io/class` annotation set.

    Example:

    ```
    defaultIpPoolName: pool1
    ```

  - **settings.nsxt.defaultTcpAppProfileName**
    string

    Name of default NSX-T application profile used for TCP connections.

    Default: `default-tcp-lb-app-profile`

    Examples:

    ```
    defaultTcpAppProfileName: default-tcp-lb-app-profile
    ```

    ```
    defaultTcpAppProfileName: tcp-profile1
    ```

  - **settings.nsxt.defaultUdpAppProfileName**
    string

    Name of default NSX-T application profile used for UDP connections.

    Default: `default-udp-lb-app-profile`

    Examples:

    ```
    defaultUdpAppProfileName: default-udp-lb-app-profile
    ```

    ```
    defaultUdpAppProfileName: udp-profile1
    ```

  - **settings.nsxt.host**
    string

    Required value

    NSX-T host.

    Example:

    ```
    host: 1.2.3.4
    ```

  - **settings.nsxt.insecureFlag**
    boolean

    To be set to true if NSX-T uses self-signed certificate.

    Examples:

```
insecureFlag: true
```

```
insecureFlag: false
```

- **settings.nsxt.loadBalancerClass**
  array

  Additional section to define Load Balancer Classes (to use class, set annotation `loadbalancer.vmware.io/class: <class name>` to SVC).

  Examples:

```
loadBalancerClass: []
```

```
loadBalancerClass:
  name: LBC1
  ipPoolName: pool2
```

```
loadBalancerClass:
  name: LBC1
  ipPoolName: pool2
  tcpAppProfileName: profile2
  udpAppProfileName: profile3
```

  - **settings.nsxt.loadBalancerClass.ipPoolName**
    string

    Required value

    Name of the IP pool.

  - **settings.nsxt.loadBalancerClass.name**
    string

    Required value

    Load Balancer Class name to use in SVC annotation `loadbalancer.vmware.io/class: <class name>`.

  - **settings.nsxt.loadBalancerClass.tcpAppProfileName**
    string

    Name of application profile used for TCP connections.

    Default: `defaultTcpAppProfileName`

  - **settings.nsxt.loadBalancerClass.udpAppProfileName**
    string

    Name of application profile used for UDP connections.

    Default: `defaultUdpAppProfileName`

- **settings.nsxt.password**
  string

  Required value

  NSX-T password.

  Example:

```
password: password
```

- **settings.nsxt.size**
  string

  Size of load balancer service.

  Default: `MEDIUM`

  Allowed values: `SMALL`, `MEDIUM`, `LARGE`, `XLARGE`

  Example:

```
size: SMALL
```

- **settings.nsxt.tier1GatewayPath**
  string

  Required value

  Policy path for the NSX-T tier1 gateway.

Example:

```
tier1GatewayPath: "/path/tier1"
```

- **settings.nsxt.user**
  string

  Required value

  NSX-T user name.

  Example:

  ```
  user: user
  ```

- **settings.password**
  string

  The user's password.

- **settings.region**
  string

  Is a tag added to the vSphere Datacenter where all actions will occur: provisioning VirtualMachines, storing virtual disks on datastores, connecting to the network.

- **settings.regionTagCategory**
  string

  The name of the tag category used to identify the region (vSphere Datacenter).

- **settings.sshKeys**
  array of strings

  A list of public SSH keys in plain-text format.

- **settings.storageClass**
  object
  - **settings.storageClass.compatibilityFlag**
    string

    A flag allowing the use of the old CSI version:

    - `Legacy` — use the old version of the driver. FCD discs only, no online-resizing;
    - `Migration` — in this case, both drivers will be available in the cluster at the same time. This mode is used to migrate from an old driver.

    Allowed values: `Legacy`, `Migration`

  - **settings.storageClass.default**
    Deprecated
    string

    The name of StorageClass that will be used in the cluster by default.

    If the parameter is omitted, the default StorageClass is either:

    - an arbitrary StorageClass present in the cluster that has the default annotation;
    - the first (in lexicographic order) StorageClass created by the module.

    > **i** **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

    Example:

    ```
    default: fast-lun102-7d0bf578
    ```

  - **settings.storageClass.exclude**
    array of strings

    A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

    Example:

    ```
    exclude:
    - ".*-lun101-.*"
    - slow-lun103-1c280603
    ```

- **settings.username**
  string

  Username.

> **Warning.** Make sure to specify the username together with the domain, for example: `username@domain.local`.
>
> You can find the correct domain in the vCenter control panel.

- **settings.vmFolderPath**
  string

  The path to the VirtualMachine Folder where the cloned VMs will be created.
- **settings.zoneTagCategory**
  string

  The name of the tag category used to identify the zone (vSphere Cluster).
- **settings.zones**
  array of strings

  The globally restricted set of zones that this Cloud Provider works with.

Provider configuration

> The module lifecycle stage: General Availability

> If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-vsphere` module in the Deckhouse configuration. Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the VsphereClusterConfiguration structure for configuration.
>
> Additional info about Vsphere Cloud Load Balancers.

VsphereClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in vSphere.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes section. Information about reducing the number of nodes and deleting nodes is provided in the Integration with VMware vSphere services section.

Example:

```
apiVersion: deckhouse.io/v1
kind: VsphereClusterConfiguration
sshPublicKey: "<SSH_PUBLIC_KEY>"
layout: Standard
vmFolderPath: folder/prefix
regionTagCategory: k8s-region
zoneTagCategory: k8s-zone
region: region2
zones:
- region2-a
externalNetworkNames:
- net3-k8s
internalNetworkNames:
- K8S_3
internalNetworkCIDR: 172.16.2.0/24
baseResourcePool: kubernetes/cloud
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: Templates/ubuntu-focal-20.04
    mainNetwork: net3-k8s
    additionalNetworks:
    - K8S_3
    datastore: lun10
    rootDiskSize: 50
    runtimeOptions:
      nestedHardwareVirtualization: false
nodeGroups:
- name: worker
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: Templates/ubuntu-focal-20.04
    datastore: lun10
    mainNetwork: net3-k8s
provider:
  server: "<SERVER>"
  username: "<USERNAME@DOMAIN.LOCAL>"
  password: "<PASSWORD>"
  insecure: true
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **baseResourcePool**
  string

  A path (relative to vSphere Cluster) to the existing parent `resourcePool` for all `resourcePool` created in each zone.

- **disableTimesync**
  boolean

  Disable time synchronization on the vSphere side.

  > **Caution!** This parameter will not disable the NTP daemons in the guest OS, but only disable the time correction on the part of ESXi.

  Default: `true`

- **externalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert ExternalIP into the `.status.addresses` field in the Node API object.

  Example:

```
externalNetworkNames:
- MAIN-1
- public
```

- **internalNetworkCIDR**
  string

  Subnet for master nodes in the internal network.

  Addresses are allocated starting with the tenth address. E.g., if you have the `192.168.199.0/24` subnet, addresses will be allocated starting with `192.168.199.10`.

  The `internalNetworkCIDR` is used if `additionalNetworks` are defined in `masterInstanceClass`.

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **internalNetworkNames**
  array of strings

  Names of networks (just the name and not the full path) connected to `VirtualMachines` and used by `vsphere-cloud-controller-manager` to insert InternalIP into the `.status.addresses` field in the Node API object.

  Example:

```
internalNetworkNames:
- KUBE-3
- devops-internal
```

- **kind**
  string

  Required value

  Allowed values: `VsphereClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the VsphereInstanceClass.

    - **masterNodeGroup.instanceClass.additionalNetworks**
      array of strings

      Paths to networks that VirtualMachines' secondary NICs will connect to. Relative to the datacenter.

      Example:

```
additionalNetworks:
- DEVOPS_32
- DEVOPS_50
```

    - **masterNodeGroup.instanceClass.datastore**
      string

      Required value

      Path to a Datastore in which VirtualMachines will be cloned. Relative to the datacenter.

      Example:

```
datastore: lun-1201
```

    - **masterNodeGroup.instanceClass.mainNetwork**

string

Required value

Path to the network that VirtualMachines' primary NICs will connect to (default gateway). Relative to the datacenter.

Example:

```
mainNetwork: k8s-msk-178
```

- **masterNodeGroup.instanceClass.mainNetworkIPAddresses**
  array of objects

  A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

  By default, the DHCP client is enabled.

  Example:

  ```
  mainNetworkIPAddresses:
  - address: 10.1.14.20/24
    gateway: 10.1.14.254
    nameservers:
      addresses:
      - 8.8.8.8
      - 8.8.4.4
  ```

  - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.address**
    string

    Required value

    An IP address with a CIDR prefix.

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.gateway**
    string

    Required value

    The IP address of the default gateway.

    It must be located in the subnet specified in the `address` parameter

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

  - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.nameservers**
    object

    Required value

    - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.nameservers.addresses**
      array of strings

      A list of DNS servers.

      Example:

      ```
      addresses:
      - 8.8.8.8
      - 8.8.4.4
      ```

      - **Element of the array**
        string

        Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

    - **masterNodeGroup.instanceClass.mainNetworkIPAddresses.nameservers.search**
      array of strings

      A list of DNS search domains.

      Example:

      ```
      search:
      - tech.lan
      ```

- **masterNodeGroup.instanceClass.memory**
  integer

  Required value

Memory in MiB to allocate to vSphere VirtualMachines.

Example:

```
memory: 8192
```

- **masterNodeGroup.instanceClass.numCPUs**
integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **masterNodeGroup.instanceClass.resourcePool**
string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  Example:

  ```
  resourcePool: rp-2012
  ```

- **masterNodeGroup.instanceClass.rootDiskSize**
integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Example:

  ```
  rootDiskSize: 50
  ```

- **masterNodeGroup.instanceClass.runtimeOptions**
object

  Additional VM’s parameters.

  - **masterNodeGroup.instanceClass.runtimeOptions.cpuLimit**
  integer

    CPU limit in MHz.

  - **masterNodeGroup.instanceClass.runtimeOptions.cpuReservation**
  integer

    CPU reservation in MHz.

  - **masterNodeGroup.instanceClass.runtimeOptions.cpuShares**
  integer

    The relative amount of CPU Shares for VMs to be created.

  - **masterNodeGroup.instanceClass.runtimeOptions.memoryLimit**
  integer

    Memory limit in MB.

  - **masterNodeGroup.instanceClass.runtimeOptions.memoryReservation**
  integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Allowed values: `0 <= X <= 100`

  - **masterNodeGroup.instanceClass.runtimeOptions.memoryShares**
  integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **masterNodeGroup.instanceClass.runtimeOptions.nestedHardwareVirtualization**
  boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

- **masterNodeGroup.instanceClass.template**
string

  Required value

  Path to the template to be cloned. Relative to the datacenter.

  Example:

```
template: dev/golden_image
```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array of strings

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the VsphereInstanceClass.

    - **nodeGroups.instanceClass.additionalNetworks**
      array of strings

      Paths to networks that VirtualMachines' secondary NICs will connect to. Relative to the datacenter.

      Example:

      ```
      additionalNetworks:
      - DEVOPS_32
      - DEVOPS_50
      ```

    - **nodeGroups.instanceClass.datastore**
      string

      Required value

      Path to a Datastore in which VirtualMachines will be cloned. Relative to the datacenter.

      Example:

      ```
      datastore: lun-1201
      ```

    - **nodeGroups.instanceClass.mainNetwork**
      string

      Required value

      Path to the network that VirtualMachines' primary NICs will connect to (default gateway). Relative to the datacenter.

      Example:

      ```
      mainNetwork: k8s-msk-178
      ```

    - **nodeGroups.instanceClass.mainNetworkIPAddresses**
      array of objects

      A list of static IP addresses (with a CIDR prefix) sequentially allocated to nodes in the `mainNetwork`.

      By default, the DHCP client is enabled.

      Example:

      ```
      mainNetworkIPAddresses:
      - address: 10.1.14.20/24
        gateway: 10.1.14.254
        nameservers:
          addresses:
          - 8.8.8.8
          - 8.8.4.4
      ```

      - **nodeGroups.instanceClass.mainNetworkIPAddresses.address**
        string

Required value

An IP address with a CIDR prefix.

Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **nodeGroups.instanceClass.mainNetworkIPAddresses.gateway**
  string

  Required value

  The IP address of the default gateway.

  It must be located in the subnet specified in the `address` parameter

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

- **nodeGroups.instanceClass.mainNetworkIPAddresses.nameservers**
  object

  Required value

  - **nodeGroups.instanceClass.mainNetworkIPAddresses.nameservers.addresses**
    array of strings

    A list of DNS servers.

    Example:

    ```
    addresses:
    - 8.8.8.8
    - 8.8.4.4
    ```

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])$`

  - **nodeGroups.instanceClass.mainNetworkIPAddresses.nameservers.search**
    array of strings

    A list of DNS search domains.

    Example:

    ```
    search:
    - tech.lan
    ```

- **nodeGroups.instanceClass.memory**
  integer

  Required value

  Memory in MiB to allocate to vSphere VirtualMachines.

  Example:

  ```
  memory: 8192
  ```

- **nodeGroups.instanceClass.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **nodeGroups.instanceClass.resourcePool**
  string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  Example:

  ```
  resourcePool: rp-2012
  ```

- **nodeGroups.instanceClass.rootDiskSize**
  integer

  Root disk size in GiB to use in vSphere VirtualMachines.

The disk will be automatically enlarged if its size in the template is less than specified.

Example:

```
rootDiskSize: 50
```

- **nodeGroups.instanceClass.runtimeOptions**
  object

  Additional VM’s parameters.

  - **nodeGroups.instanceClass.runtimeOptions.cpuLimit**
    integer

    CPU limit in MHz.

  - **nodeGroups.instanceClass.runtimeOptions.cpuReservation**
    integer

    CPU reservation in MHz.

  - **nodeGroups.instanceClass.runtimeOptions.cpuShares**
    integer

    The relative amount of CPU Shares for VMs to be created.

  - **nodeGroups.instanceClass.runtimeOptions.memoryLimit**
    integer

    Memory limit in MB.

  - **nodeGroups.instanceClass.runtimeOptions.memoryReservation**
    integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Allowed values: `0 <= X <= 100`

  - **nodeGroups.instanceClass.runtimeOptions.memoryShares**
    integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **nodeGroups.instanceClass.runtimeOptions.nestedHardwareVirtualization**
    boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

- **nodeGroups.instanceClass.template**
  string

  Required value

  Path to the template to be cloned. Relative to the datacenter.

  Example:

  ```
  template: dev/golden_image
  ```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Example:

```
labels:
  environment: production
  app: warp-drive-ai
```

- **nodeGroups.nodeTemplate.taints**
  array of objects

  The same as the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **nodeGroups.zones**
  array of strings

  A limited set of zones in which nodes can be created.

- **nsxt**
  object

  Kubernetes load balancer support using NSX-T for the vSphere cloud controller manager.

  - **nsxt.defaultIpPoolName**
    string

    Required value

    Name of the default IP pool used for the SVC's without `loadbalancer.vmware.io/class` annotation set.

    Example:

    ```
    defaultIpPoolName: pool1
    ```

  - **nsxt.defaultTcpAppProfileName**
    string

    Name of default NSX-T application profile used for TCP connections.

    Default: `default-tcp-lb-app-profile`

    Examples:

    ```
    defaultTcpAppProfileName: default-tcp-lb-app-profile
    ```

    ```
    defaultTcpAppProfileName: tcp-profile1
    ```

  - **nsxt.defaultUdpAppProfileName**
    string

    Name of default NSX-T application profile used for UDP connections.

    Default: `default-udp-lb-app-profile`

    Examples:

    ```
    defaultUdpAppProfileName: default-udp-lb-app-profile
    ```

    ```
    defaultUdpAppProfileName: udp-profile1
    ```

  - **nsxt.host**

string

Required value

NSX-T host.

Example:

```
host: 1.2.3.4
```

- **nsxt.insecureFlag**
  boolean

  To be set to true if NSX-T uses self-signed certificate.

  Examples:

  ```
  insecureFlag: true
  ```

  ```
  insecureFlag: false
  ```

- **nsxt.loadBalancerClass**
  array

  Additional section to define Load Balancer Classes (set annotation `loadbalancer.vmware.io/class: <CLASS NAME>` to SVC to use the class).

  Examples:

  ```
  loadBalancerClass: []
  ```

  ```
  loadBalancerClass:
    name: LBC1
    ipPoolName: pool2
  ```

  ```
  loadBalancerClass:
    name: LBC1
    ipPoolName: pool2
    tcpAppProfileName: profile2
    udpAppProfileName: profile3
  ```

  - **nsxt.loadBalancerClass.ipPoolName**
    string

    Required value

    Name of the IP pool.

  - **nsxt.loadBalancerClass.name**
    string

    Required value

    Load Balancer Class name to use in SVC annotation `loadbalancer.vmware.io/class: <CLASS NAME>`.

  - **nsxt.loadBalancerClass.tcpAppProfileName**
    string

    Name of application profile used for TCP connections.

    Default: `defaultTcpAppProfileName`

  - **nsxt.loadBalancerClass.udpAppProfileName**
    string

    Name of application profile used for UDP connections.

    Default: `defaultUdpAppProfileName`

- **nsxt.password**
  string

  Required value

  NSX-T password.

  Example:

  ```
  password: password
  ```

- **nsxt.size**
  string

  Size of load balancer service.

Default: `MEDIUM`

Allowed values: `SMALL`, `MEDIUM`, `LARGE`, `XLARGE`

Example:

```
size: SMALL
```

- **nsxt.tier1GatewayPath**
  string

  Required value

  Policy path for the NSX-T tier1 gateway.

  Example:

  ```
  tier1GatewayPath: "/path/tier1"
  ```

- **nsxt.user**
  string

  Required value

  NSX-T user name.

  Example:

  ```
  user: user
  ```

- **provider**
  object

  Required value

  Parameters for connecting to the vCenter.

  - **provider.insecure**
    boolean

    Set to `true` if vCenter has a self-signed certificate.

    Default: `false`

  - **provider.password**
    string

    Required value

    The user’s password.

  - **provider.server**
    string

    Required value

    The host or the IP address of the vCenter server.

  - **provider.username**
    string

    Required value

    Username.

    > **Warning.** Make sure to specify the username together with the domain, for example: `username@domain.local`.
    >
    > You can find the correct domain in the vCenter control panel.

- **region**
  string

  Required value

  Is a tag added to the vSphere Datacenter where all actions will occur: provisioning VirtualMachines, storing virtual disks on datastores, connecting to the network.

- **regionTagCategory**
  string

  Required value

  The name of the tag category used to identify the region (vSphere Datacenter).

  Default: `k8s-region`

- **sshPublicKey**

string

Required value

A public key for accessing nodes.

- **storagePolicyID**
  string

  ID of the SPBM (Storage Policy Based Management) storage policy.

- **useNestedResourcePool**
  boolean

  Create nested resource pool (`true`) or use main resource pool (`false`).

  Default: `true`

- **vmFolderExists**
  boolean

  Set the value to `true` if the path specified in `vmFolderPath` exists. Installing more than one cluster in a folder is not possible.

  Default: `false`

- **vmFolderPath**
  string

  Required value

  The path to the VirtualMachine Folder where the cloned VMs will be created.

  Example:

  ```
  vmFolderPath: dev/test
  ```

- **zoneTagCategory**
  string

  Required value

  The name of the tag category used to identify the zone (vSphere Cluster).

  Default: `k8s-zone`

- **zones**
  array of strings

  Required value

  The globally restricted set of zones that this Cloud Provider works with.

Preparing environment

> **i** The module lifecycle stage: General Availability

Environment requirements

The following prerequisites must be met for Deckhouse Kubernetes Platform to work correctly with VMware vSphere:

- Access to vCenter;
- A user account with the required set of privileges;
- Tags and tag categories created in vSphere;
- Networks with DHCP and Internet access;
- Shared Datastore resources available on all ESXi hosts in use;
- vSphere version `7.x` or `8.x` with support for `Online volume expansion`;
- vCenter accessible from inside the cluster from the master nodes;
- A configured Datacenter that includes the following objects:
  1. VirtualMachine template:
     - The virtual machine image must use `Virtual machines with hardware version 15 or later` — this is required for online resize support.
     - The image must include the `open-vm-tools`, `cloud-init`, and `cloud-init-vmware-guestinfo` packages if the `cloud-init` version is lower than `21.3`.
  2. Network:
     - The network must be available on all ESXi hosts where virtual machines are planned to be created.
  3. Datastore (one or more):
     - The Datastore must be connected to all ESXi hosts where virtual machines are planned to be created.
     - A tag from the category specified in the `zoneTagCategory` parameter must be assigned to the Datastore (default: `k8s-zone`). This tag defines the zone.
     - All Cluster objects within the same zone must have access to all Datastore objects in that zone.
  4. Cluster:
     - All ESXi hosts in use must be added to the Cluster.
     - A tag from the category specified in the `zoneTagCategory` parameter must be assigned to the Cluster (default: `k8s-zone`). This tag defines the zone.
  5. Folder for the virtual machines being created:

    - This parameter is optional.
    - By default, the root virtual machine folder is used.
  6. Role:
    - The role must include the required set of privileges.
  7. User:
    - The user must be assigned the role specified in the previous item.
- A tag from the category specified in the `regionTagCategory` parameter must be assigned to the created Datacenter (default: `k8s-region`). This tag defines the region.

List of required vSphere resources

- **User** with required set of privileges.
- **Network** with DHCP server and access to the Internet.
- **Datacenter** with a tag in `k8s-region` category.
- **Cluster** with a tag in `k8s-zone` category.
- **Datastore** with required tags.
- **Template** — prepared VM image.

List of required privileges

> **i** Read the Configuration via vSphere Client and Configuration via govc sections for details on how to create and assign a role to a user.

A detailed list of privileges required for Deckhouse Kubernetes Platform to work in vSphere:

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

—	— (assigned by default when creating a role)	`System.Anonymous`
		`System.Read`
		`System.View`
			Basic access to vSphere Inventory objects required for all Deckhouse vSphere integration components.

Cns	Searchable	`Cns.Searchable`	Search and mapping of Container Native Storage objects when the CSI driver works with Kubernetes volumes.

Datastore	Allocate space,
	Browse datastore,
	Low level file operations
		`Datastore.AllocateSpace`
		`Datastore.Browse`
		`Datastore.FileManagement`
			Disk provisioning when creating virtual machines and ordering `PersistentVolumes` in the cluster.

Folder	Create folder,
	Delete folder,
	Move folder,
	Rename folder
		`Folder.Create`
		`Folder.Delete`
		`Folder.Move`
		`Folder.Rename`
			Grouping a Deckhouse Kubernetes Platform cluster in a single `Folder` in vSphere Inventory.

Global	Global tag, System tag	`Global.GlobalTag` `Global.SystemTag`	Access to global and system tags used by Deckhouse Kubernetes Platform when working with vSphere objects.

vSphere Tagging	Assign or Unassign vSphere Tag,
	Assign or Unassign vSphere Tag on Object,
	Create vSphere Tag,
	Create vSphere Tag Category,
	Delete vSphere Tag,
	Delete vSphere Tag Category,
	Edit vSphere Tag,
	Edit vSphere Tag Category,
	Modify UsedBy Field for Category,
	Modify UsedBy Field for Tag
		`InventoryService.Tagging.AttachTag`
		`InventoryService.Tagging.ObjectAttachable`
		`InventoryService.Tagging.CreateTag`
		`InventoryService.Tagging.CreateCategory`
		`InventoryService.Tagging.DeleteTag`
		`InventoryService.Tagging.DeleteCategory`
		`InventoryService.Tagging.EditTag`
		`InventoryService.Tagging.EditCategory`
		`InventoryService.Tagging.ModifyUsedByForCategory`
		`InventoryService.Tagging.ModifyUsedByForTag`
			Deckhouse Kubernetes Platform uses tags to identify the `Datacenter`, `Cluster`, and `Datastore` objects available to it, as well as to identify the virtual machines under its control.

Network	Assign network	`Network.Assign`	Connecting networks and port groups to Deckhouse Kubernetes Platform cluster virtual machines.

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

Resource	Assign virtual machine to resource pool,
	Create resource pool,
	Modify resource pool,
	Remove resource pool,
	Rename resource pool
		`Resource.AssignVMToPool`
		`Resource.CreatePool`
		`Resource.DeletePool`
		`Resource.EditPool`
		`Resource.RenamePool`
			Placement of Deckhouse Kubernetes Platform cluster virtual machines into the target resource pool and management of this pool.

VM Storage Policies (*Profile-driven Storage Privileges* in vSphere 7)	View VM storage policies (*Profile-driven storage view* in vSphere 7)	`StorageProfile.View`	Viewing storage policies used when creating virtual machines and dynamically provisioning volumes in the cluster.

vApp	Add virtual machine,
	Assign resource pool,
	Create,
	Delete,
	Import,
	Power Off,
	Power On,
	View OVF Environment,
	vApp application configuration,
	vApp instance configuration,
	vApp resource configuration
		`VApp.ApplicationConfig`
		`VApp.AssignResourcePool`
		`VApp.AssignVM`
		`VApp.Create`
		`VApp.Delete`
		`VApp.ExtractOvfEnvironment`
		`VApp.Import`
		`VApp.InstanceConfig`
		`VApp.PowerOff`
		`VApp.PowerOn`
		`VApp.ResourceConfig`
			Managing operations related to deployment and configuration of vApp and OVF templates used when creating virtual machines.

Virtual Machine > Change Configuration	Add existing disk,
	Add new disk,
	Add or remove device,
	Advanced configuration,
	Set annotation,
	Change CPU count,
	Toggle disk change tracking,
	Extend virtual disk,
	Acquire disk lease,
	Modify device settings,
	Configure managedBy,
	Change Memory,
	Query unowned files,
	Configure Raw device,
	Reload from path,
	Remove disk,
	Rename,
	Reset guest information,
	Change resource,
	Change Settings,
	Change Swapfile placement,
	Upgrade virtual machine compatibility
		`VirtualMachine.Config.AddExistingDisk`
		`VirtualMachine.Config.AddNewDisk`
		`VirtualMachine.Config.AddRemoveDevice`
		`VirtualMachine.Config.AdvancedConfig`
		`VirtualMachine.Config.Annotation`
		`VirtualMachine.Config.CPUCount`
		`VirtualMachine.Config.ChangeTracking`
		`VirtualMachine.Config.DiskExtend`
		`VirtualMachine.Config.DiskLease`
		`VirtualMachine.Config.EditDevice`
		`VirtualMachine.Config.ManagedBy`
		`VirtualMachine.Config.Memory`
		`VirtualMachine.Config.QueryUnownedFiles`
		`VirtualMachine.Config.RawDevice`
		`VirtualMachine.Config.ReloadFromPath`
		`VirtualMachine.Config.RemoveDisk`
		`VirtualMachine.Config.Rename`
		`VirtualMachine.Config.ResetGuestInfo`
		`VirtualMachine.Config.Resource`
		`VirtualMachine.Config.Settings`
		`VirtualMachine.Config.SwapPlacement`
		`VirtualMachine.Config.UpgradeVirtualHardware`
			Managing the lifecycle of Deckhouse Kubernetes Platform cluster virtual machines.

Virtual Machine > Edit Inventory	Create new,
	Create from existing,
	Remove,
	Move
		`VirtualMachine.Inventory.Create`
		`VirtualMachine.Inventory.CreateFromExisting`
		`VirtualMachine.Inventory.Delete`
		`VirtualMachine.Inventory.Move`
			Creating, deleting, and moving Deckhouse Kubernetes Platform cluster virtual machines in vSphere Inventory.

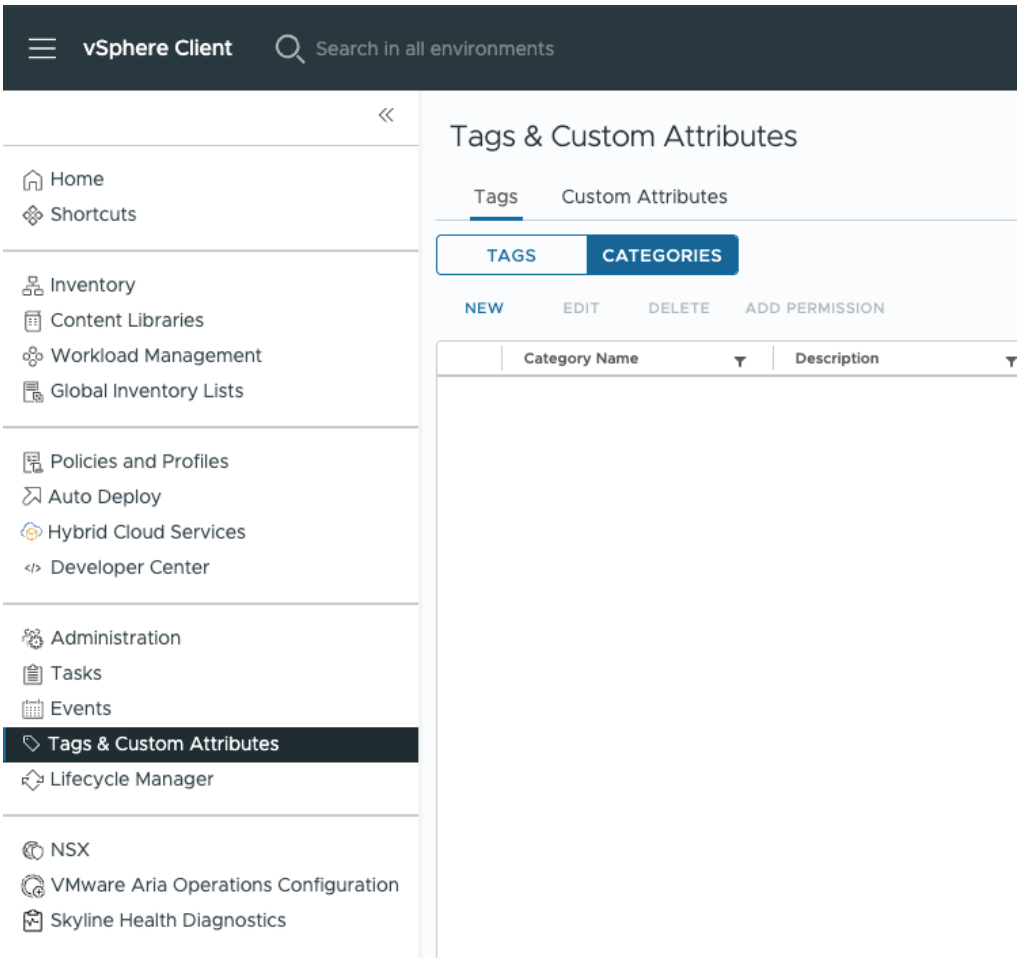
Virtual Machine > Guest Operations	Guest Operation Queries	`VirtualMachine.GuestOperations.Query`	Retrieving information from the guest operating system of virtual machines.

Privilege category in UI	Privileges in UI	Privileges in API	Purpose in Deckhouse

Virtual Machine > Interaction	Answer question,
	Device connection,
	Guest operating system management by VIX API,
	Power Off,
	Power On,
	Reset,
	Configure CD media,
	Install VMware Tools
		`VirtualMachine.Interact.AnswerQuestion`
		`VirtualMachine.Interact.DeviceConnection`
		`VirtualMachine.Interact.GuestControl`
		`VirtualMachine.Interact.PowerOff`
		`VirtualMachine.Interact.PowerOn`
		`VirtualMachine.Interact.Reset`
		`VirtualMachine.Interact.SetCDMedia`
		`VirtualMachine.Interact.ToolsInstall`
			Managing virtual machine power state, device connections, and interaction with the guest operating system.

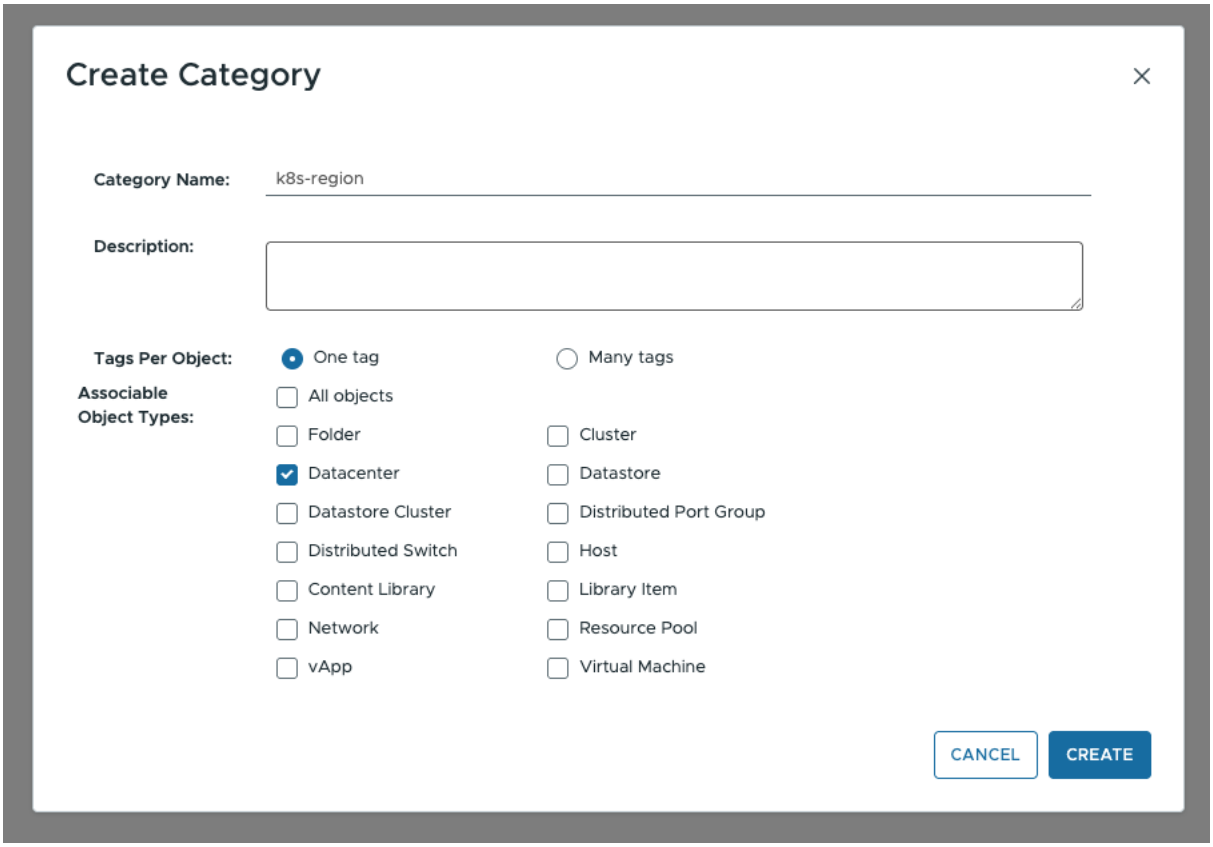
Virtual Machine > Provisioning	Clone virtual machine,
	Customize guest,
	Deploy template,
	Allow virtual machine download,
	Allow virtual machine files upload,
	Read customization specifications
		`VirtualMachine.Provisioning.Clone`
		`VirtualMachine.Provisioning.Customize`
		`VirtualMachine.Provisioning.DeployTemplate`
		`VirtualMachine.Provisioning.GetVmFiles`
		`VirtualMachine.Provisioning.PutVmFiles`
		`VirtualMachine.Provisioning.ReadCustSpecs`
			Cloning virtual machine templates, customizing them, and deploying them when creating Deckhouse Kubernetes Platform cluster nodes.

Virtual Machine > Snapshot Management	Create snapshot,
	Remove Snapshot,
	Rename Snapshot
		`VirtualMachine.State.CreateSnapshot`
		`VirtualMachine.State.RemoveSnapshot`
		`VirtualMachine.State.RenameSnapshot`
			Managing snapshots of virtual machines and volumes in scenarios where this functionality is used by platform components.



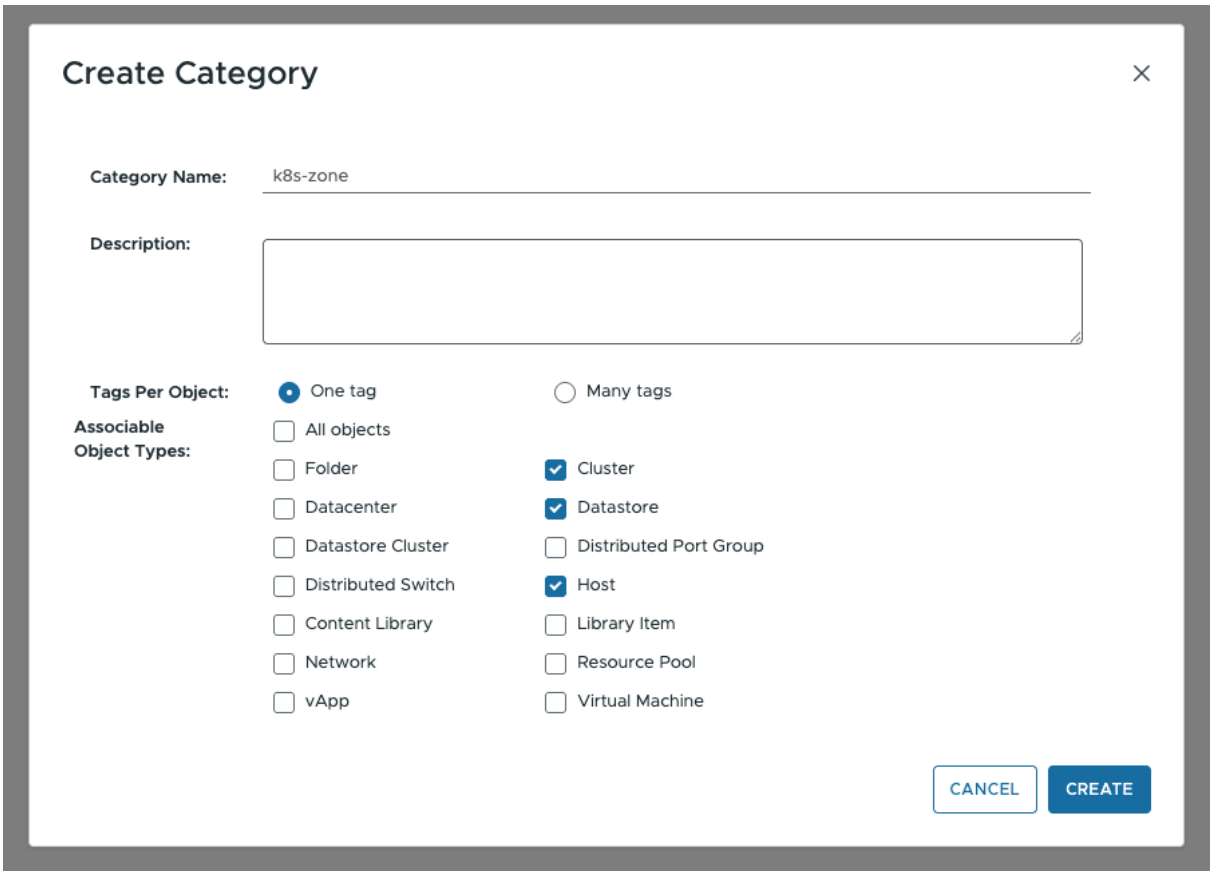
vSphere configuration

Configuration in vSphere Client

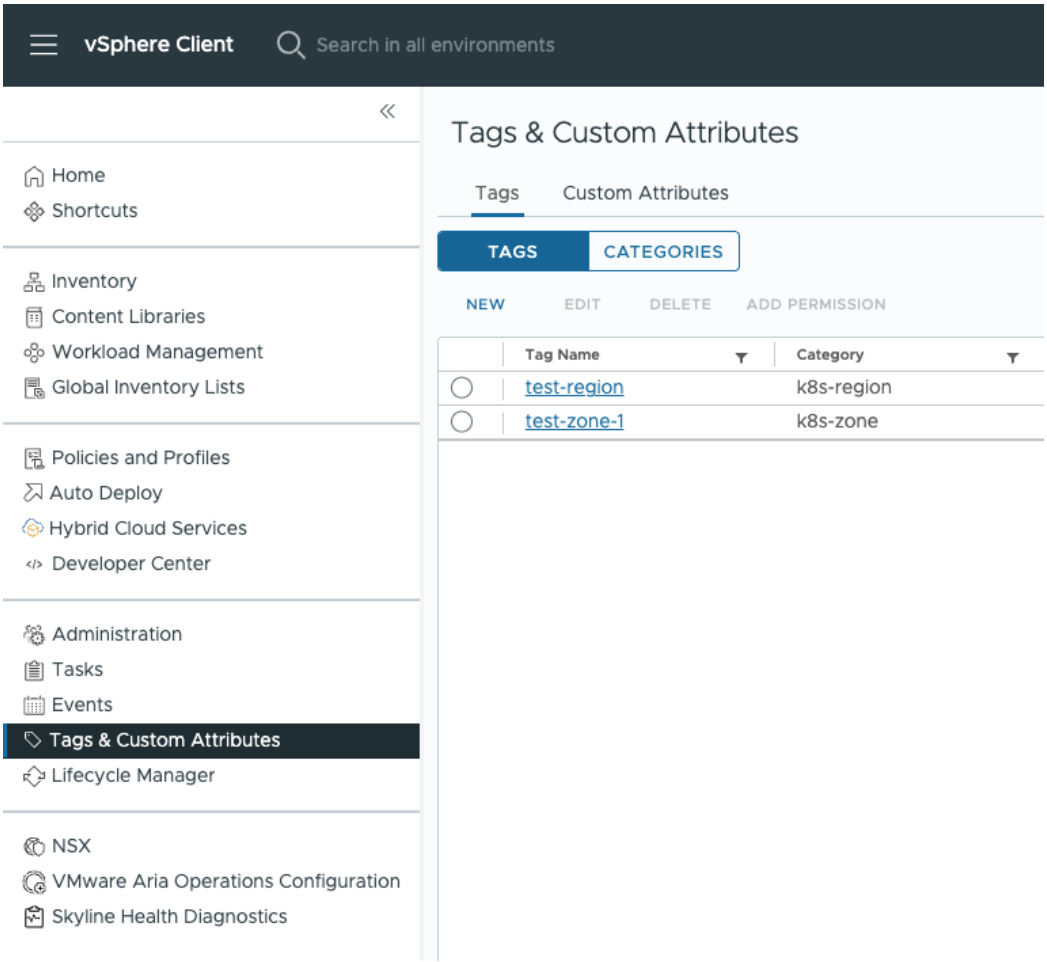


Creating tags and tag categories in vSphere Client

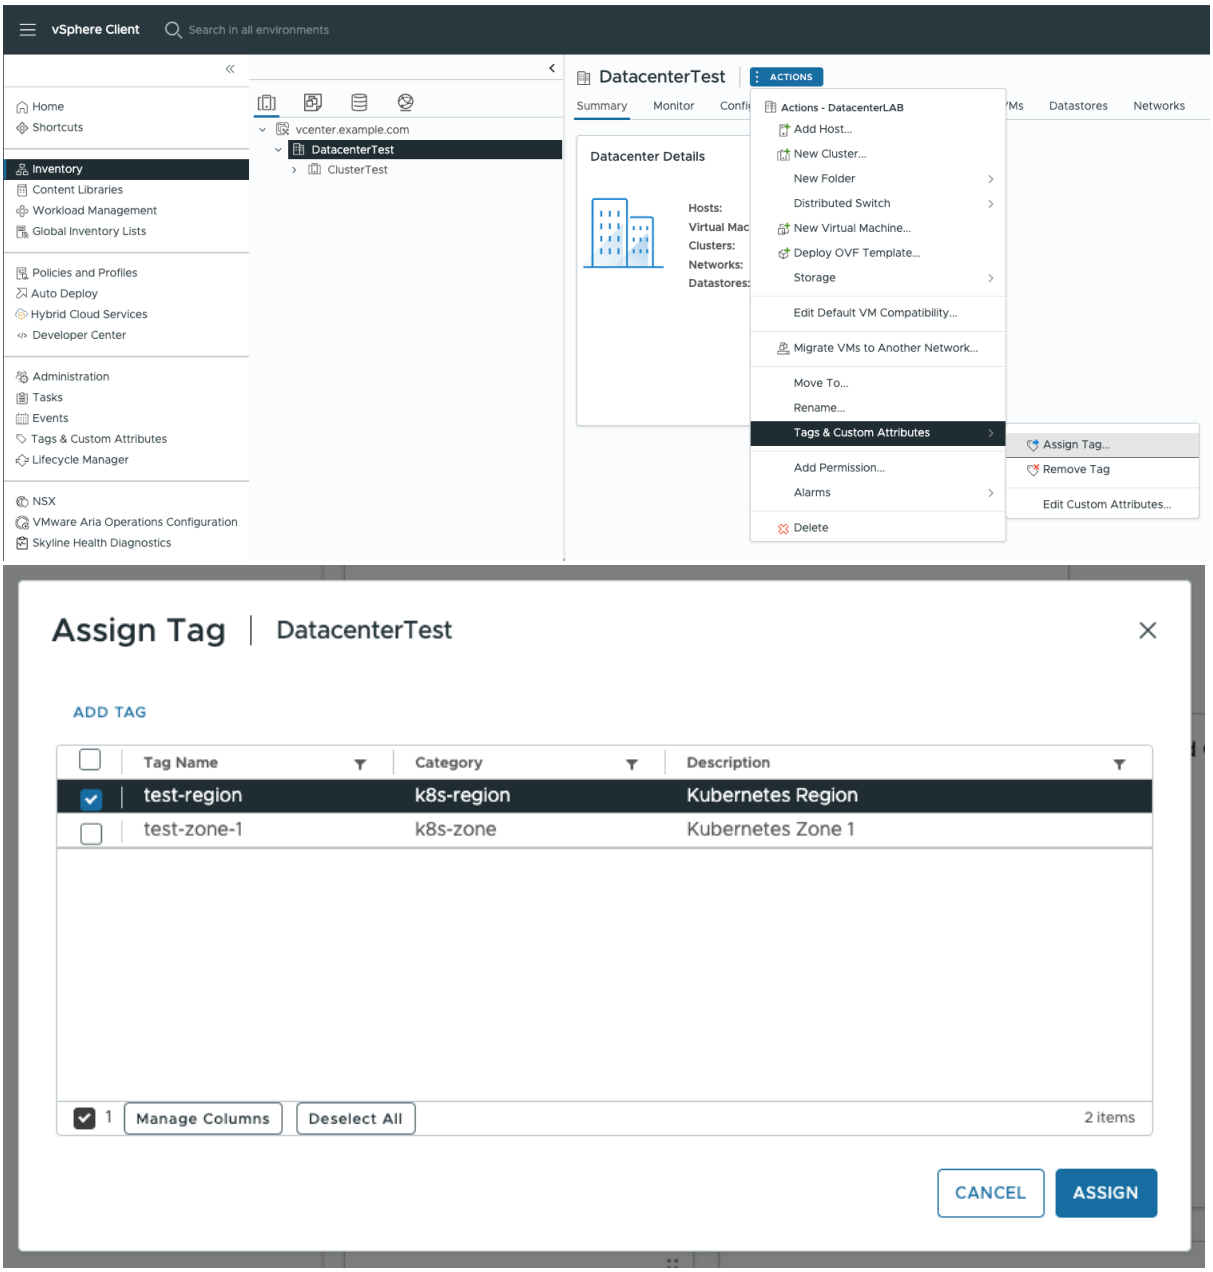
VMware vSphere does not have built-in concepts of a “region” or a “zone”. In vSphere, a Datacenter acts as a region, and a Cluster acts as a zone. Tags are used to establish this mapping.



1. Open vSphere Client and go to “Menu” → “Tags & Custom Attributes” → “Tags”.

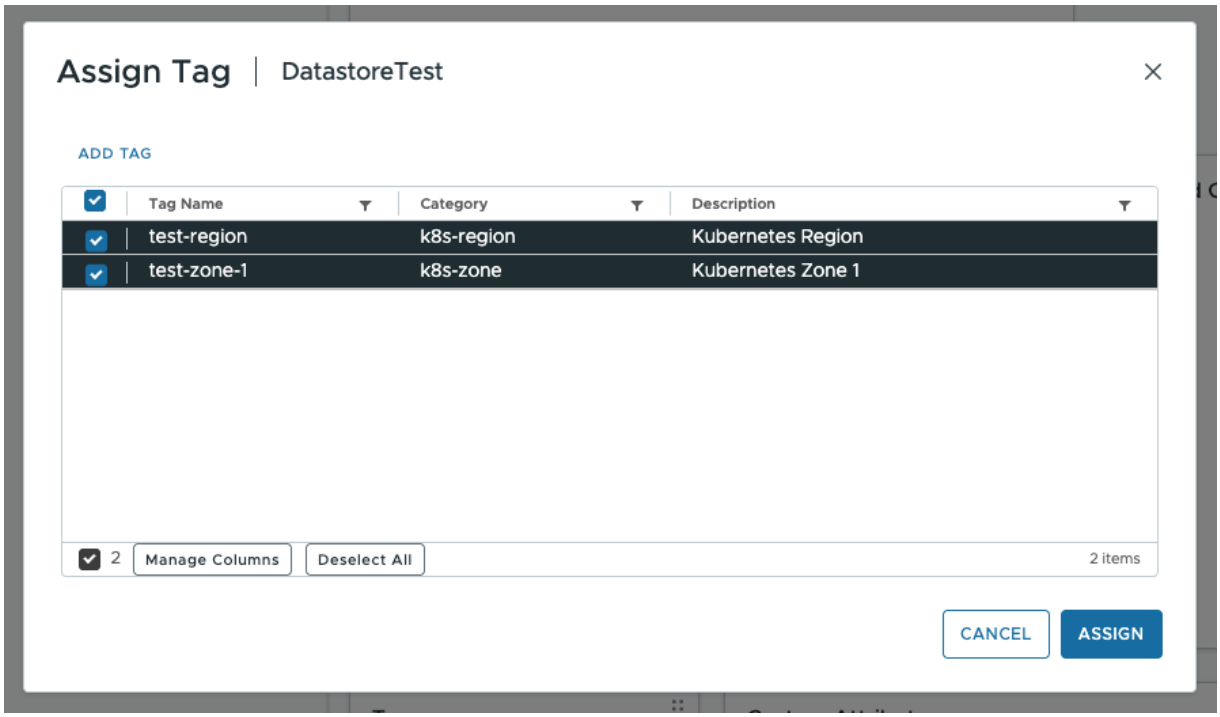


2. Open the “Categories” tab and click “NEW”. Create a category for regions (for example, `k8s-region`): set “Tags Per Object” to “One tag” and specify the applicable object types, including Datacenter.



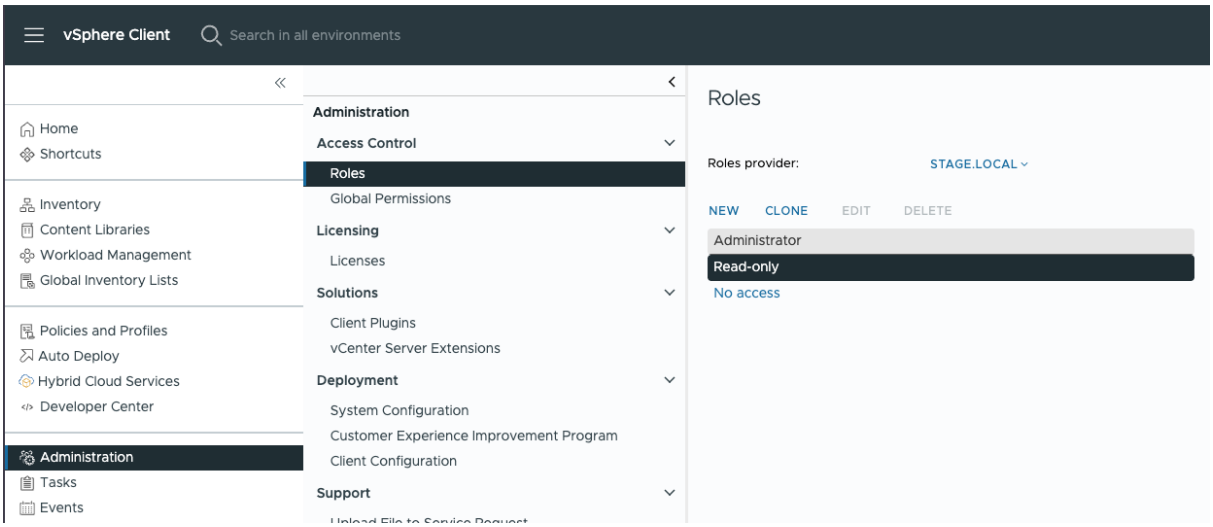
3. Create a second category for zones (for example, `k8s-zone`) with the object types Host, Cluster, and Datastore.

4. Go to the “Tags” tab and create at least one tag in the region category and one tag in the zone category (for example, `test-region`, `test-zone-1`).



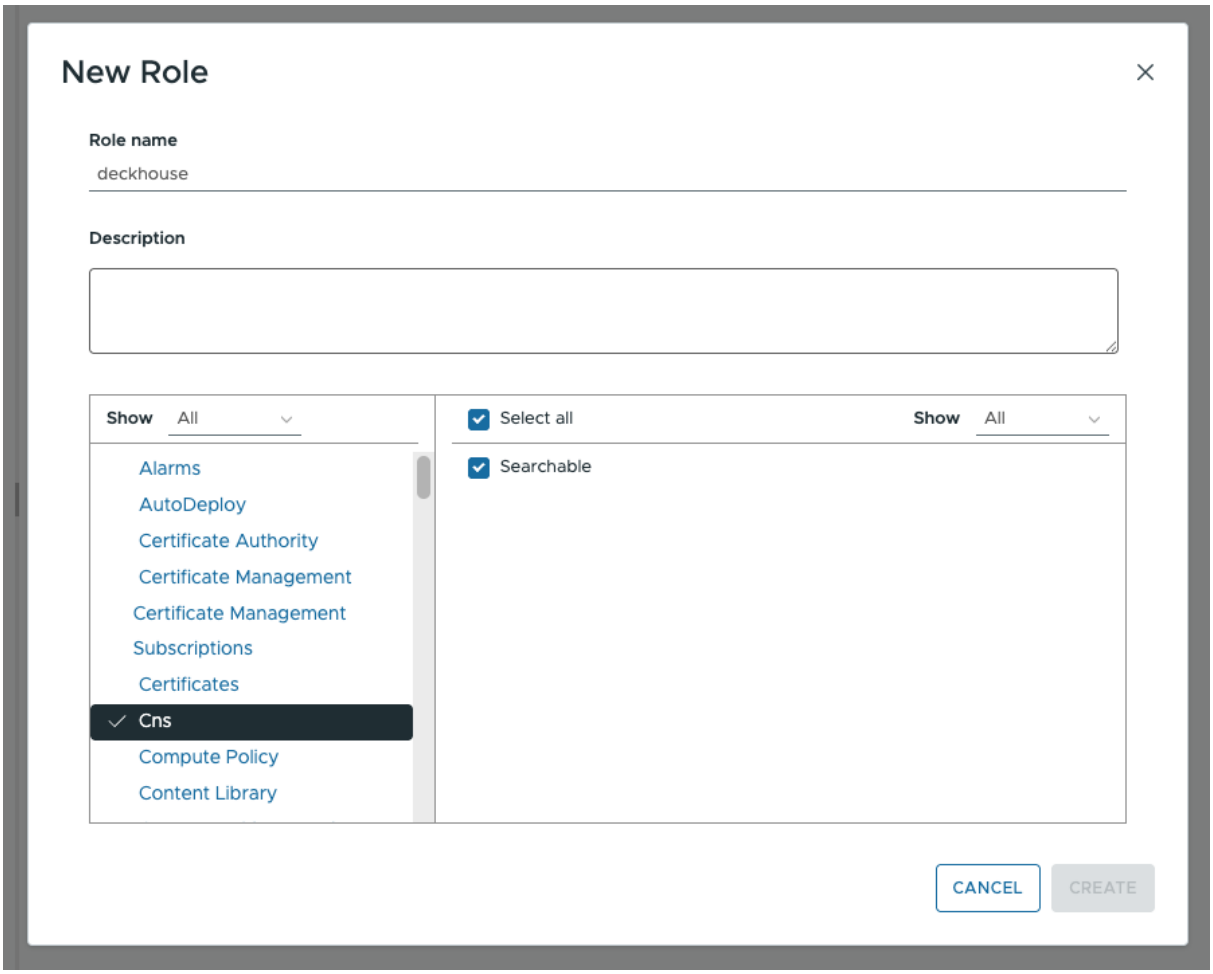
5. In the “Inventory” tab, select the target Datacenter, open the “Summary” panel, then choose “Actions” → “Tags & Custom Attributes” → “Assign Tag” and assign the region tag. Repeat this step for each Cluster that will host nodes, assigning the appropriate zone tags.

Configuring Datastore in vSphere Client

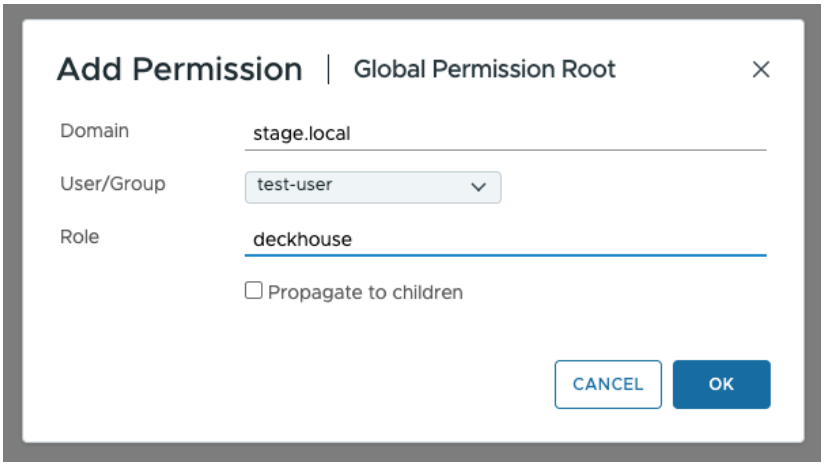


> ⚠ For dynamic provisioning of PersistentVolume, the Datastore must be available on **every** ESXi host in the zone (shared datastore).

In the “Inventory” tab, select the Datastore, open the “Summary” panel, then choose “Actions” → “Tags & Custom Attributes” → “Assign Tag”. Assign the Datastore the same region tag as the corresponding Datacenter, and the same zone tag as the corresponding Cluster.



Creating and assigning a role in vSphere Client



1. Go to “Menu” → “Administration” → “Access Control” → “Roles”.

2. Click “NEW”, enter a role name (for example, `deckhouse`), and add the privileges from the list.

3. Assign the role to the Deckhouse service account: go to “Menu” → “Administration” → “Access Control” → “Global Permissions”, click “ADD”, and select the user and the `deckhouse` role.

Configuration via govc

Installing govc

To continue configuring vSphere, install the govc CLI utility.

After installation, set the environment variables required to connect to `vCenter`.

⚠ Make sure to specify the username together with the domain, for example: `username@domain.local`.

```
export GOVC_URL=example.com
export GOVC_USERNAME=<username>@vsphere.local
export GOVC_PASSWORD=<password>
export GOVC_INSECURE=1
```

Creating tags and tag categories with govc

VMware vSphere does not have built-in concepts of a “region” or a “zone”. In vSphere, a Datacenter acts as a region, and a Cluster acts as a zone. Tags are used to establish this mapping.

Create tag categories with the following commands:

```
govc tags.category.create -d "Kubernetes Region" k8s-region
govc tags.category.create -d "Kubernetes Zone" k8s-zone
```

Create tags in each category. If you intend to use multiple “zones” (Cluster), create a tag for each one of them:

```
govc tags.create -d "Kubernetes Region" -c k8s-region test-region
govc tags.create -d "Kubernetes Zone Test 1" -c k8s-zone test-zone-1
govc tags.create -d "Kubernetes Zone Test 2" -c k8s-zone test-zone-2
```

Attach the “region” tag to Datacenter:

```
govc tags.attach -C k8s-region test-region /<DatacenterName>
```

Attach “zone” tags to the Cluster objects:

```
govc tags.attach -C k8s-zone test-zone-1 /<DatacenterName>/host/<ClusterName1>
govc tags.attach -C k8s-zone test-zone-2 /<DatacenterName>/host/<ClusterName2>
```

Datastore configuration with govc

⚠ For dynamic PersistentVolume provisioning, a Datastore must be available on **each** ESXi host (shared datastore).

Assign the “region” and “zone” tags to the Datastore objects to automatically create a StorageClass in the Kubernetes cluster:

```
govc tags.attach -C k8s-region test-region /<DatacenterName>/datastore/<DatastoreName1>
govc tags.attach -C k8s-zone test-zone-1 /<DatacenterName>/datastore/<DatastoreName1>

govc tags.attach -C k8s-region test-region /<DatacenterName>/datastore/<DatastoreName2>
govc tags.attach -C k8s-zone test-zone-2 /<DatacenterName>/datastore/<DatastoreName2>
```

Creating and assigning a role with govc

i We’ve intentionally skipped User creation since there are many ways to authenticate a user in the vSphere.

The role described below includes the privileges from the list of required privileges section. If you need a more granular Role, please contact your Deckhouse support.

Create a role with the required privileges:

```
govc role.create deckhouse \
    Cns.Searchable \
    Datastore.AllocateSpace Datastore.Browse Datastore.FileManagement \
    Folder.Create Folder.Delete Folder.Move Folder.Rename \
    Global.GlobalTag Global.SystemTag \
    InventoryService.Tagging.AttachTag InventoryService.Tagging.CreateCategory \
    InventoryService.Tagging.CreateTag InventoryService.Tagging.DeleteCategory \
    InventoryService.Tagging.DeleteTag InventoryService.Tagging.EditCategory \
    InventoryService.Tagging.EditTag InventoryService.Tagging.ModifyUsedByForCategory \
    InventoryService.Tagging.ModifyUsedByForTag InventoryService.Tagging.ObjectAttachable \
    Network.Assign \
    Resource.AssignVMToPool Resource.CreatePool Resource.DeletePool Resource.EditPool Resource.RenamePool \
    StorageProfile.View \
    System.Anonymous System.Read System.View \
    VApp.ApplicationConfig VApp.AssignResourcePool VApp.AssignVM VApp.Create VApp.Delete \
    VApp.ExtractOvfEnvironment VApp.Import VApp.InstanceConfig VApp.PowerOff VApp.PowerOn VApp.ResourceConfig \
    VirtualMachine.Config.AddExistingDisk VirtualMachine.Config.AddNewDisk VirtualMachine.Config.AddRemoveDevice \
    VirtualMachine.Config.AdvancedConfig VirtualMachine.Config.Annotation VirtualMachine.Config.CPUCount \
    VirtualMachine.Config.ChangeTracking VirtualMachine.Config.DiskExtend VirtualMachine.Config.DiskLease \
    VirtualMachine.Config.EditDevice VirtualMachine.Config.ManagedBy VirtualMachine.Config.Memory \
    VirtualMachine.Config.QueryUnownedFiles VirtualMachine.Config.RawDevice VirtualMachine.Config.ReloadFromPath \
    VirtualMachine.Config.RemoveDisk VirtualMachine.Config.Rename VirtualMachine.Config.ResetGuestInfo \
    VirtualMachine.Config.Resource VirtualMachine.Config.Settings VirtualMachine.Config.SwapPlacement \
    VirtualMachine.Config.UpgradeVirtualHardware \
    VirtualMachine.GuestOperations.Query \
    VirtualMachine.Interact.AnswerQuestion VirtualMachine.Interact.DeviceConnection \
    VirtualMachine.Interact.GuestControl VirtualMachine.Interact.PowerOff VirtualMachine.Interact.PowerOn \
    VirtualMachine.Interact.Reset VirtualMachine.Interact.SetCDMedia VirtualMachine.Interact.ToolsInstall \
    VirtualMachine.Inventory.Create VirtualMachine.Inventory.CreateFromExisting VirtualMachine.Inventory.Delete \
    VirtualMachine.Inventory.Move \
    VirtualMachine.Provisioning.Clone VirtualMachine.Provisioning.Customize VirtualMachine.Provisioning.DeployTemplate \
    VirtualMachine.Provisioning.GetVmFiles VirtualMachine.Provisioning.PutVmFiles VirtualMachine.Provisioning.ReadCustSpecs
\
    VirtualMachine.State.CreateSnapshot VirtualMachine.State.RemoveSnapshot VirtualMachine.State.RenameSnapshot
```

Assign the role to a user on the vCenter object.

⚠ Make sure to specify the username together with the domain, for example: `username@domain.local`.

```
govc permissions.set -principal <username>@vsphere.local -role deckhouse /
```

i For more detailed permission configuration, refer to the official documentation.

VM image requirements

To create a VM template (`Template`), it is recommended to use a ready-made cloud image/OVA file provided by the OS vendor:

- **Ubuntu**
- **Debian**
- **CentOS**
- **Rocky Linux** (section *Generic Cloud / OpenStack*)

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Preparing the virtual machine image

⚠ Disable VMware Guest OS Customization (and any vApp/OS customization mechanisms, if applicable in your setup) for the template and the cluster virtual machines. DKP performs the initial node configuration via `cloud-init` (VMware GuestInfo datasource). Enabled customization can conflict with `cloud-init` and lead to incorrect node initialization.

1. Install the required packages:

   If you use `cloud-init` version lower than 21.3 (VMware GuestInfo support is required):

```
sudo apt-get update
sudo apt-get install -y open-vm-tools cloud-init cloud-init-vmware-guestinfo
```

If you use `cloud-init` version 21.3 or higher:

```
sudo apt-get update
sudo apt-get install -y open-vm-tools cloud-init
```

2. Verify that the `disable_vmware_customization: false` parameter is set in `/etc/cloud/cloud.cfg`.
3. Make sure the `default_user` parameter is specified in `/etc/cloud/cloud.cfg`. It is required to add an SSH key when the VM starts.
4. Add the VMware GuestInfo datasource — create `/etc/cloud/cloud.cfg.d/99-DataSourceVMwareGuestInfo.cfg`:

```
datasource:
  VMware:
    vmware_cust_file_max_wait: 10
```

5. Before creating the VM template, reset the `cloud-init` identifiers and state using the following commands:

```
truncate -s 0 /etc/machine-id &&
rm /var/lib/dbus/machine-id &&
ln -s /etc/machine-id /var/lib/dbus/machine-id
```

6. Clear `cloud-init` event logs:

```
cloud-init clean --logs --seed
```

⚠ After the virtual machine starts, the following services related to the packages installed during `cloud-init` preparation must be running:

- `cloud-config.service`,
- `cloud-final.service`,
- `cloud-init.service`.

To ensure that the services are enabled, use the command:

```
systemctl is-enabled cloud-config.service cloud-init.service cloud-final.service
```

Example output for enabled services:

```
enabled
enabled
enabled
```

i DKP creates VM disks of type `eagerZeroedThick`, but the type of disks of created VMs may be changed without notification according to the `VM Storage Policy` settings in vSphere.
For more details, see the documentation.

i DKP uses the `ens192` interface as the default interface for VMs in vSphere. Therefore, when using static IP addresses in `mainNetwork`, you must create an interface named `ens192` in the OS image as the default interface.

Infrastructure

Networking

A VLAN with DHCP and Internet access is required for the running cluster:

- If the VLAN is public (public addresses), then you have to create a second network to deploy cluster nodes (DHCP is not needed in this network).
- If the VLAN is private (private addresses), then this network can be used for cluster nodes.

Inbound traffic

- You can use an internal load balancer (if present) and direct traffic directly to the front nodes of the cluster.
- If there is no load balancer, you can use MetalLB in BGP mode to organize fault-tolerant load balancers (recommended). In this case, front nodes of the cluster will have two interfaces. For this, you will need:
  - A dedicated VLAN for traffic exchange between BGP routers and MetalLB. This VLAN must have DHCP and Internet access.
  - IP addresses of BGP routers.

- ASN — the AS number on the BGP router.
- ASN — the AS number in the cluster.
- A range to announce addresses from.

Using the datastore

Various types of storage can be used in the cluster; for the minimum configuration, you will need:

- Datastore for provisioning PersistentVolumes to the Kubernetes cluster.
- Datastore for provisioning root disks for the VMs (it can be the same Datastore as for PersistentVolume).

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

VsphereInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of vSphere VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines' secondary NICs will connect to. Relative to the datacenter.

    Examples:

    ```
    additionalNetworks: DEVOPS_32
    ```

    ```
    additionalNetworks: DEVOPS_50
    ```

  - **spec.datastore**
    string

    Path to a Datastore (relative to the datacenter) in which VirtualMachines will be cloned.

    By default, a datastore from the `master` InstanceClass is used.

    Example:

    ```
    datastore: lun-1201
    ```

  - **spec.disableTimesync**
    boolean

    Disable time synchronization in Guest VM.

    > **i** **Note:** this won't disable any NTP daemons running on the guest OS, it only disables time synchronization from ESXi.

    Default: `true`

  - **spec.mainNetwork**
    string

    Path to the network that VirtualMachines' primary NICs will connect to (default gateway). Relative to the datacenter.

    If no value is specified, the value specified in `VsphereClusterConfiguration` will be used.

    Example:

    ```
    mainNetwork: k8s-msk-178
    ```

  - **spec.memory**

integer

Required value

Memory in MiB to allocate to vSphere VirtualMachines.

Example:

```
memory: 8192
```

- **spec.numCPUs**
integer

  Required value

  Count of vCPUs to allocate to vSphere VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **spec.resourcePool**
string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  By default, the value from `VsphereCloudDiscoveryData` is used.

  Example:

  ```
  resourcePool: rp-2012
  ```

- **spec.rootDiskSize**
integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Default: `20`

  Example:

  ```
  rootDiskSize: 20
  ```

- **spec.runtimeOptions**
object

  Additional VM’s parameters.

  - **spec.runtimeOptions.cpuLimit**
  integer

    CPU limit in MHz.

  - **spec.runtimeOptions.cpuReservation**
  integer

    CPU reservation in MHz.

  - **spec.runtimeOptions.cpuShares**
  integer

    The relative amount of CPU Shares for VMs to be created.

  - **spec.runtimeOptions.memoryLimit**
  integer

    Memory limit in MB.

  - **spec.runtimeOptions.memoryReservation**
  integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Default: `80`

    Allowed values: `0 <= X <= 100`

  - **spec.runtimeOptions.memoryShares**
  integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **spec.runtimeOptions.nestedHardwareVirtualization**
  boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

  - **spec.template**
    string

    Path to the template to be cloned. Relative to the datacenter.

    By default, a template from the `master` InstanceClass is used.

    Example:

    ```
    template: dev/golden_image
    ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of vSphere VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalNetworks**
    array of strings

    Paths to networks that VirtualMachines' secondary NICs will connect to. Relative to the datacenter.

    Examples:

    ```
    additionalNetworks: DEVOPS_32
    ```

    ```
    additionalNetworks: DEVOPS_50
    ```

  - **spec.datastore**
    string

    Path to a Datastore (relative to the datacenter) in which VirtualMachines will be cloned.

    By default, a datastore from the `master` InstanceClass is used.

    Example:

    ```
    datastore: lun-1201
    ```

  - **spec.disableTimesync**
    boolean

    Disable time synchronization in Guest VM.

    > **i** **Note:** this won't disable any NTP daemons running on the guest OS, it only disables time synchronization from ESXi.

    Default: `true`

  - **spec.mainNetwork**
    string

    Path to the network that VirtualMachines' primary NICs will connect to (default gateway). Relative to the datacenter.

    If no value is specified, the value specified in `VsphereClusterConfiguration` will be used.

    Example:

    ```
    mainNetwork: k8s-msk-178
    ```

  - **spec.memory**
    integer

    Required value

    Memory in MiB to allocate to vSphere VirtualMachines.

    Example:

    ```
    memory: 8192
    ```

  - **spec.numCPUs**
    integer

    Required value

Count of vCPUs to allocate to vSphere VirtualMachines.

Example:

```
numCPUs: 2
```

- **spec.resourcePool**
  string

  Path to a Resource Pool in which VirtualMachines will be cloned. Relative to the zone (vSphere Cluster).

  By default, the value from `VsphereCloudDiscoveryData` is used.

  Example:

  ```
  resourcePool: rp-2012
  ```

- **spec.rootDiskSize**
  integer

  Root disk size in GiB to use in vSphere VirtualMachines.

  The disk will be automatically enlarged if its size in the template is less than specified.

  Default: `20`

  Example:

  ```
  rootDiskSize: 20
  ```

- **spec.runtimeOptions**
  object

  Additional VM’s parameters.

  - **spec.runtimeOptions.cpuLimit**
    integer

    CPU limit in MHz.

  - **spec.runtimeOptions.cpuReservation**
    integer

    CPU reservation in MHz.

  - **spec.runtimeOptions.cpuShares**
    integer

    The relative amount of CPU Shares for VMs to be created.

  - **spec.runtimeOptions.memoryLimit**
    integer

    Memory limit in MB.

  - **spec.runtimeOptions.memoryReservation**
    integer

    VM memory reservation in percent (relative to `.spec.memory`).

    Default: `80`

    Allowed values: `0 <= X <= 100`

  - **spec.runtimeOptions.memoryShares**
    integer

    The relative amount of Memory Shares for VMs to be created.

    Allowed values: `0 <= X <= 100`

  - **spec.runtimeOptions.nestedHardwareVirtualization**
    boolean

    Whether to enable or disable nested Hardware Assisted Virtualization.

- **spec.template**
  string

  Path to the template to be cloned. Relative to the datacenter.

  By default, a template from the `master` InstanceClass is used.

  Example:

  ```
  template: dev/golden_image
  ```

- **status**
  object

- **status.nodeGroupConsumers**
  array of strings

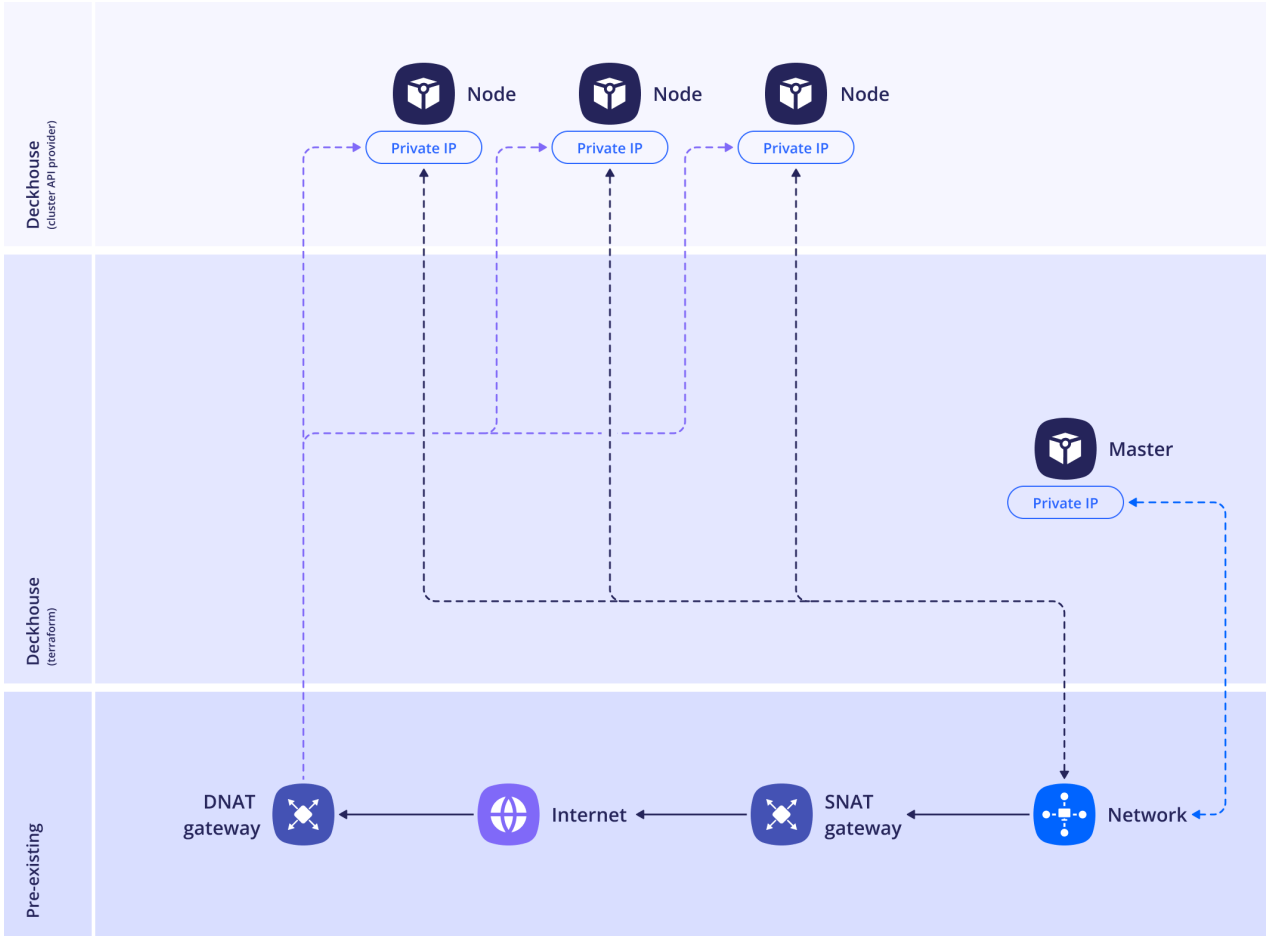
Examples

> **i** The module lifecycle stage: General Availability

Below is an example configuration for a VMware vSphere cloud provider.

An example of the configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-vsphere
spec:
  version: 2
  enabled: true
  settings:
    host: vc-3.internal
    username: user
    password: password
    vmFolderPath: dev/test
    insecure: true
    region: moscow-x001
    sshKeys:
    - "ssh-rsa AAAAB3N....6xHJwwj"
    externalNetworkNames:
    - KUBE-3
    - devops-internal
    internalNetworkNames:
    - KUBE-3
    - devops-internal
    nsxt:
      defaultIpPoolName: "External IP Pool"
      tier1GatewayPath: flant_tier1
      user: guestuser1
      password: pass
      host: 1.2.3.4
      insecureFlag: true
      size: SMALL
```



An example of the `VsphereInstanceClass` custom resource

```
apiVersion: deckhouse.io/v1
kind: VsphereInstanceClass
metadata:
  name: test
spec:
  numCPUs: 2
  memory: 2048
  rootDiskSize: 20
  template: dev/golden_image
  mainNetwork: k8s-msk-178
  datastore: <DS_PARENT_FOLDER>/lun-1201 # <DS_PARENT_FOLDER> — parent Datastore folder.
```

Cloud provider - VMware vSphere: Layouts

> **i** The module lifecycle stage: General Availability

Standard

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: VsphereClusterConfiguration
layout: Standard
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
vmFolderPath: dev
regionTagCategory: k8s-region
zoneTagCategory: k8s-zone
region: X1
internalNetworkCIDR: 192.168.199.0/24
masterNodeGroup:
  replicas: 1
  zones:
  - ru-central1-a
  - ru-central1-b
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: dev/golden_image
    datastore: dev/lun_1
    mainNetwork: net3-k8s
nodeGroups:
- name: khm
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: dev/golden_image
    datastore: dev/lun_1
    mainNetwork: net3-k8s
sshPublicKey: "<SSH_PUBLIC_KEY>"
zones:
- ru-central1-a
- ru-central1-b
```

Cloud provider — Yandex Cloud

> **i** The module lifecycle stage: General Availability

The `cloud-provider-yandex` module integrates Deckhouse Kubernetes Platform with Yandex Cloud. It allows the `node-manager` module to use Yandex Cloud resources when provisioning nodes for a NodeGroup.

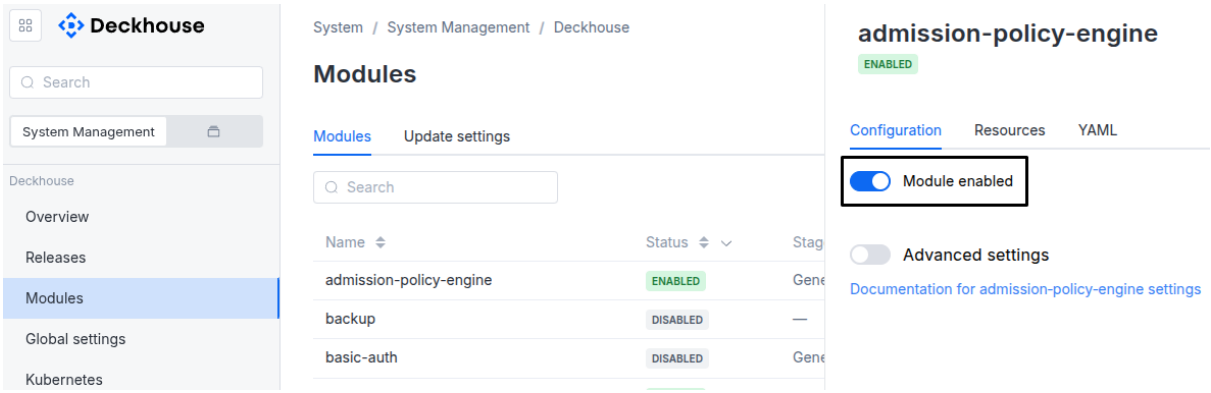
Features of the `cloud-provider-yandex` module:

- Managing Yandex Cloud resources via `cloud-controller-manager`:
  - creates network routes for the `PodNetwork` network on the Yandex Cloud side;
  - creates Network Load Balancers and target groups for Services of the LoadBalancer type;
  - updates instance and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in Yandex Cloud.
- Provisioning disks via the Yandex CSI driver (`yandex.csi.flant.com`) and creating StorageClasses for Yandex Cloud disk types so that PersistentVolumes can be requested from the cluster.
- Provisioning base infrastructure and CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-yandex`.
- Provisioning CloudEphemeral nodes via Machine Controller Manager (MCM) or Cluster API (CAPI). Virtual machine parameters are set in the YandexInstanceClass resource.
- Registering with `node-manager` so that YandexInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. Starting with DKP 1.76, `cni-cilium` is used by default.

> **⚠** The module is migrating CloudEphemeral node management from Machine Controller Manager (MCM) to Cluster API (CAPI). Existing NodeGroups continue to use MCM, while new ones are created with CAPI by default. For migrating existing groups, see How to migrate node groups to Cluster API (CAPI).

Configuration

> **i** The module lifecycle stage: General Availability



> **Note!** If the parameters provided below are changed, the **existing Machines are NOT redeployed** (new machines will be created with the updated parameters). Redeployment is only performed when `NodeGroup` and `YandexInstanceClass` are changed. Details in the node-manager module's documentation.

The module has 3 alerts.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `cloud-provider-yandex` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

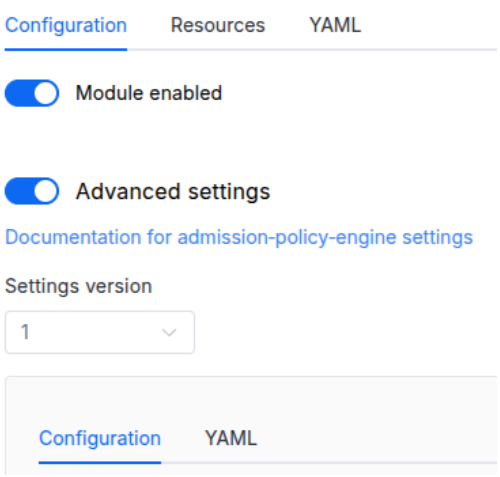
```
d8 system module enable cloud-provider-yandex
```

- **Using ModuleConfig `cloud-provider-yandex`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-yandex` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-yandex`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `cloud-provider-yandex` module and enable the "Advanced Settings" switch. Fill in the required fields in the "Configuration" tab or specify the module settings in YAML format on the "YAML" tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cloud-provider-yandex` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-yandex`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-yandex` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-yandex
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-yandex` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-yandex`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-yandex
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Storage

The module automatically creates StorageClasses covering all available disks in Yandex:

Type	StorageClass Name	Comment
network-hdd	network-hdd	
network-ssd	network-ssd	
network-ssd-nonreplicated	network-ssd-nonreplicated	
network-ssd-io-m3	network-ssd-io-m3	Disk size must be a multiple of 93 GB.

You can filter out the unnecessary StorageClasses via the exclude parameter.

LoadBalancer

The module subscribes to Service objects of the `LoadBalancer` type and creates the corresponding `NetworkLoadBalancer` and `TargetGroup` in Yandex Cloud.

For more information, see the Kubernetes Cloud Controller Manager for Yandex Cloud documentation.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.additionalExternalNetworkIDs**
    array of strings

    A list of Network IDs that will be considered `ExternalIP` when listing Node addresses.

    Default: `[]`

  - **settings.storageClass**
    object
    - **settings.storageClass.default**
      Deprecated
      string

      The name of StorageClass that will be used in the cluster by default.

      If the parameter is omitted, the default StorageClass will be one of the following:

      - an arbitrary StorageClass present in the cluster that has the default annotation;
      - the first (in lexicographic order) StorageClass created by the module.

> **Parameter is deprecated.** Instead, use the global parameter global.defaultClusterStorageClass.

Example:

```
default: network-hdd
```

- **settings.storageClass.exclude**
  array of strings

  A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster;

  Example:

```
exclude:
- network-ssd-.*
- network-hdd
```

Provider configuration

> The module lifecycle stage: General Availability

YandexClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in Yandex Cloud.

Used by the cloud provider if a cluster’s control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: YandexClusterConfiguration
layout: Standard
nodeNetworkCIDR: 127.0.0.1/8
labels:
  label-2: b
sshPublicKey: "<SSH_PUBLIC_KEY>"
masterNodeGroup:
  replicas: 1
  instanceClass:
    cores: 4
    memory: 8192
    imageID: fd83ica41cade1mj35sr
nodeGroups:
- name: worker
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    cores: 4
    memory: 8192
    imageID: fd83ica41cade1mj35sr
    coreFraction: 50
    externalIPAddresses:
    - 198.51.100.5
    - Auto
provider:
  cloudID: "<CLOUD_ID>"
  folderID: "<FOLDER_ID>"
  serviceAccountJSON: |
    {
    "id": "id",
    "service_account_id": "service_account_id",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----\nMIIwID....AQAB\n-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----\nMIIE....1ZPJeBLt+\n-----END PRIVATE KEY-----\n"
    }
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`, `deckhouse.io/v1alpha1`

- **dhcpOptions**
  object

  A list of DHCP parameters to use for all subnets.

  Note that setting dhcpOptions may lead to problems.

  - **dhcpOptions.domainName**
    string

    The name of the search domain.

  - **dhcpOptions.domainNameServers**
    array of strings

    A list of recursive DNS addresses.

    - **Element of the array**
      string

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

- **existingNetworkID**
  string

  The ID of the existing VPC Network.

- **existingZoneToSubnetIDMap**
  object

  One or more pre-existing subnets mapped to respective zone.

  Warning. When using `cni-simple-bridge`, DKP creates a route table that must be manually associated with the specified subnets. Only one route table can be associated with a subnet, so multiple clusters using `cni-simple-bridge` cannot be deployed in the same subnets. Starting with DKP 1.76, new clusters in Yandex Cloud use `cni-cilium` in `VXLAN` mode by default. In this mode, pod traffic routing does not depend on Yandex Cloud route tables.

Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

Example:

```
existingZoneToSubnetIDMap:
  ru-central1-a: e2lu8r1tbbtryhdpa9ro
  ru-central1-b: e2lu8r1tbbtryhdpa9ro
  ru-central1-d: e2lu8r1tbbtryhdpa9ro
```

- **kind**
  string

  Required value

  Allowed values: `YandexClusterConfiguration`

- **labels**
  object

  Labels to attach to resources created in the Yandex Cloud.

  Note that you have to re-create all the machines to add new labels if labels were modified in the running cluster.

- **layout**
  string

  Required value

  The way resources are located in the cloud.

  Read more about possible provider layouts.

  Allowed values: `Standard`, `WithoutNAT`, `WithNATInstance`

- **masterNodeGroup**
  object

  Required value

  The definition of the master's NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the YandexInstanceClass.

    - **masterNodeGroup.instanceClass.additionalLabels**
      object

      Additional labels.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **masterNodeGroup.instanceClass.cores**
      integer

      Required value

      Amount of CPU cores to provision on a Yandex Compute Instance.

    - **masterNodeGroup.instanceClass.diskSizeGB**
      integer

      Yandex Compute Instance disk size in gibibytes.

      Default: `50`

      Example:

      ```
      diskSizeGB: 0
      ```

    - **masterNodeGroup.instanceClass.diskType**
      string

      Yandex Compute Instance disk type. Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

      Default: `network-ssd`

Allowed values: `network-ssd`, `network-ssd-io-m3`, `network-ssd-nonreplicated`

Example:

```
diskType: network-ssd-io-m3
```

- **masterNodeGroup.instanceClass.etcdDiskSizeGb**
  integer

  etcd disk size in gibibytes.

  If this parameter is changed, each etcd disk must be manually expanded in the Yandex Cloud interface (the reason for this behavior is in the issue).

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **masterNodeGroup.instanceClass.externalIPAddresses**
  array of strings

  A list of external IP addresses, listed in the order of the zones where nodes will be created.

  The following values can be specified in the list:

  - IP address from an additional external network for the corresponding zone (parameter `externalSubnetIDs`);
  - reserved public IP address, if the list of additional external networks is not defined (parameter `externalSubnetIDs`);
  - `Auto`, to order a public IP address in the corresponding zone.

  Please note:

  - The array elements must be listed according to the order of zones (parameter `zones`) in which the nodes will be created.

    For example:

    ```
    - <RU-CENTRAL1-A-IP-ADDRESS>
    - <RU-CENTRAL1-B-IP-ADDRESS>
    - <RU-CENTRAL1-D-IP-ADDRESS>
    ```

  - The number of elements in the `externalIPAddresses` array must equal the number of nodes in the group (the `replicas` parameter). To automatically order public IP addresses in the zone, use the value `Auto` in the list of the `externalIPAddresses` parameter at the corresponding position (matching the order of zones).
  - If `externalIPAddresses` is not specified, the nodes in the group will be ordered without external IP addresses.
  - **Element of the array**
    string

    Pattern: `^([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})|(Auto)$`

- **masterNodeGroup.instanceClass.externalSubnetID**
  Deprecated
  string

  If specified, an additional network interface will be added to the node (the latter will use it as a default route).

- **masterNodeGroup.instanceClass.externalSubnetIDs**
  array of strings

  List of additional external networks connected to the nodes.

  The node interface that is in the list will be assigned as the default gateway.

  Also, a route for the node's internal network interface will be added for the entire subnet specified in nodeNetworkCIDR.

  The array elements **must** be listed in the same order as the zones (parameter `zones`) in which the nodes will be created. For example:

  ```
  - <RU-CENTRAL1-A-SUBNET-ID>
  - <RU-CENTRAL1-B-SUBNET-ID>
  - <RU-CENTRAL1-D-SUBNET-ID>
  ```

- **masterNodeGroup.instanceClass.imageID**
  string

  Required value

  Image ID to use while provisioning Yandex Compute Instances.

  Example:

```
imageID: fd83ica41cade1mj35sr
```

- **masterNodeGroup.instanceClass.memory**
  integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: 8192
  ```

- **masterNodeGroup.instanceClass.networkType**
  string

  Network type.

  Default: `Standard`

  Allowed values: `Standard`, `SoftwareAccelerated`

- **masterNodeGroup.instanceClass.platform**
  string

  The type of virtual machine to create.

  Default: `standard-v2`

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **masterNodeGroup.zones**
  array

  Not required value.

  A limited set of zones in which master nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

  - **Element of the array**

    Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the YandexInstanceClass.

    - **nodeGroups.instanceClass.additionalLabels**
      object

      Additional labels.

      Example:

      ```
      project: cms-production
      severity: critical
      ```

    - **nodeGroups.instanceClass.coreFraction**
      integer

      Percent of reserved CPU capacity on a Yandex Compute Instance. Details...

      Default: `100`

      Allowed values: `5`, `20`, `50`, `100`

      Example:

      ```
      coreFraction: 20
      ```

- **nodeGroups.instanceClass.cores**
  integer

  Required value

  Amount of CPU cores to provision on a Yandex Compute Instance.

- **nodeGroups.instanceClass.diskSizeGB**
  integer

  Yandex Compute Instance disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGB: 0
  ```

- **nodeGroups.instanceClass.diskType**
  string

  Yandex Compute Instance disk type. Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

  Default: `network-ssd`

  Allowed values: `network-ssd`, `network-ssd-io-m3`, `network-ssd-nonreplicated`

  Example:

  ```
  diskType: network-ssd-io-m3
  ```

- **nodeGroups.instanceClass.externalIPAddresses**
  array of strings

  A list of external IP addresses, listed in the order of the zones where nodes will be created.

  The following values can be specified in the list:

  - IP address from an additional external network for the corresponding zone (parameter `externalSubnetIDs`);
  - reserved public IP address, if the list of additional external networks is not defined (parameter `externalSubnetIDs`);
  - `Auto`, to order a public IP address in the corresponding zone.

  Please note:

  - The array elements must be listed according to the order of zones (parameter `zones`) in which the nodes will be created.

    For example:

    ```
    - <RU-CENTRAL1-A-IP-ADDRESS>
    - <RU-CENTRAL1-B-IP-ADDRESS>
    - <RU-CENTRAL1-D-IP-ADDRESS>
    ```

  - The number of elements in the `externalIPAddresses` array must equal the number of nodes in the group (the `replicas` parameter). To automatically order public IP addresses in the zone, use the value `Auto` in the list of the `externalIPAddresses` parameter at the corresponding position (matching the order of zones).
  - If `externalIPAddresses` is not specified, the nodes in the group will be ordered without external IP addresses.
  - **Element of the array**
    string

    Pattern: `^([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})|(Auto)$`

- **nodeGroups.instanceClass.externalSubnetID**
  Deprecated
  string

  If specified, an additional network interface will be added to the node (the latter will use it as a default route).

- **nodeGroups.instanceClass.externalSubnetIDs**
  array of strings

  List of additional external networks connected to the nodes.

  The node interface that is in the list will be assigned as the default gateway.

  Also, a route for the node’s internal network interface will be added for the entire subnet specified in nodeNetworkCIDR.

  The array elements **must** be listed in the same order as the zones (parameter `zones`) in which the nodes will be created. For example:

```
- <RU-CENTRAL1-A-SUBNET-ID>
- <RU-CENTRAL1-B-SUBNET-ID>
- <RU-CENTRAL1-D-SUBNET-ID>
```

- **nodeGroups.instanceClass.imageID**
  string

  Required value

  Image ID to use while provisioning Yandex Compute Instances.

  Example:

  ```
  imageID: fd83ica41cade1mj35sr
  ```

- **nodeGroups.instanceClass.memory**
  integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: 8192
  ```

- **nodeGroups.instanceClass.networkType**
  string

  Network type.

  Default: `Standard`

  Allowed values: `Standard`, `SoftwareAccelerated`

- **nodeGroups.instanceClass.platform**
  string

  The type of virtual machine to create.

  Default: `standard-v2`

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: "true"
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Note that you have to re-create all the machines to add new tags if tags were modified in the running cluster.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

> **i** Available fields: `effect`, `key`, and `values`.

Example:

```
taints:
- effect: NoExecute
  key: ship-class
  value: frigate
```

  - **nodeGroups.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **nodeGroups.nodeTemplate.taints.key**
    string
  - **nodeGroups.nodeTemplate.taints.value**
    string
- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.
- **nodeGroups.zones**
  array

  A limited set of zones in which nodes can be created.

  The order in which zones are specified does not influence the sequence of node creation. Nodes are assigned to zones in alphabetical order: the first node is placed in the alphabetically first zone, the second node in the second zone, and so forth. If there are more nodes than zones, the assignment process restarts from the beginning of the zone list after placing a node in the last alphabetical zone.

  - **Element of the array**

    Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`

- **nodeNetworkCIDR**
  string

  Required value

  This subnet will be split into **three** equal parts.

  They will serve as a basis for subnets in three Yandex Cloud zones.
- **provider**
  object

  Required value

  Contains settings to connect to the Yandex Cloud API.

  - **provider.cloudID**
    string

    Required value

    The cloud ID.
  - **provider.folderID**
    string

    Required value

    ID of the directory.
  - **provider.serviceAccountJSON**
    string

    Required value

    A key to the Service Account in the JSON format.

    You can get it by using `[yc iam key create](environment.html)` command.

    Pattern: `^[ \t\n]*\{(.|\n)*\}[ \t\n]*$`

    Example:

```
serviceAccountJSON: |
 {
    "id": "...",
    "service_account_id": "...",
    "created_at": "2022-08-04T05:38:34.756137618Z",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----...-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----...-----END PRIVATE KEY-----\n"
 }
```

- **sshPublicKey**
  string

  Required value

  A public key for accessing nodes.

- **withNATInstance**
  object

  Settings for the `WithNATInstance` layout.

  - **withNATInstance.exporterAPIKey**
    string

    API-key for cloud metrics exporter.

    - If parameter is empty, cloud metrics exporter will not be deployed in the cluster.
    - If parameter is `Auto`, Deckhouse will create service account with the `monitoring.viewer` role and create API-key manually. Provider service account should have the `admin` role.
    - Any other value is considered a valid API-key. See this instruction for creating API-key. Service account should have `monitoring.viewer` role.

    Default:

  - **withNATInstance.externalSubnetID**
    string

    If specified, an additional network interface will be added to the node (the node will use it as a default route).

  - **withNATInstance.internalSubnetCIDR**

    CIDR of an automatically created subnet for the internal interface. Overrides `internalSubnetID` parameter.

  - **withNATInstance.internalSubnetID**
    string

    ID of a subnet for the internal interface.

  - **withNATInstance.natInstanceExternalAddress**
    string

    A reserved external IP address (or `externalSubnetID` address if specified).

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **withNATInstance.natInstanceInternalAddress**
    Deprecated
    string

    Consider using automatically generated address instead.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **withNATInstance.natInstanceResources**
    object

    Computing resources that are allocated to the NAT instance. If not specified, the default values will be used.

    > **i** **Warning.** If these parameters are changed, `terraform-auto-converger` will automatically restart NAT-instance if autoConvergerEnabled is set to `true`. This may result in a temporary interruption of network traffic in the cluster.

    - **withNATInstance.natInstanceResources.cores**
      integer

      Amount of CPU cores to provision on the NAT instance.

      Default: `2`

    - **withNATInstance.natInstanceResources.memory**
      integer

      Amount of primary memory in MB provision on the NAT instance.

      Default: `2048`

    - **withNATInstance.natInstanceResources.platform**

string

Processor platform type on the NAT instance.

Default: `standard-v2`

- **zones**
  array

  The globally restricted set of zones that this cloud provider works with.

  - **Element of the array**

    Allowed values: `ru-central1-a`, `ru-central1-b`, `ru-central1-d`

Preparing environment

ℹ The module lifecycle stage: General Availability

⚠ To use `ContainerdV2` as the container runtime on cluster nodes, the operating systems on virtual machines must meet the following requirements:

- Linux kernel version 5.8 or newer, except for the ranges 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS).
- `CgroupsV2` support.
- Systemd version `244` or newer.
- `erofs` kernel module support.

For more information, see the documentation.

⚠ The `cloud-init` package must be installed on the VMs. After the virtual machine is started, the following services associated with this package must be started:

- `cloud-config.service`;
- `cloud-final.service`;
- `cloud-init.service`.

⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

Creating a service account

You need to create a service account with the editor role with the cloud provider so that Deckhouse Kubernetes Platform (DKP) can manage cloud resources. The detailed instructions for creating a service account with Yandex Cloud are available in the provider's documentation. Below, we will provide a brief overview of the necessary actions:

1. Create a user named `deckhouse`:

   ```
   yc iam service-account create --name deckhouse
   ```

   The command output will contain its parameters:

   ```
   id: <userID>
   folder_id: <folderID>
   created_at: "YYYY-MM-DDTHH:MM:SSZ"
   name: deckhouse
   ```

2. Assign the required roles to the newly created user for your cloud:

   ```
   yc resource-manager folder add-access-binding --id <folderID> --role compute.editor --subject serviceAccount:
   <userID>
   yc resource-manager folder add-access-binding --id <folderID> --role vpc.admin --subject serviceAccount:<userID>
   yc resource-manager folder add-access-binding --id <folderID> --role load-balancer.editor --subject
   serviceAccount:<userID>
   ```

3. Create a JSON file containing the parameters for user authorization in the cloud. These parameters will be used to log in to the cloud:

   ```
   yc iam key create --service-account-name deckhouse --output deckhouse-sa-key.json
   ```

> **i** You may need to increase quotas.
>
> Reserve a public IP address if necessary.

Quotas

> **i** Note that you need to increase the quotas using the Yandex console when provisioning a new cluster.

Recommended quotas for a new cluster:

- The number of virtual processors: 64.
- The total volume of SSD disks: 2000 GB.
- The number of virtual machines: 25.
- The total amount of RAM of virtual machines: 256 GB.

Yandex Cloud integration

> **⚠** Starting with DKP version 1.76, Yandex Cloud uses the `cilium` CNI by default for new clusters.
>
> When using CentOS 8, you must explicitly enable the `cni-simple-bridge` module in the `config.yml` file.
>
> Example configuration for CentOS 8 in Yandex Cloud...
>
> ```
> apiVersion: deckhouse.io/v1alpha1
> kind: ModuleConfig
> metadata:
>  name: cni-simple-bridge
> spec:
>  enabled: true
> ```

Configuring security groups

When creating a cloud network, Yandex Cloud creates a default security group for all networks, including the Deckhouse Kubernetes Platform cluster network. The default security group contains rules that allow for any traffic to pass in any direction (inbound and outbound) and applies to all subnets within the cloud network, unless an object (VM interface) is explicitly assigned to a different security group. You can change the default security group rules if you need to control traffic in your cluster.

> **✖** Do not delete the default rules that allow for traffic to pass in any direction before finishing configuring all the other rules for the security group. Doing so may disrupt the performance of the cluster.

This section provides general guidelines for setting up a security group. Incorrect configuration of security groups may affect the performance of the cluster. Please consult security group usage details in Yandex Cloud before using it in production environments.

1. Find out in which cloud network the Deckhouse Kubernetes Platform cluster is running.

   The network name matches the `prefix` field of the ClusterConfiguration resource. It can be retrieved using the following command:

   ```
   d8 k get secrets -n kube-system d8-cluster-configuration -ojson | \
     jq -r '.data."cluster-configuration.yaml"' | base64 -d | grep prefix | cut -d: -f2
   ```

2. In the Yandex Cloud console, select the Virtual Private Cloud service and navigate to the *Security Groups* section. You should see a single security group labeled `Default`.

3. Create rules as described in Yandex Cloud instructions.

4. Delete the rule that allows for any **inbound** traffic (in the screenshot above it has already been deleted), and save the changes.

Yandex Lockbox integration

The External Secrets Operator allows you to synchronize Yandex Lockbox secrets with the Deckhouse Kubernetes Platform cluster secrets.

The instructions below are meant to be viewed as a *Quick Start* guide. To use integration in production environments, please review the following resources:

- Yandex Lockbox
- Synchronizing with Yandex Lockbox secrets
- External Secrets Operator

Deployment instructions

1. Create a service account required for the External Secrets Operator:

   ```
   yc iam service-account create --name eso-service-account
   ```

2. Create an authorized key for the service account and save it to a file:

   ```
   yc iam key create --service-account-name eso-service-account --output authorized-key.json
   ```

3. Assign `lockbox.editor`, `lockbox.payloadViewer`, and `kms.keys.encrypterDecrypter` roles to a service account to access all catalog secrets:

```
folder_id=<folder id>
yc resource-manager folder add-access-binding --id=${folder_id} --service-account-name eso-service-account --
role lockbox.editor
yc resource-manager folder add-access-binding --id=${folder_id} --service-account-name eso-service-account --
role lockbox.payloadViewer
yc resource-manager folder add-access-binding --id=${folder_id} --service-account-name eso-service-account --
role kms.keys.encrypterDecrypter
```

For advanced customization, check out access control in Yandex Lockbox.

4. Install the External Secrets Operator using the Helm chart according to instructions.

   Note that you may need to set `nodeSelector`, `tolerations` and other parameters. To do this, use the `./external-secrets/values.yaml` file after unpacking the Helm chart.

   Pull and extract the chart:

   ```
   helm pull oci://cr.yandex/yc-marketplace/yandex-cloud/external-secrets/chart/external-secrets \
     --version 0.5.5 \
     --untar
   ```

   Install the Helm chart:

   ```
   helm install -n external-secrets --create-namespace \
     --set-file auth.json=authorized-key.json \
     external-secrets ./external-secrets/
   ```

   Where:

   - `authorized-key.json` — the name of the file with the authorized key from step 2.

5. Create a SecretStore with the `sa-creds` secret in it:

   ```
   d8 k -n external-secrets apply -f - <<EOF

   apiVersion: external-secrets.io/v1alpha1
   kind: SecretStore
   metadata:
     name: secret-store
   spec:
     provider:
       yandexlockbox:
         auth:
           authorizedKeySecretRef:
             name: sa-creds
             key: key
   EOF
   ```

   Where:

   - `sa-creds` — the name of the `Secret` that contains the authorized key. This secret should show up after the Helm chart has been installed.
   - `key` — the name of the key in the `.data` field of the secret above.

Checking that everything works as expected

1. Check the status of the External Secrets Operator and the secrets store you created:

   ```
   $ d8 k -n external-secrets get po
   NAME                                               READY   STATUS    RESTARTS   AGE
   external-secrets-55f78c44cf-dbf6q                  1/1     Running   0          77m
   external-secrets-cert-controller-78cbc7d9c8-rszhx  1/1     Running   0          77m
   external-secrets-webhook-6d7b66758-s7v9c           1/1     Running   0          77m

   $ d8 k -n external-secrets get secretstores.external-secrets.io
   NAME           AGE   STATUS
   secret-store   69m   Valid
   ```

2. Create a Yandex Lockbox secret with the following parameters:
   - **Name** — `lockbox-secret`.
   - **Key** — enter the non-confidential identifier `password`.
   - **Value** — enter the confidential data to store `p@$$w0rd`.

3. Create an ExternalSecret object that refers to the `lockbox-secret` secret in the `secret-store`:

```
d8 k -n external-secrets apply -f - <<EOF

apiVersion: external-secrets.io/v1alpha1
kind: ExternalSecret
metadata:
  name: external-secret
spec:
  refreshInterval: 1h
  secretStoreRef:
    name: secret-store
    kind: SecretStore
  target:
    name: k8s-secret
  data:
  - secretKey: password
    remoteRef:
      key: <SECRET_ID>
      property: password
EOF
```

Where:

- `spec.target.name` — the name of the new secret. The External Secrets Operator will create this secret in the Deckhouse Kubernetes Platform cluster and populate it with the parameters of the Yandex Lockbox's `lockbox-secret`.
- `spec.data[].secretKey` — the name of the key in the `.data` field of the secret that the External Secrets Operator will create.
- `spec.data[].remoteRef.key` — identifier of the Yandex Lockbox's `lockbox-secret` created earlier, e.g., `e6q28nvfmhu539******`.
- `spec.data[].remoteRef.property` — the **key** you specified earlier for the Yandex Lockbox's `lockbox-secret`.

4. Make sure that the new `k8s-secret` key contains the `lockbox-secret` value:

```
d8 k -n external-secrets get secret k8s-secret -ojson | jq -r '.data.password' | base64 -d
```

The output of the command should contain the **value** of the `password` key of the `lockbox-secret` created earlier:

```
p@$$w0rd
```

Yandex Managed Service for Prometheus integration

This integration lets you use the Yandex Managed Service for Prometheus as an external metrics repository, e.g., for long-term metrics storage.

Writing metrics

1. Create a service account with the `monitoring.editor` role.
2. Create an API key for the service account.
3. Create a PrometheusRemoteWrite resource:

```
d8 k apply -f - <<EOF
apiVersion: deckhouse.io/v1
kind: PrometheusRemoteWrite
metadata:
  name: yc-remote-write
spec:
  url: <URL_TO_WRITE_METRICS>
  bearerToken: <API_KEY>
EOF
```

Where:

- `<URL TO WRITE_METRICS>` — URL from the Yandex Monitoring/Prometheus/Writing Metrics page.
- `<API KEY>` — the API key you created in the previous step, e.g., `AQVN1HHJRSrfo9jU3aopsXrJyfq_UHs********`.

You may also specify additional parameters; refer to the documentation.

More details about this feature can be found in Yandex Cloud documentation.

Reading metrics with Grafana

1. Create a service account with the `monitoring.viewer` role.
2. Create an API key for the service account.
3. Create a GrafanaAdditionalDatasource resource:

```
d8 k apply -f - <<EOF

apiVersion: deckhouse.io/v1
kind: GrafanaAdditionalDatasource
metadata:
  name: managed-prometheus
spec:
  type: prometheus
  access: Proxy
  url: <URL_READING_METRICS_WITH_GRAFANA>
  basicAuth: false
  jsonData:
    timeInterval: 30s
    httpMethod: POST
    httpHeaderName1: Authorization
  secureJsonData:
    httpHeaderValue1: Bearer <API_KEY>
EOF
```

   Where:

   - `<URL_READING_METRICS_WITH_GRAFANA>` — URL from the Yandex Monitoring/Prometheus/Reading Metrics with Grafana page.
   - `<API_KEY>` — the API key you created in the previous step, e.g., `AQVN1HHJReSrfo9jU3aopsXrJyfq_UHs********`.

   You may also specify additional parameters; refer to the documentation.

More details about this feature can be found in Yandex Cloud documentation.

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

YandexInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of Yandex Instances used by `machine-controller-manager` (the node-manager module).

The `NodeGroup` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalLabels**
    object

    Additional labels.

    Example:

    ```
    additionalLabels:
      project: cms-production
      severity: critical
    ```

  - **spec.additionalSubnets**
    array of strings

    Subnet IDs that VirtualMachines' secondary NICs will connect to. Each subnet listed here translates into one additional network interface.

    Example:

    ```
    additionalSubnets:
    - b0csh41c1or82vuch89v
    - e2lgddi5svochh5fbq96
    ```

  - **spec.assignPublicIPAddress**
    boolean

    Should a public external IPv4 address be assigned to a provisioned Yandex Compute Instance.

    Default: `false`

    Example:

    ```
    assignPublicIPAddress: false
    ```

  - **spec.coreFraction**
    integer

    Percent of reserved CPU capacity on a Yandex Compute Instance. Details…

    Default: `100`

    Allowed values: `5`, `20`, `50`, `100`

    Example:

    ```
    coreFraction: 20
    ```

  - **spec.cores**
    integer

    Required value

Amount of CPU cores to provision on a Yandex Compute Instance.

Example:

```
cores: 4
```

- **spec.diskSizeGB**
integer

  Yandex Compute Instance disk size in gibibytes.

  Default: `50`

  Example:

  ```
  diskSizeGB: 20
  ```

- **spec.diskType**
string

  Instance disk type.

  Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

  Default: `network-hdd`

  Allowed values: `network-ssd`, `network-hdd`, `network-ssd-nonreplicated`, `network-ssd-io-m3`

  Example:

  ```
  diskType: network-hdd
  ```

- **spec.gpus**
integer

  Number of GPUs on a Yandex Compute Instance.

  Default: `0`

  Example:

  ```
  gpus: 4
  ```

- **spec.imageID**
string

  Image ID to use while provisioning Yandex Compute Instances.

  The masterNodeGroup.instanceClass.imageID parameter will be used by default.

  Example:

  ```
  imageID: fd83ica41cade1mj35sr
  ```

- **spec.mainSubnet**
string

  Subnet ID that VirtualMachines’ primary NIC will connect to.

  If the parameter is not specified, the main network is determined automatically according to the following logic: if a list of networks is set in the existingZoneToSubnetIDMap parameter, then the network is selected from the specified list; otherwise, the created Deckhouse network is used.

  Example:

  ```
  mainSubnet: e9bnc7g9mu9mper9clk4
  ```

- **spec.memory**
integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: 8192
  ```

- **spec.networkType**

string

Network type: `Standard` or `SoftwareAccelerated`.

> **i** In clusters that use Machine Controller Manager (MCM), changing the `networkType` parameter does not trigger automatic recreation of existing CloudEphemeral nodes. Details are available in the FAQ.

Default: `Standard`

Allowed values: `Standard`, `SoftwareAccelerated`

- **spec.platformID**
  string

  Paltform ID. List of available platforms...

  Default: `standard-v3`

- **spec.preemptible**
  boolean

  Should a provisioned Yandex Compute Instance be preemptible.

  For more information about preemptible virtual machines, read the provider's documentation.

  Default: `false`

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of Yandex Instances used by `machine-controller-manager` (the node-manager module).

The `NodeGroup` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.additionalLabels**
    object

    Additional labels.

    Example:

    ```
    additionalLabels:
      project: cms-production
      severity: critical
    ```

  - **spec.additionalSubnets**
    array of strings

    Subnet IDs that VirtualMachines' secondary NICs will connect to. Each subnet listed here translates into one additional network interface.

    Example:

    ```
    additionalSubnets:
    - b0csh41c1or82vuch89v
    - e2lgddi5svochh5fbq96
    ```

  - **spec.assignPublicIPAddress**
    boolean

    Should a public external IPv4 address be assigned to a provisioned Yandex Compute Instance.

    Default: `false`

    Example:

    ```
    assignPublicIPAddress: false
    ```

  - **spec.coreFraction**
    integer

Percent of reserved CPU capacity on a Yandex Compute Instance. Details...

Default: `100`

Allowed values: `5`, `20`, `50`, `100`

Example:

```
coreFraction: 20
```

- **spec.cores**
  integer

  Required value

  Amount of CPU cores to provision on a Yandex Compute Instance.

  Example:

  ```
  cores: 4
  ```

- **spec.diskSizeGB**
  integer

  Yandex Compute Instance disk size in gibibytes.

  Default: `20`

  Example:

  ```
  diskSizeGB: 50
  ```

- **spec.diskType**
  string

  Instance disk type.

  Size of `network-ssd-nonreplicated` and `network-ssd-io-m3` disks must be a multiple of 93 GB.

  For more information about possible disk types, read the provider's documentation.

  Default: `network-hdd`

  Allowed values: `network-ssd`, `network-hdd`, `network-ssd-nonreplicated`

  Example:

  ```
  diskType: network-hdd
  ```

- **spec.gpus**
  integer

  Number of GPUs on a Yandex Compute Instance.

  Default: `0`

  Example:

  ```
  gpus: 4
  ```

- **spec.imageID**
  string

  Image ID to use while provisioning Yandex Compute Instances.

  The masterNodeGroup.instanceClass.imageID parameter will be used by default.

  Example:

  ```
  imageID: fd83ica41cade1mj35sr
  ```

- **spec.mainSubnet**
  string

  Subnet ID that VirtualMachines' primary NIC will connect to.

  If the parameter is not specified, the main network is determined automatically according to the following logic: if a list of networks is set in the existingZoneToSubnetIDMap parameter, then the network is selected from the specified list; otherwise, the created Deckhouse network is used.

Example:

```
mainSubnet: e9bnc7g9mu9mper9clk4
```

- **spec.memory**
  integer

  Required value

  Amount of primary memory in MB provision on a Yandex Compute Instance.

  Example:

  ```
  memory: 8192
  ```

- **spec.networkType**
  string

  Network type: STANDARD or SOFTWARE_ACCELERATED

  Default: `STANDARD`

  Allowed values: `STANDARD`, `SOFTWARE_ACCELERATED`

- **spec.platformID**
  string

  Paltform ID. List of available platforms...

  Default: `standard-v2`

- **spec.preemptible**
  boolean

  Should a provisioned Yandex Compute Instance be preemptible.

  For more information about preemptible virtual machines, read the provider's documentation.

  Default: `false`

FAQ

> **i** The module lifecycle stage: General Availability

Setting up the INTERNAL LoadBalancer

Attach the following annotation to the service:

```
yandex.cpi.flant.com/listener-subnet-id: SubnetID
```

The annotation links the LoadBalancer with the appropriate Subnet.

Using a separate target group for a NodeGroup

By default, Yandex Cloud Controller Manager adds all suitable cluster nodes to the default target group. To assign nodes to a separate target group, use the `yandex.cpi.flant.com/target-group-name-prefix` annotation. The annotation is described in the Service annotations section.

1. In the NodeGroup whose nodes should be included in a separate target group, specify the `yandex.cpi.flant.com/target-group-name-prefix` annotation in the `spec.nodeTemplate.annotations` parameter. For example:

   ```
   spec:
     nodeTemplate:
       annotations:
         yandex.cpi.flant.com/target-group-name-prefix: frontend-
   ```

   The annotation is propagated to the Node objects. Yandex Cloud Controller Manager adds all suitable nodes carrying the same annotation value to the target group, regardless of their NodeGroup.

2. In the Service object of the LoadBalancer type, specify the same annotation with the same value. For example:

```
metadata:
  annotations:
    yandex.cpi.flant.com/target-group-name-prefix: frontend-
```

The annotation on the Service identifies the target group used by the LoadBalancer but does not select nodes.

3. Make sure that the values of `yandex.cpi.flant.com/target-group-name-prefix` in the NodeGroup and Service match. In the example above, both resources use the `frontend-` value.
4. The target group will be created with a name generated according to the following pattern:

   ```
   <ANNOTATION_VALUE><YANDEX_CLOUD_CLUSTER_NAME><NETWORK_ID>
   ```

   For example, if the annotation value is `frontend-`, the cluster name is `my-cluster-`, and the network ID is `enp123456789`, the target group name will be:

   ```
   frontend-my-cluster-enp123456789
   ```

Configuration example:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: frontend
spec:
  nodeType: CloudEphemeral
  nodeTemplate:
    annotations:
      yandex.cpi.flant.com/target-group-name-prefix: frontend-
---
apiVersion: v1
kind: Service
metadata:
  name: nginx-frontend
  annotations:
    yandex.cpi.flant.com/target-group-name-prefix: frontend-
spec:
  type: LoadBalancer
```

⚠ Yandex Cloud does not allow a single target, identified by the (`SubnetID, IP`) pair, to belong to multiple target groups at the same time.

When the target group is changed, Yandex Cloud Controller Manager first removes the target from the current group and then adds it to the new one. This transition may cause a brief interruption in traffic handling.

Nodes with a dedicated target group prefix are excluded from the default target group. As a result, load balancers that use the default target group stop routing traffic to those nodes.

This automatic transition is performed only between target groups managed by Yandex Cloud Controller Manager. If a target already belongs to another target group that is not managed by Yandex Cloud Controller Manager, remove it from that group before using the annotation.

After the prefix is changed or removed, the previous target group may remain empty. If it is no longer used by any load balancers, delete it manually.

Reserving a public IP address

This on is used in `externalIPAddresses` and `natInstanceExternalAddress`. It also can be used for a bastion host.

```
$ yc vpc address create --external-ipv4 zone=ru-central1-a
id: e9b4cfmmnc1mhgij75n7
folder_id: b1gog0h9k05lhqe5d88l
created_at: "2020-09-01T09:29:33Z"
external_ipv4_address:
  address: 178.154.226.159
  zone_id: ru-central1-a
  requirements: {}
reserved: true
```

dhcpOptions-related problems and ways to address them

Using DNS servers that differ from those provided by Yandex Cloud in the DHCP settings is a temporary solution. It will be abandoned after Yandex Cloud will introduce the Managed DNS service. To get around the restrictions described below, we recommend using `stubZones` from the `kube-dns` module.

Editing parameters

Pay attention to the following nuances:

1. When changing parameters, you need to invoke `netplan apply` or a similar command that forces the update of the DHCP lease.
2. You will need to restart all hostNetwork Pods (especially `kube-dns`) for the new `resolv.conf` settings to take effect.

Aspects of the use

If the dhcpOptions parameter is set, all DNS are routed to the DNS servers specified. These DNS servers **must** serve DNS requests to the Internet and (if needed) resolve intranet resources.

Do not use this option if the recursive DNSs specified cannot resolve the same list of zones that the recursive DNSs in the Yandex Cloud subnet can resolve.

Changing `networkType` does not recreate CloudEphemeral nodes

In clusters that use Machine Controller Manager (MCM), changing the `networkType` parameter in a YandexInstanceClass resource does not trigger automatic recreation of existing CloudEphemeral nodes. Although the MachineClass is updated, the network acceleration type of existing virtual machines in Yandex Cloud remains unchanged.

DKP intentionally does not take the `networkType` parameter into account when determining whether CloudEphemeral nodes should be recreated in MCM. If it did, updating DKP would recreate CloudEphemeral nodes in all clusters where `networkType` is specified, even if its value had not changed.

In Cluster API, the `networkType` parameter is taken into account when determining whether nodes should be recreated, so changing it automatically triggers node recreation. New CloudEphemeral NodeGroups in Yandex Cloud use Cluster API by default.

If you changed `networkType` in an MCM-based cluster and want the new value to apply to existing CloudEphemeral nodes, recreate them manually — instructions in the documentation.

Setting a custom StorageClass as default

Specify the StorageClass name in the defaultClusterStorageClass parameter in the `global` module settings. Note that after doing so, the `storageclass.kubernetes.io/is-default-class='true'` annotation will be removed from the StorageClass that was previously set as the default one.

```
d8 k edit mc global
```

Resizing a PVC

You can increase the size of an existing PVC by changing the value of the `spec.resources.requests.storage` parameter, without stopping or recreating the pod that uses it.

After the value of `spec.resources.requests.storage` is changed, the CSI driver performs the following operations:

- increases the size of the disk in Yandex Cloud;
- updates the size of the associated PersistentVolume;
- expands the file system on the node to which the volume is attached.

During the operation, the pod continues running, and the mounted volume remains available to the application. After the resize operation is complete, the new file system size becomes available inside the container without restarting the pod.

> **i** Decreasing the size of a PVC is not supported.

To increase the size of a PVC, follow these steps:

1. Get the name of the StorageClass used by the PVC:

   ```
   d8 k -n <NAMESPACE> get pvc <PVC_NAME> \
     -o jsonpath='{.spec.storageClassName}{"\n"}'
   ```

   Where:

   - `<NAMESPACE>` — the namespace containing the PVC;
   - `<PVC_NAME>` — the name of the PVC to resize.

   For example:

   ```
   d8 k -n production get pvc application-data \
     -o jsonpath='{.spec.storageClassName}{"\n"}'
   ```

   Example output:

   ```
   network-ssd
   ```

   In this example, the `application-data` PVC uses the `network-ssd` StorageClass.

2. Make sure that the StorageClass allows volume expansion:

   ```
   d8 k get storageclass <STORAGECLASS_NAME> \
     -o jsonpath='{.allowVolumeExpansion}{"\n"}'
   ```

   Where `<STORAGECLASS_NAME>` is the name of the StorageClass obtained in the previous step.

   For example:

   ```
   d8 k get storageclass network-ssd \
     -o jsonpath='{.allowVolumeExpansion}{"\n"}'
   ```

   Example output:

   ```
   true
   ```

3. Check the current status and size of the PVC:

   ```
   d8 k -n <NAMESPACE> get pvc <PVC_NAME>
   ```

   For example:

   ```
   d8 k -n production get pvc application-data
   ```

   Example output:

   ```
   NAME               STATUS   VOLUME                                     CAPACITY
   ACCESS MODES   STORAGECLASS
   application-data   Bound    pvc-65e92674-077c-4b4f-b65d-19e92f04e103   20Gi       RWO
   network-ssd
   ```

   Make sure that:

   - the PVC is in the `Bound` state;
   - the `CAPACITY` field shows the current PVC size;
   - the `STORAGECLASS` field shows the StorageClass checked in the previous step.

4. Increase the PVC size:

   ```
   d8 k -n <NAMESPACE> edit pvc <PVC_NAME>
   ```

   For example:

```
d8 k -n production edit pvc application-data
```

Specify the new PVC size in the `spec.resources.requests.storage` field:

```
spec:
  resources:
    requests:
      storage: 30Gi
```

In this example, the PVC size is increased to `30Gi`.

Save the changes and close the editor.

> ⚠ For the `network-ssd-nonreplicated` and `network-ssd-io-m3` StorageClasses, the size must be a multiple of 93Gi.

5. Wait for the PVC resize operation to complete:

```
d8 k -n <NAMESPACE> get pvc <PVC_NAME> --watch
```

Where:

- `<NAMESPACE>` — the namespace containing the PVC;
- `<PVC_NAME>` — the name of the PVC being resized.

For example:

```
d8 k -n production get pvc application-data --watch
```

During the resize operation, the `CAPACITY` field may continue to show the previous size:

```
NAME               STATUS   VOLUME                                     CAPACITY
ACCESS MODES   STORAGECLASS
application-data   Bound    pvc-65e92674-077c-4b4f-b65d-19e92f04e103   20Gi       RWO
network-ssd
```

The operation is complete when the `CAPACITY` field shows the new PVC size:

```
NAME               STATUS   VOLUME                                     CAPACITY
ACCESS MODES   STORAGECLASS
application-data   Bound    pvc-65e92674-077c-4b4f-b65d-19e92f04e103   30Gi       RWO
network-ssd
```

6. Check the PVC events:

```
d8 k -n <NAMESPACE> describe pvc <PVC_NAME>
```

For example:

```
d8 k -n production describe pvc application-data
```

The following events may appear during the resize operation:

```
ExternalExpanding
Resizing
FileSystemResizeRequired
```

The following event indicates that the file system was successfully expanded:

```
FileSystemResizeSuccessful
```

For example:

```
Normal  FileSystemResizeSuccessful  kubelet  MountVolume.NodeExpandVolume succeeded for
volume "pvc-65e92674-077c-4b4f-b65d-19e92f04e103"
```

7. Check the file system size inside the pod:

   ```
   d8 k -n <NAMESPACE> exec <POD_NAME> -- \
     df -hT <MOUNT_PATH>
   ```

   Where:

   - `<NAMESPACE>` — the namespace containing the pod;
   - `<POD NAME>` — the name of the pod using the PVC;
   - `<MOUNT_PATH>` — the path inside the container where the PVC is mounted.

   For example:

   ```
   d8 k -n production exec application-0 -- \
     df -hT /data
   ```

   Example output:

   ```
   Filesystem   Type   Size    Used   Avail   Use%   Mounted on
   /dev/vde     ext4   29.4G   22M    29.4G    1%    /data
   ```

   > **i** The actual file system size may be slightly smaller than the PVC size due to file system metadata.

Adding CloudStatic nodes to a cluster

For VMs that you want to add to the cluster as nodes, add the `node-network-cidr` key to the metadata (Edit VM -> Metadata) with a value equal to the cluster's `nodeNetworkCIDR`.

You can find out the `nodeNetworkCIDR` of the cluster using the command below:

```
d8 k -n kube-system get secret d8-provider-cluster-configuration -o json | jq --raw-output '.data."cloud-
provider-cluster-configuration.yaml"' | base64 -d | grep '^nodeNetworkCIDR'
```

Creating a cluster in a new VPC and setting up a bastion host to access the nodes

1. Bootstrap the base-infrastructure of the cluster:

   ```
   dhctl bootstrap-phase base-infra --config config.yml
   ```

2. Create a bastion host:

   ```
   yc compute instance create \
   --name bastion \
   --hostname bastion \
   --create-boot-disk image-family=ubuntu-2404-lts,image-folder-id=standard-images,size=20,type=network-
   hdd \
   --memory 2 \
   --cores 2 \
   --core-fraction 100 \
   --ssh-key ~/.ssh/<SSH_PUBLIC_KEY_FILE> \
   --zone ru-central1-a \
   --public-address 178.154.226.159
   ```

   > **i** Replace `<SSH_PUBLIC_KEY FILE>` here with the name of your public key. For example, for a key with RSA encryption, it will be `id_rsa.pub`, and for a key with ED25519 encryption, it will be with `id_ed25519.pub`.

3. Continue installing the cluster by specifying the bastion host data. Answer `y` to the question about the Terraform cache:

```
dhctl bootstrap --ssh-bastion-host=178.154.226.159 --ssh-bastion-user=yc-user \
--ssh-user=ubuntu --ssh-agent-private-keys=/tmp/.ssh/<SSH_PRIVATE_KEY_FILE> --config=/config.yml
```

> **i** Replace `<SSH_PRIVATE_KEY_FILE>` here with the name of your private key. For example, for a key with RSA encryption it can be `id_rsa`, and for a key with ED25519 encryption it can be `id_ed25519`.

Long switching to nodes in lower-priority groups

If switching to nodes in lower-priority groups takes a long time (for example, when node groups with preemptible instances are set to the highest priority and, if such instances are unavailable, switching to nodes from other groups takes a very long time), follow the instructions.

Examples

> **i** The module lifecycle stage: General Availability

Below is an example of the Yandex Cloud cloud provider configuration.

An example of the module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cloud-provider-yandex
spec:
  version: 1
  enabled: true
  settings:
    additionalExternalNetworkIDs:
    - enp6t4snovl2ko4p15em
```

An example of the `YandexInstanceClass` custom resource

```
apiVersion: deckhouse.io/v1
kind: YandexInstanceClass
metadata:
  name: test
spec:
  cores: 4
  memory: 8192
```

LoadBalancer

Service annotations

Default values are configured in the cluster for placing load balancer resources (the network for the target group and the subnet for the Listener). These values are set automatically during cluster setup and can be overridden with annotations at the individual Service level.

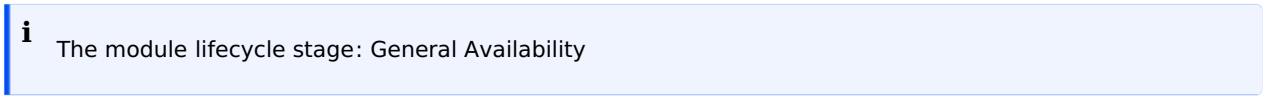
> **i** The default behavior (external or internal LB) depends on the cluster configuration. To explicitly choose the type, use the `yandex.cpi.flant.com/loadbalancer-external` annotation.

The following annotations are supported by Yandex Cloud Controller Manager:

1. `yandex.cpi.flant.com/target-group-network-id` — specifies the NetworkID in which the target group for this Service will be created. Overrides the corresponding default value.
2. `yandex.cpi.flant.com/listener-subnet-id` — sets the SubnetID for the Listeners of the LB created for this Service. Overrides the corresponding default value.
3. `yandex.cpi.flant.com/listener-address-ipv4` — sets a predefined IPv4 address for the Listeners (supported for both internal and external LBs).
4. `yandex.cpi.flant.com/loadbalancer-external` — enables creation of an external LB for this Service (use it when you need to explicitly create an external load balancer). Overrides the default behavior.

5. `yandex.cpi.flant.com/target-group-name-prefix` — specifies the name prefix of the target group used by the LoadBalancer. The annotation on the Service identifies the target group but does not select nodes. To include nodes in the target group, set the same annotation value in `spec.nodeTemplate.annotations` in the NodeGroup. Yandex Cloud Controller Manager includes all suitable nodes carrying this annotation value, regardless of their NodeGroup. The target group name is formed as `<ANNOTATION_VALUE><YANDEX_CLOUD_CLUSTER_NAME><NETWORK_ID>`. For details, see Using a separate target group for a NodeGroup.

If separate target groups are created for the control plane or master nodes, add the label `node.kubernetes.io/exclude-from-external-load-balancers: ""` to the master nodes. This prevents the controller from automatically adding master nodes to new target groups for load balancers.

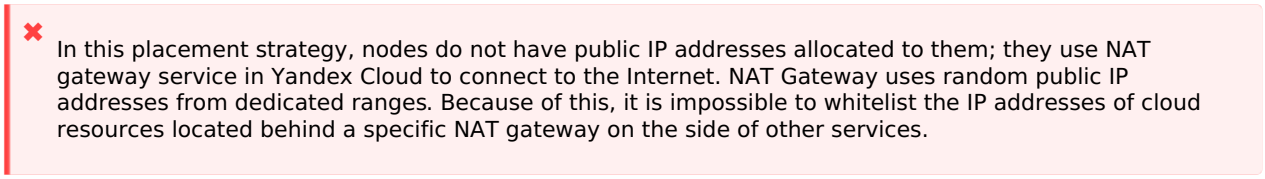


If you create your own load balancer for master nodes and want YCC to also be able to place its load balancers on master nodes, pre-create a target group with a name matching the pattern `${CLUSTER-NAME}${VPC.ID}`.

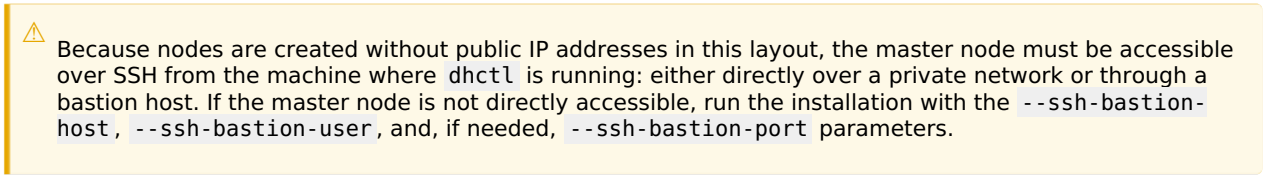
Target group health checks

Health check parameters (for LB target groups created by the controller):

1. `yandex.cpi.flant.com/healthcheck-interval-seconds` — how often to run the check, in seconds (default: 2).
2. `yandex.cpi.flant.com/healthcheck-timeout-seconds` — how long to wait for an endpoint response, in seconds. If no response is received within this time, the check is considered failed (default: 1).
3. `yandex.cpi.flant.com/healthcheck-unhealthy-threshold` — how many consecutive failed checks are required to mark an endpoint as unhealthy and exclude it from load balancing (default: 2).
4. `yandex.cpi.flant.com/healthcheck-healthy-threshold` — how many consecutive successful checks are required to return an endpoint to healthy status and include it back in load balancing (default: 2).

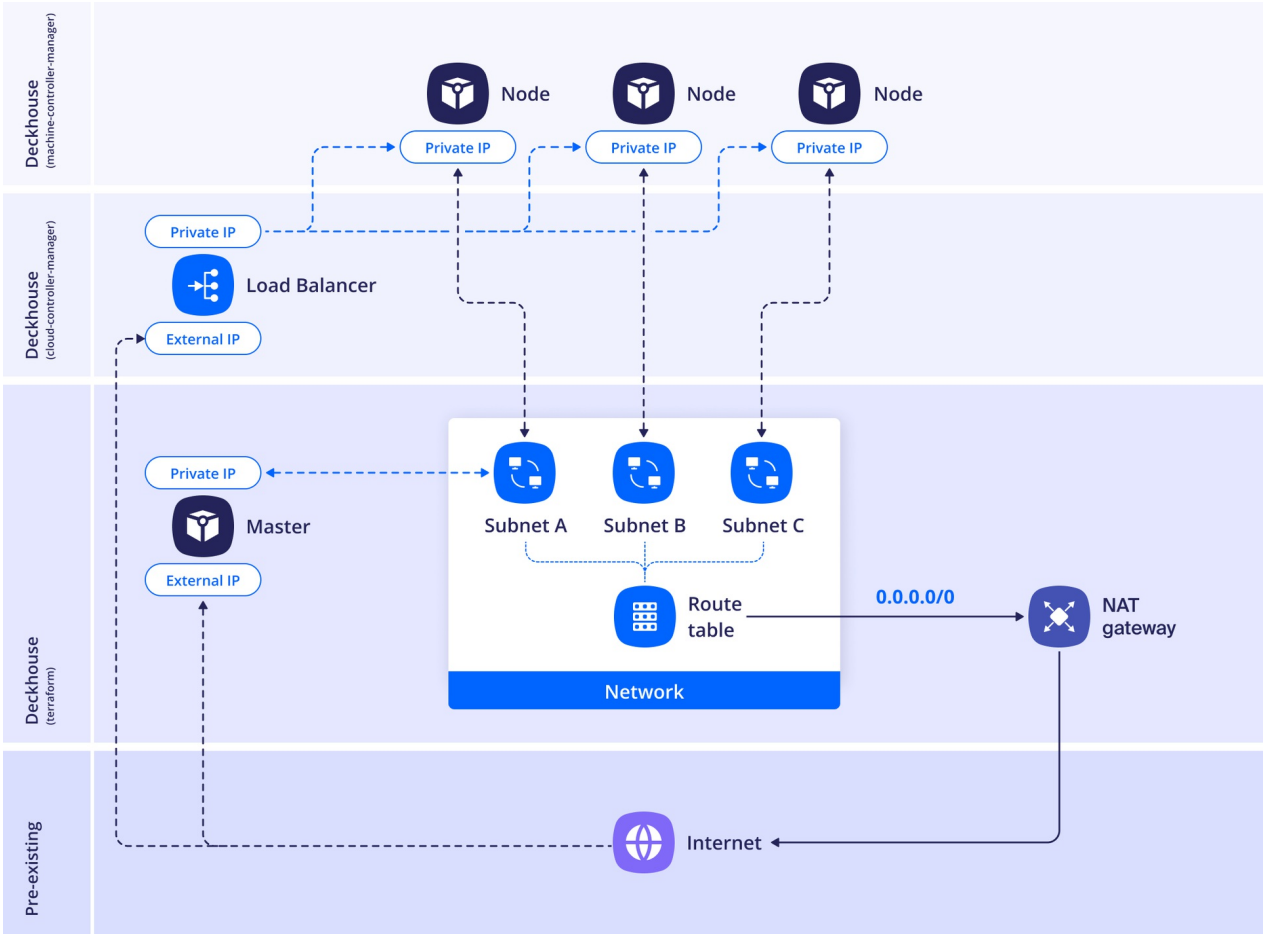


Layouts



The module lifecycle stage: General Availability

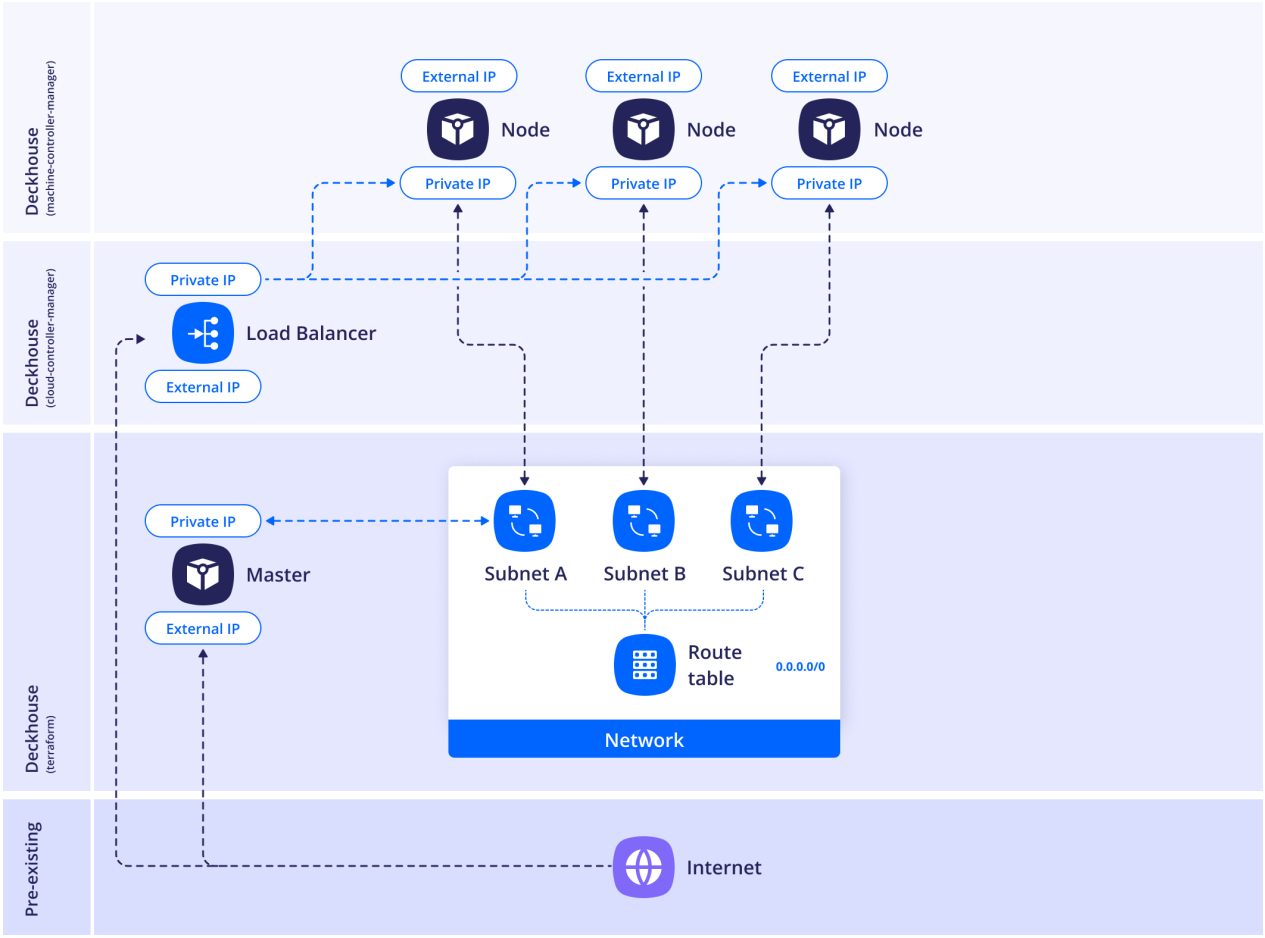
Three layouts are supported. Below is more information about each of them.



Standard

In this placement strategy, nodes do not have public IP addresses allocated to them; they use NAT gateway service in Yandex Cloud to connect to the Internet. NAT Gateway uses random public IP addresses from dedicated ranges. Because of this, it is impossible to whitelist the IP addresses of cloud resources located behind a specific NAT gateway on the side of other services.

Because nodes are created without public IP addresses in this layout, the master node must be accessible over SSH from the machine where `dhctl` is running: either directly over a private network or through a bastion host. If the master node is not directly accessible, run the installation with the `--ssh-bastion-host`, `--ssh-bastion-user`, and, if needed, `--ssh-bastion-port` parameters.



Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: YandexClusterConfiguration
layout: Standard
sshPublicKey: "<SSH_PUBLIC_KEY>"
nodeNetworkCIDR: 192.168.12.13/24
existingNetworkID: <EXISTING_NETWORK_ID>
provider:
  cloudID: <CLOUD_ID>
  folderID: <FOLDER_ID>
  serviceAccountJSON: |
    {
    "id": "id",
    "service_account_id": "service_account_id",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----\nMIIwID....AQAB\n-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----\nMIIE....1ZPJeBLt+\n-----END PRIVATE KEY-----
\n"
    }
masterNodeGroup:
  replicas: 3
  zones:
  - ru-central1-a
  - ru-central1-b
  - ru-central1-d
  instanceClass:
    cores: 4
    memory: 8192
    imageID: <IMAGE_ID>
    # Optional: uncomment to assign public IP addresses to master nodes.
    # externalIPAddresses:
    # - "<ZONE_A_EXTERNAL_IP_MASTER_1>"
    # - "Auto"
    # - "Auto"
    # externalSubnetIDs:
    # - <ZONE_A_SUBNET_ID>
    # - <ZONE_B_SUBNET_ID>
    # - <ZONE_D_SUBNET_ID>
    additionalLabels:
      takes: priority
nodeGroups:
- name: worker
  replicas: 2
  zones:
  - ru-central1-a
  - ru-central1-b
  instanceClass:
    cores: 4
    memory: 8192
    imageID: <IMAGE_ID>
    coreFraction: 50
    # Optional: uncomment to assign public IP addresses to worker nodes.
    # externalIPAddresses:
    # - "Auto"
    # - "Auto"
    # externalSubnetIDs:
    # - <ZONE_A_SUBNET_ID>
    # - <ZONE_B_SUBNET_ID>
    additionalLabels:
      role: example
labels:
  billing: prod
dhcpOptions:
  domainName: test.local
  domainNameServers:
  - <DNS_SERVER_1>
  - <DNS_SERVER_2>
```

WithoutNAT

In this layout, NAT (of any kind) is not used, and each node is assigned a public IP.

> **Caution!** The cloud-provider-yandex module does not support Security Groups, so all cluster nodes will be available without connection restrictions.

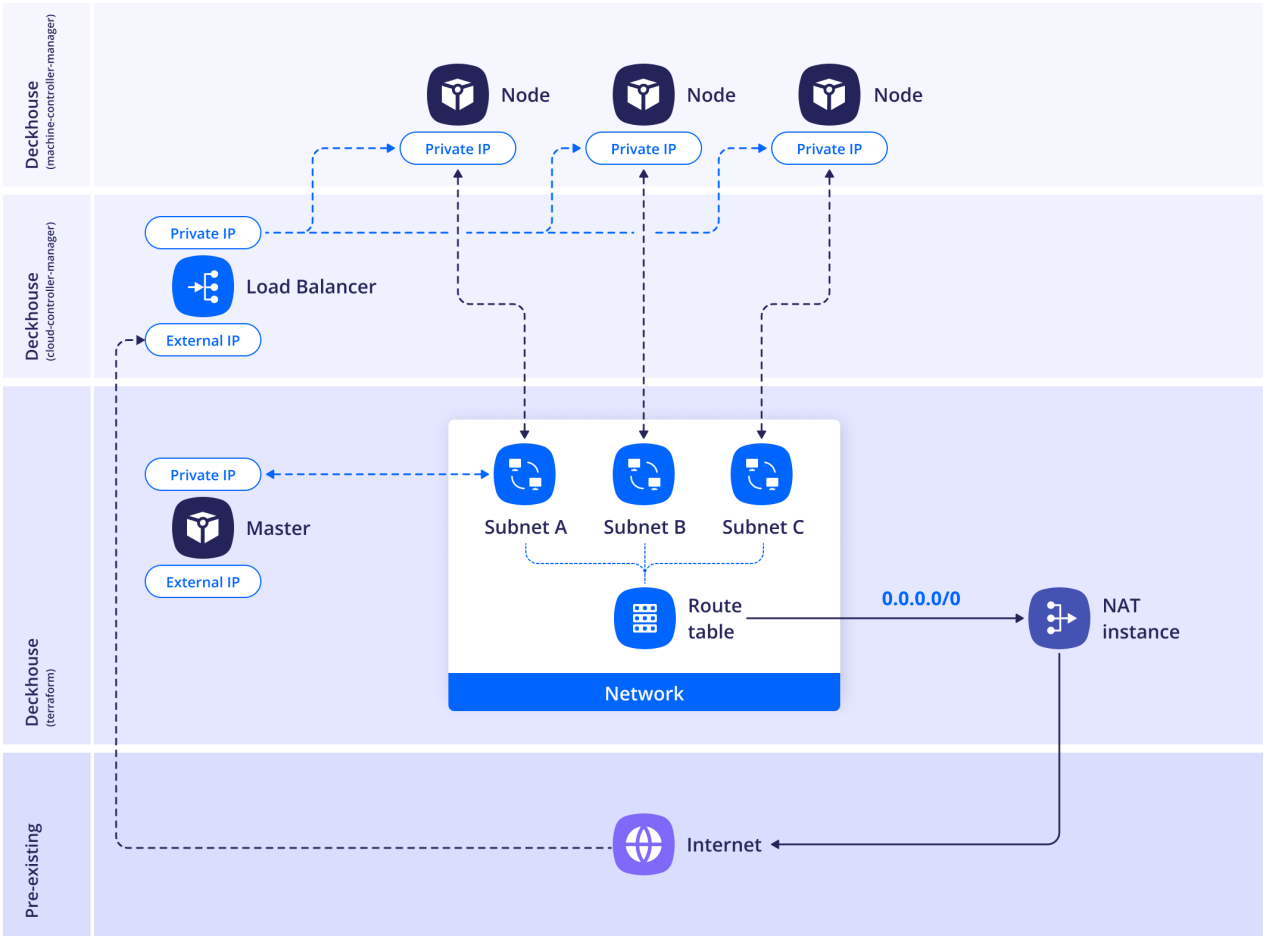
Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: YandexClusterConfiguration
layout: WithoutNAT
provider:
  cloudID: <CLOUD_ID>
  folderID: <FOLDER_ID>
  serviceAccountJSON: |
    {
    "id": "id",
    "service_account_id": "service_account_id",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----\nMIIwID....AQAB\n-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----\nMIIE....1ZPJeBLt+\n-----END PRIVATE KEY-----
\n"
    }
masterNodeGroup:
  replicas: 3
  instanceClass:
    cores: 4
    memory: 8192
    imageID: <IMAGE_ID>
    externalIPAddresses:
    - "Auto"
    - "Auto"
    - "Auto"
    externalSubnetIDs:
    - <ZONE_A_SUBNET_ID>
    - <ZONE_B_SUBNET_ID>
    - <ZONE_D_SUBNET_ID>
    zones:
    - ru-central1-a
    - ru-central1-b
    - ru-central1-d
nodeGroups:
- name: worker
  replicas: 2
  instanceClass:
    cores: 4
    memory: 8192
    imageID: <IMAGE_ID>
    coreFraction: 50
    externalIPAddresses:
    - "<ZONE_A_EXTERNAL_IP_WORKER_1>"
    - "Auto"
    externalSubnetIDs:
    - <ZONE_A_SUBNET_ID>
    - <ZONE_B_SUBNET_ID>
    zones:
    - ru-central1-a
    - ru-central1-b
sshPublicKey: "<SSH_PUBLIC_KEY>"
nodeNetworkCIDR: 192.168.12.13/24
existingNetworkID: <EXISTING_NETWORK_ID>
dhcpOptions:
  domainName: test.local
  domainNameServers:
  - <DNS_SERVER_1>
  - <DNS_SERVER_2>
```

WithNATInstance

In this placement strategy, Deckhouse creates a NAT instance inside new separate subnet and adds a rule to a route table containing a route to `0.0.0.0/0` with a NAT instance as the next hop. The subnet is allocated to prevent routing loops and must not overlap with other networks used in the cluster.

To place the NAT instance in an existing subnet, use the `withNATInstance.internalSubnetID` parameter — the instance will be created in the zone corresponding to that subnet.



If you need to create a new subnet, specify the `withNATInstance.internalSubnetCIDR` parameter — the NAT instance will be deployed in it.

One of the parameters — `withNATInstance.internalSubnetID` or `withNATInstance.internalSubnetCIDR` — is required.

When the `withNATInstance.internalSubnetCIDR` parameter is specified, the NAT instance will be created in a single instance in zone `a`.

When the `withNATInstance.internalSubnetID` parameter is specified, the NAT instance will be created in a single instance in the zone specified in the designated network settings.

If the `withNATInstance.externalSubnetID` is provided in addition to previous ones, the NAT instance will be attached to it via secondary interface.

Example of the layout configuration:

```
apiVersion: deckhouse.io/v1
kind: YandexClusterConfiguration
layout: WithNATInstance
withNATInstance:
  natInstanceExternalAddress: <NAT_INSTANCE_EXTERNAL_ADDRESS>
  internalSubnetID: <INTERNAL_SUBNET_ID>
  externalSubnetID: <EXTERNAL_SUBNET_ID>
provider:
  cloudID: <CLOUD_ID>
  folderID: <FOLDER_ID>
  serviceAccountJSON: |
    {
    "id": "id",
    "service_account_id": "service_account_id",
    "key_algorithm": "RSA_2048",
    "public_key": "-----BEGIN PUBLIC KEY-----\nMIIwID....AQAB\n-----END PUBLIC KEY-----\n",
    "private_key": "-----BEGIN PRIVATE KEY-----\nMIIE....1ZPJeBLt+\n-----END PRIVATE KEY-----
\n"
    }
masterNodeGroup:
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    cores: 4
    memory: 8192
    imageID: <IMAGE_ID>
nodeGroups:
- name: worker
  replicas: 1
  zones:
  - ru-central1-a
  instanceClass:
    cores: 4
    memory: 8192
    imageID: <IMAGE_ID>
    coreFraction: 50
sshPublicKey: "<SSH_PUBLIC_KEY>"
nodeNetworkCIDR: 192.168.12.13/24
existingNetworkID: <EXISTING_NETWORK_ID>
dhcpOptions:
  domainName: test.local
  domainNameServers:
  - <DNS_SERVER_1>
  - <DNS_SERVER_2>
```

i In this example, master and worker nodes are created without public IP addresses and without additional external network interfaces. Outbound traffic from the cluster subnets goes through the NAT instance.

The NAT instance is not automatically used by the `dhctl` installer as a bastion host or jump host. To install the cluster, the master node must be accessible over SSH from the machine where `dhctl` is running: either directly or through a bastion host.

If the master node does not have a public IP address or is not directly accessible, run the installation with the `--ssh-bastion-host` and `--ssh-bastion-user` parameters.

If you need to connect to the master node directly using a public IP address, specify the `externalIPAddresses` and `externalSubnetIDs` parameters for it. Keep in mind that the interface from the network specified in `externalSubnetIDs` will be used as the node's default gateway.

Cloud provider — zVirt

i The module lifecycle stage: General Availability

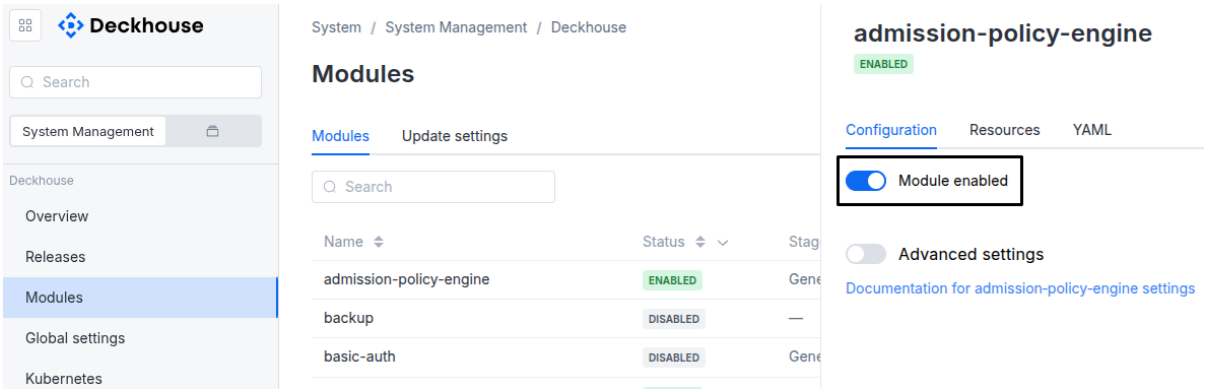
The `cloud-provider-zvirt` module integrates Deckhouse Kubernetes Platform with zVirt. It allows the `node-manager` module to use zVirt resources when provisioning nodes for a NodeGroup.

Features of the `cloud-provider-zvirt` module:

- Managing zVirt resources via `cloud-controller-manager`: updates virtual machine and Kubernetes node metadata and removes from Kubernetes nodes that no longer exist in zVirt.
- Provisioning disks via the zVirt CSI driver (`csi.ovirt.org`) so that PersistentVolumes can be requested from the cluster.
- Provisioning CloudPermanent nodes using the Terraform/OpenTofu provider `terraform-provider-ovirt`.
- Provisioning CloudEphemeral nodes via Cluster API (CAPI). Virtual machine parameters are set in the ZvirtInstanceClass resource.
- Registering with `node-manager` so that ZvirtInstanceClass can be used when describing a NodeGroup.
- Enabling CNI for new clusters automatically. By default, `cni-cilium` is used.

Configuration

> **i** The module lifecycle stage: General Availability



The module is automatically enabled for all cloud clusters deployed in zVirt.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-zvirt` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

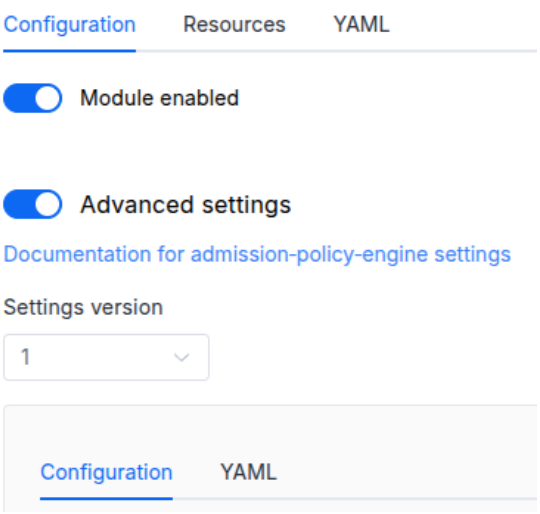
  ```
  d8 system module enable cloud-provider-zvirt
  ```

- **Using ModuleConfig `cloud-provider-zvirt`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cloud-provider-zvirt` (create it if necessary);

  Example of a manifest to enable module `cloud-provider-zvirt`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-zvirt
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cloud-provider-zvirt` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `cloud-provider-zvirt` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cloud-provider-zvirt`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cloud-provider-zvirt` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cloud-provider-zvirt
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cloud-provider-zvirt` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cloud-provider-zvirt`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cloud-provider-zvirt
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

The module does not have any settings.

Provider configuration

> **i** The module lifecycle stage: General Availability

> **i** If the cluster control plane is hosted on a virtual machines or bare-metal servers, the cloud provider uses the settings from the `cloud-provider-zvirt` module in the Deckhouse configuration. Otherwise, if the cluster control plane is hosted in a cloud, the cloud provider uses the ZvirtClusterConfiguration structure for configuration.

ZvirtClusterConfiguration

Version: deckhouse.io/v1

Describes the configuration of a cloud cluster in zVirt.

Used by the cloud provider if a cluster's control plane is hosted in the cloud.

Run the following command to change the configuration in a running cluster:

```
d8 system edit provider-cluster-configuration
```

> **i** After updating the node parameters, you need to run the `dhctl converge` command for the changes to take effect. For more information about changing the cluster configuration, see Adding and managing cloud nodes.

Example:

```
apiVersion: deckhouse.io/v1
kind: ZvirtClusterConfiguration
layout: Standard
clusterID: b46372e7-0d52-40c7-9bbf-fda31e187088
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: debian-bookworm
    vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
    storageDomainID: c4bf82a5-b803-40c3-9f6c-b9398378f424
nodeGroups:
- name: worker
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    template: debian-bookworm
    vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
provider:
  server: "<SERVER>"
  username: "<USERNAME>"
  password: "<PASSWORD>"
  insecure: true
```

- **apiVersion**
  string

  Required value

  Allowed values: `deckhouse.io/v1`

- **clusterID**
  string

  Required value

  Cluster ID with shared storage domains and CPUs of the same type to create virtual machines.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  clusterID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **kind**
  string

  Required value

  Allowed values: `ZvirtClusterConfiguration`

- **layout**
  string

  Required value

  The way resources are located in the cloud.

Read more about possible provider layouts.

- **masterNodeGroup**
  object

  Required value

  The definition of the master’s NodeGroup.

  > **i** For the changes to take effect, run `dhctl converge` after modifying the parameters of the `masterNodeGroup` section.

  - **masterNodeGroup.instanceClass**
    object

    Required value

    Partial contents of the fields of the ZvirtInstanceClass.

    - **masterNodeGroup.instanceClass.customNetworkConfig**
      object

      Enables a custom static network configuration for nodes in this NodeGroup.

      If specified, you must set `networkInterfaceName`, `networkInterfaceAddress`, `networkInterfaceGateway` and `networkInterfaceNetmask`.

      - **masterNodeGroup.instanceClass.customNetworkConfig.dnsServers**
        string

        List of DNS servers.

        Example:

        ```
        dnsServers: 8.8.8.8 8.8.4.4
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceAddress**
        array of strings

        List of IP addresses to assign to the interface (one IP address per node).

        Example:

        ```
        networkInterfaceAddress:
        - 192.168.1.10
        - 192.168.1.11
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceGateway**
        string

        Default network gateway.

        Example:

        ```
        networkInterfaceGateway: 192.168.1.1
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceName**
        string

        Name of the network interface to apply the static configuration to.

        Example:

        ```
        networkInterfaceName: enp1s0
        ```

      - **masterNodeGroup.instanceClass.customNetworkConfig.networkInterfaceNetmask**
        string

        Subnet mask for the interface.

        Example:

        ```
        networkInterfaceNetmask: 255.255.255.0
        ```

    - **masterNodeGroup.instanceClass.etcdDiskSizeGb**
      integer

      Etcd disk size in GiB.

Default: `10`

Example:

```
etcdDiskSizeGb: 10
```

- **masterNodeGroup.instanceClass.memory**
integer

  Required value

  Memory in MiB to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  memory: 8192
  ```

- **masterNodeGroup.instanceClass.numCPUs**
integer

  Required value

  Number of vCPUs to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  numCPUs: 2
  ```

- **masterNodeGroup.instanceClass.rootDiskSizeGb**
integer

  Root disk size in GiB to use in zVirt VirtualMachines.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **masterNodeGroup.instanceClass.storageDomainID**
string

  Required value

  Storage domain id which contains the shared resources that must be available to all datacenter hosts.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  storageDomainID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **masterNodeGroup.instanceClass.template**
string

  Required value

  Template name to be cloned.

  Example:

  ```
  template: debian-bookworm
  ```

- **masterNodeGroup.instanceClass.vnicProfileID**
string

  Required value

  Virtual NIC profile ID on the basis of which the virtual NIC will be created.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

```
vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
```

- **masterNodeGroup.replicas**
  integer

  Required value

  The number of master nodes to create. It is important to have an odd number of masters to ensure a quorum.

  Allowed values: `1 <= X`

- **nodeGroups**
  array of objects

  An array of additional NodeGroups for creating static nodes (e.g., for dedicated front nodes or gateways).

  - **nodeGroups.instanceClass**
    object

    Required value

    Partial contents of the fields of the.

    - **nodeGroups.instanceClass.customNetworkConfig**
      object

      Enables a custom static network configuration for nodes in this NodeGroup.

      If specified, you must set `networkInterfaceName`, `networkInterfaceAddress`, `networkInterfaceGateway` and `networkInterfaceNetmask`.

      - **nodeGroups.instanceClass.customNetworkConfig.dnsServers**
        string

        List of DNS servers.

        Example:

        ```
        dnsServers: 8.8.8.8 8.8.4.4
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceAddress**
        array of strings

        List of IP addresses to assign to the interface (one IP address per node).

        Example:

        ```
        networkInterfaceAddress:
        - 192.168.1.10
        - 192.168.1.11
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceGateway**
        string

        Default network gateway.

        Example:

        ```
        networkInterfaceGateway: 192.168.1.1
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceName**
        string

        Name of the network interface to apply the static configuration to.

        Example:

        ```
        networkInterfaceName: enp1s0
        ```

      - **nodeGroups.instanceClass.customNetworkConfig.networkInterfaceNetmask**
        string

        Subnet mask for the interface.

        Example:

        ```
        networkInterfaceNetmask: 255.255.255.0
        ```

- **nodeGroups.instanceClass.etcdDiskSizeGb**
  integer

  Etcd disk size in GiB.

  Default: `10`

  Example:

  ```
  etcdDiskSizeGb: 10
  ```

- **nodeGroups.instanceClass.memory**
  integer

  Required value

  Memory in MiB to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  memory: 8192
  ```

- **nodeGroups.instanceClass.numCPUs**
  integer

  Required value

  Number of vCPUs to allocate to the VM.

  Allowed values: `1 <= X`

  Example:

  ```
  numCPUs: 2
  ```

- **nodeGroups.instanceClass.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in zVirt VirtualMachines.

  Default: `50`

  Example:

  ```
  rootDiskSizeGb: 50
  ```

- **nodeGroups.instanceClass.storageDomainID**
  string

  Storage domain id which contains the shared resources that must be available to all datacenter hosts.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{12}$`

  Example:

  ```
  storageDomainID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **nodeGroups.instanceClass.template**
  string

  Required value

  Template name to be cloned.

  Example:

  ```
  template: debian-bookworm
  ```

- **nodeGroups.instanceClass.vnicProfileID**
  string

  Required value

  Virtual NIC profile ID on the basis of which the virtual NIC will be created.

  Pattern: `^[\da-fA-F]{8}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]{4}\-[\da-fA-F]`

`{12}$`

Example:

```
vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
```

- **nodeGroups.name**
  string

  Required value

  The name of the NodeGroup to use for generating node names.

- **nodeGroups.nodeTemplate**

  Parameters of Node objects in Kubernetes to add after registering the node.

  - **nodeGroups.nodeTemplate.annotations**
    object

    The same as the `metadata.annotations` standard field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **nodeGroups.nodeTemplate.labels**
    object

    A list of labels to attach to cluster resources.

    The same as the `metadata.labels` standard field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **nodeGroups.nodeTemplate.taints**
    array of objects

    The same as the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **nodeGroups.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **nodeGroups.nodeTemplate.taints.key**
      string
    - **nodeGroups.nodeTemplate.taints.value**
      string

- **nodeGroups.replicas**
  integer

  Required value

  The number of nodes to create.

- **provider**
  object

  Required value

  Parameters for connecting to the Zvirt.

  - **provider.caBundle**
    string

    CA certificate in base64.

    Default:

  - **provider.insecure**
    boolean

    Set to `true` if Zvirt has a self-signed certificate.

    Default: `false`

  - **provider.password**
    string

    Required value

    The user’s password.

  - **provider.server**
    string

    Required value

    The URL to the Zvirt API endpoint.

  - **provider.username**
    string

    Required value

    The login ID.

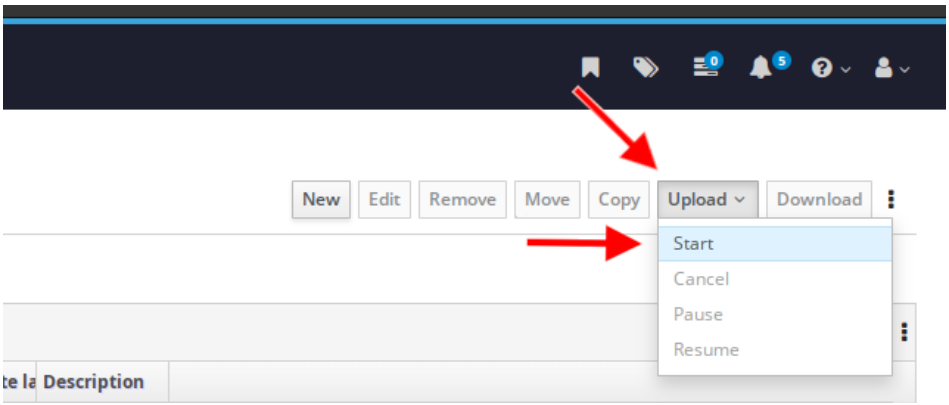
- **sshPublicKey**
  string

  Required value

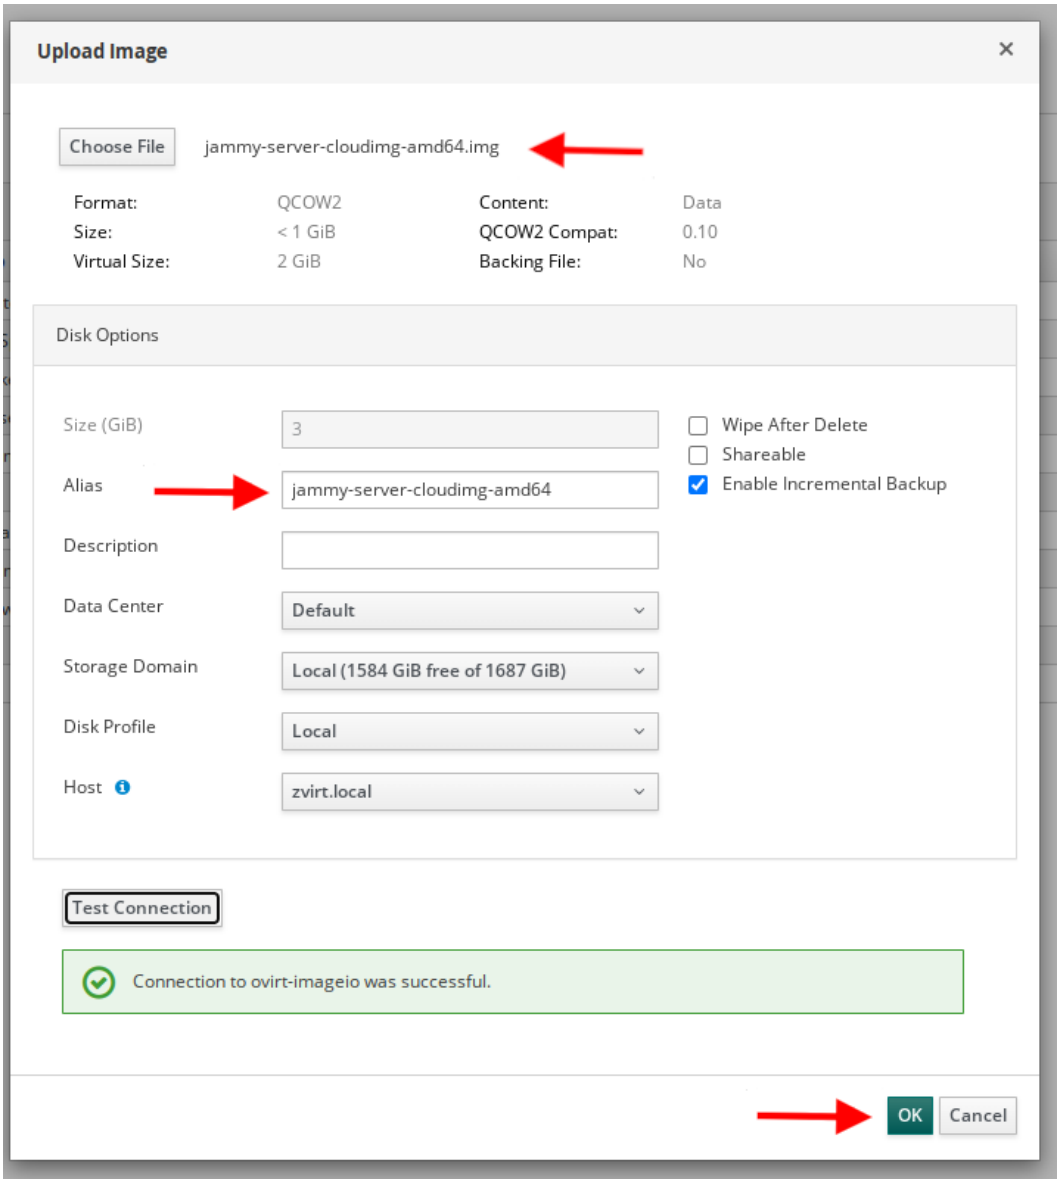
  a public key for accessing nodes.

Preparing environment

> **i** The module lifecycle stage: General Availability



Environment requirements



- A working zVirt installation with accessible API.
- zVirt version `4.0-4.4`.
- A user account with permissions to access the API and manage virtual machines.
- A storage domain with an uploaded cloud OS image.
- A prepared virtual machine template based on the cloud image.

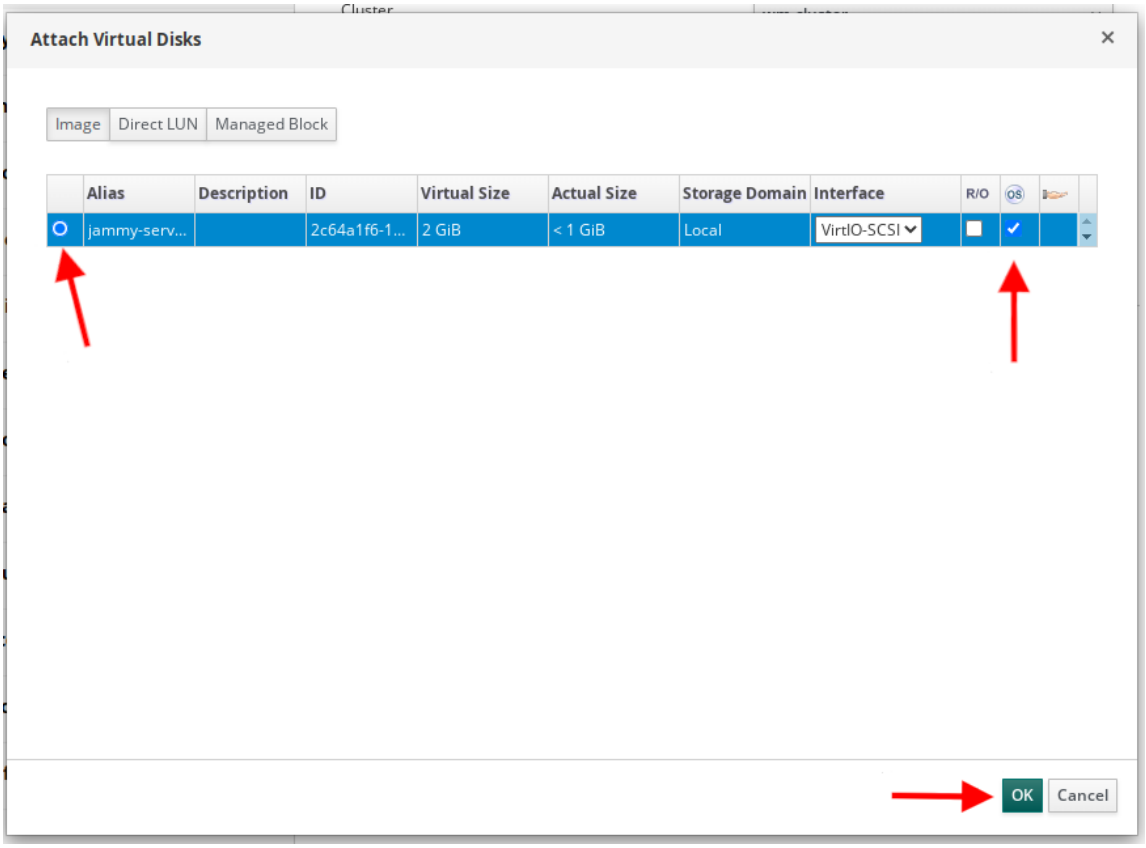
Prepare an operating system image

Operating system vendors typically provide special cloud builds of their operating systems for use in virtualization environments. These builds typically contain virtual hardware drivers, cloud-init, virtualization guest agents, and are distributed as IMG or QCOW2 disk images. We recommend that you use these cloud images as the OS on the nodes in your clusters. The cloud image of the operating system must be placed in the zVirt disk storage. Follow these steps to upload the OS image to the storage:

1. Go to the administration portal to the section *zVirt -> Storage -> Disks*.
2. Upload the cloud image of the OS to the repository.

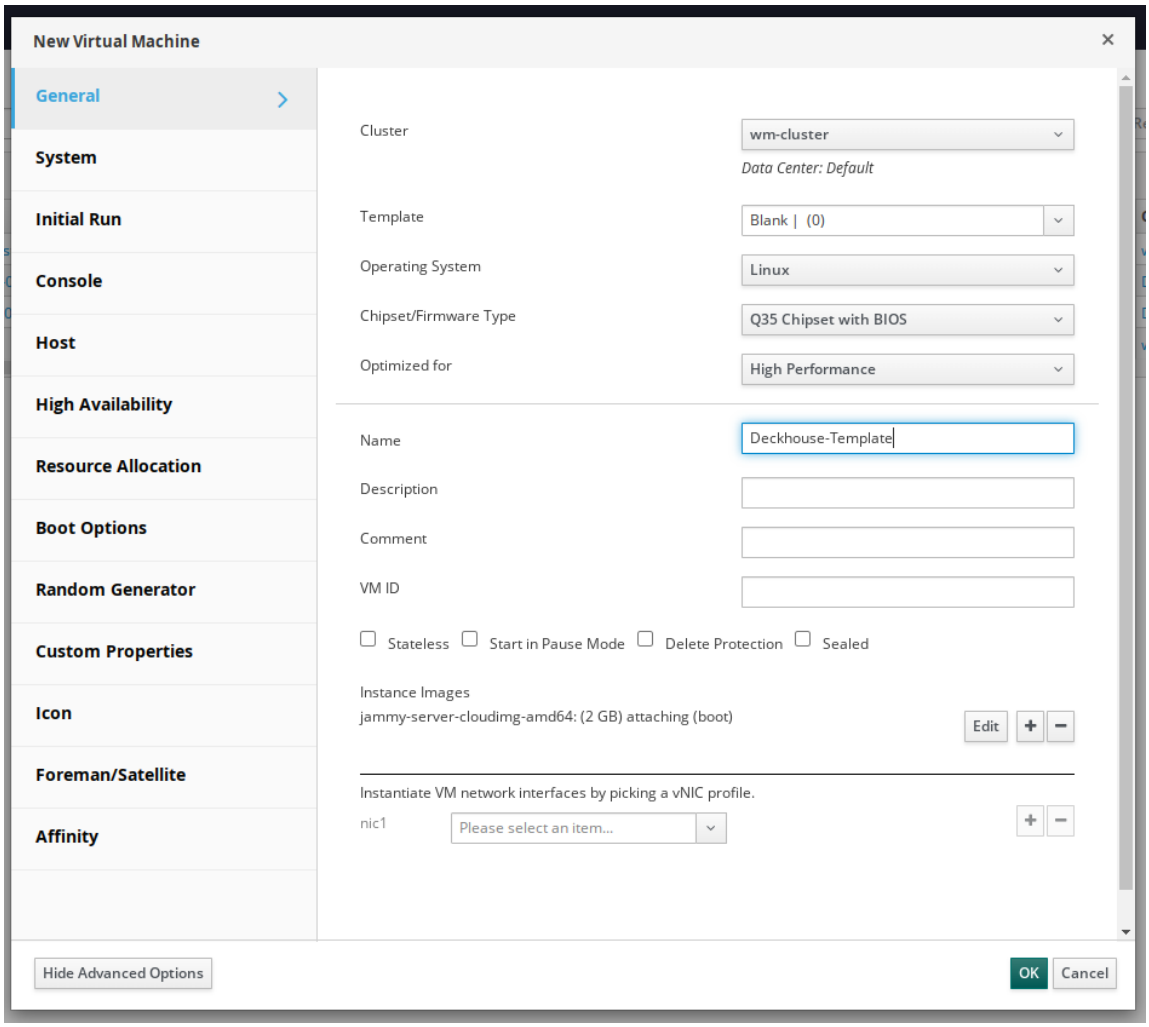
3. Wait until the image has finished loading into the storage. The status “OK” should appear in the “Status” column. This completes the preparation of the OS image.

Prepare a virtual machine template



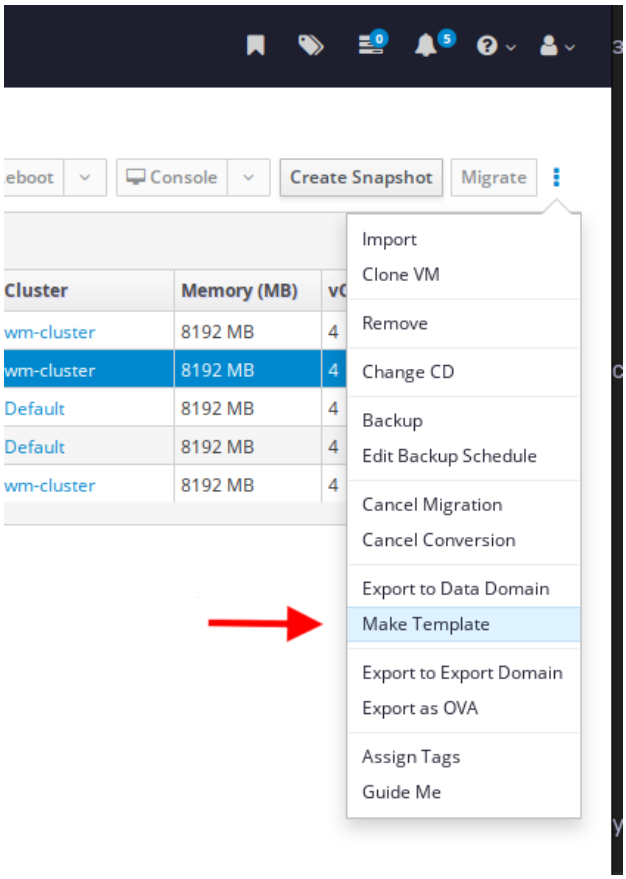
> ⚠ The provider supports working with only one disk in the virtual machine template. Make sure the template contains only one disk.

To create a virtual machine template, go to the *Compute -> Virtual Machines* section of the zVirt Administration Portal and create a new virtual machine with the following parameters:



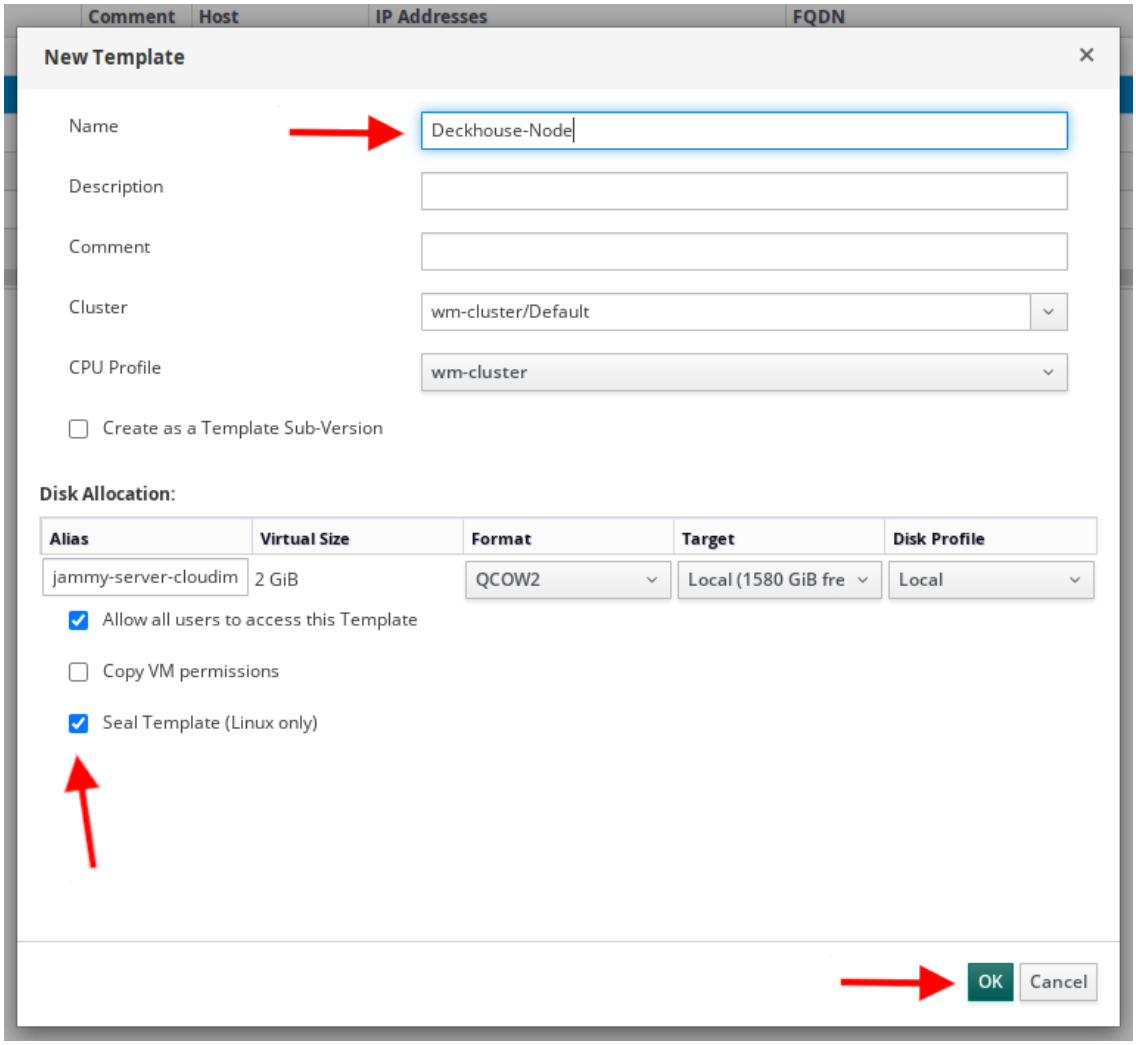
- Section *General*:

- **Template:** `Blank`
- **Operating system:** depending on the OS in the cloud image.
- **Optimized for:** High Performance.



- **Instance Images:** Attach -> Select the previously downloaded cloud-image of the OS, check “Bootable” and select “VirtIO“ interface. No other disks need to be created or attached.

- Network interfaces do not need to be attached, Deckhouse will create and configure them on the virtual machine by itself during installation.



- Leave the rest of the parameters as default and create a virtual machine. When the VM creation process is finished, create a template based on it:
  - Select the created VM in the list and go to the window of creating a new template.

  - Fill in the template parameters, only the name is mandatory. Enable the parameter *Seal Template*

(Linux only):

While the template is being created, the virtual machine and the cloud image disk will go into a state of *Image locked*. You can check that the template was successfully created in the section *Compute -> Templates*:

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

ZvirtInstanceClass

Scope: Cluster

- v1
- v1alpha1

Parameters of a group of zVirt VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.memory**
    integer

Required value

Memory in MiB to allocate to zVirt VirtualMachines.

Example:

```
memory: 8192
```

- **spec.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to zVirt VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **spec.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in zVirt VirtualMachines.

  The disk will be automatically resized if its size in the template differs from specified.

  Default: `30`

  Example:

  ```
  rootDiskSizeGb: 30
  ```

- **spec.template**
  string

  Required value

  Template name to be cloned.

  Example:

  ```
  template: debian-bookworm
  ```

- **spec.vnicProfileID**
  string

  Required value

  Virtual NIC profile ID on the basis of which the virtual NIC will be created.

  Pattern: `^[0-9a-fA-F]{8}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{12}$`

  Example:

  ```
  vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

Parameters of a group of zVirt VirtualMachines used by `machine-controller-manager` (the node-manager module).

The `CloudInstanceClass` resource of the `node-manager` module refers to this resource.

- **spec**
  object

  Required value

  - **spec.memory**
    integer

    Required value

    Memory in MiB to allocate to zVirt VirtualMachines.

    Example:

```
memory: 8192
```

- **spec.numCPUs**
  integer

  Required value

  Count of vCPUs to allocate to zVirt VirtualMachines.

  Example:

  ```
  numCPUs: 2
  ```

- **spec.rootDiskSizeGb**
  integer

  Root disk size in GiB to use in zVirt VirtualMachines.

  The disk will be automatically resized if its size in the template differs from specified.

  Default: `30`

  Example:

  ```
  rootDiskSizeGb: 30
  ```

- **spec.template**
  string

  Required value

  Template name to be cloned.

  Example:

  ```
  template: debian-bookworm
  ```

- **spec.vnicProfileID**
  string

  Required value

  Virtual NIC profile ID on the basis of which the virtual NIC will be created.

  Pattern: `^[0-9a-fA-F]{8}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{4}\-[0-9a-fA-F]{12}$`

  Example:

  ```
  vnicProfileID: 49bb4594-0cd4-4eb7-8288-8594eafd5a86
  ```

- **status**
  object
  - **status.nodeGroupConsumers**
    array of strings

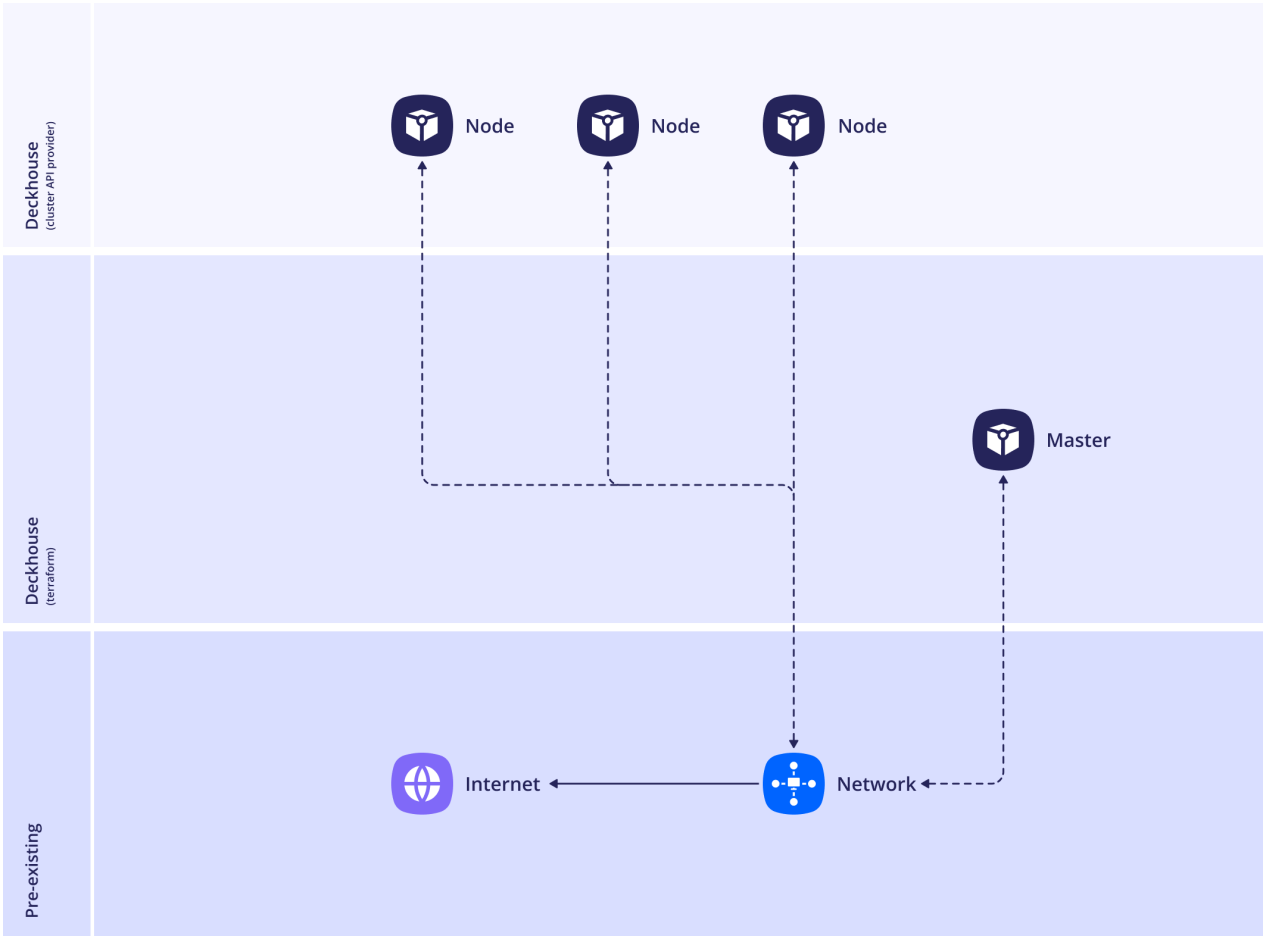
FAQ

> **i** The module lifecycle stage: General Availability

How to get vNicProfileId

VNicProfileId can be obtained by querying the zVirt API

```
curl -u "<user>@<profile>:<password>" -X GET https://<zVirt API URL>/vnicprofiles
```



Response example

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<vnic_profiles>
   <vnic_profile href="/ovirt-engine/api/vnicprofiles/49bb4594-0cd4-4eb7-8288-8594eafd5a86"
id="49bb4594-0cd4-4eb7-8288-8594eafd5a86">
      <name>vm-net-01</name>
      <link href="/ovirt-engine/api/vnicprofiles/49bb4594-0cd4-4eb7-8288-
8594eafd5a86/permissions" rel="permissions"/>
      <pass_through>
         <mode>disabled</mode>
      </pass_through>
      <port_mirroring>false</port_mirroring>
      <network href="/ovirt-engine/api/networks/74a741c9-0d40-4008-8e58-1c903ee6eba7"
id="74a741c9-0d40-4008-8e58-1c903ee6eba7"/>
   </vnic_profile>
   ...
</vnic_profiles>
```

Cloud provider - zVirt: Layouts

> **i** The module lifecycle stage: General Availability

Standard

Example of the layout configuration:

```
---
apiVersion: deckhouse.io/v1
kind: ZvirtClusterConfiguration
layout: Standard
sshPublicKey: "ssh-rsa AAAABBBB"
clusterID: "b46372e7-0d52-40c7-9bbf-fda31e187088"
provider:
  server: '<SERVER>'
  username: '<USERNAME>'
  password: '<PASSWORD>'
  insecure: true
masterNodeGroup:
  replicas: 1
  instanceClass:
    numCPUs: 4
    memory: 8192
    rootDiskSizeGb: 40
    template: ALT-p10
    vnicProfileID: "49bb4594-0cd4-4eb7-8288-8594eafd5a86"
    storageDomainID: "c4bf82a5-b803-40c3-9f6c-b9398378f424"
```

The cni-cilium module

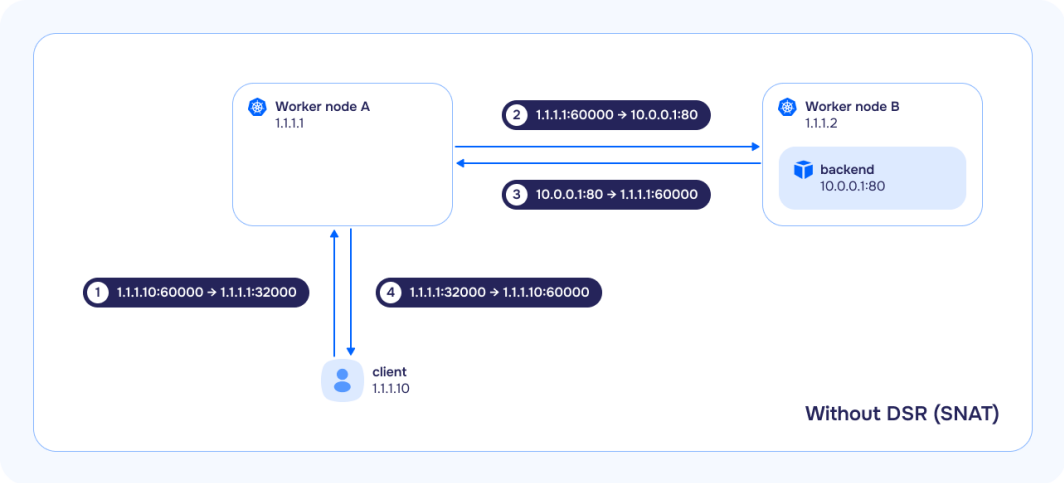
> **i** Available with limitations in: **CE, BE, SE**
>
> Available without limitations in: **SE+, EE**

> **i** The module lifecycle stage: General Availability

The `cni-cilium` module provides a network in a cluster. It is based on the Cilium project.

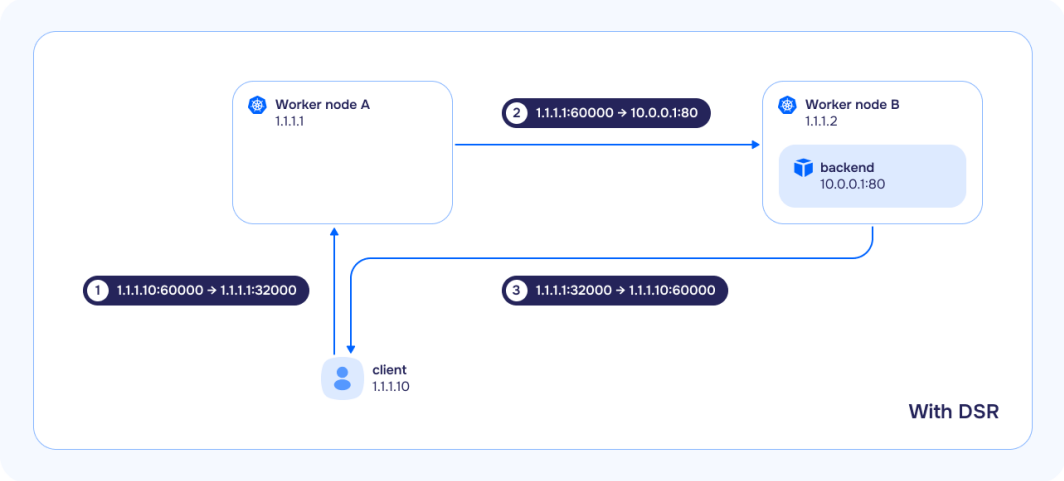
Limitations

1. Services with type `NodePort` and `LoadBalancer` are incompatible with hostNetwork endpoints in LB mode `DSR`. Switch to `SNAT` mode if it is required.
2. `HostPort` pods only bind to one IP address. If the OS has multiple interfaces/IP, Cilium will choose one, preferring `private` to `public`.
3. To ensure the stable operation of `cni-cilium` on cluster nodes, disable Elastic Agent or restrict its access to the Elastic management server. Elastic Agent includes an Elastic Endpoint component which uses the Extended Berkeley Packet Filter (eBPF) technology on cluster nodes and may remove critical eBPF programs required for `cni-cilium` to work correctly. For detailed information and discussion of the issue, refer to the publications of the Cilium and Elastic projects.
4. Kernel requirements:
   - Linux kernel version not lower than `5.8` for the `cni-cilium` module to work and work together with the istio, openvpn or node-local-dns modules.
5. OS compatibility:
   - Ubuntu:
     - incompatible with version 18.04;
     - HWE kernel installation required for working with version 20.04.
   - Astra Linux:
     - incompatible with the “Smolensk” edition.
   - CentOS:
     - for versions 7 and 8, a new kernel from the repository is required.



Handling external traffic in different `bpfLB` modes (replacing kube-proxy from Cilium)

Kubernetes typically uses schemes where traffic comes to a balancer that distributes it among many servers. Both incoming and outgoing traffic passes through the balancer. Thus, the total throughput is limited by the resources and channel width of the balancer. To optimize traffic and unload the balancer, the `DSR` mechanism was invented, in which incoming packets go through the balancer, and outgoing ones go directly from the terminating servers. Since responses are usually much larger in size than requests, this approach can significantly increase the overall throughput of the scheme.



To extend the capabilities, the module allows selectable mode of operation, which affects the behavior of `Service` with the `NodePort` and `LoadBalancer` types:

- `SNAT` (Source Network Address Translation) — is a subtype of NAT in which, for each outgoing packet, the source IP address is translated to the IP address of the gateway from the target subnet, and incoming

packets passing through the gateway are translated back based on a translation table. In this mode, `bpfLB` fully replicates the logic of `kube-proxy`:
  - if `externalTrafficPolicy: Local` is specified in the `Service`, the traffic will be forwarded and balanced only to those target pods running on the same node where the traffic arrived. If the target pod is not running on this node, the traffic will be dropped.
  - if `externalTrafficPolicy: Cluster` is specified in the `Service`, the traffic will be forwarded and balanced to all target pods in the cluster. At the same time, if the target pods are located on other nodes, SNAT will be performed when transmitting traffic to them (the source IP address will be replaced with the InternalIP of the node).

- `DSR` (Direct Server Return) — is a method where all incoming traffic passes through the load balancer, and all outgoing traffic bypasses it. This method is used instead of `SNAT`. Often, responses are much larger than requests, and `DSR` can significantly increase the overall throughput of the scheme:
  - if `externalTrafficPolicy: Local` is specified in the `Service`, its behavior is completely analogous to `kube-proxy` and `bpfLB` in `SNAT` mode.
  - if `externalTrafficPolicy: Cluster` is specified in the `Service`, the traffic will be forwarded and balanced to all target pods in the cluster. It is important to take into account the following features:
    - if the target pods are on other nodes, then the source IP address will be preserved when incoming traffic is sent to them;
    - outgoing traffic will go directly from the node on which the target pod was launched;
    - the source IP address will be replaced with the external IP address of the node to which the incoming request **originally** came.

⚠ In case of using `DSR` and `Service` mode with `externalTrafficPolicy: Cluster` additional network environment settings are required. Network equipment must be ready for asymmetric traffic flow: IP address anti-spoofing tools (`uRPF`, `sourceGuard`, etc.) must be disabled or configured accordingly.

- `Hybrid` — in this mode, TCP traffic is processed in `DSR` mode, and UDP in `SNAT` mode.

Using CiliumClusterwideNetworkPolicies

✖ Using CiliumClusterwideNetworkPolicies if the `policyAuditMode` option is absent in the cni-cilium module settings may lead to incorrect operation of Control plane or loss of SSH access to all cluster nodes.

Follow these steps to use CiliumClusterwideNetworkPolicies:

1. Apply the primary set of `CiliumClusterwideNetworkPolicy` objects. To do this, in the settings of the cni-cilium module add the configuration option `policyAuditMode` with the value `true`. The option can be removed after applying all `CiliumClusterwideNetworkPolicy` objects and verifying their functionality in Hubble UI.
2. Apply network security policy rule:

```
apiVersion: "cilium.io/v2"
kind: CiliumClusterwideNetworkPolicy
metadata:
  name: "allow-control-plane-connectivity"
spec:
  ingress:
  - fromEntities:
    - kube-apiserver
  nodeSelector:
    matchLabels:
      node-role.kubernetes.io/control-plane: ""
```

If CiliumClusterwideNetworkPolicies are not used, the control plane may work incorrectly for up to a minute during the reboot of `cilium-agent` pods. This occurs due to Conntrack table reset. Binding to the `kube-apiserver` entity helps to bypass the bug.

Changing Cilium Operation Mode

When changing Cilium's operation mode (the tunnelMode parameter) from `Disabled` to `VXLAN` or vice versa, it is necessary to reboot all nodes, otherwise, pod availability issues may occur.

Disabling the kube-proxy Module

Cilium fully replaces the functionality of the `kube-proxy` module, so `kube-proxy` is automatically disabled when the `cni-cilium` module is enabled.

Using selective load balancing algorithm for services

In Deckhouse Kubernetes Platform, you can apply the following algorithms to load balance service traffic:

- `Random`: Randomly select a backend for each connection. Easy to implement, but does not always provide even distribution.
- `Maglev`: Uses consistent hashing to distribute traffic evenly, suitable for large-scale services.
- `Least Connections`: Directs traffic to the backend with the lowest number of active connections, optimizing load for applications with long-lived connections.

By default, the **Random** balancing algorithm is set for all services. However, Deckhouse allows you to override the algorithm for individual services. To use a selective balancing algorithm for a specific service, follow these steps:

- Edit the `cni-cilium` module configuration in Deckhouse by enabling the `extraLoadBalancerAlgorithmsEnabled` parameter. This activates support for service annotations for selective algorithms.
- In the service manifest, specify the `service.cilium.io/lb-algorithm` annotation with one of the values: `random`, `maglev`, or `least-conn`.

⚠ This mechanism requires Linux kernel version 5.15 or higher to work correctly.

Using Egress Gateway

Egress Gateway in Deckhouse Kubernetes Platform can be used in one of two modes: Basic and Mode with Virtual IP. Use Custom Resource EgressGateway (parameter `spec.sourceIP.node`) to select the mode.

Basic mode

Pre-configured IP addresses are used on egress nodes.

Virtual IP mode

The ability to dynamically assign additional IP addresses to nodes is implemented.

Exporting data from Hubble

Deckhouse Kubernetes Platform allows to configure data export from Hubble running inside Cilium agents using the cluster-scoped custom resource `HubbleMonitoringConfig`. To enable export, create a HubbleMonitoringConfig resource.

⚠ Creating or modifying the HubbleMonitoringConfig resource will **restart all Cilium agents** in the cluster.

Third-party components

List of third-party software used in the `cni-cilium` module:

- Cilium 1.17.4

  License: Apache License 2.0

  Cilium is open source software for providing and transparently securing network connectivity and loadbalancing between application workloads such as application containers or processes.

- CNI plugins 1.7.1

  License: Apache License 2.0

  Some reference and example networking plugins, maintained by the CNI team.

- Gops 0.3.27

  License: BSD 3-Clause License

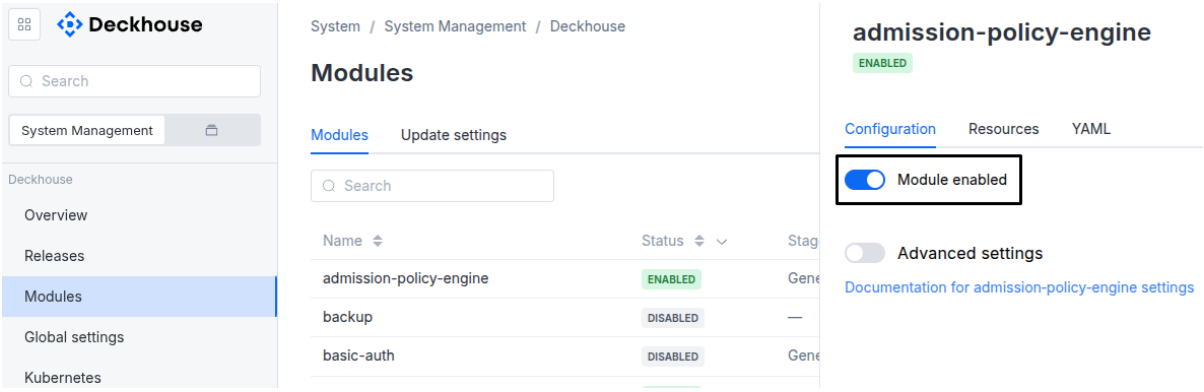
  A tool to list and diagnose Go processes currently running on your system.

Configuration

ℹ Available with limitations in: **CE, BE, SE**

Available without limitations in: **SE+, EE**

ℹ The module lifecycle stage: General Availability



The module has 8 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-cilium` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

Example of enabling the module:

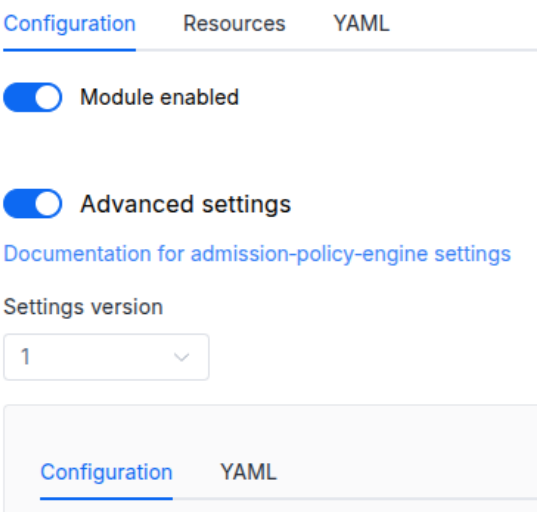
```
d8 system module enable cni-cilium
```

- **Using ModuleConfig `cni-cilium`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cni-cilium` (create it if necessary);

  Example of a manifest to enable module `cni-cilium`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cni-cilium
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-cilium` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `cni-cilium` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cni-cilium`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cni-cilium` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc cni-cilium
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cni-cilium` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

  Example of a manifest for ModuleConfig `cni-cilium`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cni-cilium
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.activeL2NeighborDiscoveryEnabled**
    boolean

    Enables the Cilium `L2 neighbor discovery` mechanism, which helps ensure that ARP table entries are kept up-to-date on all cluster nodes.

    Default: `true`
  - **settings.bpfLBMode**
    string

    eBPF LoadBalancer mode:

    - `SNAT` — traffic from the client to the pod (and back) passes through NAT, and accordingly the sender's address is lost.
    - `DSR` — traffic from the client to the pod passes with the sender's address preserved, and back - according to the routing rules (bypassing the balancer). This mode saves network traffic and reduces delays, but only works for TCP traffic.
    - `Hybrid` — TCP traffic is processed in DSR mode, and UDP traffic is processed in SNAT mode.

    Default: `Hybrid`

    Allowed values: `SNAT`, `Hybrid`, `DSR`
  - **settings.createNodeRoutes**
    boolean

    Create routes to Pods on other Nodes.

    All Nodes must be located in the same L2 domain.
  - **settings.debugLogging**
    boolean

    Enables debug logging for Cilium components.

    Default: `false`
  - **settings.encryption**
    object

    CNI Cilium encryption settings.

    - **settings.encryption.mode**
      string

      Encryption mode:

      - `Disabled` — encryption is disabled.
      - `WireGuard` — enables traffic encryption between pods using WireGuard.

        > **i** Note! Before using WireGuard encryption, please ensure that the Linux kernel running on the cluster nodes has support WireGuard (either via the CONFIG_WIREGUARD=m kernel config option on Linux 5.6 and newer, or using an external WireGuard module for older kernels).

        > **i** Note! Using WireGuard may cause significant CPU consumption by Cilium agent pods.

      Default: `Disabled`

Allowed values: `Disabled`, `WireGuard`

- **settings.encryption.nodeToNodeModeEnabled**
  boolean

  Enabling traffic encryption between nodes and pods in HostNetwork.

  > **i** Note! The node-to-node traffic from and to the control-plane nodes is left unencrypted to prevent possible communication issues when renewing WireGuard public keys. At the same time, the traffic between control-plane components is still encrypted at the application layer.

  > **i** Note! When this mode is active, `NodePort` and `HostPort` are not available from the `PodNetwork`.

  Default: `false`

- **settings.exclusiveCNIPlugin**
  boolean

  Prevents additional CNI plugins from being enabled on cluster nodes. If the Istio module's `dataPlane.trafficRedirectionSetupMode` setting is set to `CNIPlugin`, the option will be automatically set to `false`.

  Explicitly disabling this option is recommended only when using an additional CNI or a specific CNI plugin in the cluster. An example of such a use case could be the Linkerd CNI plugin.

  Default: `true`

- **settings.extraLoadBalancerAlgorithmsEnabled**
  boolean

  Allows selectively overriding the load balancing algorithm using eBPF between backends for individual services. The annotation `service.cilium.io/lb-algorithm` is used for overriding with one of the following values: `random`, `maglev`, or `least-conn`.

  > **i** Note! This option requires the Linux kernel version on the nodes to be at least 5.15.

  Default: `false`

- **settings.labelsRegex**
  array of strings

  Cilium creates security identifiers based on the k8s entity labels. The more labels are involved in this process, the higher the access granularity that can be achieved. However, in large clusters, excessive granularity can create a heavy load. You can use the `labelsRegex` option to explicitly specify which labels are to be used for security policies, and which labels are to be neglected. Refer to the documentation to learn more about reducing the identity cardinality

  Each label must be specified by a RegExp expression in YAML quoted string format. Note that special characters must be escaped.

  Example:

  ```
  labelsRegex:
  - k8s:!app\.kubernetes\.io
  - k8s:io\.cilium\.k8s\.policy
  ```

- **settings.loadBalancerICMPReplyEnabled**
  boolean

  Enable ICMP Echo Reply generation for LoadBalancer service IPs.

  When enabled, nodes respond to ICMP Echo Requests (ping) addressed to LoadBalancer external IPs.

  Default: `false`

- **settings.loadBalancerSourceRangeAllTypes**
  boolean

  Enable loadBalancerSourceRanges CIDR filtering for all service types, not just LoadBalancer services. The corresponding NodePort and ClusterIP will also apply the CIDR filter. For more detailed information, please visit the link.

  Default: `true`

- **settings.masqueradeMode**
  string

  Cilium masquerade work mode for pods traffic leaving the cluster.

  - `BPF` - use cilium BPF. Basic operation mode.

    In this mode, masquerade will not be used if the destination IP address is within the `podSubnetCIDR` or `InternalIP`/`ExternalIP` of any of the cluster nodes.

  - `Netfilter` - use kernel Netfilter(iptables/nf_tables).

    In this mode, masquerade will not be used if the destination IP address is within the `podSubnetCIDR` or `InternalIP`/`ExternalIP` of any of the cluster nodes.

  > **i** In `BPF` mode, if `ExternalIP` other than `InternalIP` is specified for a cluster node, and that IP address is not currently assigned to any interface on the node, it will not be reachable from neighboring nodes from pods network. The `Netfilter` mode allows you to bypass this limitation, but some other features stop working, such as `EgressGateway`.

  Default: `BPF`

  Allowed values: `Netfilter`, `BPF`

- **settings.policyAuditMode**
  boolean

  Do not enforce any Network Policy. Just log allowed/disallowed connections.

  Default: `false`

- **settings.resourcesManagement**

  Settings for CPU and memory requests and limits by cilium agent pods.

  Examples:

  ```
  resourcesManagement:
    mode: VPA
    vpa:
      mode: InPlaceOrRecreate
      cpu:
        min: 50m
        max: 2
        limitRatio: 1.5
      memory:
        min: 256Mi
        max: 2Gi
        limitRatio: 1.5
  ```

  ```
  resourcesManagement:
    mode: Static
    static:
      requests:
        cpu: 55m
        memory: 256Mi
      limits:
        cpu: 2
        memory: 2Gi
  ```

```
resourcesManagement:
 mode: VPA
 vpa:
   mode: Auto
   cpu:
     min: 50m
     max: 2
     limitRatio: 1.5
   memory:
     min: 256Mi
     max: 2Gi
     limitRatio: 1.5
```

- **settings.resourcesManagement.mode**
  string

  Resource management mode:

  - `Static` is a classic one. In it, you specify requests/limits. The parameters of this mode are defined in the static parameter section;
  - `VPA` mode uses VPA. You can configure this mode by modifying parameters in the vpa parameter section.

  Default: `VPA`

  Allowed values: `VPA`, `Static`

- **settings.resourcesManagement.static**
  object

  Resource management options for the `Static` mode.

  - **settings.resourcesManagement.static.limits**
    object

    Configuring CPU and memory limits.

    - **settings.resourcesManagement.static.limits.cpu**
      string or number

      Configuring CPU limits.

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.static.limits.memory**
      string or number

      Configuring memory limits.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.resourcesManagement.static.requests**
    object

    Resource requests settings for pods.

    - **settings.resourcesManagement.static.requests.cpu**
      string or number

      Configuring CPU requests.

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.static.requests.memory**
      string or number

      Configuring memory requests.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.resourcesManagement.vpa.cpu.limitRatio**
      number

The CPU limits/requests ratio.

This ratio is used for calculating the initial CPU limits for a pod.

If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

- **settings.resourcesManagement.vpa.cpu.max**
  string or number

  The maximum value that the VPA can set for the CPU requests.

  Default: `4`

  Pattern: `^[0-9]+m?$`

- **settings.resourcesManagement.vpa.cpu.min**
  string or number

  The minimum value that the VPA can set for the CPU requests.

  Default: `100m`

  Pattern: `^[0-9]+m?$`

- **settings.resourcesManagement.vpa.memory**
  object

  Memory-related VPA settings.

  - **settings.resourcesManagement.vpa.memory.limitRatio**
    number

    The memory limits/requests ratio.

    This ratio is used for calculating the initial memory limits for a pod.

    If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

  - **settings.resourcesManagement.vpa.memory.max**
    string or number

    The maximum memory requests the VPA can set.

    Default: `4Gi`

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.resourcesManagement.vpa.memory.min**
    string or number

    The minimum memory requests the VPA can set.

    Default: `128Mi`

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa.mode**
  string

  VPA operating mode.

  - `Initial` — VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
  - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.
  - `Auto` — VPA automatically recreates pods to apply updated resource values.

    > **i** Starting from Deckhouse version 1.75, this mode is considered legacy. It is recommended to use `InPlaceOrRecreate` instead.

  Default: `Initial`

  Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **settings.sctpEnabled**
  boolean

  Enable SCTP support for Cilium (for both incoming and outgoing traffic).

> **Note.** Cilium implements only basic SCTP support. Therefore, when using SCTP with Cilium, please be aware of the following limitations:
>
> - The following features are not currently supported: `SCTP multi-homing`, `NetworkPolicies for pod-to-VIP`.
> - For incoming SCTP packets port overwriting is not supported. This means that applications must be published through either HostPort or Service, where the `targetPort` MUST match the `port` specified. Otherwise, the packet will be dropped.
> - For outgoing SCTP packets, only 1:1 SNAT is supported by default. In this mode, only the src_ip is replaced, while the src_port remains unchanged. If the src_port is already in use on the node, the packet will be rejected. To enable src_port substitution, you must switch the `masqueradeMode` parameter to `Netfilter` mode.

Default: `false`

- **settings.svcSourceRangeCheck**
  boolean

  For services of the `loadBalancer` type, enables checking the source IP for compliance with loadBalancer.sourceRanges. The check is not performed if access is made from within the cluster or the `sourceRanges` parameter is empty/not specified. Some cloud providers support filtering of incoming traffic based on the `sourceRanges` parameter in their loadBalancer implementations. In such cases, the cilium documentation recommends disabling the `svcSourceRangeCheck` option.

  Do not enable if another balancer or any type of SNAT is running in front of the services.

  Default: `false`

- **settings.tunnelMode**
  string

  Tunnel mode.

  > Note! After changing the parameter, it is necessary to restart all nodes, otherwise, there may be problems with the availability of Pods!

  > Note! VXLAN mode is not compatible with following bpfLBMode modes: Hybrid, DSR. bpfLBMode will be overriden to SNAT if the tunnelMode is VXLAN.

  Default: `Disabled`

  Allowed values: `Disabled`, `VXLAN`

Custom Resources

> The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

EgressGatewayPolicy

Scope: Cluster
Version: v1alpha1

Interface for configuring policies to redirect application traffic to specific egress gateways described through the EgressGateway interface.

- **spec**
  object

  Required value

  - **spec.destinationCIDRs**
    array of strings

    Available in editions: SE+, EE

    Network requests towards these subnets will be routed through the egress gateway.

  - **spec.egressGatewayName**

string

Required value

Available in editions: SE+, EE

The name of the EgressGateway resource that describes the egress gateway for handling traffic.

- **spec.excludedCIDRs**
  array of strings

  Available in editions: SE+, EE

  Network ranges that are required to be excluded from the ranges described in `destinationCIDRs`. Note that you do not need to exclude the special cluster ranges (`podSubnetCIDR` and `serviceSubnetCIDR`).

- **spec.selectors**
  array of objects

  Available in editions: SE+, EE

  Application Pod Selectors. Their traffic will be routed through the appropriate egress gateway. For namespase designation use the `io.kubernetes.pod.namespace` pseudo-label.

  - **spec.selectors.podSelector**
    object

    Required value

    Available in editions: SE+, EE

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

    - **spec.selectors.podSelector.matchExpressions**
      array of objects

      Available in editions: SE+, EE

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **spec.selectors.podSelector.matchExpressions.key**
        string

        Required value

        Available in editions: SE+, EE

        key is the label key that the selector applies to.

      - **spec.selectors.podSelector.matchExpressions.operator**
        string

        Required value

        Available in editions: SE+, EE

        operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

      - **spec.selectors.podSelector.matchExpressions.values**
        array of strings

        Available in editions: SE+, EE

        values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

    - **spec.selectors.podSelector.matchLabels**
      object

      Available in editions: SE+, EE

      matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **status**
  object

EgressGateway

Scope: Cluster
Version: v1alpha1

Interface for configuring a fault-tolerant egress gateway based on a group of nodes.

The configured egress gateways can be used in EgressGatewayPolicy interface to configure egress gateway for application Pods.

- **spec**
  object
  - **spec.nodeSelector**
    object

    Available in editions: SE+, EE

    The selector for a group of nodes that will transfer network requests to external services.

    Among these nodes, eligible nodes will be detected and one of them will be assigned as the active one. Signs of an eligible node:

    - The node is in Ready state.
    - Node is not cordoned.
    - The cilium-agent on the node is in the Ready state.

    Different EgressGateways can use common nodes for operation, and active nodes will be selected independently for each EgressGateway, thus distributing the load between them.

  - **spec.sourceIP**
    object
    - **spec.sourceIP.mode**
      string

      Required value

      Available in editions: SE+, EE

      A method for determining the source IP address to be assigned to requests through this gateway.

      Possible options:

      - `PrimaryIPFromEgressGatewayNodeInterface` (basic mode) — the primary IP address on the *public* network interface of the node will be used as the source IP address.

        Particularities:

        - When the active node goes down and a new node is assigned, the outgoing IP address will change.
        - The network subsystem on all egress nodes must be configured in advance:
          - the *public* interfaces must have the same name (eth1, for example),
          - all necessary routes for access to all external public services must be configured.

      - `VirtualIPAddress` (Virtual IP mode) — explicitly specify the outgoing IP address.

        Particularities:

        - If the active node goes down, the outgoing IP address will not change.
        - The network subsystem on all egress nodes must be configured in advance:
          - all necessary routes for access to all external public services must be configured,
          - the *public* interface must be prepared to automatically configure a *virtual* IP as a secondary IP address (if an egress node is designated as active, the address will not appear in the IP list on the *public* interface, but the node will emulate it with ARP-responses)

      Allowed values: `VirtualIPAddress`, `PrimaryIPFromEgressGatewayNodeInterface`

    - **spec.sourceIP.primaryIPFromEgressGatewayNodeInterface**
      object

      Used for basic mode (if `mode: PrimaryIPFromEgressGatewayNodeInterface`).

      - **spec.sourceIP.primaryIPFromEgressGatewayNodeInterface.interfaceName**
        string

        Available in editions: SE+, EE

        The interface name on the egress nodes through which external requests are processed.

    - **spec.sourceIP.virtualIPAddress**
      object

      Used for mode with Virtual IP (if `mode: PrimaryIPFromEgressGatewayNodeInterface`).

      - **spec.sourceIP.virtualIPAddress.interfaces**

array of strings

Available in editions: SE+, EE

The list of network interfaces to which the *virtual* IP will be simulated.

Default: `[]`

- **spec.sourceIP.virtualIPAddress.ip**
  string

  Available in editions: SE+, EE

  The *virtual* source IP address to be assigned to outgoing requests through the egress gateway.

- **status**
  object
  - **status.activeNodeName**
    string

    The name of the current active node.

  - **status.conditions**
    array of objects
    - **status.conditions.lastHeartbeatTime**
      string
    - **status.conditions.lastTransitionTime**
      string

      Required value

      lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

    - **status.conditions.message**
      string

      Required value

      message is a human readable message indicating details about the transition. This may be an empty string.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

      Allowed values: `0 <= X`

    - **status.conditions.reason**
      string

      Required value

      reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

      Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

      Length: `1..1024`

    - **status.conditions.status**
      string

      Required value

      status of the condition, one of True, False, Unknown.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Type of condition in CamelCase or in foo.example.com/CamelCase.

Many .condition.type values are consistent across resources like Available, but because arbitrary conditions can be useful (see .node.status.conditions), the ability to deconflict is important. The regex it matches is (dns1123SubdomainFmt/)?(qualifiedNameFmt)

Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

Maximum length: `316`

- **status.observedGeneration**
  integer
- **status.readyNodes**
  integer

  Number of nodes ready to perform egress gateway functions.

HubbleMonitoringConfig

Scope: Cluster
Version: v1alpha1

- **spec**
  object

  Required value

  - **spec.extendedMetrics**
    object

    Configuration for exporting extended metrics from Cilium agents.

    Extended metrics provide deeper insight into cluster network behavior.

    > **i** **Warning.** Changing this parameter will trigger a restart of the Cilium agents.

    For more details, see the Cilium documentation.

    Example:

    ```
    extendedMetrics:
      enabled: true
      collectors:
      - name: drop
        contextOptions:
    labelsContext=source_ip,source_namespace,source_pod,destination_ip,destination_name
    space,destination_pod
      - name: flow
    ```

    - **spec.extendedMetrics.collectors**
      array of objects

      List of Hubble extended metrics to export.

      Each collector represents a specific metric type.

      For more details, see the Cilium documentation.

      Example:

      ```
      collectors:
      - name: drop
        contextOptions:
      labelsContext=source_ip,source_namespace,source_pod,destination_ip,destination
      _namespace,destination_pod
      - name: flow
      ```

      - **spec.extendedMetrics.collectors.contextOptions**
        string

        Optional context options for Hubble metrics.

        Defines which parameters are used to break down the metrics produced by a collector. If you do not specify `contextOptions`, the collector returns the default set of metrics aggregated overall, without breakdown by individual parameters. For example, for the `drop` collector, an empty `contextOptions` returns overall drop statistics without distinguishing the exact source and destination. When you set `contextOptions`, metric

values are grouped by the selected dimensions, for example by source and destination Pods, namespaces, and labels.

> **Warning.** A large number of labels on metrics can lead to Prometheus performance degradation.

For more information about supported options, see the Cilium documentation.

- **spec.extendedMetrics.collectors.name**
  string

  Name of the extended metric to export.

  Allowed values: `dns`, `drop`, `flow`, `flows-to-world`, `http`, `httpV2`, `icmp`, `kafka`, `tcp`

- **spec.extendedMetrics.enabled**
  boolean

  Enables the export of extended metrics from Cilium agents.

  Default: `false`

- **spec.flowLogs**
  object

  Configuration for exporting event logs from Cilium agents.

  Event logs provide detailed visibility into Cilium's network events.

  > **Warning.** Changing this parameter will trigger a restart of the Cilium agents.

  For more details see the Cilium documentation.

  Example:

  ```
  flowLogs:
    enabled: true
    allowFilterList:
    - verdict:
      - DROPPED
      - ERROR
    denyFilterList:
    - source_pod:
      - kube-system/
    - destination_pod:
      - kube-system/
    fieldMaskList:
    - time
    - source.namespace
    - verdict
    fileMaxSizeMB: 50
  ```

  - **spec.flowLogs.allowFilterList**
    array of objects

    Defines filters that control which events are exported for logging. Only events that match at least one of the specified filter objects will be exported. If no filters are specified, all events are allowed. Logical semantics: - Within a single filter object, all specified fields are combined using AND. - Across filter objects in the array, filters are combined using OR. For more details, see the Cilium documentation.

    - **spec.flowLogs.allowFilterList.destination_cluster_name**
      array of strings

      Destination cluster names.

    - **spec.flowLogs.allowFilterList.destination_fqdn**
      array of strings

      Destination fully qualified domain names (FQDN).

      - **Element of the array**
        string

        Maximum length: `255`

- **spec.flowLogs.allowFilterList.destination_identity**
  array of integers

  Destination security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.allowFilterList.destination_ip**
  array of strings

  Destination IP or CIDR.

- **spec.flowLogs.allowFilterList.destination_label**
  array of strings

  Destination label selectors.

  For more information, please see the Cilium documentation.

  Examples:

  ```
  destination_label: k8s:role=frontend
  ```

  ```
  destination_label: reserved:kube-apiserver
  ```

- **spec.flowLogs.allowFilterList.destination_pod**
  array of strings

  Destination Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

  ```
  destination_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
  ```

  ```
  destination_pod: kube-system/
  ```

  ```
  destination_pod: "/d8-kube-dns-7bc4648cb4-94tps"
  ```

- **spec.flowLogs.allowFilterList.destination_port**
  array of strings

  L4 destination port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.allowFilterList.destination_service**
  array of strings

  Destination service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

  ```
  destination_service: kube-system/kube-dns
  ```

  ```
  destination_service: kube-system/
  ```

  ```
  destination_service: "/kube-dns"
  ```

- **spec.flowLogs.allowFilterList.destination_workload**
  array of objects

  Destination workloads.

  - **spec.flowLogs.allowFilterList.destination_workload.kind**
    string

    Workload kind.

  - **spec.flowLogs.allowFilterList.destination_workload.name**
    string

Workload name.

- **spec.flowLogs.allowFilterList.dns_query**
  array of strings

  DNS query regex patterns.

- **spec.flowLogs.allowFilterList.drop_reason_desc**
  array of strings

  Drop reason (only for DROPPED verdict).

  - **Element of the array**
    string

    Allowed values: `DROP REASON UNKNOWN`, `INVALID SOURCE MAC`, `INVALID DESTINATION MAC`, `INVALID SOURCE IP`, `POLICY DENIED`, `INVALID PACKET DROPPED`, `CT TRUNCATED OR INVALID HEADER`, `CT MISSING TCP ACK FLAG`, `CT UNKNOWN L4 PROTOCOL`, `CT CANNOT CREATE ENTRY FROM PACKET`, `UNSUPPORTED L3 PROTOCOL`, `MISSED TAIL CALL`, `ERROR WRITING TO PACKET`, `UNKNOWN L4 PROTOCOL`, `UNKNOWN ICMPV4 CODE`, `UNKNOWN ICMPV4 TYPE`, `UNKNOWN ICMPV6 CODE`, `UNKNOWN ICMPV6 TYPE`, `ERROR RETRIEVING TUNNEL KEY`, `ERROR RETRIEVING TUNNEL OPTIONS`, `INVALID GENEVE OPTION`, `UNKNOWN L3 TARGET ADDRESS`, `STALE OR UNROUTABLE IP`, `NO MATCHING LOCAL CONTAINER FOUND`, `ERROR WHILE CORRECTING L3 CHECKSUM`, `ERROR WHILE CORRECTING L4 CHECKSUM`, `CT MAP INSERTION FAILED`, `INVALID IPV6 EXTENSION HEADER`, `IP FRAGMENTATION NOT SUPPORTED`, `SERVICE BACKEND NOT FOUND`, `NO TUNNEL OR ENCAPSULATION ENDPOINT`, `FAILED TO INSERT INTO PROXYMAP`, `REACHED EDT RATE LIMITING DROP HORIZON`, `UNKNOWN CONNECTION TRACKING STATE`, `LOCAL HOST IS UNREACHABLE`, `NO CONFIGURATION AVAILABLE TO PERFORM POLICY DECISION`, `UNSUPPORTED L2 PROTOCOL`, `NO MAPPING FOR NAT MASQUERADE`, `UNSUPPORTED PROTOCOL FOR NAT MASQUERADE`, `FIB LOOKUP FAILED`, `ENCAPSULATION TRAFFIC IS PROHIBITED`, `INVALID IDENTITY`, `UNKNOWN SENDER`, `NAT NOT NEEDED`, `IS A CLUSTERIP`, `FIRST LOGICAL DATAGRAM FRAGMENT NOT FOUND`, `FORBIDDEN ICMPV6 MESSAGE`, `DENIED BY LB SRC RANGE CHECK`, `SOCKET LOOKUP FAILED`, `SOCKET ASSIGN FAILED`, `PROXY REDIRECTION NOT SUPPORTED FOR PROTOCOL`, `POLICY DENY`, `VLAN FILTERED`, `INVALID VNI`, `INVALID TC BUFFER`, `NO SID`, `MISSING SRV6 STATE`, `NAT46`, `NAT64`, `AUTH REQUIRED`, `CT NO MAP FOUND`, `SNAT NO MAP FOUND`, `INVALID CLUSTER ID`, `UNSUPPORTED PROTOCOL FOR DSR ENCAP`, `NO EGRESS GATEWAY`, `UNENCRYPTED TRAFFIC`, `TTL EXCEEDED`, `NO NODE ID`, `DROP RATE LIMITED`, `IGMP HANDLED`, `IGMP SUBSCRIBED`, `MULTICAST HANDLED`, `DROP HOST NOT READY`, `DROP EP NOT READY`, `DROP NO EGRESS IP`

- **spec.flowLogs.allowFilterList.event_type**
  array of objects

  Event types to filter on.

  - **spec.flowLogs.allowFilterList.event_type.match_sub_type**
    boolean

    Whether to match on `sub_type`.

  - **spec.flowLogs.allowFilterList.event_type.sub_type**
    integer

    Secondary event type.

  - **spec.flowLogs.allowFilterList.event_type.type**
    integer

    Primary event type.

- **spec.flowLogs.allowFilterList.http_header**
  array of objects

  HTTP headers to match.

  - **spec.flowLogs.allowFilterList.http_header.key**
    string

    Header key.

  - **spec.flowLogs.allowFilterList.http_header.value**
    string

    Header value.

- **spec.flowLogs.allowFilterList.http_method**

array of strings

HTTP methods.

- **Element of the array**
  string

  Allowed values: `GET`, `HEAD`, `POST`, `PUT`, `DELETE`, `CONNECT`, `OPTIONS`, `TRACE`, `PATCH`

- **spec.flowLogs.allowFilterList.http_path**
  array of strings

  Regex list to match HTTP path.

- **spec.flowLogs.allowFilterList.http_status_code**
  array of strings

  HTTP status code prefixes.

  - **Element of the array**
    string

    Pattern: `^(?:[1-5]\+|[1-5][0-9]\+|[1-5][0-9]{2})$`

- **spec.flowLogs.allowFilterList.http_url**
  array of strings

  Regex list to match HTTP URL.

- **spec.flowLogs.allowFilterList.interface**
  array of objects

  Network interface where flow was observed.

  - **spec.flowLogs.allowFilterList.interface.index**
    integer

    Interface index.

    Allowed values: `0 <= X`

  - **spec.flowLogs.allowFilterList.interface.name**
    string

    Interface name.

- **spec.flowLogs.allowFilterList.ip_version**
  array of strings

  IP version.

  - **Element of the array**
    string

    Allowed values: `IP_NOT_USED`, `IPv4`, `IPv6`

- **spec.flowLogs.allowFilterList.node_labels**
  array of strings

  Node label selectors.

  Examples:

  ```
  node_labels: node-role.kubernetes.io/control-plane=
  ```

  ```
  node_labels: topology.kubernetes.io/ru-central1-a
  ```

- **spec.flowLogs.allowFilterList.node_name**
  array of strings

  Node name patterns.

- **spec.flowLogs.allowFilterList.protocol**
  array of strings

  L4 or L7 protocol.

- **spec.flowLogs.allowFilterList.source_cluster_name**
  array of strings

  Source cluster names.

- **spec.flowLogs.allowFilterList.source_fqdn**
  array of strings

Source fully qualified domain names (FQDN).

- **Element of the array**
  string

  Maximum length: `255`

- **spec.flowLogs.allowFilterList.source_identity**
  array of integers

  Source security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.allowFilterList.source_ip**
  array of strings

  Source IP or CIDR.

- **spec.flowLogs.allowFilterList.source_ip_xlated**
  array of strings

  Post-translation (SNAT) source IP or CIDR.

- **spec.flowLogs.allowFilterList.source_label**
  array of strings

  Source label selectors.

  For more information, please see the Cilium documentation.

  Examples:

  ```
  source_label: k8s:role=frontend
  ```

  ```
  source_label: reserved:kube-apiserver
  ```

- **spec.flowLogs.allowFilterList.source_pod**
  array of strings

  Source Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

  ```
  source_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
  ```

  ```
  source_pod: kube-system/
  ```

  ```
  source_pod: "/d8-kube-dns-7bc4648cb4-94tps"
  ```

- **spec.flowLogs.allowFilterList.source_port**
  array of strings

  L4 source port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.allowFilterList.source_service**
  array of strings

  Source service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

  ```
  source_service: kube-system/kube-dns
  ```

  ```
  source_service: kube-system/
  ```

  ```
  source_service: "/kube-dns"
  ```

- **spec.flowLogs.allowFilterList.source_workload**
  array of objects

  Source workloads.

  - **spec.flowLogs.allowFilterList.source_workload.kind**
    string

    Workload kind.

  - **spec.flowLogs.allowFilterList.source_workload.name**
    string

    Workload name.

- **spec.flowLogs.allowFilterList.tcp_flags**
  array of objects

  TCP flags to match.

  - **spec.flowLogs.allowFilterList.tcp_flags.ACK**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.CWR**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.ECE**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.FIN**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.NS**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.PSH**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.RST**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.SYN**
    boolean
  - **spec.flowLogs.allowFilterList.tcp_flags.URG**
    boolean
- **spec.flowLogs.allowFilterList.trace_id**
  array of strings

  Trace ID.

- **spec.flowLogs.allowFilterList.traffic_direction**
  array of strings

  Traffic direction.

  - **Element of the array**
    string

    Allowed values: `TRAFFIC_DIRECTION_UNKNOWN`, `INGRESS`, `EGRESS`

- **spec.flowLogs.allowFilterList.uuid**
  array of strings

  Filters by flow UUIDs.

- **spec.flowLogs.allowFilterList.verdict**
  array of strings

  Match by verdict.

  - **Element of the array**
    string

    Allowed values: `VERDICT UNKNOWN`, `FORWARDED`, `DROPPED`, `ERROR`, `AUDIT`, `REDIRECTED`, `TRACED`, `TRANSLATED`

- **spec.flowLogs.denyFilterList**
  array of objects

  Defines filters that control which events are explicitly excluded from logging. Any event that matches at least one of the specified filter objects will be denied from being exported. If no filters are specified, no events are denied. This allows you to refine the set of events that are logged by excluding certain types. Logical semantics: - Within a single filter object, all specified fields are combined using AND. - Across filter objects in the array, filters are combined using OR. For more details, see the Cilium documentation.

  - **spec.flowLogs.denyFilterList.destination_cluster_name**
    array of strings

    Destination cluster names.

- **spec.flowLogs.denyFilterList.destination_fqdn**
  array of strings

  Destination fully qualified domain names (FQDN).

  - **Element of the array**
    string

    Maximum length: `255`

- **spec.flowLogs.denyFilterList.destination_identity**
  array of integers

  Destination security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.denyFilterList.destination_ip**
  array of strings

  Destination IP or CIDR.

- **spec.flowLogs.denyFilterList.destination_label**
  array of strings

  Destination label selectors.

  For more information, please see the Cilium documentation.

  Examples:

  ```
  destination_label: k8s:role=frontend
  ```

  ```
  destination_label: reserved:kube-apiserver
  ```

- **spec.flowLogs.denyFilterList.destination_pod**
  array of strings

  Destination Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

  ```
  destination_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
  ```

  ```
  destination_pod: kube-system/
  ```

  ```
  destination_pod: "/d8-kube-dns-7bc4648cb4-94tps"
  ```

- **spec.flowLogs.denyFilterList.destination_port**
  array of strings

  L4 destination port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.denyFilterList.destination_service**
  array of strings

  Destination service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

  ```
  destination_service: kube-system/kube-dns
  ```

  ```
  destination_service: kube-system/
  ```

  ```
  destination_service: "/kube-dns"
  ```

- **spec.flowLogs.denyFilterList.destination_workload**
  array of objects

Destination workloads.

- **spec.flowLogs.denyFilterList.destination_workload.kind**
  string

  Workload kind.

- **spec.flowLogs.denyFilterList.destination_workload.name**
  string

  Workload name.

- **spec.flowLogs.denyFilterList.dns_query**
  array of strings

  DNS query regex patterns.

- **spec.flowLogs.denyFilterList.drop_reason_desc**
  array of strings

  Drop reason (only for DROPPED verdict).

  - **Element of the array**
    string

    Allowed values: `DROP_REASON_UNKNOWN`, `INVALID_SOURCE_MAC`, `INVALID_DESTINATION_MAC`, `INVALID_SOURCE_IP`, `POLICY_DENIED`, `INVALID_PACKET_DROPPED`, `CT_TRUNCATED_OR_INVALID_HEADER`, `CT_MISSING_TCP_ACK_FLAG`, `CT_UNKNOWN_L4_PROTOCOL`, `CT_CANNOT_CREATE_ENTRY_FROM_PACKET`, `UNSUPPORTED_L3_PROTOCOL`, `MISSED_TAIL_CALL`, `ERROR_WRITING_TO_PACKET`, `UNKNOWN_L4_PROTOCOL`, `UNKNOWN_ICMPV4_CODE`, `UNKNOWN_ICMPV4_TYPE`, `UNKNOWN_ICMPV6_CODE`, `UNKNOWN_ICMPV6_TYPE`, `ERROR_RETRIEVING_TUNNEL_KEY`, `ERROR_RETRIEVING_TUNNEL_OPTIONS`, `INVALID_GENEVE_OPTION`, `UNKNOWN_L3_TARGET_ADDRESS`, `STALE_OR_UNROUTABLE_IP`, `NO_MATCHING_LOCAL_CONTAINER_FOUND`, `ERROR_WHILE_CORRECTING_L3_CHECKSUM`, `ERROR_WHILE_CORRECTING_L4_CHECKSUM`, `CT_MAP_INSERTION_FAILED`, `INVALID_IPV6_EXTENSION_HEADER`, `IP_FRAGMENTATION_NOT_SUPPORTED`, `SERVICE_BACKEND_NOT_FOUND`, `NO_TUNNEL_OR_ENCAPSULATION_ENDPOINT`, `FAILED_TO_INSERT_INTO_PROXYMAP`, `REACHED_EDT_RATE_LIMITING_DROP_HORIZON`, `UNKNOWN_CONNECTION_TRACKING_STATE`, `LOCAL_HOST_IS_UNREACHABLE`, `NO_CONFIGURATION_AVAILABLE_TO_PERFORM_POLICY_DECISION`, `UNSUPPORTED_L2_PROTOCOL`, `NO_MAPPING_FOR_NAT_MASQUERADE`, `UNSUPPORTED_PROTOCOL_FOR_NAT_MASQUERADE`, `FIB_LOOKUP_FAILED`, `ENCAPSULATION_TRAFFIC_IS_PROHIBITED`, `INVALID_IDENTITY`, `UNKNOWN_SENDER`, `NAT_NOT_NEEDED`, `IS_A_CLUSTERIP`, `FIRST_LOGICAL_DATAGRAM_FRAGMENT_NOT_FOUND`, `FORBIDDEN_ICMPV6_MESSAGE`, `DENIED_BY_LB_SRC_RANGE_CHECK`, `SOCKET_LOOKUP_FAILED`, `SOCKET_ASSIGN_FAILED`, `PROXY_REDIRECTION_NOT_SUPPORTED_FOR_PROTOCOL`, `POLICY_DENY`, `VLAN_FILTERED`, `INVALID_VNI`, `INVALID_TC_BUFFER`, `NO_SID`, `MISSING_SRV6_STATE`, `NAT46`, `NAT64`, `AUTH_REQUIRED`, `CT_NO_MAP_FOUND`, `SNAT_NO_MAP_FOUND`, `INVALID_CLUSTER_ID`, `UNSUPPORTED_PROTOCOL_FOR_DSR_ENCAP`, `NO_EGRESS_GATEWAY`, `UNENCRYPTED_TRAFFIC`, `TTL_EXCEEDED`, `NO_NODE_ID`, `DROP_RATE_LIMITED`, `IGMP_HANDLED`, `IGMP_SUBSCRIBED`, `MULTICAST_HANDLED`, `DROP_HOST_NOT_READY`, `DROP_EP_NOT_READY`, `DROP_NO_EGRESS_IP`

- **spec.flowLogs.denyFilterList.event_type**
  array of objects

  Event types to filter on.

  - **spec.flowLogs.denyFilterList.event_type.match_sub_type**
    boolean

    Whether to match on `sub_type`.

  - **spec.flowLogs.denyFilterList.event_type.sub_type**
    integer

    Secondary event type.

  - **spec.flowLogs.denyFilterList.event_type.type**
    integer

    Primary event type.

- **spec.flowLogs.denyFilterList.http_header**
  array of objects

  HTTP headers to match.

  - **spec.flowLogs.denyFilterList.http_header.key**

string

Header key.

- **spec.flowLogs.denyFilterList.http_header.value**
  string

  Header value.

- **spec.flowLogs.denyFilterList.http_method**
  array of strings

  HTTP methods.

  - **Element of the array**
    string

    Allowed values: `GET`, `HEAD`, `POST`, `PUT`, `DELETE`, `CONNECT`, `OPTIONS`, `TRACE`, `PATCH`

- **spec.flowLogs.denyFilterList.http_path**
  array of strings

  Regex list to match HTTP path.

- **spec.flowLogs.denyFilterList.http_status_code**
  array of strings

  HTTP status code prefixes.

  - **Element of the array**
    string

    Pattern: `^(?:[1-5]\+|[1-5][0-9]\+|[1-5][0-9]{2})$`

- **spec.flowLogs.denyFilterList.http_url**
  array of strings

  Regex list to match HTTP URL.

- **spec.flowLogs.denyFilterList.interface**
  array of objects

  Network interface where flow was observed.

  - **spec.flowLogs.denyFilterList.interface.index**
    integer

    Interface index.

    Allowed values: `0 <= X`

  - **spec.flowLogs.denyFilterList.interface.name**
    string

    Interface name.

- **spec.flowLogs.denyFilterList.ip_version**
  array of strings

  IP version.

  - **Element of the array**
    string

    Allowed values: `IP_NOT_USED`, `IPv4`, `IPv6`

- **spec.flowLogs.denyFilterList.node_labels**
  array of strings

  Node label selectors.

  Examples:

  ```
  node_labels: node-role.kubernetes.io/control-plane=
  ```

  ```
  node_labels: topology.kubernetes.io/ru-central1-a
  ```

- **spec.flowLogs.denyFilterList.node_name**
  array of strings

  Node name patterns.

- **spec.flowLogs.denyFilterList.protocol**
  array of strings

L4 or L7 protocol.

- **spec.flowLogs.denyFilterList.source_cluster_name**
  array of strings

  Source cluster names.

- **spec.flowLogs.denyFilterList.source_fqdn**
  array of strings

  Source fully qualified domain names (FQDN).

  - **Element of the array**
    string

    Maximum length: `255`

- **spec.flowLogs.denyFilterList.source_identity**
  array of integers

  Source security identity.

  - **Element of the array**
    integer

    Allowed values: `0 <= X <= 4294967295`

- **spec.flowLogs.denyFilterList.source_ip**
  array of strings

  Source IP or CIDR.

- **spec.flowLogs.denyFilterList.source_ip_xlated**
  array of strings

  Post-translation (SNAT) source IP or CIDR.

- **spec.flowLogs.denyFilterList.source_label**
  array of strings

  Source label selectors.

  For more information, please see the Cilium documentation.

  Examples:

  ```
  source_label: k8s:role=frontend
  ```

  ```
  source_label: reserved:kube-apiserver
  ```

- **spec.flowLogs.denyFilterList.source_pod**
  array of strings

  Source Pod name prefixes in the form NamespacedName (`namespace/pod`).

  Examples:

  ```
  source_pod: kube-system/d8-kube-dns-7bc4648cb4-94tps
  ```

  ```
  source_pod: kube-system/
  ```

  ```
  source_pod: "/d8-kube-dns-7bc4648cb4-94tps"
  ```

- **spec.flowLogs.denyFilterList.source_port**
  array of strings

  L4 source port.

  - **Element of the array**
    string

    Pattern: `^(?:6553[0-5]|655[0-2]\d|65[0-4]\d{2}|6[0-4]\d{3}|[1-5]\d{4}|[1-9]\d{0,3})$`

- **spec.flowLogs.denyFilterList.source_service**
  array of strings

  Source service name prefixes in the form NamespacedName (`namespace/service`).

  Examples:

```
source_service: kube-system/kube-dns
```

```
source_service: kube-system/
```

```
source_service: "/kube-dns"
```

- **spec.flowLogs.denyFilterList.source_workload**
  array of objects

  Source workloads.

  - **spec.flowLogs.denyFilterList.source_workload.kind**
    string

    Workload kind.

  - **spec.flowLogs.denyFilterList.source_workload.name**
    string

    Workload name.

- **spec.flowLogs.denyFilterList.tcp_flags**
  array of objects

  TCP flags to match.

  - **spec.flowLogs.denyFilterList.tcp_flags.ACK**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.CWR**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.ECE**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.FIN**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.NS**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.PSH**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.RST**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.SYN**
    boolean
  - **spec.flowLogs.denyFilterList.tcp_flags.URG**
    boolean
- **spec.flowLogs.denyFilterList.trace_id**
  array of strings

  Trace ID.

- **spec.flowLogs.denyFilterList.traffic_direction**
  array of strings

  Traffic direction.

  - **Element of the array**
    string

    Allowed values: `TRAFFIC_DIRECTION_UNKNOWN`, `INGRESS`, `EGRESS`

- **spec.flowLogs.denyFilterList.uuid**
  array of strings

  Filters by flow UUIDs.

- **spec.flowLogs.denyFilterList.verdict**
  array of strings

  Match by verdict.

  - **Element of the array**
    string

    Allowed values: `VERDICT UNKNOWN`, `FORWARDED`, `DROPPED`, `ERROR`, `AUDIT`, `REDIRECTED`, `TRACED`, `TRANSLATED`

- **spec.flowLogs.enabled**
  boolean

  Enables event logging for Cilium agents. The log file is located on the node’s filesystem at `/var/log/cilium/hubble/flow.log`.

Default: `false`

- **spec.flowLogs.fieldMaskList**
  array of strings

  List of fields that should be displayed in events.

  For more details, see the Cilium documentation.

  - **Element of the array**
    string

    Allowed values: `time`, `uuid`, `verdict`, `drop_reason_desc`, `auth_type`, `ethernet`, `ethernet.source`, `ethernet.destination`, `IP`, `IP.source`, `IP.source_xlated`, `IP.destination`, `IP.ipVersion`, `IP.encrypted`, `l4`, `l4.TCP`, `l4.TCP.source_port`, `l4.TCP.destination_port`, `l4.TCP.flags`, `l4.TCP.flags.FIN`, `l4.TCP.flags.SYN`, `l4.TCP.flags.RST`, `l4.TCP.flags.PSH`, `l4.TCP.flags.ACK`, `l4.TCP.flags.URG`, `l4.TCP.flags.ECE`, `l4.TCP.flags.CWR`, `l4.TCP.flags.NS`, `l4.UDP`, `l4.UDP.source_port`, `l4.UDP.destination_port`, `l4.ICMPv4`, `l4.ICMPv4.type`, `l4.ICMPv4.code`, `l4.ICMPv6`, `l4.ICMPv6.type`, `l4.ICMPv6.code`, `l4.SCTP`, `l4.SCTP.source_port`, `l4.SCTP.destination_port`, `source`, `source.ID`, `source.identity`, `source.cluster_name`, `source.namespace`, `source.labels`, `source.pod_name`, `source.workloads`, `source.workloads.name`, `source.workloads.kind`, `destination`, `destination.ID`, `destination.identity`, `destination.cluster_name`, `destination.namespace`, `destination.labels`, `destination.pod_name`, `destination.workloads`, `destination.workloads.name`, `destination.workloads.kind`, `Type`, `node_name`, `node_labels`, `source_names`, `destination_names`, `l7`, `l7.type`, `l7.latency_ns`, `l7.record`, `l7.record.dns`, `l7.record.dns.query`, `l7.record.dns.ips`, `l7.record.dns.ttl`, `l7.record.dns.cnames`, `l7.record.dns.observation_source`, `l7.record.dns.rcode`, `l7.record.dns.qtypes`, `l7.record.dns.rrtypes`, `l7.record.http`, `l7.record.http.code`, `l7.record.http.method`, `l7.record.http.url`, `l7.record.http.protocol`, `l7.record.http.headers`, `l7.record.http.headers.key`, `l7.record.http.headers.value`, `l7.record.kafka`, `l7.record.kafka.error_code`, `l7.record.kafka.api_version`, `l7.record.kafka.api_key`, `l7.record.kafka.correlation_id`, `l7.record.kafka.topic`, `is_reply`, `event_type`, `event_type.type`, `event_type.sub_type`, `traffic_direction`, `trace_observation_point`, `trace_reason`, `file`, `file.name`, `file.line`, `debug_capture_point`, `interface`, `interface.index`, `interface.name`, `proxy_port`, `trace_context`, `trace_context.parent`, `trace_context.parent.trace_id`, `sock_xlate_point`, `socket_cookie`, `cgroup_id`, `extensions`, `egress_allowed_by`, `egress_allowed_by.name`, `egress_allowed_by.namespace`, `egress_allowed_by.labels`, `egress_allowed_by.revision`, `egress_allowed_by.kind`, `ingress_allowed_by`, `ingress_allowed_by.name`, `ingress_allowed_by.namespace`, `ingress_allowed_by.labels`, `ingress_allowed_by.revision`, `ingress_allowed_by.kind`, `egress_denied_by`, `egress_denied_by.name`, `egress_denied_by.namespace`, `egress_denied_by.labels`, `egress_denied_by.revision`, `egress_denied_by.kind`, `ingress_denied_by`, `ingress_denied_by.name`, `ingress_denied_by.namespace`, `ingress_denied_by.labels`, `ingress_denied_by.revision`, `ingress_denied_by.kind`, `source_service`, `source_service.name`, `source_service.namespace`, `destination_service`, `destination_service.name`, `destination_service.namespace`

- **spec.flowLogs.fileMaxSizeMB**
  integer

  Size in MB at which to rotate the Hubble export file.

  Default: `10`

  Allowed values: `1 <= X <= 150`

Examples

> **i** The module lifecycle stage: General Availability

Egress Gateway

Operation principle

Configuring an egress gateway requires two custom resources:

1. EgressGateway— describes the group of nodes that perform the egress gateway function in hot-standby mode:
   - Among the group of nodes match the `spec.nodeSelector`, the eligible nodes will be selected. One of them will be assigned as the active gateway. The active node is selected in alphabetical order.

Attributes of an eligible node:

- The node is in `Ready` state.
  - The node is not in the maintenance state (i.e., it is not cordoned).
  - The `cilium-agent` on the node is in the `Ready` state.
- When using EgressGateway in `VirtualIP` mode, an agent is launched on the active node which emulates a “virtual” IP address using the ARP protocol. The status of this agent’s pod is also taken into account when determining the eligibility of a node.
- Different EgressGateways can use the same nodes for operation. The active node is selected independently for each EgressGateway, which allows for load balancing between them.

2. EgressGatewayPolicy — describes the policy for routing network requests from pods in the cluster to a specific egress gateway defined using EgressGateway.

Node maintenance

To perform maintenance on a node that is currently the active egress gateway, follow these steps:

1. Remove the node label to exclude it from the egress gateway candidate pool. Egress-label is the label specified in `spec.nodeSelector` of your EgressGateway.

   ```
   d8 k label node <node-name> <egress-label>-
   ```

2. Cordon the node to prevent new pods from starting:

   ```
   d8 k cordon <node-name>
   ```

   After this, Cilium will automatically select a new active node from the remaining candidates. Traffic will continue routing through the new gateway without interruption.

3. After maintenance is complete, return the node to service:

   ```
   d8 k uncordon <node-name>
   d8 k label node <node-name> <egress-label>=<value>
   ```

> **i** Note: Reapplying the label may cause the node to become active again (if it is first in alphabetical order among candidates). To avoid immediate failback, temporarily reduce the number of EgressGateway replicas or adjust priorities using additional labels.

Comparison with CiliumEgressGatewayPolicy

The CiliumEgressGatewayPolicy implies configuring only one node as an egress gateway. If it fails, there are no failover mechanisms and the network connection will be broken.

Egress Gateway configuration examples

EgressGateway in PrimaryIPFromEgressGatewayNodeInterface mode (basic mode)

```
apiVersion: network.deckhouse.io/v1alpha1
kind: EgressGateway
metadata:
  name: my-egressgw
spec:
  nodeSelector:
    dedicated/egress: ""
  sourceIP:
    mode: PrimaryIPFromEgressGatewayNodeInterface
    primaryIPFromEgressGatewayNodeInterface:
      # The "public" interface must have the same name on all nodes that matching the
nodeSelector.
      # If the active node fails, traffic will be redirected through the backup node and
      # the source IP address of the network packets will change.
      interfaceName: eth1
```

EgressGateway in VirtualIPAddress mode (Virtual IP mode)

```
apiVersion: network.deckhouse.io/v1alpha1
kind: EgressGateway
metadata:
  name: my-egressgw
spec:
  nodeSelector:
    dedicated/egress: ""
  sourceIP:
    mode: VirtualIPAddress
    virtualIPAddress:
      # Each node must have all the necessary routes configured to access all external public
services,
     # the "public" interface must be prepared for automatic configuration of the "virtual"
IP as a secondary IP address.
     # In case of failure of the active node, traffic will be redirected through the backup
node and
     # the source IP address of the network packets will not change.
     ip: 172.18.18.242
     # List of network interfaces for Virtual IP
     interfaces:
     - eth1
```

EgressGatewayPolicy

```
apiVersion: network.deckhouse.io/v1alpha1
kind: EgressGatewayPolicy
metadata:
  name: my-egressgw-policy
spec:
  destinationCIDRs:
  - 0.0.0.0/0
  egressGatewayName: my-egressgw
  selectors:
  - podSelector:
      matchLabels:
        app: backend
        io.kubernetes.pod.namespace: my-ns
```

HubbleMonitoringConfig

The cluster-scoped HubbleMonitoringConfig resource is intended to configure data export from Hubble, which runs inside Cilium agents.

HubbleMonitoringConfig configuration examples

Enabling extended metrics and flow logs export (with filters and field mask)

> ⚠ The HubbleMonitoringConfig resource **must be named** `hubble-monitoring-config`.

Example of enabling metrics and export:

```
apiVersion: deckhouse.io/v1alpha1
kind: HubbleMonitoringConfig
metadata:
  name: hubble-monitoring-config
spec:
  extendedMetrics:
    enabled: true
    collectors:
      - name: drop
        # Add additional labels context for the selected collector.
        contextOptions:
"labelsContext=source_ip,source_namespace,source_pod,destination_ip,destination_namespace,de
stination_pod"
      - name: flow
  flowLogs:
    enabled: true
    # Allow only the specified events to be written to the log file
/var/log/cilium/hubble/flow.log.
    allowFilterList:
      - verdict: ["DROPPED", "ERROR"]
    # Exclude events matching the denyFilterList from the log file.
    denyFilterList:
      - source_pod:
        - kube-system/
      - destination_pod:
        - kube-system/
    # Persist only the specified fields in each record.
    fieldMaskList:
      - time
      - verdict
    # Maximum log file size (in MB) before rotation.
    fileMaxSizeMB: 30
```

Collecting Hubble flow logs with the log-shipper module

To collect flow logs, use the `log-shipper` module.

Create a ClusterLoggingConfig resource that reads the log file from the node filesystem:

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: cilium-hubble-flow-logs
spec:
  type: File
  file:
    include:
      - /var/log/cilium/hubble/flow.log
```

The cni-flannel module

> **i** The module lifecycle stage: General Availability

This module is responsible for providing a network between multiple nodes in a cluster using the flannel module.

Third-party components

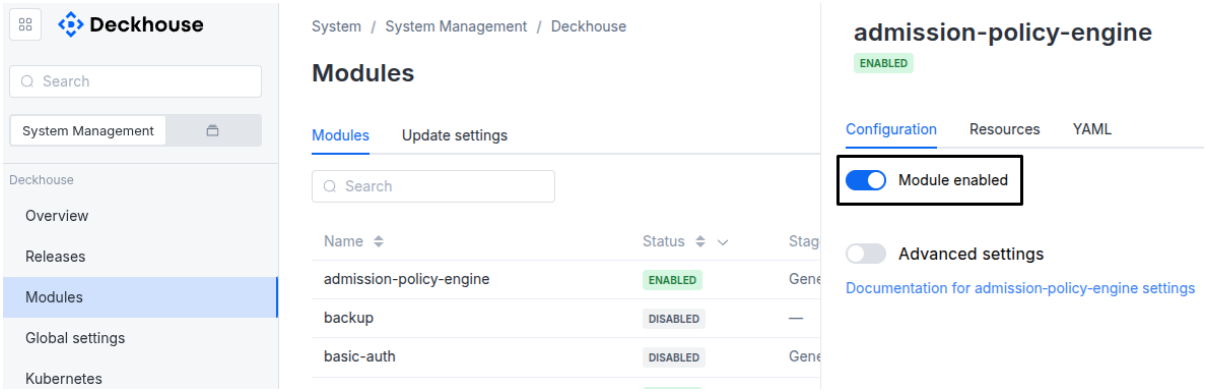
List of third-party software used in the `cni-flannel` module:

- Flannel 0.27.4

  License: Apache License 2.0

  A simple and easy way to configure a layer 3 network fabric designed for Kubernetes.

Configuration



> **i** The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-flannel` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

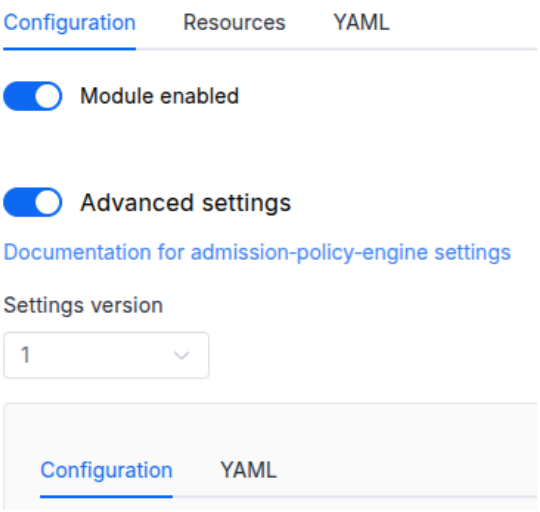
```
d8 system module enable cni-flannel
```

- **Using ModuleConfig `cni-flannel`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `cni-flannel` (create it if necessary);

  Example of a manifest to enable module `cni-flannel`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: cni-flannel
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `cni-flannel` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `cni-flannel` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `cni-flannel`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `cni-flannel` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc cni-flannel
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `cni-flannel` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `cni-flannel`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: cni-flannel
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.podNetworkMode**
    string

    Work mode.

    > **i** **NOTE!** All cluster nodes must be rebooted after switching work mode. You can change the parameter **only** in bare metal clusters.

    Default: `HostGW`

    Allowed values: `HostGW`, `VXLAN`

The cni-simple-bridge module

> **i** The module lifecycle stage: General Availability

The module does not have any settings.

It is automatically enabled for the following cloud providers:

- AWS
- Azure
- GCP

Managing control plane

> **i** The module lifecycle stage: General Availability

The `control-plane-manager` (CPM) module is responsible for managing the cluster's control plane components. It runs on all master nodes of the cluster (nodes that have the `node-role.kubernetes.io/control-plane: ""` label).

The control-plane-manager:

- **Manages certificates** required for the operation of the control plane (renews certificates and re-issues them in response to configuration changes, among other things). This feature allows the CPM to automatically maintain a secure control plane configuration and quickly add additional SANs for organizing secure access to the Kubernetes API.
- **Configures components**. The CPM module automatically creates the required configs and manifests of the control plane components.
- **Upgrades/downgrades components**. Makes sure that the versions of the components in the cluster are the same.
- **Manages the configuration of the etcd cluster** and its members. The CPM module scales master nodes and migrates the cluster from single-master to multi-master (and vice versa).
- **Configures kubeconfig**. The CPM module maintains up-to-date kubeconfig files on control-plane nodes. It generates, renews, and updates kubeconfigs for control-plane components and the admin kubeconfig (`admin.conf`). By default, it creates a symlink for the root user (`/root/.kube/config` -> `admin.conf`). When the user-authz module is enabled, the symlink can be turned off via the `rootKubeconfigSymlink` parameter in the **control-plane-manager** module (see FAQ). The CPM also hardens file permissions on `admin.conf` and `super-admin.conf`.
- **Extends scheduler functionality** by integrating external plugins via webhooks. Manages by KubeSchedulerWebhookConfiguration resource. Allows more complex logic to be used in workload scheduling tasks within the cluster. For example:
  - placing data storage application pods closer to the data itself,
  - state-based node prioritization (network load, storage subsystem status, etc.),
  - dividing nodes into zones, etc.

Managing certificates

The CPM module manages certificates of the `control-plane` components, such as:

- Server certificates for `kube-apiserver` & `etcd`. These are stored in the secret `d8-pki` of the namespace `kube-system`:
  - the root CA kubernetes certificate (`ca.crt` & `ca.key`),
  - the root CA etcd certificate (`etcd/ca.crt` & `etcd/ca.key`),
  - the RSA certificate and the key for signing Service Accounts (`sa.pub` & `sa.key`),
  - the root CA certificate for the extension API servers (`front-proxy-ca.key` & `front-proxy-ca.crt`).
- Client certificates for connecting `control-plane` components to each other. The CPM module issues, renews, and re-issues if something has changed (e.g., the SAN list). These certificates are stored on the nodes only:
  - The server-side API server certificate (`apiserver.crt` & `apiserver.key`).
  - The client-side certificate for connecting `kube-apiserver` to `kubelet` (`apiserver-kubelet-client.crt` & `apiserver-kubelet-client.key`).
  - The client-side certificate for connecting `kube-apiserver` to `etcd` (`apiserver-etcd-client.crt` & `apiserver-etcd-client.key`).
  - The client-side certificate for connecting `kube-apiserver` to the extension API servers (`front-proxy-client.crt` & `front-proxy-client.key`).
  - The server-side `etcd` certificate (`etcd/server.crt` & `etcd/server.key`).
  - The client-side certificate for connecting `etcd` to other cluster members (`etcd/peer.crt` & `etcd/peer.key`).
  - The client-side certificate for connecting `kubelet` to `etcd` for performing health-checks (`etcd/healthcheck-client.crt` & `etcd/healthcheck-client.key`).

Also, the CPM module lets you add the additional SANs to certificates (this way, you can quickly and effortlessly add more "entry points" to the Kubernetes API).

The CPM module automatically updates the kubeconfig configuration when certificates are changed.

Scaling

The CPM module supports `control plane` running in a *single-master* or *multi-master* mode.

In the *single-master* mode:

- `kube-apiserver` only uses the `etcd` instance that is hosted on the same node;
- A proxy server is configured on the node that responds to localhost, `kube-apiserver` responds to the IP address of the master node.

In the *multi-master* mode, `control plane` components are automatically deployed in a fault-tolerant manner:

- `kube-apiserver` is configured to work with all etcd instances;
- The additional proxy server that processes localhost requests is set up on each master node. By default, the proxy server sends requests to the local `kube-apiserver` instance. If it is unavailable, the proxy tries to connect to other `kube-apiserver` instances.

Scaling master nodes

The `control-plane` nodes are scaled automatically using the `node-role.kubernetes.io/control-plane=""` label:

- Attaching the `node-role.kubernetes.io/control-plane=""` label to a node results in deploying `control plane` components on this node, connecting the new `etcd` node to the etcd cluster, and regenerating all the necessary certificates and config files.
- Removing the `node-role.kubernetes.io/control-plane=""` label results in deleting all `control plane` components on a node, gracefully removing it from the etcd cluster, and regenerating all the necessary config files and certificates.

⚠ Manual `etcd` actions are required when decreasing the number of nodes from two to one. In all other cases, all the necessary actions are performed automatically. Please note that when scaling from any number of master nodes to one, sooner or later at the last step, the situation of scaling nodes from two to one will arise.

Dynamic terminated pod garbage collection threshold

Automatically configures the optimal `--terminated-pod-gc-threshold` based on cluster size:

- **Small clusters** (less than 100 nodes): 1000 terminated Pods.
- **Medium clusters** (from 100 to 300 nodes): 3000 terminated Pods.
- **Large clusters** (from 300 nodes): 6000 terminated Pods.

i Note. This feature only takes effect in environments where the `--terminated-pod-gc-threshold` parameter is configurable. On managed Kubernetes services (such as EKS, GKE, AKS), this setting is controlled by managed provider.

Version control

Patch versions of control plane components (i.e. within the minor version, for example, from `1.31.13` to `1.31.14`) are upgraded automatically together with the Deckhouse version updates. You can't manage patch version upgrades.

Upgrading **minor versions** of control plane components (e.g. from `1.31.*` to `1.32.*`) can be managed using the `kubernetesVersion` parameter. It specifies the automatic update mode (if set to `Automatic`) or the desired minor version of the control plane. The default control plane version (to use with `kubernetesVersion: Automatic`) as well as a list of supported Kubernetes versions can be found in the documentation.

The control plane upgrade is performed in a safe way for both single-master and multi-master clusters. The API server may be temporarily unavailable during the upgrade. At the same time, it does not affect the operation of applications in the cluster and can be performed without scheduling a maintenance window.

If the target version (set with the kubernetesVersion parameter) does not match the current control plane version in the cluster, a smart strategy for changing component versions is applied:

- General remarks
  - Updating in different NodeGroups is performed in parallel. Within each NodeGroup, nodes are updated sequentially, one at a time.
- When upgrading:
  - Upgrades are carried out sequentially, one minor version at a time: 1.31 -> 1.32, 1.32 -> 1.33, 1.33 -> 1.34.
  - At each step, the control plane version is upgraded first, followed by kubelet upgrades on the cluster nodes.
- When downgrading:
  - Successful downgrading is only guaranteed for a single version down from the maximum minor version of the control plane ever used in the cluster.
  - kubelets on the cluster nodes are downgraded first, followed by the control plane components.

Auditing

Kubernetes Auditing can help you if you need to keep track of operations in your Namespaces or troubleshoot the cluster. You can configure it by setting the appropriate Audit Policy. As the result you will have the log file `/var/log/kube-audit/audit.log` containing audit events according to the configured Policy.

By default, in a cluster with Deckhouse, a basic policy is created for logging events:

- related to the creation, deletion, and changing of resources;
- committed from the names of ServiceAccounts from the “system” Namespace `kube-system`, `d8-*`;
- committed with resources in the “system” Namespace `kube-system`, `d8-*`.

A basic policy can be disabled by setting the basicAuditPolicyEnabled flag to `false`.

When OIDC authentication is configured, additional user information is included in audit logs under the `user.extra` field:

- `user-authn.deckhouse.io/name` — user’s display name
- `user-authn.deckhouse.io/preferred username` — user’s preferred username
- `user-authn.deckhouse.io/dex-provider` — Dex provider identifier (requires `federated:id` scope)

You can find how to set up policies in a special FAQ section.

Feature Gates

You can configure feature gates using the enabledFeatureGates parameter of the `control-plane-manager` ModuleConfig.

Changing the list of feature gates causes a restart of the corresponding component (for example, `kube-apiserver`, `kube-scheduler`, `kube-controller-manager`, `kubelet`).

The following example enables the `ComponentFlagz` and `ComponentStatusz` feature gates:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  enabled: true
  settings:
    enabledFeatureGates:
      - ComponentFlagz
      - ComponentStatusz
```

If a feature gate is not supported or is deprecated, the monitoring system generates the D8ProblematicFeatureGateInUse alert indicating that the feature gate will not be applied.

> ⚠ The Kubernetes version update (controlled by the kubernetesVersion parameter) will not occur if the list of enabled feature gates for the new version of Kubernetes includes deprecated feature gates.

More information about feature gates is available in the Kubernetes documentation.

▼ List of available feature gates...

Kubernetes 1.31

- `AuthorizeNodeWithSelectors`
- `AuthorizeWithSelectors`
- `ConcurrentWatchObjectDecode`
- `CrossNamespaceVolumeDataSource`
- `DisableAllocatorDualWrite`
- `HPAScaleToZero`
- `ImageVolume`
- `InPlacePodVerticalScaling`
- `JobManagedBy`
- `KubeletPodResourcesGet`
- `MaxUnavailableStatefulSet`
- `MemoryQoS`
- `MutatingAdmissionPolicy`
- `OrderedNamespaceDeletion`
- `ProcMountType`
- `RecoverVolumeExpansionFailure`
- `RelaxedEnvironmentVariableValidation`
- `ResourceHealthStatus`

- `SELinuxMount`
- `SchedulerQueueingHints`
- `StrictCostEnforcementForVAP`
- `StrictCostEnforcementForWebhooks`

Kubernetes 1.32

- `AllowUnsafeMalformedObjectDeletion`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `CrossNamespaceVolumeDataSource`
- `DisableAllocatorDualWrite`
- `HPAScaleToZero`
- `ImageVolume`
- `InPlacePodVerticalScaling`
- `InPlacePodVerticalScalingAllocatedStatus`
- `KubeletPodResourcesGet`
- `MaxUnavailableStatefulSet`
- `MemoryQoS`
- `MutatingAdmissionPolicy`
- `OrderedNamespaceDeletion`
- `PodLifecycleSleepActionAllowZero`
- `PodLogsQuerySplitStreams`
- `ProcMountType`
- `RelaxedDNSSearchValidation`
- `ResourceHealthStatus`
- `SELinuxChangePolicy`
- `SELinuxMount`
- `SchedulerAsyncPreemption`

Kubernetes 1.33

- `AllowParsingUserUIDFromCertAuth`
- `AllowUnsafeMalformedObjectDeletion`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `ContainerStopSignals`
- `CrossNamespaceVolumeDataSource`
- `DeploymentReplicaSetTerminatingReplicas`
- `DisableAllocatorDualWrite`
- `HPAConfigurableTolerance`
- `HPAScaleToZero`
- `ImageVolume`
- `KubeletEnsureSecretPulledImages`
- `KubeletPSI`
- `KubeletPodResourcesGet`
- `ListFromCacheSnapshot`
- `MaxUnavailableStatefulSet`
- `MemoryQoS`
- `MutatingAdmissionPolicy`
- `PodLogsQuerySplitStreams`
- `PodObservedGenerationTracking`
- `PreferSameTrafficDistribution`
- `ResourceHealthStatus`
- `SELinuxMount`
- `StrictIPCIDRValidation`

Kubernetes 1.34

- `AllowUnsafeMalformedObjectDeletion`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `ContainerRestartRules`
- `ContainerStopSignals`
- `CrossNamespaceVolumeDataSource`
- `DeploymentReplicaSetTerminatingReplicas`
- `EnvFiles`
- `HPAConfigurableTolerance`
- `HPAScaleToZero`
- `HostnameOverride`
- `ImageVolume`
- `KubeletEnsureSecretPulledImages`
- `MaxUnavailableStatefulSet`
- `MemoryQoS`

- `MutatingAdmissionPolicy`
- `PodLogsQuerySplitStreams`
- `ResourceHealthStatus`
- `SELinuxMount`
- `StrictIPCIDRValidation`

Kubernetes 1.35

- `AllowUnsafeMalformedObjectDeletion`
- `CRDObservedGenerationTracking`
- `ComponentFlagz`
- `ComponentStatusz`
- `ConcurrentWatchObjectDecode`
- `ConstrainedImpersonation`
- `ContainerStopSignals`
- `CrossNamespaceVolumeDataSource`
- `HPAScaleToZero`
- `MemoryQoS`
- `MutablePVNodeAffinity`
- `MutablePodResourcesForSuspendedJobs`
- `MutableSchedulingDirectivesForSuspendedJobs`
- `MutatingAdmissionPolicy`
- `NodeDeclaredFeatures`
- `PodLogsQuerySplitStreams`
- `ResourceHealthStatus`
- `RestartAllContainersOnContainerExits`
- `SELinuxMount`
- `StrictIPCIDRValidation`
- `TaintTolerationComparisonOperators`

Protecting sensitive fields in custom resources

The `CRDSensitiveData` feature gate provides field-level protection for sensitive data in resources marked with the `x-kubernetes-sensitive-data: true` annotation. This feature is implemented as a patch to `kube-apiserver` (apiextensions-apiserver) and is supported starting from Kubernetes version 1.31.

The `x-kubernetes-sensitive-data` marker is validated by `kube-apiserver` when applying a resource:

- Marker requires the `CRDSensitiveData` feature gate to be enabled, which is enabled automatically when `apiserver.encryptionEnabled` is set to `true`.
- Marker can't be set on the root of the schema (the `openAPIV3Schema` node). To protect all fields of a resource, add the marker to the `spec` property (or a subtree below it), not to the schema root — the root also includes system fields (`apiVersion`, `kind`, `metadata`), which cannot be encrypted.
- Field type must be one of the OpenAPI v3 types: `string`, `integer`, `number`, `boolean`, `object`, or `array`. Applying the marker to `object` or `array` makes the entire subtree sensitive.
- Fields defined with `x-kubernetes-int-or-string: true` are supported.
- Marker is not allowed inside `anyOf`, `oneOf`, `allOf`, or `not` branches (this is enforced by the structural schema validator).

If at least one field in the resource schema is marked with `x-kubernetes-sensitive-data: true`, the following protection mechanisms are applied to all custom resources of this type:

- **Encryption in etcd**: Entire resource is encrypted using the same mechanism as Kubernetes Secrets. Requires enabling the `apiserver.encryptionEnabled` parameter.
- **RBAC-based field filtering**: For `get`, `list`, and `watch` requests, sensitive fields are removed from API responses if the caller does not have the corresponding permissions on the `<resource>/sensitive` subresource.
- **Audit log masking**: Values of sensitive fields are replaced with `"******"` in audit logs, regardless of RBAC permissions and audit level.

To enable sensitive data protection, set the `apiserver.encryptionEnabled` parameter to `true`. The `CRDSensitiveData` feature gate is enabled automatically and it shouldn't be specified manually:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  enabled: true
  settings:
    apiserver:
      encryptionEnabled: true
```

⚠ Enabling `encryptionEnabled` is irreversible and triggers a `kube-apiserver` restart.

For details, see the following sections:

- FAQ: Instructions for enabling sensitive data protection.
- Examples: Configuration examples and results.

Third-party components

List of third-party software used in the `control-plane-manager` module:

- Kubernetes

  License: Apache License 2.0

  An open source system for managing containerized applications across multiple hosts.

- Etcd 3.6.10

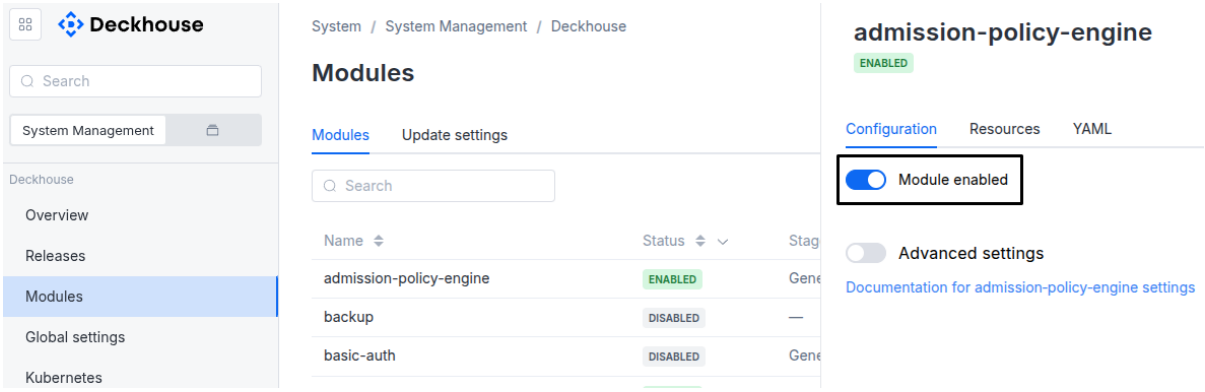
  License: Apache License 2.0

  A distributed reliable key-value store for the most critical data of a distributed system.

Configuration

i The module lifecycle stage: General Availability

Some cluster parameters that affect control plane management are derived from the ClusterConfiguration resource.



The module has 10 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `control-plane-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

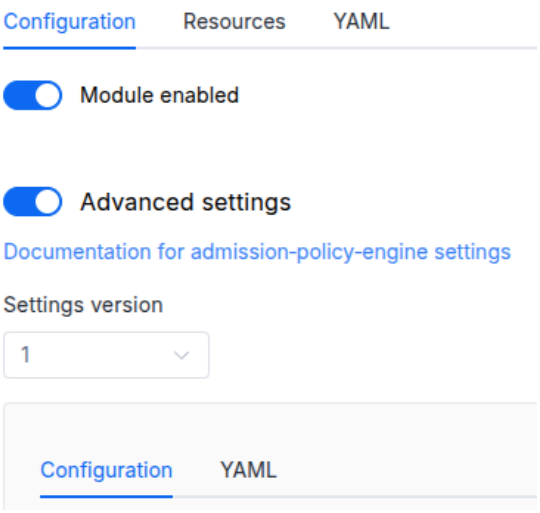
```
d8 system module enable control-plane-manager
```

- **Using ModuleConfig `control-plane-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `control-plane-manager` (create it if necessary);

  Example of a manifest to enable module `control-plane-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `control-plane-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `control-plane-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `control-plane-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `control-plane-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc control-plane-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `control-plane-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `control-plane-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: control-plane-manager
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `etcd.externalMembersNames`

Parameters

Schema version: 2

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  enabled: true
  settings:
    apiserver:
      bindToWildcard: true
      certSANs:
      - bakery.infra
      - devs.infra
      loadBalancer: {}
```

- **settings**
  object
  - **settings.apiserver**
    object

    `kube-apiserver` parameters.

    - **settings.apiserver.admissionPlugins**
      array of strings

      List of enabled additional admission plugins.

      Note, that in addition to the admission plugins enabled by default in Kubernetes, the following admission plugins are also always enabled:

      - `ExtendedResourceToleration`
      - `PodNodeSelector`
      - `PodTolerationRestriction`
      - `EventRateLimit` with the following config:

        ```
        apiVersion: eventratelimit.admission.k8s.io/v1alpha1
        kind: Configuration
        limits:
        - type: Namespace
          qps: 50
          burst: 100
          cacheSize: 2000
        ```

      > **i** Note that th `PodNodeSelector` admission plugin does not require specifiying a global configuration, it relies on annotated Namespaces.

      Example:

      ```
      admissionPlugins:
      - AlwaysPullImages
      - NamespaceAutoProvision
      ```

      - **Element of the array**
        string

Allowed values: `AlwaysPullImages`, `NamespaceAutoProvision`, `OwnerReferencesPermissionEnforcement`, `PodNodeSelector`, `PodTolerationRestriction`

- **settings.apiserver.auditLog**
  object

  Audit policy settings

  Default: `{"output":"File"}`

  - **settings.apiserver.auditLog.output**
    string

    Required value

    Audit logs target stream.

    Default: `File`

    Allowed values: `File`, `Stdout`

    Example:

    ```
    output: Stdout
    ```

  - **settings.apiserver.auditLog.path**
    string

    Directory path for logs if the output is “File”, otherwise ignored.

    Default: `/var/log/kube-audit`

    Pattern: `^[a-zA-Z0-9_/.-]+[a-zA-Z0-9_.-]$`

- **settings.apiserver.auditPolicyEnabled**
  boolean

  Set the audit policies using the configuration from the `kube-system/audit-policy` Secret.

  Default: `false`

- **settings.apiserver.authn**
  object

  Optional authentication parameters for Kubernetes API clients.

  By default, they are taken from user-authn module ConfigMap.

  - **settings.apiserver.authn.oidcCA**
    string

    OIDC provider CA.

  - **settings.apiserver.authn.oidcIssuerAddress**
    string

    OIDC provider network address alias.

    Examples:

    ```
    oidcIssuerAddress: 1.2.3.4
    ```

    ```
    oidcIssuerAddress: ''
    ```

  - **settings.apiserver.authn.oidcIssuerURL**
    string

    OIDC provider URL.

    Example:

    ```
    oidcIssuerURL: https://my-super-site.tech/
    ```

  - **settings.apiserver.authn.webhookCA**
    string

    Authorization webhook CA.

  - **settings.apiserver.authn.webhookCacheTTL**
    string

The duration to cache responses from the webhook token authenticator.

It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

Example:

```
webhookCacheTTL: 5m
```

- **settings.apiserver.authn.webhookURL**
  string

  Authentication webhook URL.

  Example:

  ```
  webhookURL: https://127.0.0.1:40443/
  ```

- **settings.apiserver.authz**
  object

  Optional authorization parameters for Kubernetes API clients.

  By default, they are taken from user-authz module ConfigMap.

  - **settings.apiserver.authz.webhookCA**
    string

    Authorization webhook CA.

  - **settings.apiserver.authz.webhookURL**
    string

    Authorization webhook URL.

    Example:

    ```
    webhookURL: https://127.0.0.1:40443/
    ```

- **settings.apiserver.basicAuditPolicyEnabled**
  boolean

  Enforce basic Deckhouse audit policies.

  Default: `true`

- **settings.apiserver.bindToWildcard**
  boolean

  Specifies whether to listen on `0.0.0.0`.

  By default, the API server listens on the hostIP. The latter usually corresponds to the Internal node address; however, the actual IP depends on the cluster type (Static or Cloud) and the layout selected.

  Default: `false`

- **settings.apiserver.certSANs**
  array of strings

  Array of SANs, with which the API server certificate will be generated.

  In addition to the passed list, the following list is always used:

  - `kubernetes`;
  - `kubernetes.default`;
  - `kubernetes.default.svc`;
  - `kubernetes.default.svc.cluster.local`;
  - Kubernetes API server address;
  - `127.0.0.1`;
  - host name;
  - host IP.

  Example:

  ```
  certSANs:
  - my-site.com
  - 192.168.67.76
  ```

- **Element of the array**
  string

  Pattern: `^[0-9a-zA-Z\.-]+$`

- **settings.apiserver.encryptionEnabled**
  boolean

  Enables data encryption in etcd (see Encrypting secret data at rest).

  When enabled, a Secret `kube-system/d8-secret-encryption-key` is created to store the encryption key.

  Enabling this parameter automatically enables the `CRDSensitiveData` feature gate for `kube-apiserver`, which protects custom resource fields marked with `x-kubernetes-sensitive-data: true` via encryption in etcd, RBAC-based field filtering with the `<resource>/sensitive` subresource and hiding values from the audit log.

  > **Warning.** Once enabled, this parameter can’t be disabled.

  Default: `false`

- **settings.apiserver.loadBalancer**
  object

  If set, a service `kube-system/d8-control-plane-apiserver` of the `LoadBalancer` type will be created.

  - **settings.apiserver.loadBalancer.annotations**
    object

    Annotations to attach to a service to fine-tune the load balancer.

    > **Caution!** The module does not take into account the specifics of setting annotations in various cloud environments. If the annotations for load balancer provisioning are only applied when creating a service, you will need to delete and add the `apiserver.loadBalancer` parameter to update such parameters.

  - **settings.apiserver.loadBalancer.port**
    integer

    External LoadBalancer TCP port.

    Default: `443`

    Allowed values: `1 <= X <= 65534`

  - **settings.apiserver.loadBalancer.sourceRanges**
    array of strings

    A list of CIDRs that are allowed to connect to the API.

    The cloud provider may not support this option or ignore it.

    - **Element of the array**
      string

      Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\/[0-9]+$`

- **settings.apiserver.serviceAccount**
  object

  ServiceAccount issuing settings.

  Examples:

  ```
  serviceAccount: {}
  ```

  ```
  serviceAccount:
    additionalAPIAudiences:
    - istio-ca
  ```

  - **settings.apiserver.serviceAccount.additionalAPIAudiences**
    array of strings

    A list of API audiences to add when provisioning ServiceAccount tokens.

    The default audiences list includes:

- `serviceAccount.issuer`, if specified.
- `serviceAccount.additionalAPIIssuers`, if specified.
- `https://kubernetes.default.svc.${clusterDomain}`, for example, `https://kubernetes.default.svc.cluster.local` – this audience is always added for backward compatibility.

The service account token authenticator will validate that tokens used against the API are bound to at least one of these audiences.

This option is beneficial when migrating from one API issuer to another.

- **settings.apiserver.serviceAccount.additionalAPIIssuers**
  array of strings

  A list of additional issuers to include when provisioning ServiceAccount tokens.

  Issuers (`iss`) are used to verify the source of the tokens, ensuring they originate from trusted entities.

  The first issuer is automatically generated based on the template `https://kubernetes.default.svc.${clusterDomain}`, for example, `https://kubernetes.default.svc.cluster.local`. When multiple issuers are specified, the first issuer is used to generate tokens, and all provided issuers are accepted for token verification.

  This option is beneficial when migrating from one API issuer to another.

- **settings.apiserver.serviceAccount.issuer**
  string

  ServiceAccount issuer. This is the URL of the API server. The values of this field are used as the `iss` claim of the token and to verify Service Account JWT tokens.

  Note, all pods in the cluster using ServiceAccount tokens must be restarted upon changing this option.

  Example:

```
issuer: https://api.example.com
```

- **settings.enabledFeatureGates**
  array of strings

  List of feature gates enabled in the control plane.

  More information about feature gates is available in the Kubernetes documentation. The list of feature gates supported in DKP can be found on the module overview page.

  Default: `[]`

  - **Element of the array**
    string

    Pattern: `^[a-zA-Z]+$`

- **settings.etcd**
  object

  `etcd` parameters.

  - **settings.etcd.backup**
    object

    etcd backup parameters.

    - **settings.etcd.backup.cronSchedule**
      string

      Backup schedule etcd in cron format. The local time zone of the `kube-controller-manager` is used.

      Default: `0 0 * * *`

      Example:

```
cronSchedule: 0 1 * * *
```

    - **settings.etcd.backup.enabled**
      boolean

      Enable etcd backup.

      Default: `true`

        - **settings.etcd.backup.hostPath**
          string

          Host path on masters nodes for etcd backup.

          Default: `/var/lib/etcd`

      - **settings.etcd.maxDbSize**
        number

        quota-backend-bytes parameter. Deckhouse automatically manages the `quota-backend-bytes` parameter. If the `maxDbSize` parameter is set, deckhouse will use this value for the `quota-backend-bytes` etcd parameter.

        Minimum: 512MB.

        Maximum: 8GB.

        Experimental. It can be removed in the future.

        Allowed values: `536870912 <= X <= 8589934592`

  - **settings.failedNodePodEvictionTimeoutSeconds**
    integer

    The number of seconds after which pods will be deleted from the node with the `Unreachable` status.

    > **Note!** If you change the parameter, the pods must be restarted.

    Default: `300`

  - **settings.nodeMonitorGracePeriodSeconds**
    integer

    The number of seconds after which the node will enter the `Unreachable` status in case of lost connection.

    Default: `40`

  - **settings.rootKubeconfigSymlink**
    boolean

    Whether to maintain a symlink from `/root/.kube/config` to `/etc/kubernetes/admin.conf` on control-plane nodes.

    When the user-authz module is enabled and this parameter is `false`, the symlink is removed and the `NODE_ADMIN_KUBECONFIG` environment variable is set on control-plane-manager pods accordingly. Use `d8 k` with `--kubeconfig=/etc/kubernetes/admin.conf` (or other credentials) when you need API access from the node.

    When the `user-authz` module is disabled, `control-plane-manager` ignores this parameter and keeps the default (symlink present).

    Setting the value back to `true` restores the symlink on the next reconciliation.

    Default: `true`

    Examples:

    ```
    rootKubeconfigSymlink: true
    ```

    ```
    rootKubeconfigSymlink: false
    ```

Custom Resources

> The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

KubeSchedulerWebhookConfiguration

Scope: Cluster
Version: v1alpha1

Defines the configuration for connecting a third-party kube-scheduler extender webhook.

An external kube-scheduler webhook allows expanding the capabilities of the scheduler and consider more complex conditions when planning the load in the Kubernetes cluster.

- **webhooks**
  array of objects

  Required value

  - **webhooks.clientConfig**
    object

    Required value

    ClientConfig defines how to communicate with the webhook.

    - **webhooks.clientConfig.caBundle**
      string

      Required value

      caBundle is a PEM encoded CA bundle which will be used to validate the webhook’s server certificate.

      Pattern: `^(?:[A-Za-z0-9+\/]{4})*(?:[A-Za-z0-9+\/]{4}|[A-Za-z0-9+\/]{3}=|[A-Za-z0-9+\/]{2}={2})$`

    - **webhooks.clientConfig.service**
      object

      Required value

      Access to webhook via cluster service.

      - **webhooks.clientConfig.service.name**
        string

        Required value

        Service name.

        Pattern: `^[0-9a-z\-]+$`

        Length: `1..255`

      - **webhooks.clientConfig.service.namespace**
        string

        Required value

        Service namespace.

        Pattern: `^[0-9a-z\-]+$`

        Length: `1..255`

      - **webhooks.clientConfig.service.path**
        string

        Required value

        URI path.

        Pattern: `^[0-9a-zA-Z._\/-]+$`

        Length: `1..255`

      - **webhooks.clientConfig.service.port**
        integer

        Required value

        Service port.

        Allowed values: `1 <= X <= 65535`

  - **webhooks.failurePolicy**
    string

    Specifies scheduling should fail or not fail when the extender returns an error or is not reachable.

    Default: `Fail`

    Allowed values: `Fail`, `Ignore`

  - **webhooks.filterVerb**

string

Verb appended to `URLPrefix` when issuing a `filter` call to the scheduler extender. If omitted, defaults to `filter` (for backward compatibility, avoid making changes unless necessary). Set to an empty string `""` to disable `filter` calls for this extender.

- **webhooks.preemptVerb**
  string

  Verb appended to `URLPrefix` when issuing a `preempt` call to this extender. Leave empty (`""`) to disable `preempt` calls for this extender.

- **webhooks.prioritizeVerb**
  string

  Verb appended to `URLPrefix` when issuing a `prioritize` call to this extender. If omitted, defaults to `prioritize` (for backward compatibility, avoid making changes unless necessary). Set to an empty string `""` to disable `prioritize` calls for this extender.

- **webhooks.timeoutSeconds**
  integer

  Webhook timeout in seconds.

  Default: `10`

  Allowed values: `1 <= X <= 60`

- **webhooks.weight**
  integer

  Required value

  The numeric multiplier for the node scores that the prioritize call generates.

  Allowed values: `1 <= X`

FAQ

> **i** The module lifecycle stage: General Availability

How do I add a master node to a static or hybrid cluster?

> **i** It is important to have an odd number of masters to ensure a quorum.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

When installing Deckhouse Kubernetes Platform with default settings, the NodeGroup `master` lacks the section `spec.staticInstances.labelSelector` with label filter settings for `staticInstances` resources. Because of this, after changing the number of `staticInstances` nodes in the NodeGroup `master` (parameter `spec.staticInstances.count`), when adding a regular node using Cluster API Provider Static (CAPS), it can be "intercepted" and added to the NodeGroup `master`, even if the corresponding `StaticInstance` (in `metadata`) specifies a label with a `role` different from `master`. To avoid this "interception", after installing DKP, edit the NodeGroup `master` — add the section `spec.staticInstances.labelSelector` with label filter settings for `staticInstances` resources. Example of NodeGroup `master` with `spec.staticInstances.labelSelector`:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: master
spec:
  nodeType: Static
  staticInstances:
    count: 2
    labelSelector:
      matchLabels:
        role: master
```

Next, when adding master nodes to the cluster using CAPS, specify the label specified in `spec.staticInstances.labelSelector` NodeGroup `master` in the corresponding `StaticInstance`. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-master-1
  labels:
    # The label specified in spec.staticInstances.labelSelector NodeGroup master.
    role: master
spec:
  # Specify the IP address of the static node server.
  address: "<SERVER-IP>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
```

> **i** When adding new master nodes using CAPS and changing the number of master nodes in the NodeGroup `master` (parameter `spec.staticInstances.count`), please note the following:
>
> During the initial cluster installation, the configuration specifies the first master node on which the installation takes place. If, after the initial cluster installation, you need to create a multi-master cluster and add master nodes using CAPS, you must specify the number of nodes in the `spec.staticInstances.count` parameter of the NodeGroup `master` as one less than the desired number.
>
> For example, if you need to create a multi-master with three master nodes in `spec.staticInstances.count` NodeGroup `master`, specify the value `2` and create two `staticInstances` for the nodes to be added. After adding them to the cluster, the number of master nodes will be three: the master node on which the installation took place and two master nodes added using CAPS.

Otherwise, adding a master node to a static or hybrid cluster is similar to adding a regular node. To do this, use the corresponding examples. All the necessary actions to configure cluster control plane components on the new master nodes are performed automatically. Wait until the master nodes appear in `Ready` status.

How do I add master nodes to a cloud cluster?

The following describes the conversion of a single-master cluster into a multi-master.

> **i** Before adding nodes, ensure you have the required quotas in the cloud provider.
>
> It is important to have an odd number of masters to ensure a quorum.

> **⚠** If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

1. Make a backup of `etcd` and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the creation of new master nodes.
4. Make sure that Deckhouse queue is empty:

   ```
   d8 system queue list
   ```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

   > **i** When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Kubernetes Platform license key.

6. Run the appropriate edition and version of the Deckhouse installer container **on the local machine** (change the container registry address if necessary):

```
DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]'
'[:lower:]' )
docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
  registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
```

7. **In the installer container**, run the following command to check the state before working:

   ```
   dhctl terraform check --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --
   ssh-host <MASTER-NODE-0-HOST>
   ```

   The command output should indicate that Terraform found no inconsistencies and no changes are required.

8. **In the installer container**, run the following command and specify the required number of replicas using the `masterNodeGroup.replicas` parameter:

   ```
   dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME>
   --ssh-user=<USERNAME> \
     --ssh-host <MASTER-NODE-0-HOST>
   ```

   > **i**
   >
   > For **Yandex Cloud**, when using external addresses on master nodes, the number of array elements in the masterNodeGroup.instanceClass.externalIPAddresses parameter must equal the number of master nodes. If `Auto` is used (public IP addresses are provisioned automatically), the number of array elements must still equal the number of master nodes.
   >
   > To illustrate, with three master nodes (`masterNodeGroup.replicas: 3`) and automatic address reservation, the `masterNodeGroup.instanceClass.externalIPAddresses` parameter would look as follows:
   >
   > ```
   > externalIPAddresses:
   > - "Auto"
   > - "Auto"
   > - "Auto"
   > ```

9. **In the installer container**, run the following command to start scaling:

   ```
   dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-
   host <MASTER-NODE-0-HOST>
   ```

10. Wait until the required number of master nodes are `Ready` and all `control-plane-manager` instances are up and running:

    ```
    d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady -l app=d8-control-plane-
    manager
    ```

How do I reduce the number of master nodes in a cloud cluster?

The following describes the conversion of a multi-master cluster into a single-master.

> ⚠ The steps described below must be performed from the first in order of the master node of the cluster (master-0). This is because the cluster is always scaled in order: for example, it is impossible to delete nodes master-0 and master-1, leaving master-2.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

1. Create a backup of etcd and the `/etc/kubernetes` directory.
2. Copy the resulting archive outside the cluster (e.g., to a local machine).
3. Ensure there are no alerts in the cluster that may interfere with the master node update process.
4. Make sure the DKP queue is empty:

```
d8 system queue list
```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

   > **i** When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Kubernetes Platform license key.

6. On the **local machine**, run the DKP installer container for the corresponding edition and version (change the container registry address if needed):

   ```
   DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
   DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]'
   '[:lower:]' )
   docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
     registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
   ```

7. **In the installer container**, run the following command and set `masterNodeGroup.replicas` to `1`:

   ```
   dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME>
   \
     --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST>
   ```

   > **i** For **Yandex Cloud**, if external IPs are used for master nodes, the number of items in the `masterNodeGroup.instanceClass.externalIPAddresses` array must match the number of master nodes. Even when using `Auto` (automatic public IP allocation), the number of entries must still match.
   >
   > For example, for a single master node (`masterNodeGroup.replicas: 1`) and automatic IP assignment, the `masterNodeGroup.instanceClass.externalIPAddresses` section would look like:
   >
   > ```
   > externalIPAddresses:
   > - "Auto"
   > ```

8. **In the installer container**, run the following command to trigger the scaling operation:

   ```
   dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-
   host <MASTER-NODE-0-HOST>
   ```

   > **i** For **OpenStack** and **VK Cloud (OpenStack)**, after confirming the node deletion, it is extremely important to check the disk deletion `<prefix>kubernetes-data-N` in Openstack itself.
   >
   > For example, when deleting the `cloud-demo-master-2` node in the Openstack web interface or in the OpenStack CLI, it is necessary to check the absence of the `cloud-demo-kubernetes-data-2` disk.
   >
   > If the kubernetes-data disk remains, there may be problems with ETCD operation as the number of master nodes increases.

9. Check the Deckhouse queue and make sure that there are no errors with the command:

   ```
   d8 system queue list
   ```

How do I dismiss the master role while keeping the node?

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module’s data before making any changes.

1. Make a backup of `etcd` and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the update of the master nodes.
4. Make sure that Deckhouse queue is empty:

   ```
   d8 system queue list
   ```

5. Remove the following labels:
   - `node-role.kubernetes.io/control-plane`
   - `node-role.kubernetes.io/master`
   - `node.deckhouse.io/group`

   Use the following command to remove labels:

   ```
   d8 k label node <MASTER-NODE-N-NAME> node-role.kubernetes.io/control-plane- node-role.kubernetes.io/master-
   node.deckhouse.io/group-
   ```

6. Make sure that the master node to be deleted is no longer listed as a member of the etcd cluster:

   ```
   for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
     d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
     --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
     --endpoints https://127.0.0.1:2379/ member list -w table
     if [ $? -eq 0 ]; then
       break
     fi
   done
   ```

7. Exec to the node and run the following commands:

   ```
   rm -f /etc/kubernetes/manifests/{etcd,kube-apiserver,kube-scheduler,kube-controller-manager}.yaml
   rm -f /etc/kubernetes/{scheduler,controller-manager}.conf
   rm -f /etc/kubernetes/authorization-webhook-config.yaml
   rm -f /etc/kubernetes/admin.conf /root/.kube/config
   rm -rf /etc/kubernetes/deckhouse
   rm -rf /etc/kubernetes/pki/{ca.key,apiserver*,etcd/,front-proxy*,sa.*}
   rm -rf /var/lib/etcd/member/
   ```

How do I switch to a different OS image in a multi-master cluster?

The OS change method depends on the cluster type: in a cloud cluster, nodes are replaced with `dhctl converge`; in a static cluster, nodes are replaced manually, one at a time.

In a cloud cluster

To change the OS image in a cloud cluster with multiple master nodes, follow these steps:

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

1. Make a backup of `etcd` and the `/etc/kubernetes` directory.
2. Transfer the archive to a server outside the cluster (e.g., on a local machine).
3. Ensure there are no alerts in the cluster that can prevent the update of the master nodes.
4. Make sure that Deckhouse queue is empty:

   ```
   d8 system queue list
   ```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

> **i** When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Kubernetes Platform license key.

6. Run the appropriate edition and version of the Deckhouse installer container **on the local machine** (change the container registry address if necessary):

```
DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]'
'[:lower:]' )
docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
  registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
```

7. **In the installer container**, run the following command to check the state before working:

```
dhctl terraform check --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> \
  --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-HOST>
```

   The command output should indicate that Terraform found no inconsistencies and no changes are required.

8. **In the installer container**, run the following command and specify the required OS image using the `masterNodeGroup.instanceClass` parameter (specify the addresses of all master nodes using the `--ssh-host` parameter):

```
dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME>
--ssh-user=<USERNAME> \
  --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-HOST>
```

9. **In the container with the installer**, run the following command to update the nodes:

   Carefully review the actions that converge plans to perform when it asks for confirmation.

   When the command is executed, the nodes will be replaced by new nodes with confirmation on each node. The replacement will be performed one by one in reverse order (2,1,0).

```
dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> \
  --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST> --ssh-host <MASTER-NODE-2-HOST>
```

   The following steps should be performed **sequentially on each** master node, starting with the node with the highest number (suffix 2) and ending with the node with the lowest number (suffix 0).

10. **On the newly created node**, check the systemd-unit log for the `bashible.service`. Wait until the node configuration is complete (you will see a message `nothing to do` in the log):

```
journalctl -fu bashible.service
```

11. Make sure the node is listed as an etcd cluster member:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ member list -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

12. Make sure `control-plane-manager` is running on the node:

```
d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady \
  -l app=d8-control-plane-manager --field-selector spec.nodeName=<MASTER-NODE-N-NAME>
```

13. Proceed to update the next node (repeat the steps above).

In a static cluster

The following instruction describes OS replacement on master nodes that were added to the cluster **manually** using the `bootstrap.sh` script. Perform the steps for each master node, one node at a time. Do not proceed to the next node until the current node has rejoined the cluster and is healthy.

> ⚠ If master nodes are managed by Cluster API Provider Static (CAPS) through StaticInstance resources, do not use this instruction. First delete the StaticInstance, install the required OS, and add the node to the `master` NodeGroup again.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

To change the OS of a manually added master node, follow these steps:

1. Make a backup of `etcd` and the `/etc/kubernetes` directory. If the `stronghold` module is enabled, make sure its data has also been backed up.
2. Check the cluster health and make sure there are no alerts or pending Deckhouse queue tasks:

   ```
   d8 status
   ```

3. Remove the master node labels from the node:

   ```
   d8 k label node <MASTER_NODE_NAME> node-role.kubernetes.io/control-plane- \
     node-role.kubernetes.io/master- node.deckhouse.io/group-
   ```

   where `<MASTER_NODE_NAME>`: Name of the master node being changed.
4. Make sure the node has been removed from the etcd cluster member list:

   ```
   for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
     d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
       --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
       --endpoints https://127.0.0.1:2379/ member list -w table
     if [ $? -eq 0 ]; then
       break
     fi
   done
   ```

5. Evict workloads from the node with `d8 k drain`:

   ```
   d8 k drain <MASTER_NODE_NAME> --ignore-daemonsets --delete-emptydir-data
   ```

6. Force-delete any Pods remaining on the node:

   ```
   d8 k delete pods --all-namespaces --field-selector spec.nodeName=<MASTER_NODE_NAME> --force
   ```

7. Delete the Node object:

   ```
   d8 k delete node <MASTER_NODE_NAME>
   ```

8. Clean up the DKP data on the removed master node. This command irreversibly removes Kubernetes and DKP data from the node. Before running it, make sure you have selected the correct node and created the required backups:

   ```
   bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
   ```

9. Install the required OS on the node.
10. On one of the remaining master nodes in the cluster, retrieve and decode the script for adding a master node:

    ```
    d8 k -n d8-cloud-instance-manager get secret manual-bootstrap-for-master \
      -o jsonpath='{.data.bootstrap\.sh}' | base64 -d > bootstrap.sh
    ```

11. Securely copy the `bootstrap.sh` file obtained in the previous step to the node being added and run it as `root` on that node:

```
bash bootstrap.sh
```

12. **On the node being added**, check the systemd-unit log for the `bashible.service`. Wait until the node configuration is complete (you will see a message `nothing to do` in the log):

    ```
    journalctl -fu bashible.service
    ```

13. Wait until the node reaches the `Ready` status:

    ```
    d8 k wait node <MASTER_NODE_NAME> --for=condition=Ready --timeout=10m
    ```

14. Make sure the node is listed as an etcd cluster member:

    ```
    for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
      d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
       --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
       --endpoints https://127.0.0.1:2379/ member list -w table
      if [ $? -eq 0 ]; then
        break
      fi
    done
    ```

15. Make sure `control-plane-manager` is running on the node:

    ```
    d8 k -n kube-system wait pod --timeout=10m --for=condition=ContainersReady \
      -l app=d8-control-plane-manager --field-selector spec.nodeName=<MASTER_NODE_NAME>
    ```

16. Make sure there are no alerts or pending queue tasks:

    ```
    d8 status
    ```

17. Repeat the procedure for the next master node.

How do I switch to a different OS image in a single-master cluster?

The method depends on the cluster type: first add extra master nodes, replace the OS in multi-master mode, then restore the original number of master nodes.

> ⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before changing master nodes. Create a backup of the module's data before making any changes.

In a cloud cluster

1. Convert your single-master cluster to a multi-master one, as described in the guide on adding master nodes to a cluster.
2. Change the OS on the master nodes according to the instructions.
3. Convert your multi-master cluster to a single-master one according to the guide on excluding master nodes from the cluster.

In a static cluster

1. Add extra master nodes according to the instructions.
2. Change the OS on the master nodes according to the instructions.
3. Remove extra master nodes from the control plane role according to the instructions. Then delete them from the cluster with `d8 k delete node <MASTER_NODE_NAME>` and power off the corresponding servers.

How to configure HA mode with two master nodes and an arbiter node?

Deckhouse Kubernetes Platform allows you to configure HA mode with two master nodes and an arbiter node. This approach allows you to meet HA requirements in conditions of limited resources.

Only etcd is placed on the arbiter node, without the other control plane components. This node is used to ensure the etcd quorum.

Requirements for the arbiter node:

- At least 2 CPU cores
- At least 4 GB of RAM
- At least 8 GB of disk space for etcd

The network latency requirements for the arbiter node are similar to those for the master nodes.

Configuring in a cloud cluster

The example below applies to a cloud cluster with three master nodes. To configure HA mode with two master nodes and an arbiter node in a cloud cluster, you need to remove one master node from the cluster and add one arbiter node.

To do this, follow these steps:

⚠ The following steps must be performed starting from the first master node (`master-0`) in the cluster. This is because the cluster scales in order — for example, it is not possible to remove `master-0` and `master-1` while leaving `master-2`.

⚠ If your cluster uses the `stronghold` module, make sure the module is fully operational before adding or removing a master node. Create a backup of the module's data before making any changes.

1. Create a backup of etcd and the `/etc/kubernetes` directory.
2. Copy the resulting archive outside the cluster (for example, to a local machine).
3. Ensure there are no alerts in the cluster that may interfere with the master node update process.
4. Make sure the DKP queue is empty:

   ```
   d8 system queue list
   ```

5. **On your local machine**, log in to the registry (change the container registry address if necessary):

   ```
   docker login registry.deckhouse.io
   ```

   During the login process, you will need to enter your `Username` and `Password`.

   i When logging in to the `registry.deckhouse.io` registry, the `Username` field must be set to `license-token`, and the `Password` field must contain the Deckhouse Kubernetes Platform license key.

6. On the **local machine**, run the DKP installer container for the corresponding edition and version (change the container registry address if needed):

   ```
   DH_VERSION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/version}')
   DH_EDITION=$(d8 k -n d8-system get deployment deckhouse -o
   jsonpath='{.metadata.annotations.core\.deckhouse\.io\/edition}' | tr '[:upper:]'
   '[:lower:]' )
   docker run --pull=always -it -v "$HOME/.ssh/:/tmp/.ssh/" \
     registry.deckhouse.io/deckhouse/${DH_EDITION}/install:${DH_VERSION} bash
   ```

7. **In the installer container**, run the following command:

   ```
   dhctl config edit provider-cluster-configuration --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME>
   \
     --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST>
   ```

   Change the cloud provider settings:

   - Set `masterNodeGroup.replicas` to `2`.
   - Create a NodeGroup for the arbiter node. The arbiter node **must have** the label `node.deckhouse.io/etcd-arbiter: ""` and a taint that prevents user workloads from being placed on it. Example of a NodeGroup description for the arbiter node:

```
nodeGroups:
  - name: arbiter
    replicas: 1
    nodeTemplate:
      labels:
        node.deckhouse.io/etcd-arbiter: ""
      taints:
        - key: node.deckhouse.io/etcd-arbiter
          effect: NoSchedule
    zones:
      - europe-west3-b
    instanceClass:
      machineType: n1-standard-4
  # ... the rest of the manifest
```

- Save your changes.

> **i** For **Yandex Cloud**, if external IPs are used for master nodes, the number of items in the `masterNodeGroup.instanceClass.externalIPAddresses` array must match the number of master nodes. Even when using `Auto` (automatic public IP allocation), the number of entries must still match.
>
> For example, for a single master node (`masterNodeGroup.replicas: 1`) and automatic IP assignment, the `masterNodeGroup.instanceClass.externalIPAddresses` section would look as follows:
>
> ```
> externalIPAddresses:
> - "Auto"
> ```

8. **In the installer container**, run the following command to trigger the scaling operation:

   ```
   dhctl converge --ssh-agent-private-keys=/tmp/.ssh/<SSH_KEY_FILENAME> --ssh-user=<USERNAME> --ssh-host <MASTER-NODE-0-HOST> --ssh-host <MASTER-NODE-1-HOST>
   ```

   > **i** **Important**. For **OpenStack** and **VK Cloud (OpenStack)**, after confirming the node deletion, it is extremely important to check the disk deletion `<prefix>kubernetes-data-N` in OpenStack itself.
   >
   > For example, when deleting the `cloud-demo-master-2` node in the OpenStack web interface or in the OpenStack CLI, it is necessary to check the absence of the `cloud-demo-kubernetes-data-2` disk.
   >
   > If the `kubernetes-data` disk remains, there may be problems with etcd operation as the number of master nodes increases.

9. Check the Deckhouse queue with the following command and make sure there are no errors:

   ```
   d8 system queue list
   ```

Configuring in a static cluster

To configure HA mode with two master nodes and an arbiter node in a static cluster, follow these steps:

1. Create a NodeGroup for the arbiter node. The arbiter node **must have** the label `node.deckhouse.io/etcd-arbiter: “”` and a taint that prevents user workloads from being placed on it. Example of a NodeGroup description for the arbiter node:

```
apiVersion: deckhouse.io/v1
  kind: NodeGroup
  metadata:
    name: arbiter
  spec:
    nodeType: Static
    nodeTemplate:
      labels:
        node.deckhouse.io/etcd-arbiter: ""
      taints:
        - key: node.deckhouse.io/etcd-arbiter
          effect: NoSchedule
  # ... the rest of the manifest
```

2. Add a node to the cluster that will be used as an arbiter node in a way that is convenient for you.
3. Ensure that the added arbiter node is in the list of etcd cluster members.
4. Remove one master node from the cluster.

How do I view the list of etcd members?

Option 1

Use the `etcdctl member list` command.

Example:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ member list -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

Warning. The last parameter in the output table shows etcd member is in `learner` state, is not in `leader` state.

Option 2

To obtain information about etcd cluster nodes in tabular form, use the `etcdctl endpoint status` command. For the leader, the `IS LEADER` column will show `true`.

Example:

```
for pod in $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name); do
  d8 k -n kube-system exec "$pod" -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ endpoint status --cluster -w table
  if [ $? -eq 0 ]; then
    break
  fi
done
```

What if something went wrong?

During its operation, `control-plane-manager` automatically creates backups of configurations and data that may be useful in case of issues. These backups are stored in the `/etc/kubernetes/deckhouse/backup` directory. If errors or unforeseen situations occur during operation, you can use these backups to restore to the previous stable state.

What if the etcd cluster fails?

If the etcd cluster is not functioning and it cannot be restored from a backup, you can attempt to rebuild it from scratch by following the steps below.

1. First, on all nodes that are part of your etcd cluster, except for one, remove the `etcd.yaml` manifest located in the `/etc/kubernetes/manifests/` directory. This last node will serve as a starting point for the new multi-master cluster.
2. On the last node, edit etcd manifest `/etc/kubernetes/manifests/etcd.yaml` and add the parameter `--`

`force-new-cluster` to `spec.containers.command`.
3. After the new cluster is ready, remove the `--force-new-cluster` parameter.

> ⚠ This operation is unsafe and breaks the guarantees given by the consensus protocol. Note that it brings the cluster to the state that was saved on the node. Any pending entries will be lost.

What if etcd restarts with an error?

This method may be necessary if the `--force-new-cluster` option doesn't restore etcd work. Such a scenario can occur during an unsuccessful converge of master nodes, where a new master node was created with an old etcd disk, changed its internal address, and other master nodes are absent. Symptoms indicating the need for this method include: the etcd container being stuck in an endless restart with the log showing the error: `panic: unexpected removal of unknown remote peer`.

1. Find the `etcdutl` utility on the master node and copy the executable to `/usr/local/bin/`:

   ```
   cp $(find /var/lib/containerd/ \
   -name etcdutl -print -quit) /usr/local/bin/etcdutl
   ```

2. Create a new etcd database snapshot from the current local snapshot (`/var/lib/etcd/member/snap/db`):

   ```
   etcdutl snapshot restore /var/lib/etcd/member/snap/db --name <HOSTNAME> \
   --initial-cluster=<HOSTNAME>=https://<ADDRESS>:2380 --initial-advertise-peer-
   urls=https://<ADDRESS>:2380 \
   --skip-hash-check=true --data-dir /var/lib/etcdtest
   ```

   where:

   - `<HOSTNAME>`: Name of the master node.
   - `<ADDRESS>`: Address of the master node.

3. Execute the following commands to use the new snapshot:

   ```
   cp -r /var/lib/etcd /tmp/etcd-backup
   rm -rf /var/lib/etcd
   mv /var/lib/etcdtest /var/lib/etcd
   ```

4. Locate the `etcd` and `api-server` containers:

   ```
   crictl ps -a | egrep "etcd|apiserver"
   ```

5. Remove the `etcd` and `api-server` containers:

   ```
   crictl rm <CONTAINER-ID>
   ```

6. Restart the master node.

What to do if the database volume of etcd reaches the limit set in quota-backend-bytes?

When the database volume of etcd reaches the limit set by the `quota-backend-bytes` parameter, it switches to "read-only" mode. This means that the etcd database stops accepting new entries but remains available for reading data. You can tell that you are facing a similar situation by executing the command:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name |
sed -n 1p) -- \
  etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt \
  --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ \
  endpoint status -w table --cluster
```

If you see a message like `alarm:NOSPACE` in the `ERRORS` field, you need to take the following steps:

1. On **each master node** (from the list of the etcd cluster members obtained earlier), find the line with `--quota-backend-bytes` in the etcd pod manifest at `/etc/kubernetes/manifests/etcd.yaml` and double the value. If there is no such line, add one, for example: `- --quota-backend-bytes=8589934592`. This sets the limit to 8 GB.

2. Disarm the active alarm that occurred due to reaching the limit. To do this, execute the command:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name
| sed -n 1p) -- \
etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt \
--cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key \
--endpoints https://127.0.0.1:2379/ alarm disarm
```

3. Change the maxDbSize parameter in the `control-plane-manager` settings to match the value specified in the manifest.

How to compact etcd storage

> ⚠ Before compacting etcd storage, back up etcd.

To view the size of the etcd database on a specific node before and after compaction, use the command (where `NODE_NAME` is the name of the master node):

```
d8 k -n kube-system exec -it etcd-NODE_NAME -- /usr/bin/etcdctl \
  --cert=/etc/kubernetes/pki/etcd/server.crt \
  --key=/etc/kubernetes/pki/etcd/server.key \
  --cacert=/etc/kubernetes/pki/etcd/ca.crt \
  endpoint status --cluster -w table
```

Output example (the size of the etcd database on the node is specified in the `DB SIZE` column):

```
+----------------------------+------------------+---------+-----------------+---------+----
----+----------------------+--------+------------+------------+-----------+------------+---
-----------------+--------+--------------------------+-------------------+
|          ENDPOINT          |        ID        | VERSION | STORAGE VERSION | DB SIZE | IN

```

How to compact etcd storage on a node in a single-master cluster

> ⚠ Compacting etcd storage is a resource-intensive operation that temporarily blocks etcd from running on that node. Keep this in mind when choosing a time to perform the operation in a cluster with a single master node.

To compact etcd storage in a cluster with a single master node, use the following command (where `NODE_NAME` is the name of the master node):

```
d8 k -n kube-system exec -ti etcd-NODE_NAME -- /usr/bin/etcdctl \
  --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt \
  --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ defrag --command-timeout=30s
```

Example output when the operation is successful:

```
Finished defragmenting etcd member[https://localhost:2379]. took 848.948927ms
```

> **i** If a timeout error occurs, increase the value of the `—command-timeout` parameter from the command above until compaction completes successfully.

How to compact etcd storage in a cluster with multiple master nodes

To compact etcd storage in a cluster with multiple master nodes:

1. Get a list of etcd pods. To do this, use the following command:

   ```
   d8 k -n kube-system get pod -l component=etcd -o wide
   ```

   Example output:

   ```
   NAME           READY    STATUS    RESTARTS   AGE     IP              NODE
   NOMINATED NODE   READINESS GATES
   etcd-master-0   1/1     Running   0          3d21h   192.168.199.80  master-0    <none>
   <none>
   etcd-master-1   1/1     Running   0          3d21h   192.168.199.81  master-1    <none>
   <none>
   etcd-master-2   1/1     Running   0          3d21h   192.168.199.82  master-2    <none>
   <none>
   ```

2. Identify the leader master node. To do this, contact any etcd pod and get a list of nodes participating in the etcd cluster using the command (where `NODE_NAME` is the name of the master node):

   ```
   d8 k -n kube-system exec -it etcd-NODE_NAME -- /usr/bin/etcdctl \
     --cert=/etc/kubernetes/pki/etcd/server.crt \
     --key=/etc/kubernetes/pki/etcd/server.key \
     --cacert=/etc/kubernetes/pki/etcd/ca.crt \
     endpoint status --cluster -w table
   ```

   Output example (the leader in the `IS LEADER` column will have the value `true`):

```
+----------------------------+-----------------+---------+----------------+---------

```

3. Compact etcd storage on the etcd cluster member nodes one by one. Use the following command (where `NODE_NAME` is the name of the master node):

> **i** Important: compact the leader node last.
>
> Restoring etcd on a node after compaction may take some time. It is recommended to wait at least a minute before proceeding to compact etcd storage on the next node.

```
d8 k -n kube-system exec -ti etcd-NODE_NAME -- /usr/bin/etcdctl \
  --cacert /etc/kubernetes/pki/etcd/ca.crt \
  --cert /etc/kubernetes/pki/etcd/ca.crt \
  --key /etc/kubernetes/pki/etcd/ca.key \
  --endpoints https://127.0.0.1:2379/ defrag --command-timeout=30s
```

Example output when the operation is successful:

```
Finished defragmenting etcd member[https://localhost:2379]. took 848.948927ms
```

> **i** If a timeout error occurs, increase the value of the `–command-timeout` parameter from the command above until compaction completes successfully.

Cluster admin access model

The control-plane-manager module maintains several kubeconfig files on master nodes. Understanding their purpose is important for secure cluster administration.

Kubeconfig files on master nodes

File	Identity	Purpose

File	Identity	Purpose
`/etc/kubernetes/admin.conf`	`kubernetes-admin` (`kubeadm:cluster-admins` group)	Machine kubeconfig for kubeadm internals (join, renewal). The group is bound to the built-in wildcard `cluster-admin` role.
`/etc/kubernetes/super-admin.conf`	`kubernetes-super-admin` (`system:masters` group)	Break-glass emergency credential. Bypasses RBAC entirely. Restrict access to this file to trusted recovery scenarios.
`/etc/kubernetes/controller-manager.conf`	`system:kube-controller-manager`	Used by kube-controller-manager.
`/etc/kubernetes/scheduler.conf`	`system:kube-scheduler`	Used by kube-scheduler.

RBAC-based admin access

Starting from Kubernetes 1.29, kubeadm generates `admin.conf` with the `kubeadm:cluster-admins` group instead of `system:masters`. This provides RBAC-controlled admin access that can be revoked by removing the RBAC binding objects for `kubeadm:cluster-admins`.

Deckhouse binds the `kubeadm:cluster-admins` group to the built-in wildcard ClusterRole `cluster-admin` (the same effective model as a plain kubeadm cluster without extra RBAC), regardless of whether the user-authz module is enabled. For full unrestricted access that also bypasses RBAC, use `super-admin.conf`.

Recommended admin access

When the user-authn module is enabled, use personalized OIDC-based kubeconfig obtained through the kubeconfig generator. This provides individual accountability and audit trail.

When `user-authn` is disabled, administrators can explicitly use the admin kubeconfig on a master node:

```
d8 k --kubeconfig=/etc/kubernetes/admin.conf <command>
```

Root kubeconfig symlink

By default, the CPM module creates a symlink `/root/.kube/config` -> `/etc/kubernetes/admin.conf` on master nodes, allowing root to run `d8 k` without specifying `--kubeconfig`.

When the **user-authz** module is enabled, you can disable this symlink by setting `rootKubeconfigSymlink: false` in the **control-plane-manager** module configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  enabled: true
  settings:
    rootKubeconfigSymlink: false
```

If **user-authz** is disabled, CPM does not apply this setting and keeps the default symlink behavior.

When the symlink is disabled (and **user-authz** is enabled), the symlink is removed when it pointed to `admin.conf`. Use personalized credentials or pass `--kubeconfig` explicitly.

Security hardening

The CPM module automatically restricts file permissions on `admin.conf` and `super-admin.conf` to `0600` (owner read/write only) during every reconciliation cycle. This prevents unauthorized users from reading these sensitive credentials.

Break-glass access

In emergency situations (RBAC misconfiguration, webhook failures), use `super-admin.conf`:

```
d8 k --kubeconfig=/etc/kubernetes/super-admin.conf <command>
```

This credential bypasses all RBAC checks. Use it only as a last resort and restrict who can read the file.

How do I configure additional audit policies?

1. Enable the auditPolicyEnabled flag in the module configuration:

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: control-plane-manager
   spec:
     version: 2
     settings:
       apiserver:
         auditPolicyEnabled: true
   ```

2. Create the `kube-system/audit-policy` Secret containing a Base64 encoded YAML file:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     name: audit-policy
     namespace: kube-system
   data:
     audit-policy.yaml: <base64>
   ```

   The minimum viable example of the `audit-policy.yaml` file looks as follows:

   ```
   apiVersion: audit.k8s.io/v1
   kind: Policy
   rules:
   - level: Metadata
     omitStages:
     - RequestReceived
   ```

   You can find detailed information on how to configure `audit-policy.yaml` file here:

   - The official Kubernetes documentation;
   - The code of the generator script used in GCE.

How to omit Deckhouse built-in policy rules?

Set the apiserver.basicAuditPolicyEnabled module parameter to `false`.

An example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  settings:
    apiserver:
      auditPolicyEnabled: true
      basicAuditPolicyEnabled: false
```

How to stream audit log to stdout instead of files?

Set the apiserver.auditLog.output parameter to `Stdout`.

An example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  settings:
    apiserver:
      auditPolicyEnabled: true
      auditLog:
        output: Stdout
```

How to deal with the audit log?

There must be some `log scraper` on master nodes *(log-shipper, promtail, filebeat)* that will monitor the log file:

```
/var/log/kube-audit/audit.log
```

The following fixed parameters of log rotation are in use:

- The maximum disk space is limited to `1000 Mb`.
- Logs older than `30 days` will be deleted.

Depending on the `Policy` settings and the number of requests to the `apiserver`, the amount of logs collected may be high. Thus, in some cases, logs can only be kept for less than 30 minutes.

> ⚠ The current implementation of this feature isn't safe and may lead to a temporary failure of the control plane.
>
> The `apiserver` will not be able to start if there are unsupported options or a typo in the Secret.

If `apiserver` is unable to start, you have to manually disable the `--audit-log-*` parameters in the `/etc/kubernetes/manifests/kube-apiserver.yaml` manifest and restart apiserver using the following command:

```
docker stop $(docker ps | grep kube-apiserver- | awk '{print $1}')
# Or (depending on your CRI).
crictl stopp $(crictl pods --name=kube-apiserver -q)
```

After the restart, you will be able to fix the Secret or delete it:

```
d8 k -n kube-system delete secret audit-policy
```

How do I speed up the restart of Pods if the connection to the node has been lost?

By default, a node is marked as unavailable if it does not report its state for 40 seconds. After another 5 minutes, its Pods will be rescheduled to other nodes. Thus, the overall application unavailability lasts approximately 6 minutes.

In specific cases, if an application cannot run in multiple instances, there is a way to lower its unavailability time:

1. Reduce the period required for the node to become `Unreachable` if the connection to it is lost by setting the `nodeMonitorGracePeriodSeconds` parameter.
2. Set a lower timeout for evicting Pods on a failed node using the `failedNodePodEvictionTimeoutSeconds` parameter.

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  settings:
    nodeMonitorGracePeriodSeconds: 10
    failedNodePodEvictionTimeoutSeconds: 50
```

In this case, if the connection to the node is lost, the applications will be restarted in about 1 minute.

Both these parameters directly impact the CPU and memory resources consumed by the control plane. By lowering timeouts, we force system components to send statuses more frequently and check the resource state more often.

When deciding on the appropriate threshold values, consider resources consumed by the control nodes (graphs can help you with this). Note that the lower parameters are, the more resources you may need to allocate to these nodes.

etcd backup and restore

What is done automatically

CronJob `kube-system/d8-etcd-backup-*` is automatically started at 00:00 UTC+0. The result is saved in `/var/lib/etcd/etcd-backup.tar.gz` on all nodes with `control-plane` in the cluster (master nodes).

How to manually backup etcd

Using Deckhouse CLI (Deckhouse Kubernetes Platform v1.65+)

Starting with Deckhouse Kubernetes Platform v1.65, a new `d8 backup etcd` tool is available for taking snapshots of etcd state.

```
d8 backup etcd ./etcd-backup.snapshot
```

Using bash (Deckhouse Kubernetes Platform v1.64 and older)

Login into any control-plane node with `root` user and use next script:

```
#!/usr/bin/env bash
set -e

pod=etcd-`hostname`
d8 k -n kube-system exec "$pod" -- /usr/bin/etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt --cert
/etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key --endpoints https://127.0.0.1:2379/
snapshot save /var/lib/etcd/${pod##*/}.snapshot && \
mv /var/lib/etcd/"${pod##*/}.snapshot" etcd-backup.snapshot && \
cp -r /etc/kubernetes/ ./ && \
tar -cvzf kube-backup.tar.gz ./etcd-backup.snapshot ./kubernetes/
rm -r ./kubernetes ./etcd-backup.snapshot
```

In the current directory etcd snapshot file `kube-backup.tar.gz` will be created from one of an etcd cluster members. From this file, you can restore the previous etcd cluster state in the future.

Also, we recommend making a backup of the `/etc/kubernetes` directory, which contains:

- manifests and configurations of control-plane components;
- Kubernetes cluster PKI.

This directory will help to quickly restore a cluster in case of complete loss of control-plane nodes without creating a new cluster and without rejoin the remaining nodes into the new cluster.

We recommend encrypting etcd snapshot backups as well as backup of the directory `/etc/kubernetes/` and saving them outside the Deckhouse cluster. You can use one of third-party files backup tools, for example: Restic, Borg, Duplicity, etc.

You can see documentation for learn about etcd disaster recovery procedures from snapshots.

How do perform a full recovery of the cluster state from an etcd backup?

The following steps will be described to restore to the previous state of the cluster from a backup in case of complete data loss.

Restoring a single-master cluster

Follow these steps to restore a single-master cluster on master node:

1. Find `etcdutl` utility on the master-node and copy the executable to `/usr/local/bin/`:

```
cp $(find /var/lib/containerd/ \
-name etcdutl -print -quit) /usr/local/bin/etcdutl
```

Check the version of `etcdutl` using the command:

```
etcdutl version
```

The result must be a correct output of `etcdutl version` command without errors.

Alternatively, you can download etcdutl executable to the node (preferably its version is the same as the etcd version in the cluster):

```
wget "https://github.com/etcd-io/etcd/releases/download/v3.6.1/etcd-v3.6.1-linux-amd64.tar.gz"
tar -xzvf etcd-v3.6.1-linux-amd64.tar.gz && mv etcd-v3.6.1-linux-amd64/etcdutl /usr/local/bin/etcdutl
```

You can check current `etcd` version using following command (might not work, if etcd and Kubernetes API are already unavailable):

```
d8 k -n kube-system exec -ti etcd-$(hostname) -- etcdutl version
```

2. Stop the etcd.

```
mv /etc/kubernetes/manifests/etcd.yaml ~/etcd.yaml
```

3. Save the current etcd data.

```
cp -r /var/lib/etcd/member/ /var/lib/deckhouse-etcd-backup
```

4. Copy or move the `etcd-backup.snapshot` file to the current user’s (root) home directory:

```
cp /path/to/backup/etcd-backup.snapshot ~/etcd-backup.snapshot
```

5. Clean the etcd directory.

```
rm -rf /var/lib/etcd
```

6. Restore the etcd database.

```
ETCDCTL_API=3 etcdutl snapshot restore ~/etcd-backup.snapshot  --data-dir=/var/lib/etcd
```

7. Run etcd. The process may take some time.

```
mv ~/etcd.yaml /etc/kubernetes/manifests/etcd.yaml
crictl ps --label io.kubernetes.pod.name=etcd-$HOSTNAME
```

To verify that etcd is running, use the command:

```
crictl ps --label io.kubernetes.pod.name=etcd-$HOSTNAME
```

Output example:

```
CONTAINER        IMAGE            CREATED              STATE     NAME      ATTEMPT
POD ID          POD
4b11d6ea0338f    16d0a07aa1e26    About a minute ago   Running   etcd      0
ee3c8c7d7bba6   etcd-gs-test
```

8. Restart the master node.

Restoring a multi-master cluster

To properly restore a multi-master cluster, follow these steps:

1. Enable High Availability (HA) mode. This is necessary to preserve at least one Prometheus replica and its PVC, since HA is disabled by default in single-master clusters.

2. Switch the cluster to single-master mode:
   - In a cloud cluster, follow the instructions.
   - In a static cluster, remove any unnecessary master nodes from the `control-plane` role by following the instructions and then remove them from the cluster.
   - In a static cluster with the configured HA mode based on two master nodes and an arbiter node, remove the arbiter node and additional master nodes.
   - In a cloud cluster with the configured HA mode based on two master nodes and an arbiter node, use the instructions to remove the additional master nodes and the arbiter node.
3. Restore etcd from the backup on the only remaining master node. Follow the instructions for restoring a cluster with a single master node.
4. Once etcd is restored, remove the records of the previously deleted master nodes from the cluster using the following command (replace with the actual node name):

   ```
   d8 k delete node <MASTER_NODE_NAME>
   ```

   > **Warning.** If the `d8 k` or `kubectl` commands are unavailable on the node, check the `/etc/kubernetes/kubernetes-api-proxy/nginx.conf` configuration file. It should only specify your current API server. If the configuration contains lines with IP addresses of old master nodes, remove them. Edit the configuration in a similar way on all other nodes.

5. Reboot the master node. Ensure that the other nodes transition to the `Ready` state.
6. Wait for Deckhouse to process all tasks in the queue:

   ```
   d8 system queue main
   ```

7. Switch the cluster back to multi-master mode. Follow the respective instructions for cloud clusters and static clusters.

Once you go through these steps, the cluster will be successfully restored in the multi-master configuration.

How do I restore a Kubernetes object from an etcd backup?

To get cluster objects data from an etcd backup, you need:

1. Start an temporary instance of etcd.
2. Fill it with data from the backup.
3. Get desired objects using `auger`.

Example of steps to restore objects from an etcd backup

In the example below, `etcd-backup.snapshot` is an etcd snapshot, `infra-production` is the namespace in which objects need to be restored.

- To decode objects from `etcd` you would need auger. It can be built from source on any machine that has Docker installed (it cannot be done on cluster nodes).

  ```
  git clone -b v1.0.1 --depth 1 https://github.com/etcd-io/auger
  cd auger
  make release
  build/auger -h
  ```

- Resulting executable `build/auger`, and also the `snapshot` from the backup copy of etcd must be uploaded on master-node, on which following actions would be performed.

Following actions are performed on a master node, to which `etcd snapshot` file and `auger` tool were copied:

1. Set the correct access permissions for the backup file:

   ```
   chmod 644 etcd-backup.snapshot
   ```

2. Set full path for snapshot file and for the tool into environmental variables:

   ```
   SNAPSHOT=/root/etcd-restore/etcd-backup.snapshot
   AUGER_BIN=/root/auger
   chmod +x $AUGER_BIN
   ```

3. Run a Pod with temporary instance of `etcd`.

- Create Pod manifest. It should schedule on current master node by `$HOSTNAME` variable, and mounts snapshot file by `$SNAPSHOT` variable, which it then restores in temporary `etcd` instance:

```
cat <<EOF >etcd.pod.yaml
apiVersion: v1
kind: Pod
metadata:
  name: etcdrestore
  namespace: default
spec:
  nodeName: $HOSTNAME
  tolerations:
  - operator: Exists
  initContainers:
  - command:
    - etcdutl
    - snapshot
    - restore
    - "/tmp/etcd-snapshot"
    - --data-dir=/default.etcd
    image: $(kubectl -n kube-system get pod -l component=etcd -o jsonpath="
{.items[*].spec.containers[*].image}" | cut -f 1 -d ' ')
    imagePullPolicy: IfNotPresent
    name: etcd-snapshot-restore
    # Uncomment the fragment below to set limits for the container if the node does
not have enough resources to run it.
    # resources:
    #   requests:
    #     ephemeral-storage: "200Mi"
    #   limits:
    #     ephemeral-storage: "500Mi"
    volumeMounts:
    - name: etcddir
      mountPath: /default.etcd
    - name: etcd-snapshot
      mountPath: /tmp/etcd-snapshot
      readOnly: true
  containers:
  - command:
    - etcd
    image: $(kubectl -n kube-system get pod -l component=etcd -o jsonpath="
{.items[*].spec.containers[*].image}" | cut -f 1 -d ' ')
    imagePullPolicy: IfNotPresent
    name: etcd-temp
    volumeMounts:
    - name: etcddir
      mountPath: /default.etcd
  volumes:
  - name: etcddir
    emptyDir: {}
    # Use the snippet below instead of emptyDir: {} to set limits for the container
if the node's resources are insufficient to run it.
    # emptyDir:
    #  sizeLimit: 500Mi
  - name: etcd-snapshot
    hostPath:
      path: $SNAPSHOT
      type: File
EOF
```

- Create Pod from the resulting manifest:

```
d8 k create -f etcd.pod.yaml
```

4. Set environment variables. In this example:
   - `infra-production` - namespace which we will search resources in.

- `/root/etcd-restore/output` - path for outputting recovered resource manifests.
- `/root/auger` - path to `auger` executable.

```
FILTER=infra-production
BACKUP_OUTPUT_DIR=/root/etcd-restore/output
mkdir -p $BACKUP_OUTPUT_DIR && cd $BACKUP_OUTPUT_DIR
```

5. Commands below will filter needed resources by `$FILTER` and output them into `$BACKUP_OUTPUT_DIR` directory:

```
files=($(d8 k -n default exec etcdrestore -c etcd-temp -- etcdctl  --endpoints=localhost:2379 get / --prefix --keys-only | grep "$FILTER"))
for file in "${files[@]}"
do
  OBJECT=$(d8 k -n default exec etcdrestore -c etcd-temp -- etcdctl  --endpoints=localhost:2379 get "$file" --print-value-only | $AUGER_BIN decode)
  FILENAME=$(echo $file | sed -e "s#/registry/##g;s#/#_#g")
  echo "$OBJECT" > "$BACKUP_OUTPUT_DIR/$FILENAME.yaml"
  echo $BACKUP_OUTPUT_DIR/$FILENAME.yaml
done
```

6. From resulting `yaml` files, delete `creationTimestamp`, `UID`, `status` and other operational fields, and then restore the objects:

```
d8 k create -f deployments_infra-production_supercronic.yaml
```

7. Delete the Pod with a temporary instance of etcd:

```
d8 k -n default delete pod etcdrestore
```

How the node to run the Pod on is selected

The Kubernetes scheduler component selects the node to run the Pod on.

The selection process involves two phases, namely `Filtering` and `Scoring`. They are supposed to efficiently distribute the Pods between the nodes.

Although there are some additional phases, such as `pre-filtering`, `post-filtering`, and so on, you can safely narrow them down to the global phases mentioned above, as they merely increase flexibility and help to optimize things.

The structure of the Kubernetes scheduler

The Scheduler comprises plugins that function in either or both phases.

Example of plugins:

- **ImageLocality** — favors nodes that already have the container images that the Pod runs. Phase: `Scoring`.
- **TaintToleration** — implements taints and tolerations. Phases: `Filtering`, `Scoring`.
- **NodePorts** - checks whether the ports required for the Pod to run are available on the node. Phase: `Filtering`.

The full list of plugins is available in the Kubernetes documentation.

Working logic

Scheduler profiles

There are two predefined scheduler profiles:

- `default-scheduler`: The default profile that distributes pods to nodes with the lowest load;
- `high-node-utilization`: A profile that places pods on nodes with the highest load.

To specify a scheduler profile, use the `spec.schedulerName` parameter in the pod manifest.

Example of using a profile:

```
apiVersion: v1
kind: Pod
metadata:
  name: scheduler-example
  labels:
    name: scheduler-example
spec:
  schedulerName: high-node-utilization
  containers:
  - name: example-pod
    image: registry.k8s.io/pause:2.0
```

Pod scheduling stages

The selection process starts with the `Filtering` phase. During it, `filter` plugins select nodes that satisfy filter conditions such as `taints`, `nodePorts`, `nodeName`, `unschedulable`, etc. If the nodes are in different zones, the scheduler alternates zones when selecting to ensure that all Pods will not end up in the same zone.

Suppose there are two zones with the following nodes:

```
Zone 1: Node 1, Node 2, Node 3, Node 4
Zone 2: Node 5, Node 6
```

In this case, the nodes will be selected in the following order:

```
Node 1, Node 5, Node 2, Node 6, Node 3, Node 4.
```

Note that Kubernetes limits the number of nodes to calculate their scores during scheduling. This optimizes the selection process and prevents unnecessary scoring. By default, the threshold is linear. For clusters with less than or equal to 50 nodes, 100% of nodes are considered for scheduling; for clusters with 100 nodes, a 50%-threshold is used; and for clusters with 5000 nodes, a 10%-threshold is used. The minimum threshold value is 5% for clusters with more than 5000 nodes. Therefore, even if all the conditions are met, a node may not be included in the list of candidates for scheduling if the default settings are used.

This logic can be changed (read more about the parameter `percentage Of Nodes To Score` in the Kubernetes documentation), but Deckhouse does not provide such an option.

The `Scoring` phase follows once the nodes that meet the conditions are selected. Each plugin evaluates the filtered node list and assigns a score to each node based on available resources: `pod capacity`, `affinity`, `volume provisioning`, and other factors. The scores from the different plugins are then summed up and the node with the highest score is selected. If several nodes have the same score, the node is selected at random.

Finally, the scheduler assigns the Pod to the node with the highest ranking.

Documentation

- General description of the scheduler.
- Plugin system.
- Node Filtering Details.
- Scheduler source code.

How to change or extend the scheduler logic

To change the logic of the scheduler it is possible to use the extension mechanism Extenders.

Each plugin is a webhook that must satisfy the following requirements:

- Use of TLS.
- Accessibility through a service within the cluster.
- Support for standard `Verbs` (`filterVerb = filter`, `prioritizeVerb = prioritize`).
- It is also assumed that all plugins can cache node information (`nodeCacheCapable: true`).

You can connect an `extender` using KubeSchedulerWebhookConfiguration resource.

✖ When using the `failurePolicy: Fail` option, in case of an error in the webhook's operation, the scheduler will stop working and new pods will not be able to start.

How does kubelet certificate rotation work?

In Deckhouse Kubernetes Platform, kubelet certificate rotation is automatic.

The kubelet uses a client TLS certificate (`/var/lib/kubelet/pki/kubelet-client-current.pem`) with which it can request a new client certificate or a new server certificate (`/var/lib/kubelet/pki/kubelet-server-current.pem`) from kube-apiserver.

When there is 5-10% (random value from the range) of time left before the certificate expires, kubelet requests a new certificate from kube-apiserver. For a description of the algorithm, see the official Kubernetes documentation.

Certificates lifetime

By default, lifetime of certificates is 1 year (8760 hours). If necessary, this value can be changed using `--cluster-signing-duration` argument in `/etc/kubernetes/manifests/kube-controller-manager.yaml` manifest. But to ensure that kubelet has time to install the certificate before it expires, we recommend setting the certificate lifetime to more than 1 hour.

> ⚠ If the client certificate lifetime has expired, kubelet will not be able to make requests to kube-apiserver and will not be able to renew certificates. In this case, the node will be marked as `NotReady` and recreated.

Specifics of working with kubelet server certificates in Deckhouse Kubernetes Platform

Deckhouse Kubernetes Platform uses IP addresses for kubelet API requests. The kubelet configuration does not use the `tlsCertFile` and `tlsPrivateKeyFile` fields, but uses a dynamic certificate that kubelet generates itself. Also, the CIS benchmark `AVD-KCV-0088` and `AVD-KCV-0089` checks, which track whether the `--tls-cert-file` and `--tls-private-key-file` arguments were passed to kubelet, are disabled in the Deckhouse Kubernetes Platform (in the `operator-trivy` module).

Information about the logic of working with server certificates in Kubernetes

Kubelet handles server certificates using the following logic:

- If `tlsCertFile` and `tlsPrivateKeyFile` are not empty, kubelet will use them as the default certificate and key.
  - When a client requests the kubelet API by specifying an IP address (e.g., `https://10.1.1.2:10250/`), the default private key (`tlsPrivateKeyFile`) will be used to establish a TLS connection. In this case, certificate rotation will not work.
  - When a client requests the kubelet API by specifying a host name (e.g., `https://k8s-node:10250/`), a dynamically generated private key from the `/var/lib/kubelet/pki/` directory will be used to establish a TLS connection. In this case, certificate rotation will work.
- If `tlsCertFile` and `tlsPrivateKeyFile` are empty, a dynamically generated private key from the `/var/lib/kubelet/pki/` directory will be used to establish the TLS connection. In this case, certificate rotation will work.

How to manually update control plane component certificates?

There may be a situation when the cluster’s master nodes are powered off for an extended period. During this time, the control plane component certificates may expire. After the nodes are powered back on, the certificates will not update automatically and must be renewed manually.

Control plane component certificates are updated using the `kubeadm` utility. To update the certificates, do the following on each master node:

1. Find the `kubeadm` utility on the master node and create a symbolic link using the following command:

   ```
   ln -s $(find /var/lib/containerd -name kubeadm -type f -executable -print -quit) /usr/bin/kubeadm
   ```

2. Update the certificates:

   ```
   kubeadm certs renew all
   ```

How do I protect sensitive fields in custom resources?

To protect sensitive fields (such as passwords, tokens, or keys) in resource schemas from unauthorized access via the API, unencrypted storage in etcd, or exposure in audit logs, use the `CRDSensitiveData` feature gate together with the `x-kubernetes-sensitive-data` schema marker.

To enable field protection, do the following:

1. Enable etcd encryption using the `apiserver.encryptionEnabled` parameter in the module settings. The `CRDSensitiveData` feature gate is enabled automatically along with the encryption and shouldn’t be specified manually.

> ⚠ Enabling `apiserver.encryptionEnabled` is irreversible and triggers a `kube-apiserver` restart.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  version: 2
  enabled: true
  settings:
    apiserver:
      encryptionEnabled: true
```

2. Mark sensitive fields in the resource schema with `x-kubernetes-sensitive-data: true`.

   The marker can be applied to the fields of the following types: `string`, `integer`, `number`, `boolean`, `object` and `array` (applying the marker to an `object` or `array` makes the entire subtree sensitive). Fields marked with `x-kubernetes-int-or-string: true` are supported as well.

   The marker can't be set on the schema root (the `openAPIV3Schema` node) and inside `anyOf`, `oneOf`, `allOf`, or `not` branches.

3. For users and ServiceAccounts that require access to full data, grant RBAC permissions for the `<resource>/sensitive` subresource.

Protection mechanisms

Protection	Description
Encryption in etcd	The entire resource is encrypted using the same AES-CBC transformer as Kubernetes Secrets.
API field filtering	Sensitive fields are removed from responses to `get`, `list`, and `watch` requests if the caller does not have permissions on the `<resource>/sensitive` subresource.
Audit log masking	Values of sensitive fields are replaced with `"******"` in all audit events, regardless of RBAC permissions and audit level.

A complete configuration example and results are available in the Examples section.

Examples

> **i** The module lifecycle stage: General Availability

The connection of an external scheduler plugin

Example of connecting an external scheduler plugin via webhook.

```
apiVersion: deckhouse.io/v1alpha1
kind: KubeSchedulerWebhookConfiguration
metadata:
  name: sds-replicated-volume
webhooks:
- weight: 5
  failurePolicy: Ignore
  clientConfig:
    service:
      name: scheduler
      namespace: d8-sds-replicated-volume
      port: 8080
      path: /scheduler
    caBundle: ABCD=
  timeoutSeconds: 5
```

Protecting resources with sensitive fields

The following example demonstrates how to protect sensitive fields in resources using the `CRDSensitiveData` feature gate and the `x-kubernetes-sensitive-data` schema marker.

For instructions on enabling this feature, see FAQ.

1. Enabling etcd encryption with the `encryptionEnabled` parameter. This automatically enables the `CRDSensitiveData` feature gate for `kube-apiserver`.

   ```
   apiVersion: deckhouse.io/v1alpha1
   kind: ModuleConfig
   metadata:
     name: control-plane-manager
   spec:
     version: 2
     enabled: true
     settings:
       apiserver:
         encryptionEnabled: true
   ```

2. Defining sensitive fields in the resource schema.

   Fields marked with `x-kubernetes-sensitive-data: true` are encrypted in etcd and removed from API responses for callers that do not have access to the `<resource>/sensitive` subresource.

   ```
   apiVersion: apiextensions.k8s.io/v1
   kind: CustomResourceDefinition
   metadata:
     name: dbconfigs.example.com
   spec:
     group: example.com
     scope: Namespaced
     names:
       plural: dbconfigs
       singular: dbconfig
       kind: DbConfig
     versions:
       - name: v1
         served: true
         storage: true
         schema:
           openAPIV3Schema:
             type: object
             properties:
               spec:
                 type: object
                 properties:
                   host:
                     type: string
                   username:
                     type: string
                   password:
                     type: string
                     x-kubernetes-sensitive-data: true
   ```

3. Creating a custom resource with values filled in sensitive fields.

   ```
   apiVersion: example.com/v1
   kind: DbConfig
   metadata:
     name: primary
     namespace: default
   spec:
     host: db.example.com
     username: admin
     password: s3cr3t
   ```

   Once saved, the entire object is encrypted in etcd and the `password` value is hidden in the audit log and

removed from the API responses of the caller has no permissions to the `dbconfigs/sensitive` subresource.

4. Configuring access to sensitive fields using RBAC and the `<resource>/sensitive` subresource.

```
# Regular role: can read the resource, but sensitive fields are removed from responses.
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: dbconfig-reader
rules:
- apiGroups: ["example.com"]
  resources: ["dbconfigs"]
  verbs: ["get", "list", "watch"]
---
# Privileged role: can read full data, including sensitive fields.
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: dbconfig-sensitive-reader
rules:
- apiGroups: ["example.com"]
  resources: ["dbconfigs"]
  verbs: ["get", "list", "watch"]
- apiGroups: ["example.com"]
  resources: ["dbconfigs/sensitive"]
  verbs: ["get", "list", "watch"]
```

5. A result of sensitive field protection.
   - A user with the `dbconfig-reader` role who runs `d8 k get dbconfig primary -o json` can see the resource with sensitive fields removed:

     ```
     {
       "spec": {
         "host": "db.example.com",
         "username": "admin"
       }
     }
     ```

   - A user with the `dbconfig-sensitive-reader` role can see the full data:

     ```
     {
       "spec": {
         "host": "db.example.com",
         "username": "admin",
         "password": "s3cr3t"
       }
     }
     ```

   - In audit logs, values of sensitive fields are always masked, regardless of caller permissions:

     ```
     {
       "spec": {
         "host": "db.example.com",
         "username": "admin",
         "password": "******"
       }
     }
     ```

The csi-vsphere module

✖ The module lifecycle stage: Deprecated

The `csi-vsphere` module provides Container Storage Interface (CSI) support for VMware vSphere environments, enabling dynamic provisioning and management of persistent storage volumes in Kubernetes clusters running

on vSphere infrastructure.

This module is specifically designed for **static Kubernetes clusters** (non-cloud) deployed on VMware vSphere and works independently from the cloud-provider-vsphere module. It integrates with vSphere datastores to provide persistent storage capabilities through the vSphere CSI driver.

> **i** Use the `csi-vsphere` module when the cluster cannot use the `cloud-provider-vsphere` module but still requires dynamic volume provisioning on vSphere infrastructure.

Main Features

- Provides dynamic persistent volume provisioning for static Kubernetes clusters on VMware vSphere.
- Automatically discovers vSphere datastores and creates StorageClass resources.
- Supports topology-aware volume placement using vSphere region and zone tags.
- Handles volume creation, deletion, attachment, detachment, and online resizing (Default mode).
- Supports Legacy, Default, and Migration compatibility modes for smooth driver transitions.

The module deploys the VMware vSphere CSI driver components that:

- **Automatically discover vSphere datastores**: Reads discovery data from the `d8-cloud-provider-discovery-data` secret to identify available datastores and their topology.
- **Create StorageClasses**: Automatically generates StorageClass resources for each discovered datastore, filtered by the exclude list if configured.
- **Provision persistent volumes**: Dynamically creates persistent volumes on vSphere datastores when PersistentVolumeClaims are created.
- **Support volume operations**: Handles volume creation, deletion, attachment, detachment, and online resizing (in Default mode).
- **Implement topology awareness**: Uses zone and region labels for proper volume placement according to vSphere cluster topology.

System requirements

To use the module in a cluster, the following system requirements must be met:

- All cluster nodes must be virtual machines created with vSphere tooling.
- The vSphere VM name must **exactly match** the node hostname in the Deckhouse Kubernetes Platform cluster.
- Each VM must have `disk.EnableUUID:TRUE` set so the platform can identify attached volumes reliably.

Architecture

The CSI driver consists of components:

1. **CSI Controller** (runs on master nodes):
   - **vsphere-csi-controller**: Main controller managing volume lifecycle operations;
   - **csi-provisioner**: Watches for PVCs and triggers volume creation;
   - **csi-attacher**: Handles volume attachment to nodes;
   - **csi-resizer**: Manages online volume expansion;
   - **vsphere-syncer**: Synchronizes metadata between Kubernetes and vSphere every 30 minutes;
   - **liveness-probe**: Monitors controller health.
2. **CSI Node** (DaemonSet on all nodes):
   - **vsphere-csi-node**: Node-level CSI driver handling volume mounting/unmounting;
   - **node-driver-registrar**: Registers the CSI driver with kubelet;
   - **liveness-probe**: Monitors node driver health.

Compatibility modes

The module supports the following operational modes (the mode is set via the `compatibilityFlag` parameter):

- **Default mode** (used by default, `compatibilityFlag` not set or empty):
  - uses the current vSphere CSI driver (`csi.vsphere.vmware.com`);
  - supports CNS (Cloud Native Storage) volumes;
  - enables online volume resizing;
  - recommended for new deployments.
- **Legacy mode** (`compatibilityFlag: "Legacy"`):
  - uses the older vSphere CSI driver (`vsphere.csi.vmware.com`);
  - works with FCD (First Class Disk) volumes only;
  - no online volume resizing support;
  - used for backward compatibility.
- **Migration mode** (`compatibilityFlag: "Migration"`):
  - runs both driver versions simultaneously,
  - facilitates migration from Legacy to Default mode,
  - allows gradual transition of workloads.

Storage discovery and provisioning

The module automatically:

1. **Discovers datastores** from the cloud provider discovery data.
2. **Generates StorageClass names** by sanitizing datastore names to meet Kubernetes DNS naming requirements.
3. **Filters excluded storage** based on storageClass.exclude configuration (supports regex patterns).
4. **Creates StorageClasses** with appropriate parameters:
   - `allowVolumeExpansion: true` (Default mode only).
   - `volumeBindingMode: WaitForFirstConsumer`: Ensures volumes are created in the same zone as the pod.
   - Topology constraints matching vSphere regions and zones.

Default StorageClass and exclusions

The module automatically creates a StorageClass for each Datastore and DatastoreCluster from the zones.

To set the default StorageClass for a cluster, use the global parameter `defaultClusterStorageClass`. To filter out unwanted StorageClass objects, specify exclusion patterns in the `storageClass.exclude` parameter.

Volume lifecycle

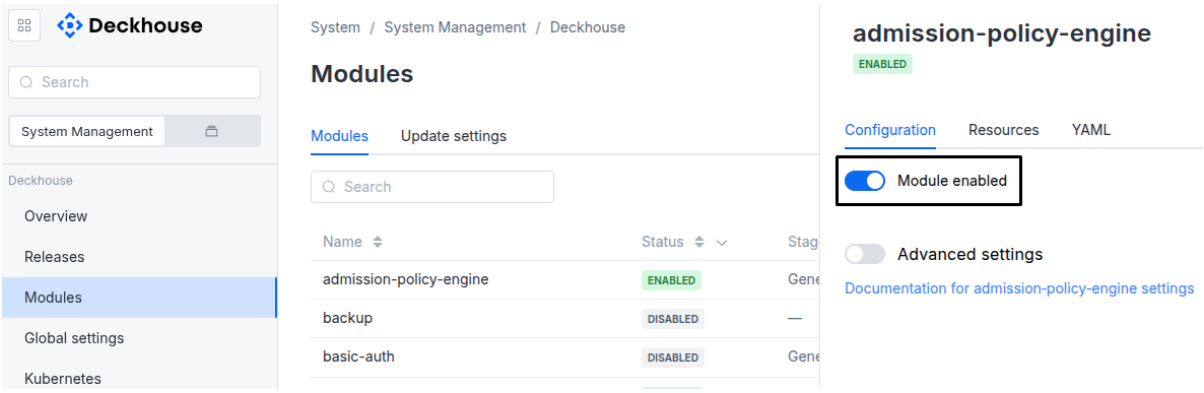
When a pod requests storage:

1. A PVC is created referencing a StorageClass managed by this module.
2. The CSI provisioner creates a volume on the specified vSphere datastore.
3. The CSI attacher attaches the volume to the appropriate node.
4. The CSI node driver mounts the volume into the pod.
5. The vsphere-syncer periodically synchronizes metadata to ensure consistency.

Limitations

- This module is designed exclusively for static (non-cloud) Kubernetes clusters on vSphere.
- Legacy mode does not support online volume resizing.
- Volume expansion requires the current CSI driver (`csi.vsphere.vmware.com`).
- StorageClasses are automatically managed — manual modifications may be overwritten.

Configuration



> ✖ The module lifecycle stage: Deprecated

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `csi-vsphere` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

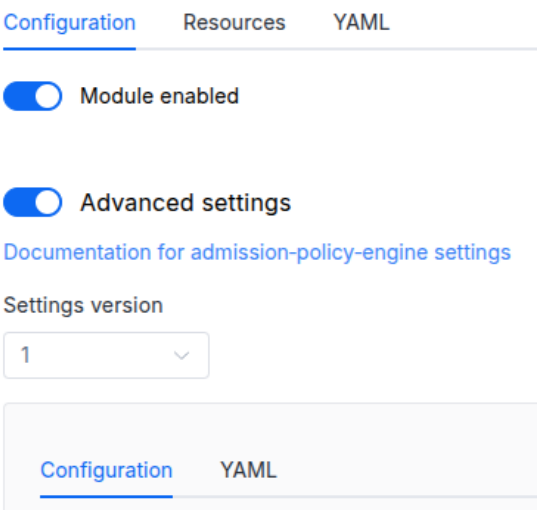
```
d8 system module enable csi-vsphere
```

- **Using ModuleConfig `csi-vsphere`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `csi-vsphere` (create it if necessary);

Example of a manifest to enable module `csi-vsphere`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: csi-vsphere
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `csi-vsphere` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `csi-vsphere` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `csi-vsphere`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `csi-vsphere` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc csi-vsphere
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `csi-vsphere` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `csi-vsphere`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: csi-vsphere
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.disableTimesync**
    boolean

    Disable time synchronization on the vSphere side.

    > **Warning.** This parameter does not disable NTP daemons in the guest OS; it only disables time correction on the ESXi side.

  - **settings.host**
    string

    Required value

    The domain of the vCenter server.

    Example:

    ```
    host: myhost
    ```

  - **settings.insecure**
    boolean

    Set to `true` if vCenter has a self-signed certificate.

  - **settings.password**
    string

    Required value

    The user’s password.

    Example:

    ```
    password: myPaSsWd
    ```

  - **settings.region**
    string

    Required value

    Is a tag added to the vSphere Datacenter where all actions will occur: provisioning VirtualMachines, storing virtual disks on datastores, connecting to the network.

    Example:

    ```
    region: myreg
    ```

  - **settings.regionTagCategory**
    string

    Required value

    The name of the tag category used to identify the region (vSphere Datacenter).

    Example:

    ```
    regionTagCategory: myregtagcat
    ```

  - **settings.storageClass**
    object

- **settings.storageClass.compatibilityFlag**
  string

  A flag allowing the use of the old CSI version:

  - `Legacy` — use the old version of the driver. FCD discs only, no online-resizing;
  - `Migration` — in this case, both drivers will be available in the cluster at the same time. This mode is used to migrate from an old driver.

  Allowed values: `Legacy`, `Migration`

- **settings.storageClass.exclude**
  array of strings

  A list of StorageClass names (or regex expressions for names) to exclude from the creation in the cluster.

  Example:

  ```
  exclude:
  - ".*-lun101-.*"
  - slow-lun103-1c280603
  ```

- **settings.username**
  string

  Required value

  The login.

  Example:

  ```
  username: myuname
  ```

- **settings.vmFolderPath**
  string

  Required value

  The path to the VirtualMachine Folder where the cloned VMs will be created.

  Example:

  ```
  vmFolderPath: dev/test
  ```

- **settings.zoneTagCategory**
  string

  Required value

  The name of the tag category used to identify the zone (vSphere Cluster).

  Example:

  ```
  zoneTagCategory: myzonetagcat
  ```

- **settings.zones**
  array of strings

  Required value

  The globally restricted set of zones that this Cloud Provider works with.

  Example:

  ```
  zones:
  - zonea
  - zoneb
  ```

Preparing environment

✖ The module lifecycle stage: Deprecated

This section describes how to prepare vCenter and vSphere for the `csi-vsphere` module.

Required resources

The following resources are required for the module to function:

- User with the required permissions.
- Network with DHCP and internet access.
- Datacenter tagged as `k8s-region`.
- Cluster tagged as `k8s-zone`.
- One or more Datastores with the appropriate tags.

Installing govc

Use the vSphere CLI govc.

Set environment variables for vCenter access:

```
export GOVC_URL=example.com
export GOVC_USERNAME=<username>@vsphere.local
export GOVC_PASSWORD=<password>
export GOVC_INSECURE=1
```

Create tags and tag categories

`csi-vsphere` maps Kubernetes topology to vSphere objects: a **region** is a vSphere Datacenter, and a **zone** is a vSphere Cluster. The relationship between these objects is defined using tags.

To link Cluster and Datacenter objects, follow these steps:

1. Create tag categories:

   ```
   govc tags.category.create -d "Kubernetes Region" k8s-region
   govc tags.category.create -d "Kubernetes Zone" k8s-zone
   ```

2. Create tags in each category. If you use several zones (Cluster), create one tag per cluster:

   ```
   govc tags.create -d "Kubernetes Region" -c k8s-region test-region
   govc tags.create -d "Kubernetes Zone Test 1" -c k8s-zone test-zone-1
   govc tags.create -d "Kubernetes Zone Test 2" -c k8s-zone test-zone-2
   ```

3. Attach the region tag to the Datacenter:

   ```
   govc tags.attach -c k8s-region test-region /<DatacenterName>
   ```

4. Attach zone tags to Cluster objects:

   ```
   govc tags.attach -c k8s-zone test-zone-1 /<DatacenterName>/host/<ClusterName1>
   govc tags.attach -c k8s-zone test-zone-2 /<DatacenterName>/host/<ClusterName2>
   ```

Datastore configuration

> **i** For dynamic PersistentVolume provisioning, each Datastore must be reachable from every ESXi host (shared datastore).

Attach region and zone tags to Datastore objects so the module can create StorageClass resources automatically:

```
govc tags.attach -c k8s-region test-region /<DatacenterName>/datastore/<DatastoreName1>
govc tags.attach -c k8s-zone test-zone-1 /<DatacenterName>/datastore/<DatastoreName1>

govc tags.attach -c k8s-region test-region /<DatacenterName>/datastore/<DatastoreName2>
govc tags.attach -c k8s-zone test-zone-2 /<DatacenterName>/datastore/<DatastoreName2>
```

Create and assign the role

> **i** Due to the variety of SSO providers connected to csi-vsphere, the steps for creating a user are not covered in this article.
>
> The role to be created below includes all possible privileges for all DKP components. For a detailed list of privileges, refer to the `cloud-provider-vsphere` documentation.

Create the role:

```
govc role.create deckhouse \
   Cns.Searchable Datastore.AllocateSpace Datastore.Browse Datastore.FileManagement \
   Global.GlobalTag Global.SystemTag Network.Assign StorageProfile.View \
   $(govc role.ls Admin | grep -F -e 'Folder.' -e 'InventoryService.' -e 'Resource.' -e
'VirtualMachine.')
```

Grant the role on the `vCenter` root object:

```
govc permissions.set -principal <username>@vsphere.local -role deckhouse /
```

The deckhouse module

> **i** The module lifecycle stage: General Availability

In Deckhouse, this module sets up:

- **The logging level**;
- **The set of modules enabled by default**;

  Usually, the `Default` set is used (it is suitable for most cases).

  Regardless of the set of modules enabled by default, any module can be explicitly enabled or disabled in the Deckhouse configuration (learn more about enabling and disabling a module).
- **The release channel**;

  Deckhouse has a built-in mechanism for automatic updates. This mechanism uses 5 release channels with various stability and frequency of releases. Learn more about how the automatic update mechanism works and how you can set the desired release channel
- **The update mode** and **update windows**;

  Deckhouse supports **manual** and **automatic** update modes.

  In the manual upgrade mode, only critical fixes (patch releases) are automatically applied, and upgrading to a more current Deckhouse release requires manual confirmation.

  In the automatic update mode, Deckhouse switches to a newer release as soon as it is available in the corresponding release channel unless update windows are **configured** for the cluster. If update windows are **configured** for the cluster, Deckhouse will upgrade to a newer release during the next available update window.
- **Service for validating Custom Resources**.

  The validation service prevents creating Custom Resources with invalid values or adding such values to the existing Custom Resources. Note that it only tracks Custom Resources managed by Deckhouse modules.

Deckhouse releases update

Get Deckhouse releases status

You can get Deckhouse releases list via the command `d8 k get deckhousereleases`. By default, a cluster keeps the last 10 Superseded releases and all deployed/pending releases.

Every release can have one of the following statuses:

- `Pending` - release is waiting to be deployed: waiting for update window, canary deployment, etc. You can see the detailed status via the `d8 k describe deckhouserelease $name` command.
- `Deployed` - release is applied. It means that the image tag of the Deckhouse Pod was changed, but the update process of all components is going asynchronously and could not have been finished yet.
- `Superseded` - release is outdated and not used anymore.
- `Suspended` - release was suspended (for example, due to an error found). A release can have this status if it was suspended before being deployed in the cluster.

Update process

When release status is changed to `Deployed` state, release is updating only a tag of the Deckhouse image. Deckhouse will start checking and updating process of the all modules, which were changed from the last release. Duration of an update could be different and connected to cluster size, enabled modules count and settings. Foe example: if you cluster have a lot of `NodeGroup` resources, it will take some time to update them because these resources are updated one by one `IngressNginxControllers` also updating one by one.

Manual release deployment

If you have a manual update mode enabled and have a few Pending releases, you can approve them all at once. In that case Deckhouse will update in series keeping a release order and changing their status during the update.

Pin a release

To pin a release means fully or partially disable the automatic Deckhouse version update.

There are three options to limit the automatic update of Deckhouse:

- Enable a manual update mode.

  In this case, Deckhouse holds on a current version and able to receive updates. But to apply the update, a manual action will need to be performed. This applies to both patch versions and minor versions.

  To enable manual update mode, you need to set the parameter settings.update.mode in ModuleConfig `deckhouse` to `Manual`:

  ```
  d8 k patch mc deckhouse --type=merge -p='{"spec":{"settings":{"update":{"mode":"Manual"}}}}'
  ```

- Set the automatic update mode for patch versions.

  In this case, Deckhouse holds on a current version and will automatically update to patch versions of the current release (taking into account the update windows). To apply a minor version update, a manual action will need to be performed.

  For example: the current version of DKP is `v1.70.1`, after setting the automatic update mode for patch versions, Deckhouse can be updated to version `v1.70.2`, but will not update to version `v1.71.*` or higher.

  To set the automatic update mode for patch versions, you need to set the parameter settings.update.mode to `AutoPatch` in the ModuleConfig `deckhouse`:

  ```
  d8 k patch mc deckhouse --type=merge -p='{"spec":{"settings":{"update":
  {"mode":"AutoPatch"}}}}'
  ```

- Set a specified image tag for Deployment `deckhouse` and remove releaseChannel parameter from `deckhouse` module configuration.

  In that case, DKP holds on a current version, and no information about new available versions in the cluster (DeckhouseRelease objects) will be received.

  An example of installing version `v1.66.3` for DKP EE and removing the `releaseChannel` parameter from the configuration of the `deckhouse` module:

  ```
  d8 k -ti -n d8-system exec svc/deckhouse-leader -c deckhouse -- kubectl set image deployment/deckhouse
  deckhouse=registry.deckhouse.io/deckhouse/ee:v1.66.3
  d8 k patch mc deckhouse --type=json -p='[{"op": "remove", "path":
  "/spec/settings/releaseChannel"}]'
  ```

Priority Classes

This module creates a set of priority classes and assigns them to components installed by Deckhouse and applications in the cluster.

Priority classes are utilized by the scheduler to determine a Pod’s priority based on the class it belongs to during scheduling.

For example, when deploying Pods with `priorityClassName: production-low`, if the cluster lacks sufficient resources, Kubernetes will start evicting Pods with the lowest priority to accommodate the `production-low` Pods. That is, Kubernetes will first evict all Pods with `priorityClassName: develop` Pods, then proceed to `cluster-low` Pods, and so on.

When setting the priority class, it is crucial to understand the type of application and the environment it operates in. Assigning any priority class does not lower a Pod’s priority because Pods without a specified priority class are considered to have the lowest priority.

⚠ You cannot use the following priority classes: `system-node-critical`, `system-cluster-critical`, `cluster-medium`, `cluster-low`.

Below is the list of priority classes set by the module (sorted by the priority from highest to lowest):

Priority class	Description	Value
`system-node-critical`	Cluster components that must be present on the node. This priority class fully protects components against eviction by kubelet. Examples: `node-exporter`, `csi`, and others.	2000001000
`system-cluster-critical`	Cluster components that are critical to its correct operation. This PriorityClass is mandatory for MutatingWebhooks and Extension API servers. It also fully protects components against eviction by kubelet. Examples: `kube-dns`, `kube-proxy`, `cni-flannel`, `cni-cilium`, and others.	2000000000
`production-high`	Stateful applications in the production environment. Their unavailability leads to service downtime or data loss. Examples: `PostgreSQL`, `Memcached`, `Redis`, `MongoDB`, and others.	9000
`cluster-medium`	Cluster components responsible for monitoring (alerts, diagnostic tools) and autoscaling. Without monitoring, assessing the scale of incidents is impossible; without autoscaling, applications cannot receive necessary resources. Examples: `deckhouse`, `node-local-dns`, `grafana`, `upmeter`, and others.	7000
`production-medium`	Main stateless applications in the production environment that are responsible for operating the service for end-users.	6000
`deployment-machinery`	Cluster components that are responsible for deploying/building.	5000
`production-low`	Non-critical, secondary applications in the production environment (crons, admin dashboards, batch processing). For important batch or cron jobs, consider assigning them the `production-medium` priority.	4000
`staging`	Staging environments for applications.	3000
`cluster-low`	Cluster components that are desirable but not essential for proper cluster operation. Examples: `dashboard`, `cert-manager`, `prometheus`, and others.	2000
`develop` (default)	Develop environments for applications. The default class for a component (if other priority classes aren’t set).	1000
`standby`	This class is not intended for applications. It is used for system purposes (reserving nodes).	-1

Third-party components

List of third-party software used in the `deckhouse` module:

- Shell operator 1.9.3

  License: Apache License 2.0

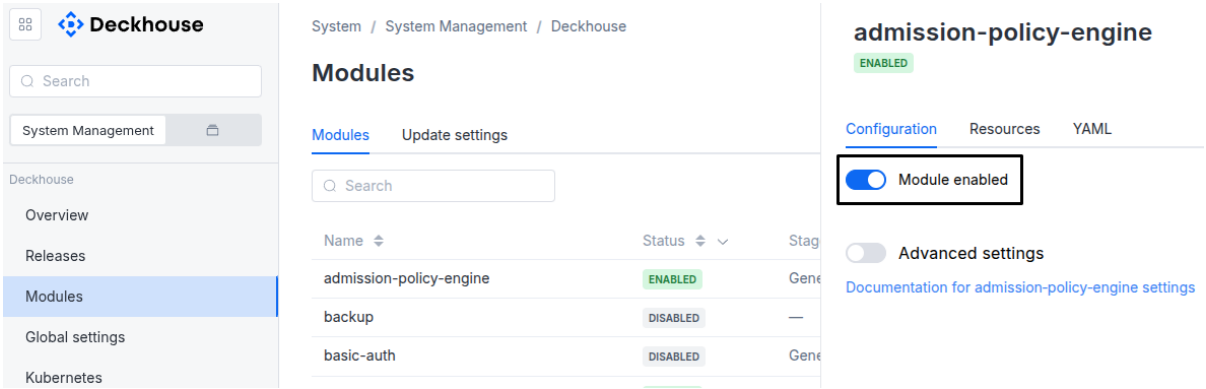
  A tool for running event-driven scripts in a Kubernetes cluster

- JQ 1.7.1

  License: Mixed (https://github.com/stedolan/jq/blob/master/COPYING)

  A lightweight and flexible command-line JSON processor.

Configuration



> The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

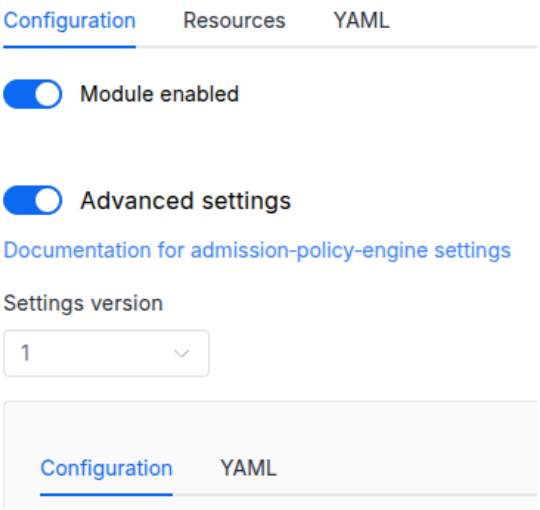
```
d8 system module enable deckhouse
```

- **Using ModuleConfig `deckhouse`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `deckhouse` (create it if necessary);

  Example of a manifest to enable module `deckhouse`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `deckhouse` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `deckhouse`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `deckhouse` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc deckhouse
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `deckhouse` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `deckhouse`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: deckhouse
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.allowExperimentalModules**
    boolean

    Allows the use of experimental modules (modules in the `Experimental` lifecycle stage).

    Experimental modules can be unstable and are not supported under the Deckhouse SLA. Use them with caution.

    Default: `false`

    Example:

    ```
    allowExperimentalModules: false
    ```

  - **settings.bundle**

string

The set of DKP modules that are enabled by default.

Changing the parameter value in an already deployed cluster is not possible.

Possible values:

- `Default`: Recommended set of modules for cluster operation. Includes modules for monitoring, authorization control, networking, and other basic platform needs.
- `Managed`: Set of modules for managed clusters from cloud providers.
- `Minimal`: Minimum possible set, which includes a single module (this one).

  Warning. Several basic platform modules (for example, the CNI module) are not included in the `Minimal` module set. Without the basic modules, DKP can only operate in an already deployed cluster. Read the “Things to keep in mind when working with the Minimal module set” section for more details.

Default: `Default`

Allowed values: `Default`, `Minimal`, `Managed`

Example:

```
bundle: Default
```

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

  Example:

  ```
  highAvailability: true
  ```

- **settings.license**
  object

  Edition settings of the Deckhouse Kubernetes Platform.

  - **settings.license.edition**
    string

    Edition of the Deckhouse Kubernetes Platform:

    - `CE` — Community Edition.
    - `BE` - Basic edition.
    - `EE` — Enterprise Edition.
    - `SE` — Standard Edition.
    - `SE-plus` — Standard Edition+.
    - `CSE` — Certified Security Edition.

    Default: `CE`

    Example:

    ```
    edition: CE
    ```

- **settings.logLevel**
  string

  Deckhouse logging level.

  Default: `Info`

  Allowed values: `Trace`, `Debug`, `Info`, `Error`

  Example:

  ```
  logLevel: Info
  ```

- **settings.nodeSelector**
  object

  The same as in the Pods’ `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, `nodeSelector` will be determined automatically.

Caution! Deckhouse will stop working if there is a nonexistent label in `nodeSelector`. You need to change the values to the correct ones in `ModuleConfig/deckhouse` and `deployment/deckhouse` to get Deckhouse back on track.

- **settings.registry**
  object

  Settings for accessing the container registry with Deckhouse images.

  This parameter allows configuring how DKP connects to the container registry to pull its own component images. Settings are processed by the internal registry module. In clusters where this configuration is not supported, the registry connection setup is done manually using the `change-registry` helper script.

  Examples:

  ```
  registry:
    mode: Unmanaged
  ```

  ```
  registry:
    mode: Unmanaged
    unmanaged:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
  ```

  ```
  registry:
    mode: Direct
    direct:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
  ```

  ```
  registry:
    mode: Proxy
    proxy:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
  ```

  ```
  registry:
    mode: Local
  ```

  - **settings.registry.direct**
    object

    Parameters for the `Direct` access mode. These parameters are required when `mode` is set to `Direct`.

    Examples:

    ```
    direct:
      imagesRepo: registry.deckhouse.io/deckhouse/ee
      license: DECKHOUSE_LICENSE_KEY
    ```

    ```
    direct:
      imagesRepo: my-private-registry.com/deckhouse
      username: user
      password: password
      scheme: HTTPS
      ca: |
        -----BEGIN CERTIFICATE-----
        MIIC...
        -----END CERTIFICATE-----
    ```

    - **settings.registry.direct.ca**
      string

      The root CA certificate (in PEM format) for validating the container registry's server certificate. This is necessary if the registry uses a self-signed certificate or a certificate issued by a private Certificate Authority. If not provided, the system's trusted root CAs will be used.

    - **settings.registry.direct.checkMode**

string

Mode for checking the container registry:

- `Default` — checks for the presence of all critical components in the container registry.
- `Relax` — checks only for the presence of the Deckhouse image tag in the container registry (used for switching between Deckhouse editions).

Default: `Default`

Allowed values: `Default`, `Relax`

- **settings.registry.direct.imagesRepo**
string

Required value

The address of the container registry repository where Deckhouse images are stored.

In firewalled environments, this might be a private registry address that mirrors the public one.

Default: `registry.deckhouse.io/deckhouse/ce`

Pattern: `^[0-9a-zA-Z\.\-]+(\:[0-9]{1,5})?(\/[0-9a-zA-Z\.\-\_]+)*$`

Examples:

```
imagesRepo: registry.deckhouse.io/deckhouse/ee
```

```
imagesRepo: private-registry:5000/deckhouse/ce
```

- **settings.registry.direct.license**
string

The license key for accessing the Deckhouse container registry. This key is used as a password with the username `license-token`. This field is mutually exclusive with `username`/`password`.

Example:

```
license: DECKHOUSE_LICENSE_KEY
```

- **settings.registry.direct.password**
string

The password for authenticating with the container registry. This field is required if `license` is not provided.

Example:

```
password: registry-password
```

- **settings.registry.direct.scheme**
string

The protocol to use for connecting to the registry.

Use `HTTP` only for insecure, trusted registries (e.g., in a firewalled environment). Defaults to `HTTPS` for secure communication.

Default: `HTTPS`

Allowed values: `HTTP`, `HTTPS`

Example:

```
scheme: HTTPS
```

- **settings.registry.direct.username**
string

The username for authenticating with the container registry. This field is required if `license` is not provided.

Example:

```
username: registry-user
```

- **settings.registry.mode**
  string

  The mode for accessing the container registry with Deckhouse images.

  - `Unmanaged`: The default mode. In this mode, the `registry` module does not run an internal registry. To configure it, set the parameters in the `unmanaged` section. **Important.** Changing the registry in `Unmanaged` mode will result in a full restart of all DKP components.
  - `Direct`: A mode for direct access to the registry. It uses a “virtual” registry address that is overwritten on the fly to the real registry address. This allows for registry changes without a full component restart. **Important.** The first switch from `Unmanaged` to `Direct` mode will result in a full restart of all DKP components.
  - `Proxy`: A proxy mode for the registry. It launches static pods with a caching proxy registry. This mode allows for reducing requests to the external registry by caching images. Cached data is stored on master nodes. Access to the proxy registry is done through a fixed address, similar to `Direct` mode. **Important.** Supported only on static clusters. The first switch from `Unmanaged` to `Proxy` mode will result in a full restart of all DKP components.
  - `Local`: A local registry mode. It launches static pods with a local registry. This mode allows the cluster to operate in an isolated environment. Data storage is performed on master nodes. Access to the registry is done through a fixed address, similar to `Direct` mode. **Important.** Supported only on static clusters. The first switch from `Unmanaged` to `Local` mode will result in a full restart of all DKP components.

  Default: `Unmanaged`

  Allowed values: `Unmanaged`, `Direct`, `Proxy`, `Local`

- **settings.registry.proxy**
  object

  Parameters for the `Proxy` access mode. These parameters are required when `mode` is set to `Proxy`.

  - **settings.registry.proxy.ca**
    string

    The root CA certificate (in PEM format) for validating the container registry’s server certificate. This is necessary if the registry uses a self-signed certificate or a certificate issued by a private Certificate Authority. If not provided, the system’s trusted root CAs will be used.

  - **settings.registry.proxy.checkMode**
    string

    Mode for checking the container registry:

    - `Default` — checks for the presence of all critical components in the container registry.
    - `Relax` — checks only for the presence of the Deckhouse image tag in the container registry (used for switching between Deckhouse editions).

    Default: `Default`

    Allowed values: `Default`, `Relax`

  - **settings.registry.proxy.imagesRepo**
    string

    Required value

    The address of the container registry repository where Deckhouse images are stored.

    In firewalled environments, this might be a private registry address that mirrors the public one.

    Default: `registry.deckhouse.io/deckhouse/ce`

    Pattern: `^[0-9a-zA-Z\.\-]+(\:[0-9]{1,5})?(\/[0-9a-zA-Z\.\-\_]+)*$`

    Examples:

    ```
    imagesRepo: registry.deckhouse.io/deckhouse/ee
    ```

    ```
    imagesRepo: private-registry:5000/deckhouse/ce
    ```

  - **settings.registry.proxy.license**
    string

    The license key for accessing the Deckhouse container registry. This key is used as a password with the username `license-token`. This field is mutually exclusive with `username`/`password`.

Example:

```
license: DECKHOUSE_LICENSE_KEY
```

- **settings.registry.proxy.password**
  string

  The password for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  password: registry-password
  ```

- **settings.registry.proxy.scheme**
  string

  The protocol to use for connecting to the registry.

  Use `HTTP` only for insecure, trusted registries (e.g., in a firewalled environment). Defaults to `HTTPS` for secure communication.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

  Example:

  ```
  scheme: HTTPS
  ```

- **settings.registry.proxy.ttl**
  string

  TTL determines the lifetime of cached images. Once the TTL expires, the images will be automatically removed from the cache. If not set, the TTL defaults to 7 days (168 hours).

  Supported units: `h` (hours), `m` (minutes), `s` (seconds). The minimum allowable value is 5 minutes.

  Pattern: `^(?:(\d+)h)?(?:(\d+)m)?(?:(\d+)s)?$`

- **settings.registry.proxy.username**
  string

  The username for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  username: registry-user
  ```

- **settings.registry.unmanaged**
  object

  Parameters for the `Unmanaged` access mode.

  Examples:

  ```
  unmanaged:
    imagesRepo: registry.deckhouse.io/deckhouse/ee
    license: DECKHOUSE_LICENSE_KEY
  ```

  ```
  unmanaged:
    imagesRepo: my-private-registry.com/deckhouse
    username: user
    password: password
    scheme: HTTPS
    ca: |
      -----BEGIN CERTIFICATE-----
      MIIC...
      -----END CERTIFICATE-----
  ```

  - **settings.registry.unmanaged.ca**
    string

    The root CA certificate (in PEM format) for validating the container registry’s server certificate. This is necessary if the registry uses a self-signed certificate or a certificate

issued by a private Certificate Authority. If not provided, the system’s trusted root CAs will be used.

- **settings.registry.unmanaged.checkMode**
  string

  Mode for checking the container registry:

  - `Default` — checks for the presence of all critical components in the container registry.
  - `Relax` — checks only for the presence of the Deckhouse image tag in the container registry (used for switching between Deckhouse editions).

  Default: `Default`

  Allowed values: `Default`, `Relax`

- **settings.registry.unmanaged.imagesRepo**
  string

  Required value

  The address of the container registry repository where Deckhouse images are stored.

  In firewalled environments, this might be a private registry address that mirrors the public one.

  Default: `registry.deckhouse.io/deckhouse/ce`

  Pattern: `^[0-9a-zA-Z\.\-]+(\:[0-9]{1,5})?(\/[0-9a-zA-Z\.\-\_]+)*$`

  Examples:

  ```
  imagesRepo: registry.deckhouse.io/deckhouse/ee
  ```

  ```
  imagesRepo: private-registry:5000/deckhouse/ce
  ```

- **settings.registry.unmanaged.license**
  string

  The license key for accessing the Deckhouse container registry. This key is used as a password with the username `license-token`. This field is mutually exclusive with `username`/`password`.

  Example:

  ```
  license: DECKHOUSE_LICENSE_KEY
  ```

- **settings.registry.unmanaged.password**
  string

  The password for authenticating with the container registry. This field is required if `license` is not provided.

  Example:

  ```
  password: registry-password
  ```

- **settings.registry.unmanaged.scheme**
  string

  The protocol to use for connecting to the registry.

  Use `HTTP` only for insecure, trusted registries (e.g., in a firewalled environment). Defaults to `HTTPS` for secure communication.

  Default: `HTTPS`

  Allowed values: `HTTP`, `HTTPS`

  Example:

  ```
  scheme: HTTPS
  ```

- **settings.registry.unmanaged.username**
  string

  The username for authenticating with the container registry. This field is required if `license` is not provided.

Example:

```
username: registry-user
```

- **settings.releaseChannel**
  string

  Target Deckhouse release channel (Deckhouse will switch to it when such an opportunity appears).

  The order in which the stability of the release channel increases (from **less** stable to **more** stable): `Alpha`, `Beta`, `EarlyAccess`, `Stable`, `RockSolid`, `LTS`.

  Allowed values: `Alpha`, `Beta`, `EarlyAccess`, `Stable`, `RockSolid`, `LTS`

  Example:

  ```
  releaseChannel: Stable
  ```

- **settings.reservedPublicHosts**
  object

  Settings of the reservation that keeps the hostnames of the Deckhouse web interfaces from being claimed by a workload.

  Accepted so that a ModuleConfig that already has these fields continues to validate. Admission is disabled in this patch: the policies reserved every hostname some `publicDomainTemplate` values can produce, which blocked tenant Ingresses. The settings below are ignored until a release that enforces them again. The default `mode` is `List` so that restore does not come back as `Template` for a cluster that never set the field.

  Deckhouse renders those hostnames from the `global.modules.publicDomainTemplate` global parameter and reserves them cluster-wide: an `Ingress`, or a `Gateway`, `GRPCRoute`, `HTTPRoute`, `ListenerSet` or `TLSRoute` of the Gateway API, created outside a system namespace cannot name one of them. These parameters adjust the reserved set in both directions.

  The reservation is per hostname and applies to every namespace. To exempt a whole namespace from the reservation instead, label the namespace with `security.deckhouse.io/reserved-hosts-bypass: "true"`.

  Example:

  ```
  reservedPublicHosts:
    mode: List
    additionalHosts:
    - admin.example.com
    excludedServices:
    - grafana
  ```

  - **settings.reservedPublicHosts.additionalHosts**
    array of strings

    Hostnames to reserve on top of the ones Deckhouse publishes.

    Every entry is a complete hostname, matched exactly and case-insensitively, the same way the built-in ones are. Wildcards are not supported.

    An entry always reserves, whatever `excludedServices` says, so the two settings cannot contradict each other.

    Default: `[]`

    Example:

    ```
    additionalHosts:
    - admin.example.com
    ```

    - **Element of the array**
      string

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  - **settings.reservedPublicHosts.excludedServices**
    array of strings

    Service names whose hostname must not be reserved.

    Use it for a cluster where a workload outside a system namespace legitimately serves a path under one of those hostnames.

A name is the part `global.modules.publicDomainTemplate` substitutes, `grafana` for `grafana.example.com`, not the hostname itself. The hostname it renders to is published in the `excludedHosts` key of the `d8-reserved-public-hosts` ConfigMap in the `d8-system` namespace, which is where to check that the name did what was meant.

Under `mode: Template` any name works, because the reservation covers the whole domain and not only what Deckhouse publishes. Under `mode: List` only a name Deckhouse actually publishes has an effect, because only those are reserved there; the rest are listed in the `unknownExcludedServices` key of the same ConfigMap, which is where to look if a hostname stayed reserved unexpectedly.

Excluding a name lifts the reservation of that hostname in every namespace, including the ones Deckhouse itself uses to serve it.

Default: `[]`

Example:

```
excludedServices:
- grafana
```

- **Element of the array**
  string

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **settings.reservedPublicHosts.mode**
  string

  How much of the platform's domain is reserved.

  Default is `List`.

  - `Template` — every hostname `global.modules.publicDomainTemplate` can render, plus its wildcard form where the template's `%s` is the whole first label. A module never has to ask to be covered, and a hostname is reserved as soon as the template can produce it, whether or not any Deckhouse module publishes it today. A hostname that a workload legitimately serves is given back with `excludedServices` below, or with the per-namespace label. The wildcard form is the exception: it is reserved by exact match and `excludedServices` cannot free it, so a workload that serves it needs the per-namespace label or `List` below.
  - `List` — only the hostnames of the Deckhouse services Deckhouse knows it publishes. Narrower, and it leaves a public domain that Deckhouse learns to publish later unreserved until the list catches up.

  The hostnames workloads already serve are recorded once, when `Template` first takes effect, and stay allowed. Switching from `List` to `Template` later takes that record then, so a workload that appeared while `List` was in force is grandfathered too.

  The record is taken once and is not taken again. Switching to `List` and back to `Template` keeps the record of the first time, so a workload that claimed a reserved hostname in between is denied on its next write. Recording again on every return would make the reservation avoidable by switching to `List`, claiming the hostname and switching back.

  Ecosystem applications are unaffected either way: `global.applications.publicDomainTemplate` puts the application name and its namespace in two different labels, so an application hostname has one label more than anything this reservation covers.

  Default: `List`

  Allowed values: `Template`, `List`

  Examples:

  ```
  mode: Template
  ```

  ```
  mode: List
  ```

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, `tolerations` will be determined automatically.

  Caution! Deckhouse will stop working if `tolerations` specified are incorrect. You need to change the values to the correct ones in `ModuleConfig/deckhouse` and `deployment/deckhouse` to get Deckhouse back on track.

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

- **settings.update**
  object

  Settings of the Deckhouse update mode and windows.

  Example:

  ```
  update:
    windows:
    - from: '8:00'
      to: '15:00'
      days:
      - Tue
      - Sat
    disruptionApprovalMode: Manual
    notification:
      webhook: https://release-webhook.mydomain.com
      minimalNotificationTime: 6h
      auth:
        basic:
          username: user
          password: password
  ```

  - **settings.update.disruptionApprovalMode**
    Deprecated
    string

    Update mode for disruptive Deckhouse releases:

    - `Auto` — a disruptive release is approved automatically.
    - `Manual` — requires a manual release confirmation (set the `release.deckhouse.io/disruption-approved=true` annotation on the appropriate DeckhouseRelease resource to apply the update).

    Default: `Auto`

    Allowed values: `Auto`, `Manual`

  - **settings.update.mode**
    string

    Update mode of Deckhouse on the selected release channel.

    - `AutoPatch` — automatic update mode for patch releases.

      To change a minor version (for example, from `v1.69.*` to `v1.70.*`), confirmation is required.

      A patch version update (for example, from `v1.70.1` to `v1.70.2`) is applied taking into account the update windows, if they are set.

    - `Auto` — automatic update mode for all versions.

      A minor version updates (for example, from `v1.69.*` to `v1.70.*`) and patch version updates (for example, from `v1.70.1` to `v1.70.2`) are applied taking into account the update windows, if they are set.

    - `Manual` — manual update mode for all versions.

      Confirmation is required for updating both minor and patch versions.

    To confirm the version update, it is necessary to set the `approved` field to `true` in the corresponding resource DeckhouseRelease.

    Default: `AutoPatch`

    Allowed values: `AutoPatch`, `Auto`, `Manual`

  - **settings.update.notification**
    object

Settings for notifications of scheduled Deckhouse updates.

Has the effect **only** when the automatic update mode is set.

Example:

```
notification:
  webhook: https://release-webhook.mydomain.com
  minimalNotificationTime: 8h
  retryMinTime: 2s
```

- **settings.update.notification.auth**
  object

  Authentication settings for the webhook.

  If the parameter is omitted, the webhook will be called without authentication.

  - **settings.update.notification.auth.basic**
    object

    Basic authentication settings for the webhook.

    If the parameter is omitted, the webhook will be called without authentication.

    - **settings.update.notification.auth.basic.password**
      string

      Required value

      The password for the webhook.

      The username and password will be sent in the `Authorization` header in the format `Basic <base64(username:password)>`.

    - **settings.update.notification.auth.basic.username**
      string

      Required value

      The username for the webhook.

      The username and password will be sent in the `Authorization` header in the format `Basic <base64(username:password)>`.

  - **settings.update.notification.auth.bearerToken**
    string

    The token for the webhook.

    The token will be sent in the `Authorization` header in the format `Bearer <token>`.

- **settings.update.notification.minimalNotificationTime**
  string

  The minimum time that must pass before updating from the moment a new minor version appears on the release channel used.

  It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

  The update mechanism ensures that Deckhouse will not be updated until a specified period of time has passed.

  When using update windows, the Deckhouse update will happen at the nearest possible update window but not before the time specified in `minimalNotificationTime` expires.

  Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

  Example:

  ```
  minimalNotificationTime: 6h
  ```

- **settings.update.notification.releaseType**
  string

  Defines the type of version for which the notification will be sent:

  - `Minor` — only for updating the minor version.
  - `All` — for any updates, including updating a patch version.

  Default: `Minor`

Allowed values: `All`, `Minor`

Example:

```
releaseType: All
```

- **settings.update.notification.retryMinTime**
  string

  The minimum time between webhook retry attempts when the webhook request fails.

  It is specified as a string containing the time unit in hours, minutes, or seconds: 30s, 1m, 2m30s, 1h, 2h30m.

  The retry mechanism uses exponential backoff: each subsequent retry attempt waits twice as long as the previous one. For example, if `retryMinTime` is set to `2s`, the retry delays will be: 2s, 4s, 8s, 16s, 32s.

  Default value is 2 seconds if not specified.

  Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m|[0-9]+s)$`

  Example:

  ```
  retryMinTime: 2s
  ```

- **settings.update.notification.tlsSkipVerify**
  boolean

  Skip TLS certificate verification while webhook request.

  Default: `false`

- **settings.update.notification.webhook**
  string

  URL for an external webhook handler.

  The POST request will be sent to the webhook URL after a new minor version of Deckhouse appears on the release channel before it is applied to the cluster.

  > **i** **Caution!** If you specify an invalid webhook address, Deckhouse update will be blocked.

  > **i** Use the minimalNotificationTime parameter if necessary to set the minimum time that must pass before updating from the moment a new minor version appears on the release channel used.

  Example of the POST request payload (`Content-Type: application/json`):

  ```
  {
    "subject":"Deckhouse",
    "version": "1.36.0",
    "requirements":  {"k8s": "1.20.0"},
    "changelogLink":
  "https://github.com/deckhouse/deckhouse/changelog/1.36.md",
    "applyTime": "2023-01-01T14:30:00Z00:00",
    "message": "New Deckhouse Release 1.36.0 is available. Release will be
  applied at: Friday, 01-Jan-23 14:30:00 UTC"
  }
  ```

  Description of POST request fields:

  - `subject` — string, the update event type. Possible values: `Deckhouse`, `Module`;
  - `moduleName` — string, the name of the module. Set only if `subject: Module`.
  - `version` - string, x.y.z (semantic versioning);
  - `requirements` - object, version requirements;
  - `changelogLink` - string, a URL to the minor version changelog;
  - `applyTime` - string, date and time of the scheduled update (taking into account the configured update windows) in RFC3339 format;
  - `message` - string, a text message about the availability of the new minor version and the scheduled update time.

  Pattern: `^https?://[^\s/$.?#].[^\s]*$`

Example:

```
webhook: https://webhook.site/#!/bc8f71ac-c182-4181-9159-6ba6950afffa
```

- **settings.update.windows**
  array of objects

  List of update windows during the day.

  - **settings.update.windows.days**
    array of strings

    The days of the week on which the update window is applied.

    Example:

    ```
    days:
    - Mon
    - Wed
    ```

    - **Element of the array**
      string

      Day of the week.

      Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

      Example:

      ```
      Mon
      ```

  - **settings.update.windows.from**
    string

    Required value

    Start time of the update window (UTC timezone).

    Should be less than the end time of the update window.

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    from: '13:00'
    ```

  - **settings.update.windows.to**
    string

    Required value

    End time of the update window (UTC timezone).

    Should be more than the start time of the update window.

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    to: '18:30'
    ```

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

ConversionWebhook

Short names: cwhc

Scope: Cluster

Version: v1alpha1

ConversionWebhook is the Schema for the conversionwebhooks API

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **context**
  array of objects

  Run a hook on a Kubernetes object changes.

  - **context.kubernetes**
    object
    - **context.kubernetes.allowFailure**
      boolean

      If `true`, Shell-operator skips the hook execution errors. If `false` or the parameter is not set, the hook is restarted after a 5 seconds delay in case of an error.

    - **context.kubernetes.apiVersion**
      string

      Is an optional group and version of object API. For example, it is `v1` for core objects (Pod, etc.), `rbac.authorization.k8s.io/v1beta1` for ClusterRole and `monitoring.coreos.com/v1` for prometheus-operator.

    - **context.kubernetes.fieldSelector**
      object
      - **context.kubernetes.fieldSelector.matchExpressions**
        array of objects

        Required value

        - **context.kubernetes.fieldSelector.matchExpressions.field**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.operator**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.value**
          string
    - **context.kubernetes.includeSnapshotsFrom**
      array of strings

      An array of names of kubernetes bindings in a hook. When specified, a list of monitored objects from that bindings will be added to the binding context in a snapshots field. Self-include is also possible.

    - **context.kubernetes.jqFilter**
      string

      An optional parameter that specifies event filtering using jq syntax. The hook will be triggered on the “Modified” event only if the filter result is changed after the last event.

    - **context.kubernetes.kind**
      string

      Required value

      Is the type of a monitored Kubernetes resource. This field is required.

    - **context.kubernetes.labelSelector**
      object

      A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

      - **context.kubernetes.labelSelector.matchExpressions**
        array of objects

        matchExpressions is a list of label selector requirements. The requirements are ANDed.

        A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

- **context.kubernetes.labelSelector.matchExpressions.key**
  string

  Required value

  key is the label key that the selector applies to.

- **context.kubernetes.labelSelector.matchExpressions.operator**
  string

  Required value

  operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

- **context.kubernetes.labelSelector.matchExpressions.values**
  array of strings

  values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **context.kubernetes.labelSelector.matchLabels**
  object

  matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **context.kubernetes.nameSelector**
  object
  - **context.kubernetes.nameSelector.matchNames**
    array of strings

    Required value

- **context.kubernetes.namespace**
  object

  Filters to choose namespaces.

  - **context.kubernetes.namespace.labelSelector**
    object

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

    - **context.kubernetes.namespace.labelSelector.matchExpressions**
      array of objects

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **context.kubernetes.namespace.labelSelector.matchExpressions.key**
        string

        Required value

        key is the label key that the selector applies to.

      - **context.kubernetes.namespace.labelSelector.matchExpressions.operator**
        string

        Required value

        operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

      - **context.kubernetes.namespace.labelSelector.matchExpressions.values**
        array of strings

        values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

    - **context.kubernetes.namespace.labelSelector.matchLabels**
      object

      matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are

ANDed.

- **context.kubernetes.namespace.nameSelector**
  object
  - **context.kubernetes.namespace.nameSelector.matchNames**
    array of strings

    Required value

- **context.kubernetes.queue**
  string

  A name of a separate queue. It can be used to execute long-running hooks in parallel with hooks in the “main” queue.

- **context.name**
  string

  Required value

  It is used to distinguish different bindings during runtime.

- **conversions**
  array of objects

  Required value

  This binding transforms a hook into a handler for conversions defined in CustomResourceDefinition. The Shell-operator updates a CRD with `.spec.conversion`, starts HTTPS server, and runs hooks to handle ConversionReview requests.

  - **conversions.from**
    string

    Required value

    A version of a custom resource that hook can convert.

  - **conversions.handler**
    object

    Required value

    Code of the conversion handler.

    - **conversions.handler.python**
      string

      Python script handler for object.

  - **conversions.includeSnapshotsFrom**
    array of strings

    An array of names of Kubernetes bindings in a hook. When specified, a list of monitored objects from these bindings will be added to the binding context in the snapshots field.

  - **conversions.to**
    string

    Required value

    A version of a custom resource that hook can produce.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **status**
  object

  Status defines the observed state of ConversionWebhook.

ValidationWebhook

Short names: vwhc

Scope: Cluster
Version: v1alpha1

ValidationWebhook is the Schema for the validationwebhooks API

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **context**
  array of objects

  Run a hook on a Kubernetes object changes.

  - **context.kubernetes**
    object
    - **context.kubernetes.allowFailure**
      boolean

      If `true`, Shell-operator skips the hook execution errors. If `false` or the parameter is not set, the hook is restarted after a 5 seconds delay in case of an error.

    - **context.kubernetes.apiVersion**
      string

      Is an optional group and version of object API. For example, it is `v1` for core objects (Pod, etc.), `rbac.authorization.k8s.io/v1beta1` for ClusterRole and `monitoring.coreos.com/v1` for prometheus-operator.

    - **context.kubernetes.fieldSelector**
      object
      - **context.kubernetes.fieldSelector.matchExpressions**
        array of objects

        Required value

        - **context.kubernetes.fieldSelector.matchExpressions.field**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.operator**
          string

          Required value

        - **context.kubernetes.fieldSelector.matchExpressions.value**
          string
    - **context.kubernetes.includeSnapshotsFrom**
      array of strings

      An array of names of kubernetes bindings in a hook. When specified, a list of monitored objects from that bindings will be added to the binding context in a snapshots field. Self-include is also possible.

    - **context.kubernetes.jqFilter**
      string

      An optional parameter that specifies event filtering using jq syntax. The hook will be triggered on the “Modified” event only if the filter result is changed after the last event.

    - **context.kubernetes.kind**
      string

      Required value

      Is the type of a monitored Kubernetes resource. This field is required.

    - **context.kubernetes.labelSelector**
      object

      A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

      - **context.kubernetes.labelSelector.matchExpressions**
        array of objects

        matchExpressions is a list of label selector requirements. The requirements are ANDed.

        A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

        - **context.kubernetes.labelSelector.matchExpressions.key**
          string

          Required value

key is the label key that the selector applies to.

- **context.kubernetes.labelSelector.matchExpressions.operator**
  string

  Required value

  operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

- **context.kubernetes.labelSelector.matchExpressions.values**
  array of strings

  values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **context.kubernetes.labelSelector.matchLabels**
  object

  matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **context.kubernetes.nameSelector**
  object
  - **context.kubernetes.nameSelector.matchNames**
    array of strings

    Required value

- **context.kubernetes.namespace**
  object

  Filters to choose namespaces.

  - **context.kubernetes.namespace.labelSelector**
    object

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

    - **context.kubernetes.namespace.labelSelector.matchExpressions**
      array of objects

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **context.kubernetes.namespace.labelSelector.matchExpressions.key**
        string

        Required value

        key is the label key that the selector applies to.

      - **context.kubernetes.namespace.labelSelector.matchExpressions.operator**
        string

        Required value

        operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

      - **context.kubernetes.namespace.labelSelector.matchExpressions.values**
        array of strings

        values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

    - **context.kubernetes.namespace.labelSelector.matchLabels**
      object

      matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

  - **context.kubernetes.namespace.nameSelector**
    object
    - **context.kubernetes.namespace.nameSelector.matchNames**

array of strings

Required value

- **context.kubernetes.queue**
  string

  A name of a separate queue. It can be used to execute long-running hooks in parallel with hooks in the “main” queue.

- **context.name**
  string

  Required value

  It is used to distinguish different bindings during runtime.

- **handler**
  object

  Required value

  Code of the ValidatingWebhook handler

  - **handler.cel**
    string

    CEL rules handler for object.

  - **handler.python**
    string

    Python script handler for object.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **status**
  object

  Status defines the observed state of ValidationWebhook.

- **validationObject**
  object

  Required value

  ValidatingWebhook describes an webhook and the resources and operations it applies to.

  - **validationObject.failurePolicy**
    string

    Defines how errors from the hook are handled.

  - **validationObject.group**
    string

    A key to include snapshots from a group of schedule and Kubernetes bindings. See grouping.

  - **validationObject.labelSelector**
    object

    A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

    - **validationObject.labelSelector.matchExpressions**
      array of objects

      matchExpressions is a list of label selector requirements. The requirements are ANDed.

      A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

      - **validationObject.labelSelector.matchExpressions.key**
        string

        Required value

        key is the label key that the selector applies to.

        - **validationObject.labelSelector.matchExpressions.operator**
          string

          Required value

          operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

        - **validationObject.labelSelector.matchExpressions.values**
          array of strings

          values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

      - **validationObject.labelSelector.matchLabels**
        object

        matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

  - **validationObject.matchConditions**
    array of objects

    An optional list of match conditions for fine-grained request filtering. Available only since v1.27 of Kubernetes.

    MatchCondition represents a condition which must by fulfilled for a request to be sent to a webhook.

      - **validationObject.matchConditions.expression**
        string

        Required value

        Expression represents the expression which will be evaluated by CEL. Must evaluate to bool. CEL expressions have access to the contents of the AdmissionRequest and Authorizer, organized into CEL variables:

        ‘object’ - The object from the incoming request. The value is null for DELETE requests. ‘oldObject’ - The existing object. The value is null for CREATE requests. ‘request’ - Attributes of the admission request(/pkg/apis/admission/types.go#AdmissionRequest). ‘authorizer’ - A CEL Authorizer. May be used to perform authorization checks for the principal (user or service account) of the request. See https://pkg.go.dev/k8s.io/apiserver/pkg/cel/library#Authz ‘authorizer.requestResource’ - A CEL ResourceCheck constructed from the ‘authorizer’ and configured with the request resource. Documentation on CEL: https://kubernetes.io/docs/reference/using-api/cel/

        Required.

      - **validationObject.matchConditions.name**
        string

        Required value

        Name is an identifier for this match condition, used for strategic merging of MatchConditions, as well as providing an identifier for logging purposes. A good name should be descriptive of the associated expression. Name must be a qualified name consisting of alphanumeric characters, ‘-‘, ‘*’ or ‘.’, and must start and end with an alphanumeric character (e.g. ‘MyName’, or ‘my.name’, or ‘123-abc’, regex used for validation is ‘([A-Za-z0-9][-A-Za-z0-9.]*)?[A-Za-z0-9]’) with an optional DNS subdomain prefix and ‘/’ (e.g. ‘example.com/MyName’)

        Required.

  - **validationObject.name**
    string

    Required value

    Name should be a domain with at least three segments separated by dots.

  - **validationObject.namespace**
    object

    Namespace filtering. Only labelSelector is supported (not nameSelector). To filter by namespace name, use labelSelector with kubernetes.io/metadata.name label.

      - **validationObject.namespace.labelSelector**
        object

        labelSelector is a selector to filter namespaces by labels. Use kubernetes.io/metadata.name label to filter by namespace name.

          - **validationObject.namespace.labelSelector.matchExpressions**

array of objects

matchExpressions is a list of label selector requirements. The requirements are ANDed.

A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

- **validationObject.namespace.labelSelector.matchExpressions.key**
  string

  Required value

  key is the label key that the selector applies to.

- **validationObject.namespace.labelSelector.matchExpressions.operator**
  string

  Required value

  operator represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

- **validationObject.namespace.labelSelector.matchExpressions.values**
  array of strings

  values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **validationObject.namespace.labelSelector.matchLabels**
  object

  matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is "key", the operator is "In", and the values array contains only "value". The requirements are ANDed.

- **validationObject.rules**
  array of objects

  A required list of rules used to determine if a request to the Kubernetes API server should be sent to the hook.

  RuleWithOperations is a tuple of Operations and Resources. It is recommended to make sure that all the tuple expansions are valid.

  - **validationObject.rules.apiGroups**
    array of strings

    APIGroups is the API groups the resources belong to. ' *' is all groups. If ''* is present, the length of the slice must be one. Required.

  - **validationObject.rules.apiVersions**
    array of strings

    APIVersions is the API versions the resources belong to. ' *' is all versions. If ''* is present, the length of the slice must be one. Required.

  - **validationObject.rules.operations**
    array of strings

    Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or * for all of those operations and any future admission operations that are added. If '*' is present, the length of the slice must be one. Required.

    - **Element of the array**
      string

      OperationType specifies an operation for a request.

  - **validationObject.rules.resources**
    array of strings

    Resources is a list of resources this rule applies to.

    For example: 'pods' means pods. 'pods/log' means the log subresource of pods. ' *' means all resources, but not subresources. 'pods/'* means all subresources of pods. '*/scale' means all scale subresources. '*/*' means all resources and their subresources.

    If wildcard is present, the validation rule will ensure resources do not overlap with each other.

    Depending on the enclosing object, subresources might not be allowed. Required.

  - **validationObject.rules.scope**
    string

scope specifies the scope of this rule. Valid values are “Cluster”, “Namespaced”, and “ ” *“Cluster” means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. “Namespaced” means that only namespaced resources will match this rule. “”* means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is “*”.

- **validationObject.sideEffects**
  string

  Determines whether the hook is dryRun-aware.

- **validationObject.timeoutSeconds**
  integer

  Seconds API server should wait for a hook to respond before treating the call as a failure. Default is 10 (seconds).

Usage

> **i** The module lifecycle stage: General Availability

Setting up the update mode

You can manage DKP updates in the following ways:

- Using the `settings.update` parameter of the ModuleConfig `deckhouse` resource.
- Using the `disruptions` parameters section of the NodeGroup resource.

Update windows configuration

You can configure the time windows when Deckhouse will automatically install updates in the following ways:

- For general update management, in the `update.windows` parameter of the `deckhouse` ModuleConfig resource.
- For managing disruptive updates, in the `disruptions.automatic.windows` and `disruptions.rollingUpdate.windows` parameters of the NodeGroup resource.

An example of setting up two daily update windows — from 8 a.m. to 10 a.m. and from 8 p.m. to 10 p.m. (UTC):

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    releaseChannel: EarlyAccess
    update:
      windows:
        - from: "8:00"
          to: "10:00"
        - from: "20:00"
          to: "22:00"
```

You can also set up updates on certain days, for example, on Tuesdays and Saturdays from 6 p.m. to 7:30 p.m. (UTC):

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    releaseChannel: Stable
    update:
      windows:
        - from: "18:00"
          to: "19:30"
          days:
            - Tue
            - Sat
```

Manual update confirmation

Manual confirmation of Deckhouse version updates is provided in the following cases:

- The Deckhouse update confirmation mode is enabled.

  This means that the parameter settings.update.mode in the ModuleConfig `deckhouse` is set to `Manual` (confirmation for both patch and minor versions of Deckhouse) or `AutoPatch` (confirmation for the minor version of Deckhouse). Run the following command to confirm the update (use the corresponding Deckhouse version):

  ```
  d8 k patch DeckhouseRelease <VERSION> --type=merge -p='{"approved": true}'
  ```

- If automatic application of disruptive updates is disabled for a node group.

  This means that the corresponding NodeGroup has the parameter `spec.disruptions.approvalMode` set to `Manual`.

  For updating **each** node in such a group, the node must have `update.node.deckhouse.io/disruption-approved=` annotation. Example:

  ```
  d8 k annotate node ${NODE_1} update.node.deckhouse.io/disruption-approved=
  ```

Deckhouse update notifications

In the `Auto` update mode, you can configure a webhook call to receive a notification about an upcoming minor Deckhouse version update.

In addition, notifications are generated not only for Deckhouse updates but also for updates of any modules, including their individual updates. In some cases, the system may initiate the sending of multiple notifications at once (10–20 notifications) at approximately 15-second intervals.

> **i** Notifications are available only in the `Auto` update mode; in the `Manual` mode they are not generated.

> **i** Specifying a webhook is optional: if the `update.notification.webhook` parameter is not set but the `update.notification.minimalNotificationTime` parameter is specified, the update will still be postponed for the specified period. In this case, the appearance of a DeckhouseRelease resource in the cluster with the name of the new version can be considered the notification of its availability.

Notifications are sent only once for a specific update. If something goes wrong (for example, the webhook receives incorrect data), they will not be resent automatically. To resend the notification, you must delete the corresponding DeckhouseRelease resource.

Example of notification configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    update:
      releaseChannel: Stable
      mode: Auto
      notification:
        webhook: https://release-webhook.mydomain.com
```

After a new minor Deckhouse version appears on the selected release channel, but before it is applied in the cluster, a POST request will be sent to the configured webhook address.

The minimalNotificationTime parameter allows you to postpone the update installation for the specified period, providing time to react to the notification while respecting update windows. If the webhook is unavailable, each failed attempt to send the notification will postpone the update by the same duration, which may lead to the update being deferred indefinitely.

> ⚠ If your webhook returns any status code out of 2xx range, DKP retries sending the notification up to five times with exponential backoff. If all attempts fail, the release is blocked until the webhook becomes available again.

For easier error handling and debugging, when returning error codes the webhook should return a JSON response with the following structure:

- `code` — optional internal error code for programmatic handling;
- `message` — a human-readable description of what went wrong.

If the webhook returns a successful HTTP status (2xx), DKP treats the notification as successful regardless of the response body.

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    update:
      releaseChannel: Stable
      mode: Auto
      notification:
        webhook: https://release-webhook.mydomain.com
        minimalNotificationTime: 8h
```

Minimal Go webhook example...

```
package main

import (
  "encoding/json"
  "fmt"
  "log"
  "net/http"
)

// Payload structure Deckhouse sends in POST body.
type WebhookData struct {
  Subject      string          `json:"subject"`
  Version      string          `json:"version"`
  Requirements  map[string]string `json:"requirements,omitempty"`
  ChangelogLink string          `json:"changelogLink,omitempty"`
  ApplyTime    string          `json:"applyTime,omitempty"`
  Message      string          `json:"message"`
```

```
}

// Response structure that Deckhouse expects from webhook on error
type ResponseError struct {
  Code    string `json:"code,omitempty"`
  Message string `json:"message"`
}

func handler(w http.ResponseWriter, r *http.Request) {
  if r.Method != http.MethodPost {
    w.WriteHeader(http.StatusMethodNotAllowed)
    return
  }
  defer r.Body.Close()

  var data WebhookData
  if err := json.NewDecoder(r.Body).Decode(&data); err != nil {
    log.Printf("failed to decode payload: %v", err)
    w.WriteHeader(http.StatusInternalServerError)
    return
  }

  // Print payload fields
  log.Printf("subject=%s version=%s applyTime=%s changelog=%s requirements=%v",
    data.Subject, data.Version, data.ApplyTime, data.ChangelogLink, data.Requirements)
  log.Printf("message=%s", data.Message)

  // Example conditional logic: fail intentionally for testing
  if data.Version == "v0.0.0-fail" {
    // Return structured error response with error status code
    errorResp := ResponseError{
      Code:    "TEST_FAILURE",
      Message: "intentional failure for testing",
    }

    w.WriteHeader(http.StatusBadRequest)
    json.NewEncoder(w).Encode(errorResp)
    return
  }

  // Return success response with 2xx status code
  w.WriteHeader(http.StatusOK)
  w.Write([]byte("Notification processed successfully"))
}

func main() {
  mux := http.NewServeMux()
  mux.HandleFunc("/webhook", handler)

  addr := ":8080"
  fmt.Printf("listening on %s, POST to http://localhost%s/webhook\n", addr, addr)
  if err := http.ListenAndServe(addr, mux); err != nil {
    log.Fatal(err)
  }
}
```

Reserving the hostnames of the platform web interfaces

DKP publishes its own web interfaces under hostnames rendered from the `publicDomainTemplate` global parameter: the API, the web interface, Grafana, Dex, the kubeconfig generator and others. Those hostnames are reserved cluster-wide. An Ingress, HTTPRoute, GRPCRoute, TLSRoute, ListenerSet or Gateway resource created outside a namespace labeled `heritage: deckhouse` cannot claim such a name, and such a request is rejected with a message naming the hostname:

```
Hostname console.example.com is reserved for Deckhouse platform services
and cannot be claimed outside a system namespace
```

Only resource creation and modification are checked. An object that already claims a reserved hostname keeps serving traffic until it is modified.

Reserved hostnames

The reserved set is controlled by the `settings.reservedPublicHosts.mode` parameter of the ModuleConfig `deckhouse`:

- `Template` (by default): Every hostname the template can render are reserved.
- `List`: Only the hostnames of the services DKP knows it publishes.

For details on each reservation method, refer to the parameter description.

Excluding a name from reservation

Under `Template` mode, the reservation covers not only the hostnames used by DKP but also others matching the template. A workload that requires such a hostname can be excluded from reservation in one of the following ways:

- Free a single hostname with the `settings.reservedPublicHosts.excludedServices` parameter.

  The parameter includes not the entire hostname, only the service name (the value included in the template). For example, for the `%s.example.com` template, the `grafana` value excludes `grafana.example.com` from reservation.

- Exclude a whole namespace with the `security.deckhouse.io/reserved-hosts-bypass: "true"` label.

  The label is set on the namespace, not on the object, so a tenant who is allowed to manage resources only in their own namespaces can’t set it.

- Return to the previous reservation by setting `mode: List`.

The following is an example that frees `grafana.example.com` from reservation and additionally reserves `admin.corp.example.org` that doesn’t match the template:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  settings:
    reservedPublicHosts:
      mode: Template
      excludedServices:
        - grafana
      additionalHosts:
        - admin.corp.example.org
```

The `settings.reservedPublicHosts.additionalHosts` parameter lets you reserve additional hostnames regardless of the `excludedServices` value.

⚠ The `excludedServices` parameter accepts service names only, therefore it can’t be used to exclude a wildcard name from reservation.

To allow a workload to use a wildcard name (such as `*.example.com`), disable the checking for its namespace using the above-mentioned label or use the `List` mode.

Excluding the shared Gateway

The Gateway to which DKP module ListenerSet resources are attached is automatically excluded from reservation, regardless of the hostnames specified in its listeners.

The following Gateway is considered the shared Gateway:

- The Gateway specified in the global `gatewayAPIGateway` parameter.
- If the parameter is not set, the Gateway specified in the `default-gateway` ConfigMap in the `d8-alb` namespace.

The exclusion applies by name and namespace and only to the Gateway resource. It does not apply to other resources using the same hostnames, such as Ingress, HTTPRoute, or another Gateway.

This exclusion is necessary because such a Gateway typically has a listener with a wildcard hostname and wildcard certificate and is often located in a dedicated namespace without the `heritage: deckhouse` label. Without the exclusion, the Gateway could not be modified after hostname reservation is enabled, even though the attached DKP routes continue to depend on it.

Any other Gateway with a `*.example.com` listener is rejected, even if that hostname was already in use when

reservation was enabled. To use such a Gateway, add the `security.deckhouse.io/reserved-hosts-bypass: "true"` label to its namespace or enable `List` mode.

If the shared Gateway is neither specified in the `gatewayAPIGateway` parameter nor defined through the `default-gateway` ConfigMap, no automatic exclusion is applied.

Reservation with existing applications in the cluster

When hostname reservation takes effect, hostnames already used by applications are automatically added to the list of allowed hostnames. Otherwise, the next modification of the corresponding resources would be rejected.

The list is stored in the `grandfatheredHosts` key of the `d8-reserved-public-hosts` ConfigMap in the `d8-system` namespace, separately from hostnames manually excluded from reservation.

The list is created only when `Template` mode is enabled for the first time and is not updated afterward. This prevents reservation from being bypassed: an application cannot claim a reserved hostname after reservation has been enabled and then have that hostname allowed through subsequent regeneration of the list.

If an application that used a hostname allowed this way is removed and the hostname is no longer needed, remove the corresponding entry from `grandfatheredHosts`.

Before being stored, hostnames are converted to lowercase and any trailing dot is removed. Invalid values, such as a URL instead of a hostname, are ignored. If a resource uses the corresponding reserved hostname, its next modification will be rejected.

Wildcard hostnames, such as `*.example.com`, are not added to `grandfatheredHosts`. Otherwise, an application could use any hostname matching the template, including hostnames of services that DKP may publish in the future. To allow an application to use a wildcard hostname in the platform domain, add the `security.deckhouse.io/reserved-hosts-bypass: "true"` label to its namespace or enable `List` mode.

This restriction does not apply to the Gateway to which DKP is attached. This Gateway is automatically excluded from the check.

Switching from `Template` mode to `List` mode and back does not regenerate `grandfatheredHosts`. Therefore, hostnames that applications start using while `List` mode is enabled are not added to the list of allowed hostnames after switching back to `Template` mode. When the corresponding resources are modified, these hostnames are checked according to the standard reservation rules.

Checking reservation status

Information about the current reservation status is stored in the `d8-reserved-public-hosts` ConfigMap in the `d8-system` namespace.

To view the ConfigMap, run the following command:

```
d8 k -n d8-system get configmap d8-reserved-public-hosts -o yaml
```

The ConfigMap contains the following keys:

Key	Description
`mode`	Current reservation mode. If `publicDomainTemplate` does not match the schema, the value is `List`
`hostPattern`	Regular expression describing the hostnames that can be generated from the template. The value is empty in `List` mode
`hosts`	Hostnames matched exactly. In `Template` mode, contains the values from `additionalHosts` and the wildcard domain name; in `List` mode, contains the hostnames of platform services
`allowedHosts`	Hostnames excluded from matching against `hostPattern`: hostnames from `excludedServices` and `grandfatheredHosts`
`excludedHosts`	Hostnames excluded from reservation using `excludedServices`
`grandfatheredHosts`	Hostnames that were already used by applications when reservation was enabled and were automatically added to the list of allowed hostnames
`sharedGateway`	Gateway to which DKP is attached, in the `<NAMESPACE>/<NAME>` format. The value is empty if no such Gateway is configured or detected

Key	Description
`platformHosts`	Hostnames of services published by DKP. Used as a reference in both reservation modes
`unknownExcludedServices`	Names from `excludedServices` that are not published by any module. A value in this key most likely indicates a typo in the service name

Collect debug info

Read the FAQ to learn more about collecting debug information.

FAQ

> **i** The module lifecycle stage: General Availability

How to run kube-bench in my cluster?

First, you have to exec in Deckhouse Pod:

```
d8 k -n d8-system exec -ti svc/deckhouse-leader -c deckhouse -- bash
```

Then you have to select which node you want to run kube-bench.

- Run on random node:

  ```
  curl -s https://raw.githubusercontent.com/aquasecurity/kube-bench/main/job.yaml | d8 k create -f -
  ```

- Run on specific node, e.g. control-plane node:

  ```
  curl -s https://raw.githubusercontent.com/aquasecurity/kube-bench/main/job.yaml | d8 k apply -f - --dry-run=client -o json | jq '.spec.template.spec.tolerations=[{"operator": "Exists"}] | .spec.template.spec.nodeSelector={"node-role.kubernetes.io/control-plane": ""}' | d8 k create -f -
  ```

Then you can check report:

```
d8 k logs job.batch/kube-bench
```

> **⚠** Deckhouse set the log retention period to 7 days. However, according to the security requirements specified in kube-bench, logs should be retained for at least 30 days. Use separate storage for logs if you need to keep logs for more than 7 days.

How to collect debug info?

1. Create a diagnostic archive with the `d8` utility, redirecting its output (stdout) to a file:

   ```
   d8 system collect-debug-info > deckhouse-debug-$(date +"%Y_%m_%d").tar.gz
   ```

2. Send the resulting archive to the Deckhouse team for further debugging.

> **i** The `--exclude` flag omits the specified items from the archive. Example:

```
d8 system collect-debug-info --exclude=queue global-values > deckhouse-debug-$(date +"%Y_%m_%d").tar.gz
```

> **i** The `--list-exclude` flag prints the list of items available for exclusion. Example:

```
d8 system collect-debug-info --list-exclude
```

The following information is produced when creating the archive. Names in the “File in archive” column

correspond to top-level items inside the resulting `tar.gz` archive. Certain sensitive values (e.g., `kubeRBACProxyCA` and `registry.dockercfg`) are excluded.

Category	Collected data	File in archive
Deckhouse	Deckhouse queue state	`queue`
	Deckhouse values (excluding `kubeRBACProxyCA` and `registry.dockercfg`)	`global-values`
	Current `deckhouse` pod version	`deckhouse-version`
	All `DeckhouseRelease` objects	`deckhouse-releases`
	Deckhouse pod logs	`deckhouse-logs`
	Manifests of controllers and pods from all Deckhouse namespaces	`d8-all`
Cluster objects	`NodeGroup`	`node-groups`
	`NodeGroupConfiguration`	`node-group-configuration`
	`Node`	`nodes`
	`Machine`	`machines`
	`Instance`	`instances`
	`StaticInstance`	`staticinstances`
	`MachineDeployment`	`cloud-machine-deployment`, `static-machine-deployment`
	`ClusterAuthorizationRule`	`cluster-authorization-rules`
	`AuthorizationRule`	`authorization-rules`
	`ModuleConfig`	`module-configs`
	Events (all namespaces)	`events`
Modules and states	List of enabled modules	`deckhouse-enabled-modules`
	`ModuleSource` objects in the cluster	`deckhouse-module-sources`
	`ModulePullOverride` objects in the cluster	`deckhouse-module-pull-overrides`
	Modules in `maintenance` mode	`deckhouse-maintenance-modules`
Controller logs and manifests	`machine-controller-manager` logs	`mcm-logs`
	`cloud-controller-manager` logs	`ccm-logs`
	`csi-controller` logs	`csi-controller-logs`
	`cluster-autoscaler` logs	`cluster-autoscaler-logs`
	Vertical Pod Autoscaler admission controller logs	`vpa-admission-controller-logs`
	Vertical Pod Autoscaler recommender logs	`vpa-recommender-logs`
	Vertical Pod Autoscaler updater logs	`vpa-updater-logs`
	`capi-controller-manager` YAML	`capi-controller-manager`
	`caps-controller-manager` YAML	`caps-controller-manager`
	`machine-controller-manager` YAML	`machine-controller-manager`
Monitoring and alerts	Prometheus logs	`prometheus-logs`
	Active (firing) Prometheus alerts	`alerts`
	Pods not in `Running` (excluding `Completed` and `Evicted`)	`bad-pods`
	List of Audit Policies	`audit-policy`

Category	Collected data	File in archive
Network	All objects in the `d8-istio` namespace	`d8-istio-resources`
	All `istio` custom resources	`d8-istio-custom-resources`
	Envoy configuration for `istio`	`d8-istio-envoy-config`
	`istio` logs	`d8-istio-system-logs`
	`istio` ingress gateway logs	`d8-istio-ingress-logs`
	`istio` users logs	`d8-istio-users-logs`
	Cilium connection status (`cilium health status`)	`cilium-health-status`

How to debug pod problems with ephemeral containers?

Run the following command:

```
d8 k -n <namespace_name> debug -it <pod_name> --image=ubuntu <container_name>
```

More info in official documentation.

How to debug node problems with ephemeral containers?

Run the following command:

```
d8 k debug node/mynode -it --image=ubuntu
```

More info in official documentation.

The deckhouse-tools module

> **i** The module lifecycle stage: General Availability

> **i** Web interfaces associated with the module: deckhouse-tools

The module creates a web UI with links to download Deckhouse CLI tool for various operating systems.

The web interface address is composed based on the publicDomainTemplate template of the Deckhouse global configuration parameter (the `%s` key is replaced with `tools`).

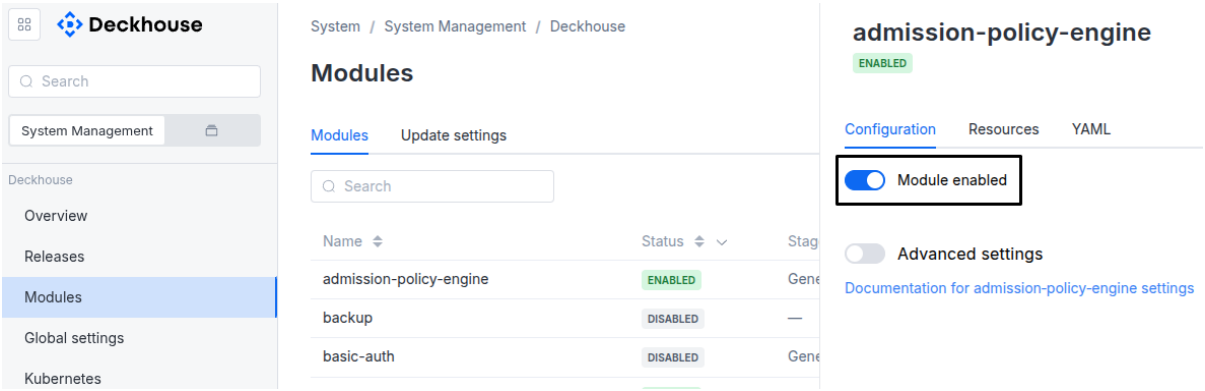
For example, if `publicDomainTemplate` is set to `%s-kube.company.my`, the tools web interface will be exposed at `tools-kube.company.my`.

Configuration

> **i** The module lifecycle stage: General Availability

The module does not have any mandatory parameters.

An example of the configuration



```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse-tools
spec:
  enabled: true
  version: 1
```

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse-tools` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

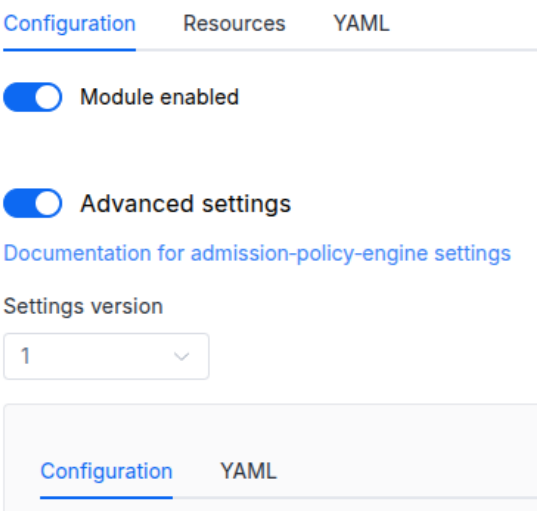
```
d8 system module enable deckhouse-tools
```

- **Using ModuleConfig `deckhouse-tools`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `deckhouse-tools` (create it if necessary);

  Example of a manifest to enable module `deckhouse-tools`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse-tools
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `deckhouse-tools` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `deckhouse-tools` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `deckhouse-`

`tools`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `deckhouse-tools` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc deckhouse-tools
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `deckhouse-tools` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `deckhouse-tools`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: deckhouse-tools
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.auth**
    object

    Parameters to authenticate and authorize access to the module’s web interface.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module’s public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

      An array of groups whose users can browse the module’s web interface.

      This parameter is used if the `user-authn` module is enabled or if the `externalAuthentication` parameter is set.

      > **Caution!** Note that you must add those groups to the appropriate field in the `DexProvider` config if this module is used together with the `user-authn` one.

      Default: `[]`

      Examples:

      ```
      allowedUserGroups:
      - admin
      - users
      ```

      ```
      allowedUserGroups: []
      ```

    - **settings.auth.externalAuthentication**

object

Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

> **i** External authentication is enabled automatically if the user-authn module is enabled.

- **settings.auth.externalAuthentication.authSignInURL**
  string

  The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response).

  Default:

  Example:

  ```
  authSignInURL: https://$host/dex-authenticator/sign_in
  ```

- **settings.auth.externalAuthentication.authURL**
  string

  The URL of the authentication service.

  If the user is authenticated, the service should return an HTTP 200 response code.

  Default:

  Example:

  ```
  authURL: https://deckhouse-tools-dex-authenticator.d8-
  system.svc.cluster.local/dex-authenticator/auth
  ```

- **settings.https**
  object

  What certificate type to use.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: Disabled
  ```

  ```
  https:
    mode: OnlyInURI
  ```

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object

    Parameters for certmanager.

    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are supported; you can also define your own).

      Default: `letsencrypt`

      Example:

```
clusterIssuerName: letsencrypt
```

- **settings.https.customCertificate**
  object

  Parameters for custom certificate usage.

  - **settings.https.customCertificate.secretName**
    string

    The name of the secret in the `d8-system` namespace to use with the module's web interface.

    Note that this secret must conform to the kubernetes.io/tls format.

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager` — the web UI is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate` — the web UI is accessed over HTTPS using a certificate from the `d8-system` namespace.
  - `Disabled` — in this mode, the module's web interface can only be accessed over HTTP.
  - `OnlyInURI` — the module's web interface will work over HTTP (implies there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. The load balancer should provide redirection from HTTP to HTTPS.

  Default: `CertManager`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller of the module web interface.

  An optional parameter; by default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

The descheduler module

> **i** The module lifecycle stage: General Availability

Every 15 minutes, the module analyzes the cluster state and performs pod eviction according to the conditions described in the active strategies. Evicted pods go through the scheduling process again, considering the current state of the cluster. This helps redistribute workloads according to the chosen strategy.

The module is based on the descheduler project.

Features of the module

- The module can take into account the pod priority class (parameter spec.priorityClassThreshold), restricting its operation to only those pods that have a priority class lower than the specified threshold;
- The module does not evict pods in the following cases:
  - a pod is in the `d8-*` or `kube-system` namespaces;
  - a pod has a `priorityClassName` `system-cluster-critical` or `system-node-critical`;
  - a pod is associated with a local storage;
  - a pod is associated with a DaemonSet;
  - pod eviction will violate Pod Disruption Budget (PDB);
  - there are no available nodes to run the evicted pod.
- Pods with the `Best effort` priority class are evicted before those with `Burstable` and `Guaranteed`.

Descheduler uses parameters with the `labelSelector` syntax from Kubernetes to filter pods and nodes:

- `podLabelSelector` — limits pods by labels;
- `namespaceLabelSelector` — filters pods by namespaces;
- `nodeLabelSelector` — selects nodes by labels.

Metrics provider

If the cluster has a registered `metrics.k8s.io` API group (for example, when metrics-server is installed), the module automatically detects it and enables the **KubernetesMetrics** metrics provider in the `descheduler` policy. This allows to use the **actual** resource consumption data from the Metrics API instead of relying solely on pod requests and limits when the `LowNodeUtilization` strategy is set. Accordingly, the values in thresholds and targetThresholds are then interpreted as a percentage of actual consumption, not of pod requests. The `HighNodeUtilization` strategy is not affected: it always uses pod requests and limits.

No user action is required: the module discovers the `metrics.k8s.io` API group by watching APIService resources and configures the policy accordingly. If metrics-server is installed **after** the module is already running, the `descheduler` Pod will be automatically restarted with the updated policy.

> **i** When `metrics.k8s.io` is not available, the module falls back to the default behavior: resource usage is estimated from pod requests and limits.

Strategies

HighNodeUtilization

> **i** More compactly places pods. Requires scheduler configuration and enabling auto-scaling.
>
> To use `HighNodeUtilization`, you must explicitly specify the high-node-utilization scheduler profile for each pod (this profile cannot be set as the default).

This strategy identifies *under utilized nodes* and evicts pods from them to redistribute them more compactly across fewer nodes.

Under utilized node — A node whose resource usage is below all the threshold values specified in the strategies.highNodeUtilization.thresholds section.

The strategy is enabled by the parameter spec.strategies.highNodeUtilization.enabled.

> **⚠** In GKE, you cannot configure the default scheduler, but you can use the `optimize-utilization` strategy or deploy a second custom scheduler.

⚠ Node resource usage takes into account extended resources and is calculated based on pod requests and limits (requests and limits), not actual consumption. This approach ensures consistency with the kube-scheduler, which uses a similar principle when scheduling pods on nodes.

This strategy always uses pod requests and limits, regardless of whether the `metrics.k8s.io` API is available in the cluster (see Metrics provider).

LowNodeUtilization

i Loads the nodes more evenly.

This strategy identifies *under utilized nodes* and evicts pods from other *over utilized nodes*. The strategy assumes that the evicted pods will be recreated on the under utilized nodes (following normal scheduler behavior).

Under utilized node — A node whose resource usage is below all the threshold values specified in the strategies.lowNodeUtilization.thresholds section.

Over utilized node — A node whose resource usage exceeds at least one of the threshold values specified in the strategies.lowNodeUtilization.targetThresholds section.

Nodes with resource usage in the range between `thresholds` and `targetThresholds` are considered optimally utilized. Pods on these nodes will not be evicted.

The strategy is enabled by the parameter spec.strategies.lowNodeUtilization.enabled.

⚠ If the `metrics.k8s.io` API is **not** available in the cluster, node resource usage takes into account extended resources and is calculated based on pod requests and limits (requests and limits), not actual consumption. This approach ensures consistency with the kube-scheduler, which uses a similar principle when scheduling pods on nodes.

If the `metrics.k8s.io` API **is** available (see Metrics provider), the strategy uses the **actual** resource consumption from the Metrics API *instead of* requests and limits. In this case the values used by the descheduler are close to what `kubectl top` shows, but they no longer match the kube-scheduler's view: a node whose requests are exhausted may still be considered under utilized, and its pods will not be evicted.

RemoveDuplicates

i Prevents multiple pods from the same controller (ReplicaSet, ReplicationController, StatefulSet) or the same Job from running on the same node.

The strategy ensures that no more than one pod of a ReplicaSet, ReplicationController, StatefulSet, or pods of a single Job is running on the same node. If there are two or more such pods, the module evicts the excess pods so that they are better distributed across the cluster.

The situation can occur if some nodes in the cluster have failed for any reason, and the pods from those nodes have been moved to other nodes. Once the failed nodes become available again to accept load, this strategy can be used to evict duplicate pods from other nodes.

The strategy is enabled by the parameter strategies.removeDuplicates.enabled.

RemovePodsHavingTooManyRestarts

The strategy evicts pods having too many restarts from nodes. Pods become eviction candidates when the total number of restarts across all containers, including init containers, exceeds the `podRestartThreshold` threshold. This strategy is useful for evicting pods in the `CrashLoopBackOff` state or with repeated failures, as well as for freeing up resources and allowing fresh pods to be scheduled on potentially healthier nodes.

RemovePodsViolatingInterPodAntiAffinity

i Evicts pods violating inter-pod affinity and anti-affinity rules to ensure compliance.

The strategy ensures that pods violating inter-pod affinity and anti-affinity rules are evicted from nodes.

For example, if there is **podA** on a node and **podB** and **podC** (running on the same node) have anti-affinity rules which prohibit them to run on the same node, then **podA** will be evicted from the node so that **podB** and **podC** could run. This issue could happen, when the anti-affinity rules for **podB** and **podC** are created when they are

already running on node.

The strategy is enabled by the parameter spec.strategies.highNodeUtilization.enabled.

RemovePodsViolatingNodeAffinity

> **i** Evicts pods violating node affinity rules to ensure compliance.

The strategy makes sure all pods violating node affinity are eventually removed from nodes.

Essentially, depending on the settings of the parameter strategies.removePodsViolatingNodeAffinity.nodeAffinityType, the strategy temporarily implement the rule `requiredDuringSchedulingIgnoredDuringExecution` of the pod's node affinity as the rule `requiredDuringSchedulingRequiredDuringExecution`, and the rule `preferredDuringSchedulingIgnoredDuringExecution` as the rule `preferredDuringSchedulingPreferredDuringExecution`.

Example for `nodeAffinityType: requiredDuringSchedulingIgnoredDuringExecution`. There is a pod scheduled to a node which satisfies the node affinity rule `requiredDuringSchedulingIgnoredDuringExecution` at the time of scheduling. If over time this node no longer satisfies the node affinity rule, and there is another node available that satisfies the node affinity rule, the strategy evicts the pod from the node it was originally scheduled to.

Example for `nodeAffinityType: preferredDuringSchedulingIgnoredDuringExecution`. There is a pod scheduled to a node because at the time of scheduling there were no other nodes that satisfied the node affinity rule `preferredDuringSchedulingIgnoredDuringExecution`. If over time an available node that satisfies this rule appears in the cluster, the strategy evicts the pod from the node it was originally scheduled to.

The strategy is enabled by the parameter strategies.removePodsViolatingNodeAffinity.enabled.

RemovePodsViolatingTopologySpreadConstraint

The strategy ensures that pods violating topology spread constraints are evicted from nodes. It evicts the minimum number of pods required to balance topology domains to within each constraint's `maxSkew`. This is useful for rebalancing pods across zones after a zone outage recovery.

Third-party components

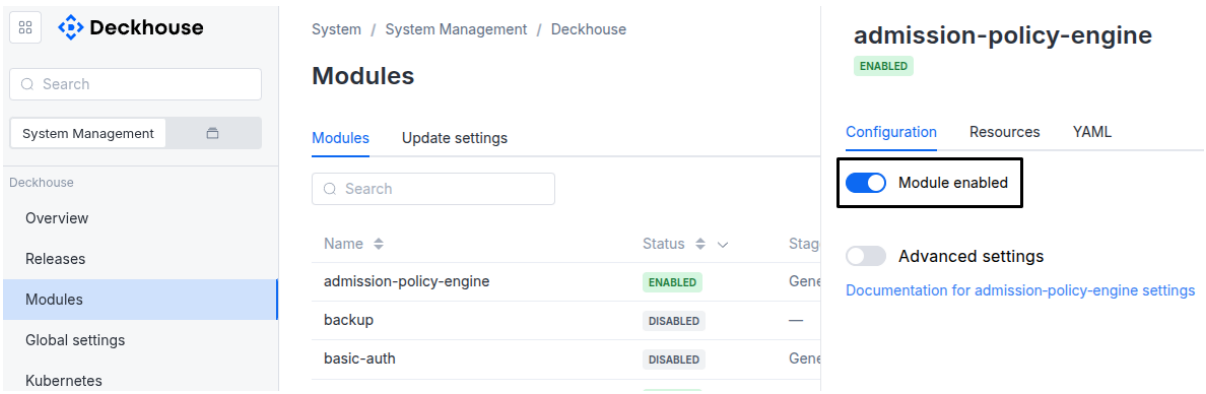
List of third-party software used in the `descheduler` module:

- Descheduler 0.35.1

  License: Apache License 2.0

  A tool to auto-fix scheduling issues Kubernetes does not cover itself.

Configuration



> **i** The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `descheduler` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

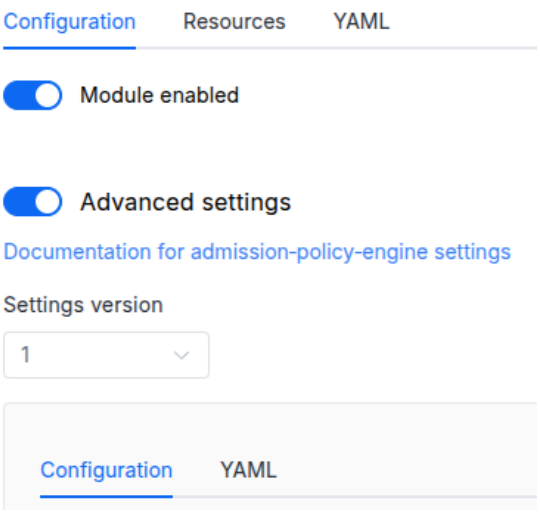
  ```
  d8 system module enable descheduler
  ```

- **Using ModuleConfig `descheduler`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `descheduler` (create it if necessary);

  Example of a manifest to enable module `descheduler`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: descheduler
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `descheduler` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `descheduler` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `descheduler`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `descheduler` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc descheduler
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `descheduler` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `descheduler`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: descheduler
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `settings`.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.deschedulingInterval**
    string

    Interval between pod redistribution runs.

    Supported values:

    - `Frequent`: Runs every 5 minutes. Suitable for clusters where faster pod redistribution is important.
    - `Moderate`: Runs every 15 minutes (default).
    - `Rare`: Runs every 30 minutes. Suitable for clusters where it’s important to minimize the number of pod redistributions.

    Default: `Moderate`

    Allowed values: `Frequent`, `Moderate`, `Rare`

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

Descheduler

Scope: Cluster

- v1alpha2
- v1alpha1

Descheduler is a description of a single descheduler instance.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
  - **metadata.name**
    string
- **spec**
  object

  Required value

  Defines the behavior of a descheduler instance.

  - **spec.evictLocalStoragePods**
    boolean

    Allows Pods using local storage to be evicted.

    Default: `false`
  - **spec.namespaceLabelSelector**
    object

    Limiting the pods which are processed by namespace labels.

    - **spec.namespaceLabelSelector.matchExpressions**
      array of objects

      List of label expressions that a node should have to qualify for the filter condition.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      - key: tier
        operator: NotIn
        values:
        - production
      ```

      - **spec.namespaceLabelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.namespaceLabelSelector.matchExpressions.operator**
        string

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.namespaceLabelSelector.matchExpressions.values**
        array of strings

        A label value.

        - **Element of the array**
          string

          Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

          Length: `1..63`
    - **spec.namespaceLabelSelector.matchLabels**
      object
  - **spec.nodeLabelSelector**
    object

    Limiting the pods which are processed to fit evicted pods by labels in set representation. If set, `nodeSelector` must not be set.

    - **spec.nodeLabelSelector.matchExpressions**
      array of objects

List of label expressions that a node should have to qualify for the filter condition.

Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.nodeLabelSelector.matchExpressions.key**
  string

  A label name.

- **spec.nodeLabelSelector.matchExpressions.operator**
  string

  A comparison operator.

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.nodeLabelSelector.matchExpressions.values**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

- **spec.nodeLabelSelector.matchLabels**
  object

- **spec.podLabelSelector**
  object

  Limiting the pods which are processed by labels.

  - **spec.podLabelSelector.matchExpressions**
    array of objects

    List of label expressions that a node should have to qualify for the filter condition.

    Example:

    ```
    matchExpressions:
    - key: tier
      operator: In
      values:
      - production
      - staging
    - key: tier
      operator: NotIn
      values:
      - production
    ```

    - **spec.podLabelSelector.matchExpressions.key**
      string

      A label name.

    - **spec.podLabelSelector.matchExpressions.operator**
      string

      A comparison operator.

      Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

    - **spec.podLabelSelector.matchExpressions.values**
      array of strings

      A label value.

      - **Element of the array**
        string

        Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

        Length: `1..63`

  - **spec.podLabelSelector.matchLabels**
    object

- **spec.priorityClassThreshold**
  object

  Limiting the pods which are processed by priority class. Only pods under the threshold can be evicted.

  You can specify either the name of the priority class (priorityClassThreshold.name), or the actual value of the priority class (priorityThreshold.value).

By default, this threshold is set to the value of `system-cluster-critical` priority class.

- **spec.priorityClassThreshold.name**
  string

  Name of the priority class.

- **spec.priorityClassThreshold.value**
  integer

  Value of the priority class.

- **spec.strategies**
  object

  Required value

  Settings of strategies for the Descheduler instances.

  - **spec.strategies.highNodeUtilization**
    object

    This strategy finds nodes that are under utilized and evicts Pods from the nodes in the hope that these pods will be scheduled compactly into fewer nodes. When combined with node auto-scaling, it helps reduce the number of underutilized nodes. The strategy works with the `MostAllocated` scheduler.

    > **i** In GKE, you cannot configure the default scheduler, but you can use the `optimize-utilization` strategy or deploy a second custom scheduler.

    Node resource usage takes into account extended resources and is based on pod requests and limits, not actual consumption.

    - **spec.strategies.highNodeUtilization.enabled**
      boolean

      Makes the strategy active.

      Default: `false`

    - **spec.strategies.highNodeUtilization.thresholds**
      object

      Sets threshold values to identify to identify under utilized nodes.

      If the resource usage of the node is below **all** threshold values, then the node is considered under utilized.

      If a resource threshold is not specified, it is treated as 100% and does not participate in node utilization calculations.

      - **spec.strategies.highNodeUtilization.thresholds.cpu**
        integer

        CPU fraction in percents

        Allowed values: `0 <= X <= 100`

      - **spec.strategies.highNodeUtilization.thresholds.memory**
        integer

        Memory fraction in percents

        Allowed values: `0 <= X <= 100`

      - **spec.strategies.highNodeUtilization.thresholds.pods**
        integer

        Pods count in percents

        Allowed values: `0 <= X <= 100`

  - **spec.strategies.lowNodeUtilization**
    object

    This strategy identifies *under utilized nodes* and evicts pods from other *over utilized nodes*. The strategy assumes that the evicted pods will be recreated on the under utilized nodes (following normal scheduler behavior).

    Under utilized node — A node whose resource usage is below all the threshold values specified in the thresholds section.

    Over utilized node — A node whose resource usage exceeds at least one of the threshold values specified in the targetThresholds section.

    Node resource usage takes into account extended resources and is based on pod requests and limits, not actual consumption.

    If the `metrics.k8s.io` API group is registered in the cluster, the module automatically switches this strategy to the **actual** resource consumption from the Metrics API.

    - **spec.strategies.lowNodeUtilization.enabled**
      boolean

      Makes the strategy active.

      Default: `false`

    - **spec.strategies.lowNodeUtilization.targetThresholds**
      object

      Sets threshold values to identify to identify over utilized nodes.

      If the resource usage of the node exceeds at least one of the threshold values, then the node is considered over utilized.

If a resource threshold is not specified, it is treated as 100% and does not participate in node utilization calculations.

- **spec.strategies.lowNodeUtilization.targetThresholds.cpu**
  integer

  CPU fraction in percents

  Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.targetThresholds.memory**
  integer

  Memory fraction in percents

  Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.targetThresholds.pods**
  integer

  Pods count in percents

  Allowed values: `0 <= X <= 100`

- **spec.strategies.lowNodeUtilization.thresholds**
  object

  Sets threshold values to identify to identify under utilized nodes.

  If the resource usage of the node is below **all** threshold values, then the node is considered under utilized.

  If a resource threshold is not specified, it is treated as 100% and does not participate in node utilization calculations.

  - **spec.strategies.lowNodeUtilization.thresholds.cpu**
    integer

    CPU fraction in percents

    Allowed values: `0 <= X <= 100`

  - **spec.strategies.lowNodeUtilization.thresholds.memory**
    integer

    Memory fraction in percents

    Allowed values: `0 <= X <= 100`

  - **spec.strategies.lowNodeUtilization.thresholds.pods**
    integer

    Pods count in percents

    Allowed values: `0 <= X <= 100`

- **spec.strategies.removeDuplicates**
  object

  The strategy ensures that no more than one pod of a ReplicaSet, ReplicationController, StatefulSet, or pods of a single Job is running on the same node. If there are two or more such pods, the module evicts the excess pods so that they are better distributed across the cluster.

  - **spec.strategies.removeDuplicates.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

- **spec.strategies.removePodsHavingTooManyRestarts**
  object

  The strategy evicts pods having too many restarts from nodes.

  Pods become eviction candidates when the total number of restarts across all containers, including init containers, exceeds the `podRestartThreshold` threshold.

  This strategy is useful for evicting pods in the `CrashLoopBackOff` state or with repeated failures, as well as for freeing up resources and allowing fresh pods to be scheduled on potentially healthier nodes.

  - **spec.strategies.removePodsHavingTooManyRestarts.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

  - **spec.strategies.removePodsHavingTooManyRestarts.podRestartThreshold**
    integer

    Threshold for the total number of restarts across all pod containers, including init containers.

    If the number of restarts exceeds this value, the pod is considered unhealthy and becomes a candidate for eviction.

    Default: `100`

    Allowed values: `1 <= X`

- **spec.strategies.removePodsViolatingInterPodAntiAffinity**
  object

  The strategy ensures that pods violating inter-pod affinity and anti-affinity rules are evicted from nodes.

  - **spec.strategies.removePodsViolatingInterPodAntiAffinity.enabled**
    boolean

    Makes the strategy active.

Default: `false`

- **spec.strategies.removePodsViolatingNodeAffinity**
  object

  The strategy makes sure all pods violating node affinity are eventually removed from nodes.

  Essentially, depending on the settings of the parameter nodeAffinityType, the strategy temporarily implement the rule `requiredDuringSchedulingIgnoredDuringExecution` of the pod's node affinity as the rule `requiredDuringSchedulingRequiredDuringExecution`, and the rule `preferredDuringSchedulingIgnoredDuringExecution` as the rule `preferredDuringSchedulingPreferredDuringExecution`.

  - **spec.strategies.removePodsViolatingNodeAffinity.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

  - **spec.strategies.removePodsViolatingNodeAffinity.nodeAffinityType**
    array of strings

    Defines the list of node affinity rules used.

    Default: `["requiredDuringSchedulingIgnoredDuringExecution"]`

    - **Element of the array**
      string

      Allowed values: `requiredDuringSchedulingIgnoredDuringExecution`, `preferredDuringSchedulingIgnoredDuringExecution`

- **spec.strategies.removePodsViolatingTopologySpreadConstraint**
  object

  The strategy ensures that pods violating topology spread constraints are evicted from nodes. It evicts the minimum number of pods required to balance topology domains to within each constraint's `maxSkew`.

  This is useful for rebalancing pods across zones after a zone outage recovery.

  - **spec.strategies.removePodsViolatingTopologySpreadConstraint.constraints**
    array of strings

    List of topology spread constraint types to consider when deciding which pods to evict.

    Topology spread constraints control how pods are distributed across your cluster topology (e.g. regions, zones, nodes).

    By default, only `DoNotSchedule` (hard constraints) are considered — these are constraints that the scheduler strictly enforces: a pod will NOT be placed if doing so would violate the constraint. `Descheduler` will evict pods that are currently violating such constraints (e.g. due to node failures or cluster topology changes after initial scheduling).

    Optionally, `ScheduleAnyway` (soft constraints) can also be included — these are constraints that the scheduler tries to satisfy but does not strictly enforce: a pod WILL be placed even if the constraint cannot be satisfied, though the scheduler will attempt to minimize the imbalance. Including this type causes `descheduler` to also evict pods that violate soft constraints.

    Default: `["DoNotSchedule"]`

    - **Element of the array**
      string

      Allowed values: `DoNotSchedule`, `ScheduleAnyway`

  - **spec.strategies.removePodsViolatingTopologySpreadConstraint.enabled**
    boolean

    Makes the strategy active.

    Default: `false`

  - **spec.strategies.removePodsViolatingTopologySpreadConstraint.topologyBalanceNodeFit**
    boolean

    If set to `true`, the strategy will consider whether the pods can fit on other nodes when balancing topology domains.

    Default: `true`

Deprecated resource. Support for the resource might be removed in a later release.

Descheduler is a description of a single descheduler instance.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
  - **metadata.name**
    string
- **spec**
  object

  Required value

  Defines the behavior of a descheduler instance.

  - **spec.deploymentTemplate**
    object

    Defines Template of a descheduler Deployment.

- **spec.deploymentTemplate.nodeSelector**
  object
- **spec.deploymentTemplate.tolerations**
  array of objects
  - **spec.deploymentTemplate.tolerations.effect**
    string
  - **spec.deploymentTemplate.tolerations.key**
    string
  - **spec.deploymentTemplate.tolerations.operator**
    string
  - **spec.deploymentTemplate.tolerations.tolerationSeconds**
    integer
  - **spec.deploymentTemplate.tolerations.value**
    string

- **spec.deschedulerPolicy**
  object

  `globalParameters` and `strategies` follow the descheduler's documentation.

  - **spec.deschedulerPolicy.globalParameters**
    object

    Parameters that apply to all policies.

    - **spec.deschedulerPolicy.globalParameters.evictFailedBarePods**
      boolean

      Allows Pods without `ownerReferences` and in `failed` phase to be evicted.

    - **spec.deschedulerPolicy.globalParameters.evictLocalStoragePods**
      boolean

      Allows Pods using local storage to be evicted.

    - **spec.deschedulerPolicy.globalParameters.evictSystemCriticalPods**
      boolean

      Allows eviction of Pods of any priority (including Kubernetes system Pods).

    - **spec.deschedulerPolicy.globalParameters.ignorePvcPods**
      boolean

      Prevents Pods with PVCs from being evicted.

    - **spec.deschedulerPolicy.globalParameters.maxNoOfPodsToEvictPerNamespace**
      integer

      Restricts maximum of Pods to be evicted per namespace.

    - **spec.deschedulerPolicy.globalParameters.maxNoOfPodsToEvictPerNode**
      integer

      Restricts maximum of Pods to be evicted per node.

    - **spec.deschedulerPolicy.globalParameters.nodeSelector**
      string
  - **spec.deschedulerPolicy.strategies**
    object

    List of strategies with corresponding parameters for a given Descheduler instances.

    - **spec.deschedulerPolicy.strategies.highNodeUtilization**
      object

      This strategy finds nodes that are under utilized and evicts Pods from the nodes in the hope that these Pods will be scheduled compactly into fewer nodes.

      - **spec.deschedulerPolicy.strategies.highNodeUtilization.enabled**
        boolean

        Required value

      - **spec.deschedulerPolicy.strategies.highNodeUtilization.namespaceFilter**
        object

        Restricts Namespaces to which this strategy applies.

      - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFilter**
        object

        Filters Nodes to which the strategy applies.

      - **spec.deschedulerPolicy.strategies.highNodeUtilization.nodeFit**
        boolean

        If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

      - **spec.deschedulerPolicy.strategies.highNodeUtilization.priorityFilter**
        object

        Only Pods with priority lower than this will be descheduled.

    - **spec.deschedulerPolicy.strategies.lowNodeUtilization**
      object

      This strategy finds nodes that are under utilized and evicts Pods, if possible, from other nodes in the hope that recreation of evicted Pods will be scheduled on these underutilized nodes.

      - **spec.deschedulerPolicy.strategies.lowNodeUtilization.enabled**
        boolean

        Required value

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.namespaceFilter**
  object

  Restricts Namespaces to which this strategy applies.

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFilter**
  object

  Filters Nodes to which the strategy applies.

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.nodeFit**
  boolean

  If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.lowNodeUtilization.priorityFilter**
  object

  Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removeDuplicates**
  object

  This strategy makes sure that there is only one Pod associated with a ReplicaSet (RS), ReplicationController (RC), StatefulSet, or Job running on the same node.

  - **spec.deschedulerPolicy.strategies.removeDuplicates.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removeDuplicates.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

  - **spec.deschedulerPolicy.strategies.removeDuplicates.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removeDuplicates.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removeFailedPods**
  object

  This strategy evicts Pods that are in `failed` status phase.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removeFailedPods.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removeFailedPods.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts**
  object

  This strategy makes sure that Pods having too many restarts are removed from nodes.

  - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.nodeFit**
  boolean

  If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

- **spec.deschedulerPolicy.strategies.removePodsHavingTooManyRestarts.priorityFilter**
  object

  Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity**
  object

  This strategy makes sure that Pods violating interpod anti-affinity are removed from nodes.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingInterPodAntiAffinity.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity**
  object

  This strategy makes sure all Pods violating node affinity are eventually removed from nodes.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeAffinity.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

- **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints**
  object

  This strategy makes sure that Pods violating `NoSchedule` taints on nodes are removed.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.enabled**
    boolean

    Required value

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.namespaceFilter**
    object

    Restricts Namespaces to which this strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFilter**
    object

    Filters Nodes to which the strategy applies.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.nodeFit**
    boolean

    If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.

  - **spec.deschedulerPolicy.strategies.removePodsViolatingNodeTaints.priorityFilter**
    object

    Only Pods with priority lower than this will be descheduled.

        - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint**
          object

          This strategy makes sure that Pods violating topology spread constraints are evicted from nodes.

          - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.enabled**
            boolean

            Required value
          - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.namespaceFilter**
            object

            Restricts Namespaces to which this strategy applies.
          - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFilter**
            object

            Filters Nodes to which the strategy applies.
          - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.nodeFit**
            boolean

            If set to `true`, the descheduler will consider whether or not the Pods that meet eviction criteria will fit on other nodes before evicting them.
          - **spec.deschedulerPolicy.strategies.removePodsViolatingTopologySpreadConstraint.priorityFilter**
            object

            Only Pods with priority lower than this will be descheduled.

- **status**
  object

  Most recently observed status of a descheduler instance.

  - **status.ready**
    boolean

    Required value

Examples

> **i** The module lifecycle stage: General Availability

Configuring the pod redistribution interval

To set how often the `descheduler` module runs the pod redistribution cycle, use the `deschedulingInterval` parameter.

For example, to run `descheduler` every 5 minutes, set `deschedulingInterval: Frequent`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: descheduler
spec:
  enabled: true
  settings:
    deschedulingInterval: Frequent
```

Supported values:

- `Frequent`: Runs every 5 minutes. Suitable for clusters where faster pod redistribution is important.
- `Moderate`: Runs every 15 minutes (default).
- `Rare`: Runs every 30 minutes. Suitable for clusters where it's important to minimize the number of pod redistributions.

Example LowNodeUtilization strategy

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: low-node-utilization
spec:
  strategies:
    lowNodeUtilization:
      enabled: true
      thresholds:
        cpu: 20
      targetThresholds:
        cpu: 50
```

Example HighNodeUtilization strategy

```
---
apiVersion: deckhouse.io/v1alpha2
kind: Descheduler
metadata:
  name: high-node-utilization
spec:
  strategies:
    highNodeUtilization:
      enabled: true
      thresholds:
        cpu: 50
        memory: 50
```

The documentation module

> **i** The module lifecycle stage: General Availability

> **i** Web interfaces associated with the module: documentation

The `documentation` module creates a documentation web UI for the Deckhouse version currently used in a cluster.

This can be useful when Deckhouse works in a network with limited Internet access.

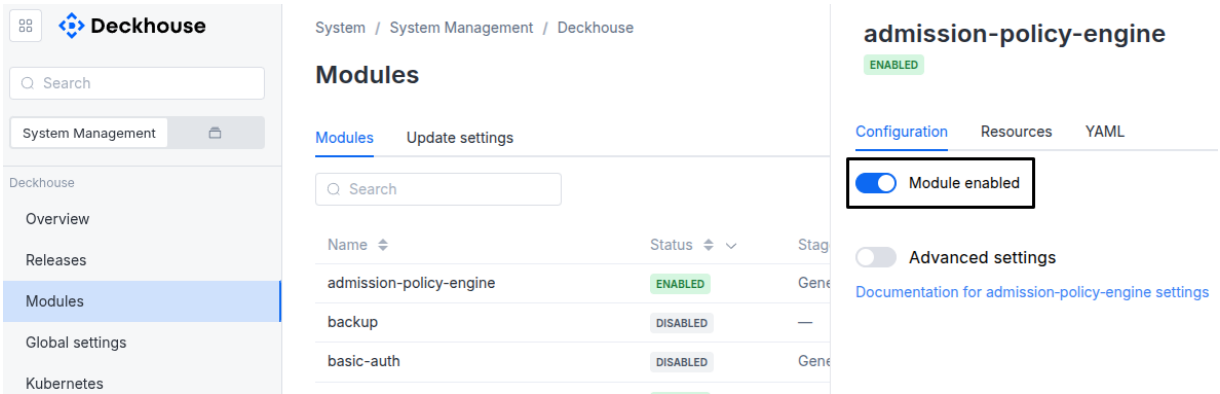
To get the web interface address, in the publicDomainTemplate template of the Deckhouse global configuration parameter, replace the `%s` key with `documentation`.

For example, if `publicDomainTemplate` is set as `%s-kube.company.my`, then the documentation web interface will be available at `documentation-kube.company.my`.

Configuration

> **i** The module lifecycle stage: General Availability

The module does not have any mandatory parameters.



The module has 2 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `documentation` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

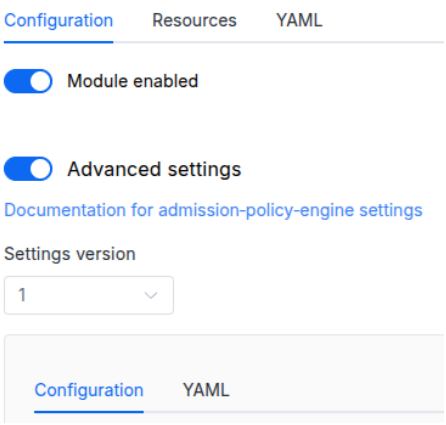
  ```
  d8 system module enable documentation
  ```

- **Using ModuleConfig `documentation`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `documentation` (create it if necessary);

  Example of a manifest to enable module `documentation`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: documentation
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `documentation` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `documentation` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `documentation`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `documentation` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc documentation
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `documentation` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `documentation`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: documentation
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.auth**
    object

    Parameters to authenticate and authorize access to the documentation web interface.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module’s public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

An array of groups whose users can browse the documentation.

This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

> **Caution!** Note that you must add those groups to the appropriate field in the `DexProvider` config if this module is used together with the `user-authn` one.

Default: `[]`

Examples:

```
allowedUserGroups:
- admin
- users
```

```
allowedUserGroups: []
```

- **settings.auth.externalAuthentication**
  object

  Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

  > External authentication is enabled automatically if the user-authn module is enabled.

  - **settings.auth.externalAuthentication.authSignInURL**
    string

    The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response.

    Default:

    Example:

    ```
    authSignInURL: https://$host/dex-authenticator/sign_in
    ```

  - **settings.auth.externalAuthentication.authURL**
    string

    The URL of the authentication service.

    If the user is authenticated, the service should return an HTTP 200 response code.

    Default:

    Example:

    ```
    authURL: https://documentation-dex-authenticator.d8-system.svc.cluster.local/dex-authenticator/auth
    ```

- **settings.https**
  object

  What certificate type to use.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: Disabled
  ```

  ```
  https:
    mode: OnlyInURI
  ```

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object

    Parameters for certmanager.

    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

      Default: `letsencrypt`

Example:

```
clusterIssuerName: letsencrypt
```

- **settings.https.customCertificate**
  object

  Parameters for custom certificate usage.

  - **settings.https.customCertificate.secretName**
    string

    The name of the secret in the `d8-system` namespace to use with the documentation web UI.

    This secret must have the kubernetes.io/tls format.

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager` — the web UI is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate` — the web UI is accessed over HTTPS using a certificate from the `d8-system` namespace.
  - `Disabled` — in this mode, the documentation web UI can only be accessed over HTTP.
  - `OnlyInURI` — HTTP access with an external HTTPS balancer. The balancer terminates HTTPS, and all links in `user-authn` are generated with the HTTPS scheme. The balancer must provide redirection from HTTP to HTTPS.

  Default: `CertManager`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller of the documentation web UI.

  An optional parameter; by default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

Authentication

user-authn module provides authentication by default. Also, externalAuthentication can be configured (see below). If these options are disabled, the module will use basic auth with the auto-generated password.

Use d8 k to see password:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values documentation -o json | jq
'.internal.auth.password'
```

Delete the Secret to re-generate password:

```
d8 k -n d8-system delete secret/documentation-basic-auth
```

> **Note!** The `auth.password` parameter is deprecated.

Examples

> The module lifecycle stage: General Availability

An example of the module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: documentation
spec:
  version: 1
  enabled: true
  settings:
    nodeSelector:
      node-role/system: ""
    tolerations:
    - key: dedicated.deckhouse.io
      operator: Equal
      value: system
    externalAuthentication:
      authURL: "https://<applicationDomain>/auth"
      authSignInURL: "https://<applicationDomain>/sign-in"
      authResponseHeaders: "Authorization"
```

The extended-monitoring module

> The module lifecycle stage: General Availability
> The module has requirements for installation

The `extended-monitoring` module extends cluster monitoring capabilities with additional Prometheus exporters, which allow you to identify potential problems before they affect the operation of services.

Module features:

- Advanced Metrics Collection — collects additional metrics, and also includes ready-made alerts and dashboards that allow you to detect and diagnose incidents faster:
  - collects and expounds metrics for free space and inodes on nodes, as well as for objects with a label `extended-monitoring.deckhouse.io/enabled =""` in the namespace;
  - automatically generates alerts when the thresholds are reached.
- Container image monitoring:
  - adds metrics and sends alerts about unavailability of container images to registry for all types of workload (`Deployments`, `StatefulSets`, `DaemonSets`, `CronJobs`);
  - helps to find out in advance about possible problems with launching or updating pods.
- Cluster Events — collects Kubernetes events and displays them as metrics, which allows you to track the dynamics of changes and respond faster to incidents:
- Certificate control:
  - scans the cluster's Secrets and generates metrics about the expiration of x509 certificates;
  - allows you not to miss critical moments and update certificates on time, avoiding application downtime due to expired certificates.

Configuration

> The module lifecycle stage: General Availability
> The module has requirements for installation

How to use `extended-monitoring-exporter`

Attach the `extended-monitoring.deckhouse.io/enabled` label to the Namespace to enable the export of extended monitoring metrics. You can do it by:

- adding the appropriate helm-chart to the project (recommended method);
- adding it to `.gitlab-ci.yml` (kubectl patch/create);
- attaching it manually (`d8 k label namespace my-app-production extended-monitoring.deckhouse.io/enabled=""`).
- configuring via namespace-configurator module.

Any of the methods above would result in the emergence of the default metrics (+ any custom metrics with the `threshold.extended-monitoring.deckhouse.io/` prefix) for all supported Kubernetes objects in the target namespace. Note that monitoring is enabled automatically for a number of non-namespaced Kubernetes objects described below.

You can also add custom labels with the specified value to `threshold.extended-monitoring.deckhouse.io/something` Kubernetes objects, e.g., `d8 k label pod test threshold.extended-monitoring.deckhouse.io/disk-inodes-warning=30`. In this case, the label value will replace the default one.

If you want to override the default thresholds for all objects in a namespace, you can set the `threshold.extended-monitoring.deckhouse.io/` label at the namespace level. For example: `d8 k label namespace my-app-production threshold.extended-monitoring.deckhouse.io/5xx-warning=20` This will replace the default value for all objects in the namespace that do not already have this label set.

You can disable monitoring on a per-object basis by adding the `extended-monitoring.deckhouse.io/enabled=false` label to it. Thus,

the default labels will also be disabled (as well as label-based alerts).

Standard labels and supported Kubernetes objects

Below is the list of labels used in Prometheus Rules and their default values.

Note, that all the labels start with the `threshold.extended-monitoring.deckhouse.io/` prefix. The value specified in a label is a number that sets the alert trigger threshold.

For example, the label `threshold.extended-monitoring.deckhouse.io/5xx-warning: "5"` on the Ingress resource changes the alert threshold from 10% (default) to 5%.

Non-namespaced Kubernetes objects

Non-namespaced Kubernetes objects do not need labels on the namespace, and monitoring on them is enabled by default when the module is enabled.

Node

Label	Type	Default value
disk-bytes-warning	int (percent)	70
disk-bytes-critical	int (percent)	80
disk-inodes-warning	int (percent)	90
disk-inodes-critical	int (percent)	95
load-average-per-core-warning	int	3
load-average-per-core-critical	int	10

Caution! These labels **do not** apply to `imagefs` (`/var/lib/docker` by default) and `nodefs` (`/var/lib/kubelet` by default) volumes. The thresholds for these volumes are configured completely automatically according to the kubelet's eviction thresholds. The default values are available here; for more info, see the exporter.

Namespaced Kubernetes objects

Pod

Label	Type	Default value
disk-bytes-warning	int (percent)	85
disk-bytes-critical	int (percent)	95
disk-inodes-warning	int (percent)	85
disk-inodes-critical	int (percent)	90

Ingress

Label	Type	Default value
5xx-warning	int (percent)	10
5xx-critical	int (percent)	20

Deployment

Label	Type	Default value
replicas-not-ready	int (count)	0

The threshold implies the number of unavailable replicas **in addition** to maxUnavailable. This threshold will be triggered if the number of unavailable replicas is greater than `maxUnavailable` by the amount specified. Suppose `replicas-not-ready` is 0. In this case, the threshold will be triggered if the number of unavailable replicas is greater than `maxUnavailable`. If `replicas-not-ready` is set to 1, then the threshold will be triggered if the number of unavailable replicas is greater than `maxUnavailable` + 1. This way, you can fine-tune this parameter for specific Deployments (that may be unavailable) in the namespace with the extended monitoring enabled to avoid getting excessive alerts.

StatefulSet

Label	Type	Default value
replicas-not-ready	int (count)	0

The threshold implies the number of unavailable replicas **in addition** to maxUnavailable (see the comments on Deployment).

DaemonSet

Label	Type	Default value
replicas-not-ready	int (count)	0

The threshold implies the number of unavailable replicas **in addition** to maxUnavailable (see the comments on Deployment).

CronJob

Note that only the deactivation using the `extended-monitoring.deckhouse.io/enabled=false` label is supported.

How does it work?

The module exports specific Kubernetes object labels to Prometheus. It allows you to improve Prometheus rules by adding the thresholds for triggering alerts. Using metrics that this module exports, you can, e.g., replace the “magic” constants in rules.

Before:

```
(
  kube_statefulset_status_replicas - kube_statefulset_status_replicas_ready
)
> 1
```

After:

```
(
  kube_statefulset_status_replicas - kube_statefulset_status_replicas_ready
)
> on (namespace, statefulset)
(

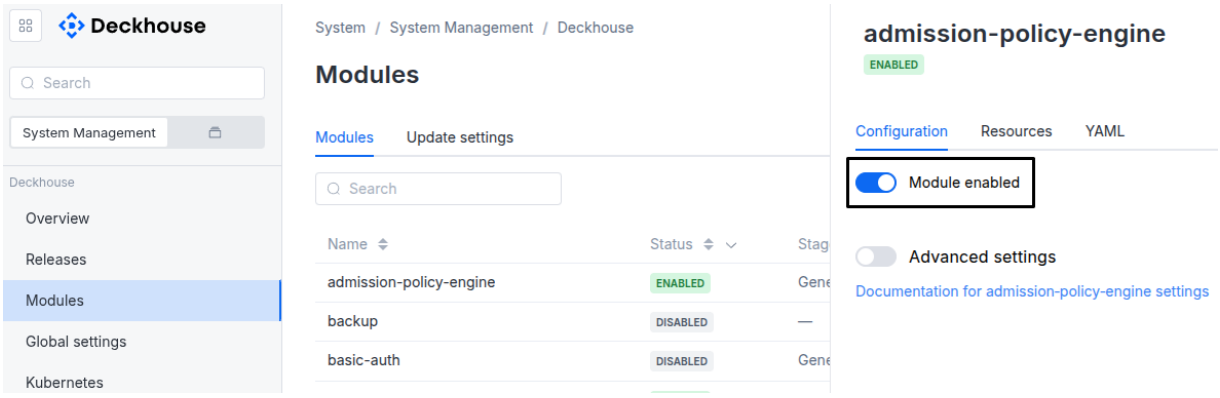
)
```



The module has 58 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `extended-monitoring` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

  ```
  d8 system module enable extended-monitoring
  ```

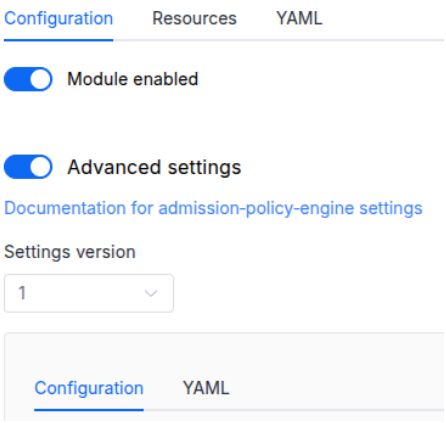
- **Using ModuleConfig `extended-monitoring`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `extended-monitoring` (create it if necessary);

  Example of a manifest to enable module `extended-monitoring`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: extended-monitoring
  spec:
    enabled: true
  ```

How to configure the module...



You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `extended-monitoring` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML

format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `extended-monitoring` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `extended-monitoring`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `extended-monitoring` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc extended-monitoring
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `extended-monitoring` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `extended-monitoring`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: extended-monitoring
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `prometheus`: any version.

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  If the `.imageAvailability.skipRegistryCertVerification` field is set to `true`, add `.imageAvailability.registry.tlsConfig.insecureSkipVerify=true`. Then, delete the `skipRegistryCertVerification` field from the object. If the `.imageAvailability` object becomes empty after this change, delete it.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.certificates**
    object

    Settings for monitoring the certificates in the Kubernetes cluster.

    - **settings.certificates.exporterEnabled**
      boolean

      Enables x509-certificate-exporter.

      Default: `false`

- **settings.events**
  object

  Settings for monitoring the events in the Kubernetes cluster.

  - **settings.events.exporterEnabled**
    boolean

    Enables eventsExporter.

    Default: `false`

  - **settings.events.severityLevel**
    string

    Whether to expose only crucial events.

    Default: `OnlyWarnings`

    Allowed values: `All`, `OnlyWarnings`

- **settings.imageAvailability**
  object

  Settings for monitoring the availability of images in the cluster.

  - **settings.imageAvailability.defaultRegistry**
    string

    Default registry to use when an image name is not fully qualified.

    If not set, index.docker.io is used by default.

    Default: `index.docker.io`

  - **settings.imageAvailability.exporterEnabled**
    boolean

    Enables imageAvailabilityExporter.

    Default: `true`

  - **settings.imageAvailability.forceCheckDisabledControllers**
    array of strings

    A list of controller kinds for which image is forcibly checked, even when workloads are disabled or suspended.

    Specify `All` to check all controller kinds.

    Example:

    ```
    forceCheckDisabledControllers:
    - Deployment
    - StatefulSet
    ```

    - **Element of the array**
      string

      Allowed values: `Deployment`, `StatefulSet`, `DaemonSet`, `CronJob`, `All`

  - **settings.imageAvailability.ignoredImages**
    array of strings

    A list of images to ignore when checking the presence in the registry, e.g., `alpine:3.12` or `quay.io/test/test:v1.1`.

    Example:

    ```
    ignoredImages:
    - alpine:3.10
    - alpine:3.2
    ```

  - **settings.imageAvailability.imageCheckInterval**
    string

    Interval for checking container registries for image availability.

    Supports Go-style duration format (e.g. “10s”, “10m”, “10h”).

    If not specified, the default value is “60s”.

    Default: `60s`

  - **settings.imageAvailability.mirrors**
    array of objects

    List of mirrors for container registries.

    Example:

    ```
    mirrors:
    - original: docker.io
      mirror: mirror.gcr.io
    - original: internal-registry.com
      mirror: mirror.internal-registry.com
    ```

    - **settings.imageAvailability.mirrors.mirror**
      string

      Required value

        - **settings.imageAvailability.mirrors.original**
          string

          Required value

    - **settings.imageAvailability.registry**
      object

      Connection settings for container registry.

      - **settings.imageAvailability.registry.scheme**
        string

        Container registry access scheme.

        Default: `HTTPS`

        Allowed values: `HTTP`, `HTTPS`

      - **settings.imageAvailability.registry.tlsConfig**
        object

        Connection settings for container registry.

        - **settings.imageAvailability.registry.tlsConfig.ca**
          string

          Root CA certificate to validate the container registry's HTTPS certificate (if self-signed certificates are used).

        - **settings.imageAvailability.registry.tlsConfig.insecureSkipVerify**
          boolean

          Whether to skip the verification of the container registry certificate.

          Default: `false`

  - **settings.nodeSelector**
    object

    The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations**
    array of objects

    The same as in the pods' `spec.tolerations` parameter in Kubernetes;

    If the parameter is omitted or `false`, it will be determined automatically.

    - **settings.tolerations.effect**
      string
    - **settings.tolerations.key**
      string
    - **settings.tolerations.operator**
      string
    - **settings.tolerations.tolerationSeconds**
      integer
    - **settings.tolerations.value**
      string

The extended monitoring module: FAQ

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

How to switch to HTTP instead of HTTPS checks of my registry?

To change the protocol used for checking your container registry from HTTPS to HTTP, change the `settings.imageAvailability.registry.scheme` parameter in the module configuration.

For detailed instructions, please refer to the module configuration documentation.

The ingress-nginx module

> **i** The module lifecycle stage: General Availability

Installs and manages the Ingress NGINX Controller using custom resources. The module installs the Ingress NGINX Controller in the HA mode if there is more than one node. In doing so, it takes into account all the aspects of cloud and bare-metal infrastructure and various types of Kubernetes clusters.

The module supports running and configuring several Ingress NGINX Controllers simultaneously (one of the controllers is the **primary** one; you can create any number of **additional** controllers). This approach allows you to separate extranet and intranet Ingress resources of applications.

> **i** In 2025, Ingress NGINX was placed in maintenance mode, with no plans for active development of new features. Further evolution of inbound traffic load balancing in Kubernetes is focused on the Gateway API.
>
> This does not apply to the module as part of Deckhouse Kubernetes Platform: the module is maintained by the Deckhouse team, including security updates. For details, see Module support and security.

Current nginx version is 1.30.3.

Traffic routing

Traffic to `ingress-nginx` can be routed in several ways:

- Directly without the use of an external load balancer
- Using an external LoadBalancer; the following LB varieties are supported:
  - Qrator
  - Cloudflare
  - AWS LB
  - GCE LB
  - ACS LB
  - Yandex LB
  - OpenStack LB

Supported Protocols

The module allows the following protocols to be used for receiving and further routing traffic:

- HTTP/HTTPS: The primary traffic routing protocol. You can select between HTTP/1.1, HTTP/2, and HTTP/3 versions;
- WebSocket: Supported natively by nginx without additional user configuration;
- gRPC: Supported; requires applying the annotation;
- FCGI: Supported; requires applying the annotation;
- Proxy Protocol: Support for receiving Proxy Protocol traffic is provided through the use of the corresponding inlets;
- SSL Passthrough: End-to-end SSL traffic routing is supported via the corresponding inlets.

Currently, our `ingress-nginx` implementation does not support TCP/UDP traffic routing (`tcp-services/udp-services` functionality). To route TCP/UDP traffic, we recommend using the native Kubernetes NodePort Service or consider using `alb` module to route traffic using Gateway API approach (available since DKP 1.76 version).

Using HTTPS

The module allows you to manage HTTPS security policies for each Ingress NGINX Controller, including:

- HSTS parameters;
- Available SSL/TLS versions and encryption protocols.

By default controllers of all versions use TLSv1.2 and TLSv1.3 with the option to configure legacy versions. In case of using TLSv1.2 the following protocols are used:

- Key Exchange: ECDHE, DHE;
- Authentication: ECDSA, RSA;
- Encryption (AEAD): AES-GCM (128/256), ChaCha20-Poly1305;
- Integrity (MAC): SHA256, SHA384.

When using TLSv1.3 the available cipher suites are defined by the OpenSSL library (version 3.3.3+).

The `ingress-nginx` module is integrated with with the `cert-manager` module. Thus, it can request SSL certificates automatically and pass them to Ingress NGINX Controllers for further use.

Monitoring and statistics

Our Ingress Nginx implementation has a Prometheus-based system for collecting statistical data built-in. It uses a variety of metrics based on:

- The overall and upstream response time
- Response codes
- Number of repeated requests (retries)
- Request and response sizes
- Request methods
- `content-types`
- Geography of requests, and others

The data can be grouped by the:

- `namespace`
- `vhost`
- `ingress` resource
- `location` (in nginx)

The graphs are collected in convenient dashboards in Grafana, and there is a drill-down option for graphs. For example, when viewing namespace statistics, you can click a link to a dashboard in Grafana and drill down into the `vhosts` statistics in the corresponding `namespace`.

Statistics

Basic principles of collecting statistics

1. The module is called for each request (at the `log_by_lua_block` stage). It calculates the necessary data and forwards it to the buffer (each nginx worker has its own buffer).
2. For every nginx worker at the `init by lua block` stage, the process is run that asynchronously sends data in the `protobuf` format over a tcp socket to `protobuf_exporter` (DKP development) once a second.
3. `protobuf_exporter` runs as a sidecar container in the ingress-controller's Pod. It receives messages in the protobuf format, parses them, aggregates them according to the specified rules, and exports them in the Prometheus format.
4. Every 30 seconds, Prometheus scrapes both the ingress-controller (since it exports some of the required metrics) and protobuf_exporter. Then these data are used for stats.

What information does Prometheus collect, and in what form?

All the collected metrics have service labels that allow you to identify the controller's instance: `controller`, `app`, `instance`, and `endpoint` (displayed in `/prometheus/targets`).

- All metrics (except for geo) exported by protobuf_exporter have three levels of detail:
  - `ingress_nginx_overall_*` — the "bird's-eye view"; all the metrics have `namespace`, `vhost`, and `content_kind` labels attached;
  - `ingress_nginx_detail_*` — — in addition to the `overall` level labels, `ingress`, `service`, `service_port` and `location` are added;

    - `ingress_nginx_detail_backend_*` — some detailed data; they are collected on a per-backend basis. The `pod_ip` label is added to those listed for the detail level.
- The following metrics are collected for the overall and detail levels:
    - `* requests total` — the total number of requests (additional labels: `scheme`, `method`);
    - `* responses total` — the total number of responses (additional labels: `status`);
    - `*_request_seconds_{sum,count,bucket}` — histogram of the response time;
    - `*_bytes_received_{sum,count,bucket}` — histogram of the request size;
    - `* bytes sent {sum,count,bucket}` — histogram of the response size;
    - `*_upstream_response_seconds_{sum,count,bucket}` — histogram of the upstream response time (the sum of the response times of all upstreams is used if several of them are present);
    - `*_lowres_upstream_response_seconds_{sum,count,bucket}` — the same as above but less detailed (it is suitable for visualization, but not at all for calculating quantiles);
    - `*_upstream_retries_{count,sum}` — the number of requests for which retries were sent to backends, and the number of retries;
- The following metrics are collected for the overall level:
    - `*_geohash_total` — the total number of requests with a specific geohash (additional labels: `geohash`, `place`);
- The following metrics are collected for the detail_backend level:
    - `*_lowres_upstream_response_seconds` — same as a similar metric for overall and detail;
    - `*_responses_total` — the total number of responses (additional labels: `status_class` instead of `status`);
    - `*_upstream_bytes_received_sum` — the sum of the backend's response sizes.

Module support and security

The `ingress-nginx` module is covered by Deckhouse Kubernetes Platform maintenance for the entire platform support lifecycle, regardless of the upstream project's development status. The Deckhouse team tracks CVEs in the controller and its dependencies — NGINX, Lua modules, and base images — and delivers fixes in platform releases. For compliance with PCI DSS expectations regarding vendor support and vulnerability remediation timelines, Flant is the responsible vendor of the module.

Third-party components

List of third-party software used in the `ingress-nginx` module:

- Ingress NGINX Controller 1.10.4

  License: Apache License 2.0

  A ingress controller for Kubernetes using NGINX as a reverse proxy and load balancer.

- Ingress NGINX Controller 1.12.1

  License: Apache License 2.0

  A ingress controller for Kubernetes using NGINX as a reverse proxy and load balancer.

- Ingress NGINX Controller 1.14.4

  License: Apache License 2.0

  A ingress controller for Kubernetes using NGINX as a reverse proxy and load balancer.

- nlohmannJson 3.11.3

  License: MIT License

  JSON for Modern C++

- ModSecurity 3.0.14

  License: Apache License 2.0

  ModSecurity is an open source, cross platform web application firewall (WAF) engine for Apache, IIS and Nginx.

- OWASP CRS 4.10.0

  License: Apache License 2.0

  The OWASP CRS is a set of generic attack detection rules for use with ModSecurity or compatible web application firewalls.

- OpenKruise 898dc482a0cbf4fa0db214f952319aa5e1229152

  License: Apache License 2.0

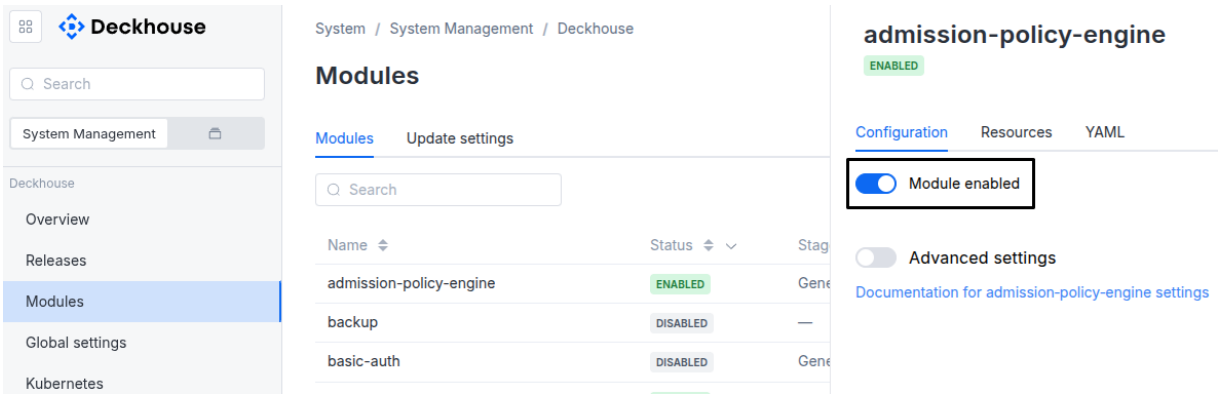
  OpenKruise is an extended component suite for Kubernetes, which mainly focuses on application automations, such as deployment, upgrade, ops and availability protection.

Configuration

> **i** The module lifecycle stage: General Availability

> **i** Pay attention to the global parameter publicDomainTemplate, if you are turning the module on. If the parameter is not specified, the Ingress resources for DKP service components (dashboard, user-auth, grafana, upmeter, etc.) will not be created.

Ingress controllers are configured using the IngressNginxController Custom Resource.



The module has 14 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `ingress-nginx` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

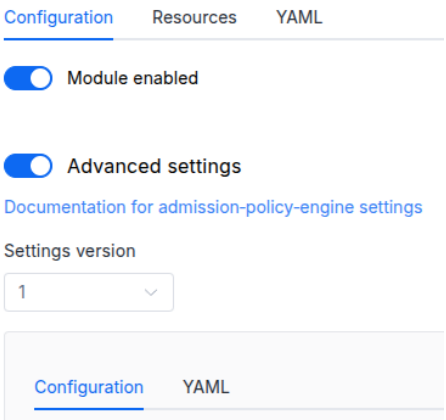
  ```
  d8 system module enable ingress-nginx
  ```

- **Using ModuleConfig `ingress-nginx`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `ingress-nginx` (create it if necessary);

  Example of a manifest to enable module `ingress-nginx`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: ingress-nginx
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `ingress-nginx` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `ingress-nginx` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `ingress-nginx`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `ingress-nginx` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc ingress-nginx
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `ingress-nginx` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

Example of a manifest for ModuleConfig `ingress-nginx`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: ingress-nginx
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.defaultControllerVersion**
    string

    The version of the ingress-nginx controller that is used for all controllers by default if the `controllerVersion` parameter is omitted in the IngressNginxController CR.

    Default: `1.10`

    Allowed values: `1.10`, `1.12`, `1.14`
  - **settings.highAvailability**
    boolean

    Manually enable the high availability mode.

    By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

    Example:

    ```
    highAvailability: true
    ```
  - **settings.storageClass**
    string

    The name of the StorageClass to use for storing GeoIP databases (the `geoproxy` StatefulSet).

    If omitted, the StorageClass of the existing PVC is used. If there is no PVC yet, the StorageClass will be chosen according to the global storageClass parameter.

    The global `storageClass` parameter is only considered when the module is enabled. Changing it while the module is enabled will not trigger automatic disk re-provisioning.

    If `false` is specified, `emptyDir` will be used.

    Examples:

    ```
    storageClass: ceph-ssd
    ```

    ```
    storageClass: 'false'
    ```

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

IngressNginxController

Scope: Cluster

- v1
- v1alpha1

- **status**
  object
  - **status.loadBalancer**
    object
    - **status.loadBalancer.hostname**
      string

      Hostname of the load balancer.
    - **status.loadBalancer.ip**
      string

      IP address of the load balancer.

- **spec**
  object

Required value

- **spec.acceptRequestsFrom**
  array of strings

  List of IP addresses in the CIDR format that are allowed accessing the load balancer.

  Regardless of the inlet type, the address to be verified (the `original_address` field in logs) is always the original IP address the connection is established from and not the client address that can be passed in some inlets via headers or using the proxy protocol.

  This parameter is implemented using the map module. If the original address is not allowed, nginx closes the connection, returning the code `444`.

  > **i** By default, the controller can be connected to from any address.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.additionalHeaders**
  object

  Additional headers to add to all requests. Use the `key: value(string)` format.

- **spec.additionalLogFields**
  object

  Additional fields to add to nginx logs. Use the `key: value(string)` format.

- **spec.annotationValidationEnabled**
  boolean

  Enables validation for Ingress rule annotations.

  Default: `false`

- **spec.chaosMonkey**
  boolean

  Tool for unexpected and random termination of Ingress controller Pods in a systemic manner.

  Intended for testing the fault tolerance of the Ingress controller.

  Default: `false`

- **spec.config**
  object

  Section of the Ingress controller parameters where you can add any supported option in the `key: value(string)` format.

  > **i** An error in options may lead to the failure of the Ingress controller.
  >
  > Be careful when using this parameter, as backward compatibility or stability of the target Ingress controller are not guaranteed.

- **spec.controllerLogLevel**
  string

  Defines the verbosity level for the Ingress controller logs.

  Default: `Info`

  Allowed values: `Error` — Only critical errors will be logged.
  `Warn` — Warnings and errors will be logged.
  `Info` — Informational messages, including basic debugging information.
  `Extended` — Extended information about changes in system state.
  `Debug` — Verbose debugging output, potentially very noisy.
  `Trace` — Trace-level logs with detailed step-by-step context.

- **spec.controllerPodsAdditionalAnnotations**
  object

  Additional custom annotations for Ingress controller pods.

  > **i** Be careful when using this parameter, as backward compatibility or stability of the target Ingress controller are not guaranteed.

- **spec.controllerVersion**
  string

  Ingress NGINX Controller version.

  By default, the version set in the module settings is used.

  Allowed values: `1.10`, `1.12`, `1.14`

- **spec.customErrors**
  object

  Section with parameters for HTTP error customization.

> **i** If this section is defined in the configuration, all its parameters are required.
>
> Changing any parameter causes the restart of all Ingress NGINX Controllers.

- **spec.customErrors.codes**
  array of strings

  Required value

  List of response codes (array) causing redirection to the custom backend.

  - **Element of the array**
    string

    Pattern: `^[1-5][0-9][0-9]$`

- **spec.customErrors.namespace**
  string

  Required value

  Name of a namespace keeping the service used as a default custom backend.

  Example:

  ```
  namespace: default
  ```

- **spec.customErrors.serviceName**
  string

  Required value

  Name of a service to be used as a default custom backend.

  Example:

  ```
  serviceName: custom-errors-backend-service
  ```

- **spec.defaultSSLCertificate**
  object

  The certificate that is used:

  - For `catch-all` server requests (here, “catch-all server” refers to the nginx server directive. Requests without a corresponding Ingress resource end up on the `catch-all` server.
  - For Ingress resources that do not have a `secretName` specified in the `tls` section.

  By default, a self-signed certificate is used.

  > **i** **Caution.** This parameter does not affect certificates used in the Ingress resources of the Deckhouse modules. To specify the certificate to use in the Ingress resources of Deckhouse modules, use the global parameter `modules.https.customCertificate`.

  - **spec.defaultSSLCertificate.secretRef**
    object

    Link to the Secret for passing to the Ingress controller.

    - **spec.defaultSSLCertificate.secretRef.name**
      string

      Name of Secret containing the SSL certificate.

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    - **spec.defaultSSLCertificate.secretRef.namespace**
      string

      Name of the namespace containing the Secret with the SSL certificate.

      Default: `d8-ingress-nginx`

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **spec.disableHTTP2**
  boolean

  Disables HTTP/2 support.

  Default: `false`

- **spec.enableHTTP3**
  boolean

  Enables HTTP/3 support.

  > **i** HTTP/3 cannot be enabled when the inlet is set to `HostPortWithProxyProtocol` or `LoadBalancerWithProxyProtocol`.
  >
  > For the `HostWithFailover` inlet, HTTP/3 is applied only to the primary controller; the failover controller always runs without HTTP/3.

  Default: `false`

- **spec.enableIstioSidecar**
  boolean

Attaches annotations to the controller pods to automatically inject Istio sidecar containers.

After setting this parameter, the `sidecar.istio.io/inject: "true"` and `traffic.sidecar.istio.io/includeOutboundIPRanges: "<Service CIDR>"` annotations will be attached to the Ingress controller pods. When these pods are created, Istio sidecars will be automatically added to them via a mutating webhook. After that, the sidecar will intercept all traffic directed to the Service CIDR.

To use this feature, add the following annotations to your Ingress resources:

- `nginx.ingress.kubernetes.io/service-upstream: "true"`: Using this annotation, the Ingress controller sends requests to a service ClusterIP (from Service CIDR) instead of sending them to the application pods. The `istio-proxy` sidecar only intercepts traffic directed to Service CIDR, while the remaining requests are sent directly.
- `nginx.ingress.kubernetes.io/upstream-vhost: myservice.myns.svc`: Using this annotation, the sidecar can identify the application service that serves requests.

> **i** **Caution.** This parameter cannot be enabled if the Ingress controller inlet is set to `HostWithFailover`.

- **spec.geoIP2**
  object

  GeoIP2 activation options.

  - **spec.geoIP2.maxmindAccountID**
    integer

    MaxMind Account ID used to authenticate GeoIP2 database downloads.

    Required when `licenseKey` is set. If `accountID` parameter is provided, downloads are performed using the official library `geoipupdate`, which allows you to skip unchanged updates and save the license limit. [https://github.com/maxmind/geoipupdate]

    Allowed values: `1 <= X`

  - **spec.geoIP2.maxmindEditionIDs**
    array of strings

    List of database revisions to download at startup.

    For details on GeoLite databases, refer to the MaxMind blog article.

    Default: `["GeoLite2-City","GeoLite2-ASN"]`

    - **Element of the array**
      string

      Allowed values: `GeoIP2-Anonymous-IP`, `GeoIP2-Country`, `GeoIP2-City`, `GeoIP2-Connection-Type`, `GeoIP2-Domain`, `GeoIP2-ISP`, `GeoIP2-ASN`, `GeoLite2-ASN`, `GeoLite2-Country`, `GeoLite2-City`

  - **spec.geoIP2.maxmindLicenseKey**
    string

    License key to download the GeoIP2 database.

    If the key is set in the configuration, the module downloads the GeoIP2 database every time the controller is started. For details on obtaining a key, refer to the MaxMind blog article.

  - **spec.geoIP2.maxmindMirror**
    object

    Mirror configuration for downloading GeoIP databases. If no parameter is specified or the parameter has an empty value, the default value will be used, which is `https://download.maxmind.com`.

    If this mirror is used to host preloaded archives, the `licenseKey` parameter may be omitted.

    - **spec.geoIP2.maxmindMirror.ca**
      string

      Custom CA certificate in PEM format for verifying TLS connections to the mirror.

      Example: —–BEGIN CERTIFICATE—– … —–END CERTIFICATE—–

    - **spec.geoIP2.maxmindMirror.insecureSkipVerify**
      boolean

      Skip TLS certificate verification for the mirror, for example when using self-signed certificates.

    - **spec.geoIP2.maxmindMirror.url**
      string

      Required value

      The URL for downloading GeoIP databases.

      Pattern: `^https?://.+$`

      Examples:

      ```
      url: https://mirror.local
      ```

      ```
      url: absolute path https://mirror.local/GeoLite2-City.tar.gz
      ```

- **spec.hostPort**
  object

  Section of the `HostPort` inlet parameters.

  - **spec.hostPort.acceptClientIPHeadersFrom**
    array of strings

    Defines a list of trusted CIDR ranges that are known to send correct `X-Forwarded-*/ProxyProtocol` headers.

Default: `["0.0.0.0/0"]`

Example:

```
acceptClientIPHeadersFrom:
- 192.168.0.0/24
```

- **Element of the array**
  string

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.hostPort.behindL7Proxy**
  boolean

  Enables processing and passing of the incoming `X-Forwarded-*` headers.

  > **Caution.** Before using that option, ensure that requests to the Ingress come from trusted sources only. To set restrictions, use the `acceptRequestsFrom` parameter.

- **spec.hostPort.httpPort**
  integer

  Port for insecure HTTP connections.

  If the parameter is not set, HTTP connections cannot be established.

  > This parameter is required if `httpsPort` is not set.

  Example:

  ```
  httpPort: 80
  ```

- **spec.hostPort.httpsPort**
  integer

  Port for secure HTTPS connections.

  If the parameter is not set, HTTPS connections cannot be established.

  > This parameter is required if `httpPort` is not set.

  Example:

  ```
  httpsPort: 443
  ```

- **spec.hostPort.realIPHeader**
  string

  The header for identifying the original IP address of a client.

  > This option works only if `behindL7Proxy` is enabled.

  Default: `X-Forwarded-For`

  Example:

  ```
  realIPHeader: CF-Connecting-IP
  ```

- **spec.hostPortWithProxyProtocol**
  object

  Section of the `HostPortWithProxyProtocol` inlet parameters.

  - **spec.hostPortWithProxyProtocol.acceptClientIPHeadersFrom**
    array of strings

    Defines a list of trusted CIDR ranges that are known to send correct `X-Forwarded-*`/`ProxyProtocol` headers.

    Default: `["0.0.0.0/0"]`

    Example:

    ```
    acceptClientIPHeadersFrom:
    - 192.168.0.0/24
    ```

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **spec.hostPortWithProxyProtocol.httpPort**
    integer

    Port for insecure HTTP connections.

If the parameter is not set, HTTP connections cannot be established.

> **i** This parameter is required if `httpsPort` is not set.

Example:

```
httpPort: 80
```

- **spec.hostPortWithProxyProtocol.httpsPort**
  integer

  Port for secure HTTPS connections.

  If the parameter is not set, HTTPS connections cannot be established.

  > **i** This parameter is required if `httpPort` is not set.

  Example:

  ```
  httpsPort: 443
  ```

- **spec.hostPortWithSSLPassthrough**
  object

  Section of the `HostPortWithSSLPassthrough` inlet parameters.

  - **spec.hostPortWithSSLPassthrough.httpPort**
    integer

    Port for insecure HTTP connections.

    If the parameter is not set, HTTP connections cannot be established.

    > **i** This parameter is required if `httpsPort` is not set.

    Example:

    ```
    httpPort: 80
    ```

  - **spec.hostPortWithSSLPassthrough.httpsPort**
    integer

    Port for secure HTTPS connections.

    If the parameter is not set, HTTPS connections cannot be established.

    > **i** This parameter is required if `httpPort` is not set.

    Example:

    ```
    httpsPort: 443
    ```

- **spec.hsts**
  boolean

  Enables HTTP Strict-Transport-Security (HSTS) response headers. For details on HSTS headers, refer to the MDN Web Docs article.

  Default: `false`

- **spec.hstsOptions**
  object

  HSTS parameters.

  - **spec.hstsOptions.includeSubDomains**
    boolean

    Applies HSTS parameters to all subdomains of a website.

    Default: `false`

  - **spec.hstsOptions.maxAge**
    string

    Time in seconds during which the browser remembers that the website is only accessible via HTTPS.

    Default: `31536000`

    Pattern: `^[1-9][0-9]*$`

    Example:

    ```
    maxAge: '31536000'
    ```

  - **spec.hstsOptions.preload**
    boolean

    Adds a website to the preload list.

The list instructs browsers to establish connections to the specified websites over HTTPS only.

Default: `false`

- **spec.ingressClass**
  string

  Name of the Ingress class to use with the Ingress NGINX Controller.

  Using this option, you can create several controllers to use with a single Ingress class.

  > **i** If you set it to `nginx`, Ingress resources without the `kubernetes.io/ingress.class` annotation or the `spec.ingressClassName` field will be handled as well.

  Default: `nginx`

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  ingressClass: nginx
  ```

- **spec.inlet**
  string

  Required value

  The way external traffic is routed to the cluster. Once you set the method, you cannot change it later.

  Allowed values:

  - `LoadBalancer`: The Ingress controller is deployed, and a `LoadBalancer`-type service is provisioned.
  - `LoadBalancerWithProxyProtocol`: The Ingress controller is deployed, and a `LoadBalancer`-type service is provisioned. The Ingress controller uses the proxy-protocol to get a real IP address of the client.

    > **i** **Note.** HTTP/3 (`enableHTTP3`) cannot be enabled with this inlet because QUIC is incompatible with PROXY protocol.

  - `LoadBalancerWithSSLPassthrough`: The Ingress controller is deployed, and a `LoadBalancer`-type service is provisioned. This option enables the SSL Passthrough feature, allowing backends to be configured to accept SSL traffic directly without termination at the Ingress controller.

    > **i** The SSL Passthrough feature is implemented by intercepting all traffic on the configured HTTPS port (default: `443`) and routing it to a local TCP proxy. This implementation bypasses nginx completely and introduces a significant performance penalty.

    The SSL Passthrough protocol leverages Server Name Indication (SNI) and reads the virtual domain data from the TLS handshake protocol, which requires a compatible client.

    If the host name doesn't match the requested host name, the request is forwarded to NGINX on the configured SSL Passthrough proxy port (default: `442`), which subsequently proxies the request to the default backend.

    > **i** Unlike HTTP backends, traffic to SSL Passthrough backends is routed to the ClusterIP of the backing service instead of individual endpoints.
    >
    > Since SSL Passthrough works at layer 4 of the OSI model (TCP) and not layer 7 (HTTP), using SSL Passthrough makes it impossible to use other annotations configured on an Ingress object.

  - `HostPort`: The Ingress controller is deployed and made available on node ports via `hostPort`.
  - `HostPortWithProxyProtocol`: The Ingress controller is deployed and made available on node ports via `hostPort`. The Ingress controller uses the proxy-protocol to get a real IP address of the client.

    > **i** **Caution.** When using this inlet, ensure that requests to the Ingress come from trusted sources only. To enforce it, use the `acceptRequestsFrom` parameter.
    >
    > **Note.** HTTP/3 (`enableHTTP3`) cannot be enabled with this inlet because QUIC is incompatible with PROXY protocol.

  - `HostPortWithSSLPassthrough`: The Ingress controller is deployed and made available on node ports via `hostPort`. This option enables the SSL Passthrough feature, allowing backends to be configured to accept SSL traffic directly without termination at the Ingress controller.

    Specify inlet parameters in the `spec.HostPortWithSSLPassthrough` section.

    The SSL Passthrough protocol leverages SNI and reads the virtual domain data from the TLS handshake protocol, which requires a compatible client.

    If the host name doesn't match the requested host name, the request is forwarded to NGINX on the configured SSL Passthrough proxy port (default: `442`), which subsequently proxies the request to the default backend.

> **i** The SSL Passthrough feature is implemented by intercepting all traffic on the configured HTTPS port (default: `443`) and routing it to a local TCP proxy. This implementation bypasses nginx completely and introduces a significant performance penalty.
>
> Unlike HTTP backends, traffic to SSL Passthrough backends is routed to the ClusterIP of the backing service instead of individual endpoints.
>
> Since SSL Passthrough works at layer 4 of the OSI model (TCP) and not layer 7 (HTTP), using SSL Passthrough makes it impossible to use other annotations configured on an Ingress object.

- `HostWithFailover`: Two Ingress controllers are deployed: a primary and a backup. The primary controller runs in a `hostNetwork`. If the primary controller pods are unavailable, traffic is routed to the backup controller.

  > **i** There can be only one controller with this inlet type on a single host.
  >
  > Ensure the following ports are available on the node: `80`, `81`, `443`, `444`, `4207`, `4208`.
  >
  > To change the inlet, remove the iptables rules and restart the `kube-proxy` pods or reboot the nodes hosting Ingress controllers.
  >
  > This inlet cannot be used if the `enableIstioSidecar` parameter is enabled.
  >
  > **Note.** When HTTP/3 (`enableHTTP3`) is enabled, it is applied only to the primary controller; the failover controller always runs without HTTP/3.

Allowed values: `LoadBalancer`, `LoadBalancerWithSSLPassthrough`, `LoadBalancerWithProxyProtocol`, `HostPort`, `HostPortWithSSLPassthrough`, `HostPortWithProxyProtocol`, `HostWithFailover`

- **spec.legacySSL**
  boolean

  Enables outdated versions of the TLS protocol and cipher suites.

  Enables the following TLS protocol versions: `TLSv1`, `TLSv1.1`, `TLSv1.2`, `TLSv1.3`.

  Enables the following combinations of cipher suites in order from the strongest to the weakest: `ECDHE-ECDSA-AES256-GCM-SHA384`, `ECDHE-RSA-AES256-GCM-SHA384`, `ECDHE-ECDSA-CHACHA20-POLY1305`, `ECDHE-RSA-CHACHA20-POLY1305`, `ECDHE-ECDSA-AES128-GCM-SHA256`, `ECDHE-RSA-AES128-GCM-SHA256`, `ECDHE-ECDSA-AES256-SHA384`, `ECDHE-RSA-AES256-SHA384`, `ECDHE-ECDSA-AES128-SHA256`, `ECDHE-RSA-AES128-SHA256`, `ECDHE-ECDSA-AES256-SHA`, `ECDHE-RSA-AES256-SHA`, `ECDHE-ECDSA-AES128-SHA`, `ECDHE-RSA-AES128-SHA`, `AES256-GCM-SHA384`, `AES128-GCM-SHA256`, `AES256-SHA256`, `AES128-SHA256`, `AES256-SHA`, `AES128-SHA`.

  > **i** By default, only `TLSv1.2` and `TLSv1.3` with the newest cipher suites are enabled.

- **spec.loadBalancer**
  object

  Not required value.

  Section of the `LoadBalancer` inlet parameters.

  - **spec.loadBalancer.acceptClientIPHeadersFrom**
    array of strings

    Defines a list of trusted CIDR ranges that are known to send correct `X-Forwarded-*/ProxyProtocol` headers.

    Default: `["0.0.0.0/0"]`

    Example:

    ```
    acceptClientIPHeadersFrom:
    - 192.168.0.0/24
    ```

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **spec.loadBalancer.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

    > **i** The module does not take into account the specifics of setting annotations in different clouds.
    >
    > If annotations for provisioning a load balancer are only applied when creating a service, recreate the IngressNginxController resource to update respective parameters (or create a new resource and then delete the old one).

  - **spec.loadBalancer.behindL7Proxy**
    boolean

    Enables processing and passing of the incoming `X-Forwarded-*` headers.

    > **i** **Caution.** Before using that option, ensure that requests to the Ingress come from trusted sources only.

  - **spec.loadBalancer.httpPort**
    integer

External port for insecure HTTP connections exposed by the provisioned `LoadBalancer` service.

If neither `httpPort` nor `httpsPort` is set, the service exposes the standard ports `80` and `443`. If at least one of these parameters is specified, the service will listen only to explicitly specified ports for the corresponding connection type. For connection types for which no parameter is specified, nothing changes: the standard port is listened to.

> **Caution.** Changing service ports may trigger provider-specific side effects (for example, recreating the LoadBalancer or changing its public IP address). Such behavior depends on the cloud implementation; test it before using it in production.
>
> **Caution.** ACME HTTP-01 challenges (e.g. Let's Encrypt via cert-manager) require the Ingress controller to be reachable on TCP port `80`. If you set `httpsPort` without `httpPort`, or set `httpPort` to a value other than `80`, certificate issuance/renewal may stop working unless you use DNS-01 or forward port `80` to the controller externally.
>
> **Caution.** Many applications (including some Deckhouse module components) form absolute URLs and redirects without an explicit port (assuming standard ports `80/443`). If you expose the Ingress controller on non-standard external ports, users may be redirected to the wrong port and links may be generated incorrectly; prefer using standard ports externally or configure external port forwarding/proxying.

Default: `80`

Allowed values: `1 <= X <= 65535`

- **spec.loadBalancer.httpsPort**
  integer

  External port for secure HTTPS connections exposed by the provisioned `LoadBalancer` service.

  If neither `httpPort` nor `httpsPort` is set, the service exposes the standard ports `80` and `443`. If at least one of these parameters is specified, the service will listen only to explicitly specified ports for the corresponding connection type. For connection types for which no parameter is specified, nothing changes: the standard port is listened to.

  > **Caution.** Changing service ports may trigger provider-specific side effects (for example, recreating the LoadBalancer or changing its public IP address). Such behavior depends on the cloud implementation; test it before using it in production.
  >
  > **Caution.** Many applications (including some Deckhouse module components) form absolute URLs and redirects without an explicit port (assuming standard ports `80/443`). If you set `httpsPort` to a non-standard value, users may be redirected to TCP port `443` and links may be generated incorrectly; prefer using standard ports externally or configure external port forwarding/proxying.

  Default: `443`

  Allowed values: `1 <= X <= 65535`

- **spec.loadBalancer.loadBalancerClass**
  string

  Class of the load balancer for incoming network requests (passed to the `spec.loadBalancerClass` parameter of the provisioned service with the `LoadBalancer` type).

- **spec.loadBalancer.realIPHeader**
  string

  The header for identifying the original IP address of a client.

  > This option works only if `behindL7Proxy` is enabled.

  Default: `X-Forwarded-For`

  Example:

  ```
  realIPHeader: CF-Connecting-IP
  ```

- **spec.loadBalancer.sourceRanges**
  array of strings

  List of IP addresses in the CIDR format that are allowed accessing the load balancer.

  > **Caution.** A cloud provider may not support this option or ignore it.
  >
  > Providers supporting this option: AWS, Azure, GCP. Providers ignoring this option: Yandex Cloud.
  >
  > For other cloud providers, behavior may vary depending on the cloud implementation specifics. Test this option before using it in a production environment.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.loadBalancerWithProxyProtocol**
  object

  Not required value.

  Section of the `LoadBalancerWithProxyProtocol` inlet parameters.

  - **spec.loadBalancerWithProxyProtocol.acceptClientIPHeadersFrom**
    array of strings

Defines a list of trusted CIDR ranges that are known to send correct `X-Forwarded-*`/`ProxyProtocol` headers.

Default: `["0.0.0.0/0"]`

Example:

```
acceptClientIPHeadersFrom:
- 192.168.0.0/24
```

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.loadBalancerWithProxyProtocol.annotations**
  object

  Annotations to assign to the service for flexible configuration of the load balancer.

  > **i**
  >
  > The module does not take into account the specifics of setting annotations in different clouds.
  >
  > If annotations for provisioning a load balancer are only applied when creating a service, recreate the IngressNginxController resource to update respective parameters (or create a new resource and then delete the old one).

- **spec.loadBalancerWithProxyProtocol.httpPort**
  integer

  External port for insecure HTTP connections exposed by the provisioned `LoadBalancer` service.

  If neither `httpPort` nor `httpsPort` is set, the service exposes the standard ports `80` and `443`. If at least one of these parameters is specified, the service will listen only to explicitly specified ports for the corresponding connection type. For connection types for which no parameter is specified, nothing changes: the standard port is listened to.

  > **i**
  >
  > **Caution.** Changing service ports may trigger provider-specific side effects (for example, recreating the LoadBalancer or changing its public IP address). Such behavior depends on the cloud implementation; test it before using it in production.
  >
  > **Caution.** ACME HTTP-01 challenges (e.g. Let’s Encrypt via cert-manager) require the Ingress controller to be reachable on TCP port `80`. If you set `httpsPort` without `httpPort`, or set `httpPort` to a value other than `80`, certificate issuance/renewal may stop working unless you use DNS-01 or forward port `80` to the controller externally.
  >
  > **Caution.** Many applications (including some Deckhouse module components) form absolute URLs and redirects without an explicit port (assuming standard ports `80`/`443`). If you expose the Ingress controller on non-standard external ports, users may be redirected to the wrong port and links may be generated incorrectly; prefer using standard ports externally or configure external port forwarding/proxying.

  Default: `80`

  Allowed values: `1 <= X <= 65535`

- **spec.loadBalancerWithProxyProtocol.httpsPort**
  integer

  External port for secure HTTPS connections exposed by the provisioned `LoadBalancer` service.

  If neither `httpPort` nor `httpsPort` is set, the service exposes the standard ports `80` and `443`. If at least one of these parameters is specified, the service will listen only to explicitly specified ports for the corresponding connection type. For connection types for which no parameter is specified, nothing changes: the standard port is listened to.

  > **i**
  >
  > **Caution.** Changing service ports may trigger provider-specific side effects (for example, recreating the LoadBalancer or changing its public IP address). Such behavior depends on the cloud implementation; test it before using it in production.
  >
  > **Caution.** Many applications (including some Deckhouse module components) form absolute URLs and redirects without an explicit port (assuming standard ports `80`/`443`). If you set `httpsPort` to a non-standard value, users may be redirected to TCP port `443` and links may be generated incorrectly; prefer using standard ports externally or configure external port forwarding/proxying.

  Default: `443`

  Allowed values: `1 <= X <= 65535`

- **spec.loadBalancerWithProxyProtocol.loadBalancerClass**
  string

  Class of the load balancer for incoming network requests (passed to the `spec.loadBalancerClass` parameter of the provisioned service with the `LoadBalancer` type).

- **spec.loadBalancerWithProxyProtocol.sourceRanges**
  array of strings

  List of IP addresses in the CIDR format that are allowed accessing the load balancer.

> **Caution.** A cloud provider may not support this option or ignore it.
>
> Providers supporting this option: AWS, Azure, GCP. Providers ignoring this option: Yandex Cloud.
>
> For other cloud providers, behavior may vary depending on the cloud implementation specifics. Test this option before using it in a production environment.

- **Element of the array**
  string

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.loadBalancerWithSSLPassthrough**
  object

  Not required value.

  Section of the `LoadBalancerWithSSLPassthrough` inlet parameters.

  - **spec.loadBalancerWithSSLPassthrough.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

    > The module does not take into account the specifics of setting annotations in different clouds.
    >
    > If annotations for provisioning a load balancer are only applied when creating a service, recreate the IngressNginxController resource to update respective parameters (or create a new resource and then delete the old one).

  - **spec.loadBalancerWithSSLPassthrough.httpPort**
    integer

    External port for insecure HTTP connections exposed by the provisioned `LoadBalancer` service.

    If neither `httpPort` nor `httpsPort` is set, the service exposes the standard ports `80` and `443`. If at least one of these parameters is specified, the service will listen only to explicitly specified ports for the corresponding connection type. For connection types for which no parameter is specified, nothing changes: the standard port is listened to.

    > **Caution.** Changing service ports may trigger provider-specific side effects (for example, recreating the LoadBalancer or changing its public IP address). Such behavior depends on the cloud implementation; test it before using it in production.
    >
    > **Caution.** ACME HTTP-01 challenges (e.g. Let’s Encrypt via cert-manager) require the Ingress controller to be reachable on TCP port `80`. If you set `httpsPort` without `httpPort`, or set `httpPort` to a value other than `80`, certificate issuance/renewal may stop working unless you use DNS-01 or forward port `80` to the controller externally.
    >
    > **Caution.** Many applications (including some Deckhouse module components) form absolute URLs and redirects without an explicit port (assuming standard ports `80`/`443`). If you expose the Ingress controller on non-standard external ports, users may be redirected to the wrong port and links may be generated incorrectly; prefer using standard ports externally or configure external port forwarding/proxying.

    Default: `80`

    Allowed values: `1 <= X <= 65535`

  - **spec.loadBalancerWithSSLPassthrough.httpsPort**
    integer

    External port for secure HTTPS connections exposed by the provisioned `LoadBalancer` service.

    If neither `httpPort` nor `httpsPort` is set, the service exposes the standard ports `80` and `443`. If at least one of these parameters is specified, the service will listen only to explicitly specified ports for the corresponding connection type. For connection types for which no parameter is specified, nothing changes: the standard port is listened to.

    > **Caution.** Changing service ports may trigger provider-specific side effects (for example, recreating the LoadBalancer or changing its public IP address). Such behavior depends on the cloud implementation; test it before using it in production.
    >
    > **Caution.** Many applications (including some Deckhouse module components) form absolute URLs and redirects without an explicit port (assuming standard ports `80`/`443`). If you set `httpsPort` to a non-standard value, users may be redirected to TCP port `443` and links may be generated incorrectly; prefer using standard ports externally or configure external port forwarding/proxying.

    Default: `443`

    Allowed values: `1 <= X <= 65535`

  - **spec.loadBalancerWithSSLPassthrough.loadBalancerClass**
    string

    Class of the load balancer for incoming network requests (passed to the `spec.loadBalancerClass` parameter of the provisioned service with the `LoadBalancer` type).

  - **spec.loadBalancerWithSSLPassthrough.sourceRanges**
    array of strings

    List of IP addresses in the CIDR format that are allowed accessing the load balancer.

> **Caution.** A cloud provider may not support this option or ignore it.
>
> Providers supporting this option: AWS, Azure, GCP. Providers ignoring this option: Yandex Cloud.
>
> For other cloud providers, behavior may vary depending on the cloud implementation specifics. Test this option before using it in a production environment.

- **Element of the array**
  string

  Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.maxReplicas**
  integer

  Maximum number of `LoadBalancer`, `LoadBalancerWithProxyProtocol` and `LoadBalancerWithSSLPassthrough` replicas for HPA.

  Default: `1`

  Allowed values: `1 <= X`

- **spec.minReplicas**
  integer

  Minimum number of `LoadBalancer`, `LoadBalancerWithProxyProtocol` and `LoadBalancerWithSSLPassthrough` replicas for HPA.

  Default: `1`

  Allowed values: `1 <= X`

- **spec.nginxProfilingEnabled**
  boolean

  Enables NGINX profiling using Valgrind. A memory analysis report is saved to the `/var/log/valgrind` directory on the host. When enabled, Valgrind creates a file named `memcheck.${timestamp}.log`.

  After debugging is complete, don’t forget to disable profiling mode!

  The report contains information about the process behavior, including potential memory leaks.

  > **Caution**. Enabling this option significantly increases memory usage and slows down HTTP/HTTPS request handling by the NGINX process.

  > **Be aware.** When the option is enabled, the ingress-nginx controller pod starts in privileged mode.

- **spec.nodeSelector**
  object

  Same as the `spec.nodeSelector` parameter in Kubernetes Pods.

  If the parameter is omitted or set to `false`, Deckhouse will try to determine the value automatically.

  Use the format of a standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resourcesRequests**
  object

  Maximum amount of CPU and memory resources a Pod can request when selecting a node. If the VPA is disabled, these max values become the default ones.

  - **spec.resourcesRequests.mode**
    string

    Required value

    Resource request management mode.

    Default: `VPA`

    Allowed values: `VPA`, `Static`

  - **spec.resourcesRequests.static**
    object

    Static management mode parameters.

    - **spec.resourcesRequests.static.cpu**
      string

      Value for CPU requests.

      Default: `350m`

    - **spec.resourcesRequests.static.memory**
      string

      Value for memory requests.

      Default: `500Mi`

  - **spec.resourcesRequests.vpa**
    object

    Vertical Pod Autoscaler (VPA) mode parameters.

- **spec.resourcesRequests.vpa.cpu**
  object

  Parameters of CPU request restrictions.

  - **spec.resourcesRequests.vpa.cpu.max**
    string

    Maximum value of allowed CPU requests to be submitted by the VPA.

    Default: `50m`

  - **spec.resourcesRequests.vpa.cpu.min**
    string

    Minimum value of allowed CPU requests to be submitted by the VPA.

    Default: `10m`

- **spec.resourcesRequests.vpa.memory**
  object

  Parameters of memory request restrictions.

  - **spec.resourcesRequests.vpa.memory.max**
    string

    Maximum value of allowed memory requests to be submitted by the VPA.

    Default: `200Mi`

  - **spec.resourcesRequests.vpa.memory.min**
    string

    Minimum value of allowed memory requests to be submitted by the VPA.

    Default: `50Mi`

- **spec.resourcesRequests.vpa.mode**
  string

  VPA usage mode.

  Default: `Initial`

  Allowed values: `Initial`, `Auto`

- **spec.tolerations**
  array of objects

  Same as the `spec.tolerations` parameter in Kubernetes Pods.

  If the parameter is omitted or set to `false`, all the possible tolerations are automatically applied the module's Pods.

  Use the format of a standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string
  - **spec.tolerations.operator**
    string

    Default: `Equal`

    Allowed values: `Exists`, `Equal`

  - **spec.tolerations.tolerationSeconds**
    integer
  - **spec.tolerations.value**
    string
- **spec.underscoresInHeaders**
  boolean

  Enables using the underscore symbol in headers.

  Related resources:

  - On using the underscores in headers.
  - Why you should be careful when enabling underscores in headers .

  Default: `false`

- **spec.validationEnabled**
  boolean

  Enables validation for Ingress rules.

  > **i** **Warning.** Enabling validation increases the load on the master nodes of the cluster.

  Default: `true`

- **spec.waitLoadBalancerOnTerminating**
  integer

  Number of seconds before the `/healthz` endpoint begins returning the `500` code when the pod enters the `Terminating` state.

Deprecated resource. Support for the resource might be removed in a later release.

- **spec**
  object

  Required value

  - **spec.acceptRequestsFrom**
    array of strings

    IP or CIDR that is allowed to access the Ingress controller.

    Regardless of the inlet type, the source IP address gets always verified (the `original_address` field in logs) (the address that the connection was established from) and not the “address of the client” that can be passed in some inlets via headers or using the proxy protocol.

    This parameter is implemented using the map module. If the source address is not in the list of allowed addresses, nginx closes the connection immediately using HTTP code 444.

    By default, the connection to the controller can be made from any address.

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

  - **spec.additionalHeaders**
    object

    Additional headers to add to all request. (map: key (string)).

  - **spec.additionalLogFields**
    object

    Additional fields to add to nginx logs. (map: key (string)).

  - **spec.annotationValidationEnabled**
    boolean

    Enables the annotation validation feature.

    Default: `false`

  - **spec.chaosMonkey**
    boolean

    The instrument for unexpected and random termination of ingress controller Pods in a systemic manner. Chaos Monkey tests the resilience of ingress controller.

    Default: `false`

  - **spec.config**
    object

    The section with the Ingress controller parameters.

    You can specify any supported parameter in it in the `key: value (string)` format.

    > **i** **Caution.** An erroneous option may lead to the failure of the ingress controller;

    > **i** **Caution.** The usage of this parameter is not recommended; the backward compatibility or operability of the ingress controller that uses this option is not guaranteed

  - **spec.controllerVersion**
    string

    One of the supported Ingress NGINX Controller versions.

    By default: the version in the module settings is used.

    Allowed values: `1.10`, `1.12`, `1.14`

  - **spec.customErrors**
    object

    The section with parameters of custom HTTP errors.

    All parameters in this section are mandatory if it is defined. Changing any parameter **leads to the restart of all Ingress NGINX Controllers**.

    - **spec.customErrors.codes**
      array of strings

      Required value

      Error codes which should be redirected to custom errors backend.

      - **Element of the array**
        string

        Pattern: `^[1-5][0-9][0-9]$`

    - **spec.customErrors.namespace**
      string

      Required value

      Namespace of custom errors backend.

      Example:

```
namespace: default
```

- **spec.customErrors.serviceName**
  string

  Required value

  Name of kubernetes service that leads to custom errors backend.

  Example:

  ```
  serviceName: custom-errors-backend-service
  ```

- **spec.defaultSSLCertificate**
  object

  This certificate is used:

  - for `catch-all` server requests (here, “catch-all server” refers to the nginx server directive. Requests for which there is no corresponding Ingress resource end up on the `catch-all` server.
  - for Ingress resources that do not have a `secretName` specified in the `tls` section.

  By default, a self-signed certificate is used.

  > **Caution.** This parameter does not affect certificates used in the Ingress resources of the Deckhouse modules. You can specify the certificate to be used in the Ingress resources of the Deckhouse modules with the modules.https.customCertificate global parameter.

  - **spec.defaultSSLCertificate.secretRef**
    object

    The Secret reference to pass to the Ingress Controller.

    - **spec.defaultSSLCertificate.secretRef.name**
      string

      Name of Secret containing SSL—certificate.

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    - **spec.defaultSSLCertificate.secretRef.namespace**
      string

      Namespace, where the Secret is located.

      Default: `d8-ingress-nginx`

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **spec.disableHTTP2**
  boolean

  Switch off HTTP2 support.

  Default: `false`

- **spec.enableIstioSidecar**
  boolean

  Attach annotations to the controller pods to automatically inject Istio sidecar containers.

  After setting this parameter, the `sidecar.istio.io/inject: "true"` and `traffic.sidecar.istio.io/includeOutboundIPRanges: "<Service CIDR>"` annotations will be attached to the ingress-controller pods. During pod creation, the Istio’s mutating webhook will add the sidecar to it. After that, the sidecar will catch the network traffic to Service CIDR.

  To use this feature in your application, you must add these annotations to your Ingress resources:

  - `nginx.ingress.kubernetes.io/service-upstream: "true"` — using this annotation, the ingress-controller sends requests to a single ClusterIP (from Service CIDR) while envoy load balances them. Istio sidecar containers only catching traffic directed to Service CIDR.
  - `nginx.ingress.kubernetes.io/upstream-vhost: myservice.myns.svc` — using this annotation, the sidecar can identify the application service that serves requests.

  > **Caution.** This parameter cannot be enabled if the Ingress controller inlet is set to `HostWithFailover`.

- **spec.geoIP2**
  object

  Enable GeoIP2 databases.

  - **spec.geoIP2.maxmindEditionIDs**
    array of strings

    A list of database editions to download at startup.

    More info...

    Default: `["GeoLite2-City","GeoLite2-ASN"]`

    - **Element of the array**
      string

      Allowed values: `GeoIP2-Anonymous-IP`, `GeoIP2-Country`, `GeoIP2-City`, `GeoIP2-Connection-Type`, `GeoIP2-Domain`, `GeoIP2-ISP`, `GeoIP2-ASN`, `GeoLite2-ASN`, `GeoLite2-Country`, `GeoLite2-City`

  - **spec.geoIP2.maxmindLicenseKey**

string

A license key to download the GeoIP2 database.

If the key is set, the module downloads the GeoIP2 database every time the controller is started. Click here to learn more about obtaining a license key.

- **spec.hostPort**
  object

  `HostPort` inlet settings.

  - **spec.hostPort.behindL7Proxy**
    boolean

    Accepts all the incoming X-Forwarded-* headers and passes them to upstreams.

    > **Caution.** Make sure that requests to the ingress are sent from trusted sources when using this option. The `acceptRequestsFrom` parameter can help you with defining trusted sources.

  - **spec.hostPort.httpPort**
    integer

    Port for insecure HTTP connections.

    If the parameter is not set, the connection over HTTP cannot be established.

    This parameter is mandatory if `httpsPort` is not set.

    Example:

    ```
    httpPort: 80
    ```

  - **spec.hostPort.httpsPort**
    integer

    Port for secure HTTPS connections.

    If the parameter is not set, the connection over HTTPS cannot be established.

    This parameter is mandatory if `httpPort` is not set.

    Example:

    ```
    httpsPort: 443
    ```

  - **spec.hostPort.realIPHeader**
    string

    Sets the header field for identifying the originating IP address of a client.

    This option works only if `behindL7Proxy` is enabled.

    Default: `X-Forwarded-For`

    Example:

    ```
    realIPHeader: CF-Connecting-IP
    ```

- **spec.hostPortWithProxyProtocol**
  object

  A section of parameters of the `HostPortWithProxyProtocol` inlet.

  - **spec.hostPortWithProxyProtocol.httpPort**
    integer

    Port for insecure HTTP connections.

    If the parameter is not set, the connection over HTTP cannot be established.

    This parameter is mandatory if `httpsPort` is not set.

    Example:

    ```
    httpPort: 80
    ```

  - **spec.hostPortWithProxyProtocol.httpsPort**
    integer

    Port for secure HTTPS connections.

    If the parameter is not set, the connection over HTTPS cannot be established.

    This parameter is mandatory if `httpPort` is not set.

    Example:

    ```
    httpsPort: 443
    ```

- **spec.hsts**
  boolean

  Determines whether hsts is enabled. Read more...).

  Default: `false`

- **spec.hstsOptions**
  object

  Options for HTTP Strict Transport Security.

  - **spec.hstsOptions.includeSubDomains**
    boolean

    If this optional parameter is specified, this rule applies to all of subdomains as well.

    Default: `false`

  - **spec.hstsOptions.maxAge**
    string

    The time, in seconds, that the browser should remember that a site is only to be accessed using HTTPS.

    Default: `31536000`

    Pattern: `^[1-9][0-9]*$`

    Example:

    ```
    maxAge: '31536000'
    ```

  - **spec.hstsOptions.preload**
    boolean

    Add your site to preload list to enforce to use SSL/TLS connections on your site.

    Default: `false`

- **spec.ingressClass**
  string

  The name of the Ingress class to use with the Ingress NGINX Controller.

  Using this option, you can create several controllers to use with a single ingress

  > **Caution.** If you set it to “nginx”, then Ingress resources lacking the `kubernetes.io/ingress.class` annotation or `spec.ingressClassName` field will also be handled.

  Default: `nginx`

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  ingressClass: nginx
  ```

- **spec.inlet**
  string

  Required value

  The way traffic from the external network is routed to the cluster. Once you have set the method, you cannot change it later.

  - `LoadBalancer` — Ingress controller is deployed and the service of `LoadBalancer` type is provisioned.
  - `LoadBalancerWithProxyProtocol` — Ingress controller is deployed and the service of `LoadBalancer` type is provisioned. Ingress controller uses proxy-protocol to get a real IP of the client.
  - `HostPort` — Ingress controller is deployed and available through nodes’ ports via `hostPort`;

    Settings are required in spec.HostPort.

  - `HostPortWithProxyProtocol` — Ingress controller is deployed and available through nodes’ ports via `hostPort, it uses proxy-protocol to get a real IP of the client;

    Settings are required in spec.HostPortWithProxyProtocol.

    > **Caution.** Make sure that requests to the Ingress are sent from trusted sources when using this inlet. The acceptRequestsFrom parameter can help you with defining trusted sources.

  - `HostWithFailover` — installs two ingress controllers, the primary and the backup one. The primary controller runs in a hostNetwork. If the pods of the primary controller are not available, the traffic is routed to the backup one;

    > **Caution.** There can be only one controller with this inlet type on a host.

    > **Caution.** The following ports must be available on the node: 80, 81, 443, 444, 4207, 4208.

    > **Caution.** To change inlet, remove the iptables rules and restart the `kube-proxy` pods or reboot the nodes hosting Ingress controllers.

    > **Caution.** This inlet cannot be used if the `enableIstioSidecar` parameter is enabled.

  Allowed values: `LoadBalancer`, `LoadBalancerWithProxyProtocol`, `HostPort`, `HostPortWithProxyProtocol`, `HostWithFailover`

- **spec.legacySSL**
  boolean

  Enable outdated versions of the TLS protocol and cipher suites.

  Enables the following TLS protocol versions: `TLSv1`, `TLSv1.1`, `TLSv1.2`, `TLSv1.3`.

  Enables the following combinations of cipher suites in order from the strongest to the weakest: `ECDHE-ECDSA-AES256-GCM-SHA384`, `ECDHE-RSA-AES256-GCM-SHA384`, `ECDHE-ECDSA-CHACHA20-POLY1305`, `ECDHE-RSA-CHACHA20-POLY1305`, `ECDHE-ECDSA-AES128-GCM-SHA256`, `ECDHE-RSA-AES128-GCM-SHA256`, `ECDHE-ECDSA-AES256-SHA384`, `ECDHE-RSA-AES256-SHA384`, `ECDHE-ECDSA-AES128-SHA256`, `ECDHE-RSA-AES128-SHA256`, `ECDHE-ECDSA-AES256-SHA`, `ECDHE-RSA-AES256-SHA`, `ECDHE-ECDSA-AES128-SHA`, `ECDHE-RSA-AES128-SHA`, `AES256-GCM-SHA384`, `AES128-GCM-SHA256`, `AES256-SHA256`, `AES128-SHA256`, `AES256-SHA`, `AES128-SHA`.

  By default, only `TLSv1.2` and `TLSv1.3` with the newest cipher suites are enabled.

- **spec.loadBalancer**
  object

  Not required value.

  A section of parameters of the `LoadBalancer` inlet.

  - **spec.loadBalancer.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

    > **Caution.** The module does not take into account the specifics of setting annotations in different clouds. Note that you will need to recreate `IngressNginxController` (or create a new controller and then delete the old one) if annotations to provision a load balancer are only used when creating the service.

  - **spec.loadBalancer.behindL7Proxy**
    boolean

    Accepts all the incoming `X-Forwarded-*` headers and passes them to upstreams.

    > **Caution.** Make sure that requests to the Ingress controller are sent from trusted sources when using this option.

  - **spec.loadBalancer.loadBalancerClass**
    string

    The LoadBalancer class (it is passed to the `spec.loadBalancerClass` parameter of the provisioned service of the LoadBalancer type).

  - **spec.loadBalancer.realIPHeader**
    string

    Sets the header field for identifying the originating IP address of a client.

    This option works only if `behindL7Proxy` is enabled.

    Default: `X-Forwarded-For`

    Example:

    ```
    realIPHeader: CF-Connecting-IP
    ```

  - **spec.loadBalancer.sourceRanges**
    array of strings

    IP ranges (CIDR) that are allowed to access the load balancer.

    > **Caution.** The cloud provider may not support this option or ignore it. Providers supporting the option: *AWS*, *GCP*, *Azure*. Providers ignoring the option: *YandexCloud*. For other cloud providers, the behavior may depend on the specifics of the cloud implementation. Testing is recommended before use of the option in production.

    - **Element of the array**
      string

      Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.loadBalancerWithProxyProtocol**
  object

  Not required value.

  A section of parameters of the `LoadBalancerWithProxyProtocol` inlet.

  - **spec.loadBalancerWithProxyProtocol.annotations**
    object

    Annotations that will be passed to service with type load balancer to configure it.

    > **Caution.** The module does not take into account the specifics of setting annotations in different clouds. Note that you will need to recreate `IngressNginxController` (or create a new controller and then delete the old one) if annotations to provision a load balancer are only used when creating the service.

  - **spec.loadBalancerWithProxyProtocol.loadBalancerClass**
    string

    The LoadBalancer class (it is passed to the `spec.loadBalancerClass` parameter of the provisioned service of the

LoadBalancer type).

- **spec.loadBalancerWithProxyProtocol.sourceRanges**
  array of strings

  IP ranges (CIDR) that are allowed to access the load balancer.

  > **Caution.** The cloud provider may not support this option or ignore it. Providers supporting the option: *AWS*, *GCP*, *Azure*. Providers ignoring the option: *YandexCloud*. For other cloud providers, the behavior may depend on the specifics of the cloud implementation. Testing is recommended before use of the option in production.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))$`

- **spec.maxReplicas**
  integer

  LoadBalancer and LoadBalancerWithProxyProtocol controller's Horizontal Pod Autoscaler maximum replicas count.

  Default: `1`

  Allowed values: `1 <= X`

- **spec.minReplicas**
  integer

  LoadBalancer and LoadBalancerWithProxyProtocol controller's Horizontal Pod Autoscaler minimum replicas count.

  Default: `1`

  Allowed values: `1 <= X`

- **spec.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resourcesRequests**
  object

  Max amounts of CPU and memory resources that the pod can request when selecting a node (if the VPA is disabled, then these values become the default ones).

  - **spec.resourcesRequests.mode**
    string

    Required value

    The mode for managing resource requests.

    Default: `VPA`

    Allowed values: `VPA`, `Static`

  - **spec.resourcesRequests.static**
    object

    Static mode settings.

    - **spec.resourcesRequests.static.cpu**
      string

      CPU requests.

      Default: `350m`

    - **spec.resourcesRequests.static.memory**
      string

      Memory requests.

      Default: `500Mi`

  - **spec.resourcesRequests.vpa**
    object

    Parameters of the vpa mode.

    - **spec.resourcesRequests.vpa.cpu**
      object

      CPU-related parameters.

      - **spec.resourcesRequests.vpa.cpu.max**
        string

        Maximum allowed CPU requests.

        Default: `50m`

      - **spec.resourcesRequests.vpa.cpu.min**
        string

        Minimum allowed CPU requests.

Default: `10m`

- **spec.resourcesRequests.vpa.memory**
  object

  The amount of memory requested.

  - **spec.resourcesRequests.vpa.memory.max**
    string

    Maximum allowed memory requests.

    Default: `200Mi`

  - **spec.resourcesRequests.vpa.memory.min**
    string

    Minimum allowed memory requests.

    Default: `50Mi`

- **spec.resourcesRequests.vpa.mode**
  string

  The VPA usage mode.

  Default: `Initial`

  Allowed values: `Initial`, `Auto`

- **spec.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string
  - **spec.tolerations.operator**
    string

    Default: `Equal`

    Allowed values: `Exists`, `Equal`

  - **spec.tolerations.tolerationSeconds**
    integer
  - **spec.tolerations.value**
    string
- **spec.underscoresInHeaders**
  boolean

  Determines whether underscores are allowed in headers. Learn more....

  This tutorial sheds light on why you should not enable it without careful consideration.

  Default: `false`

- **spec.validationEnabled**
  boolean

  Enable ingress validation admission.

  Default: `true`

- **spec.waitLoadBalancerOnTerminating**
  integer

  The number of seconds before the /healthz location will start to return a 500 code when the pod enters the Terminating state. This parameter has default values:

  - 0s - for HostWithFailover
  - 60s - for HostPort and HostPortWithProxyProtocol
  - 120s - for LoadBalancer and LoadBalancerWithProxyProtocol

FAQ

> **i** The module lifecycle stage: General Availability

How do I limit access to the application in the cluster to Ingress controllers only?

If you need to limit access to your application inside the cluster exclusively from Ingress Pods, you should add a kube-rbac-proxy container to the application Pod as shown in the example below:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-app
  namespace: my-namespace
spec:
  selector:
    matchLabels:
      app: my-app
  replicas: 1
  template:
    metadata:
      labels:
        app: my-app
    spec:
      serviceAccountName: my-sa
      containers:
      - name: my-cool-app
        image: mycompany/my-app:v0.5.3
        args:
        - "--listen=127.0.0.1:8080"
        livenessProbe:
          httpGet:
            path: /healthz
            port: 443
            scheme: HTTPS
      - name: kube-rbac-proxy
        image: flant/kube-rbac-proxy:v0.1.0
        # It is recommended to use a proxy from Deckhouse repository.
        args:
        - "--secure-listen-address=0.0.0.0:443"
        - "--config-file=/etc/kube-rbac-proxy/config-file.yaml"
        - "--v=2"
        - "--logtostderr=true"
        # The user authentication and authorization are not possible if the kube-apiserver is not available.
        # Stale Cache stores the results of successful authorization and is used only if the apiserver is not
available.
        - "--stale-cache-interval=1h30m"
        ports:
        - containerPort: 443
          name: https
        volumeMounts:
        - name: kube-rbac-proxy
          mountPath: /etc/kube-rbac-proxy
      volumes:
      - name: kube-rbac-proxy
        configMap:
          name: kube-rbac-proxy
```

The application only accepts localhost (127.0.0.1) requests. That means that an unsecured connection can only be established to it from within the Pod. At the same time, the proxy listens on 0.0.0.0 and intercepts all external traffic to the Pod.

How do I provide minimum rights to the Service Account?

The proxy needs permissions to create `TokenReview` and `SubjectAccessReview` to authenticate and authorize users using the kube-apiserver.

DKP clusters already have a ready-made ClusterRole — **d8-rbac-proxy**, you don’t need to create it yourself! Link it to your Deployment’s ServiceAccount, as shown in the example below.

```
---
apiVersion: v1
kind: ServiceAccount
metadata:
  name: my-sa
  namespace: my-namespace
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: my-namespace:my-sa:d8-rbac-proxy
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: d8:rbac-proxy
subjects:
- kind: ServiceAccount
  name: my-sa
  namespace: my-namespace
```

The Kube-RBAC-Proxy configuration

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: kube-rbac-proxy
data:
  config-file.yaml: |+
    excludePaths:
    - /healthz
  # No authorization for liveness probes is required.
    upstreams:
    - upstream: http://127.0.0.1:8081/
  # The destination address
      path: /
  # The path to the proxy to forward requests to the upstream.
      authorization:
        resourceAttributes:
          namespace: my-namespace
          apiGroup: apps
          apiVersion: v1
          resource: deployments
          subresource: http
          name: my-app
```

According to the configuration, the user must have access to the `my-app` Deployment and its `http` subresource in the `my-namespace` namespace.

Such permissions have the following RBAC form:

```
---
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: kube-rbac-proxy:my-app
  namespace: my-namespace
rules:
- apiGroups: ["apps"]
  resources: ["deployments/http"]
  resourceNames: ["my-app"]
  verbs: ["get", "create", "update", "patch", "delete"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: kube-rbac-proxy:my-app
  namespace: my-namespace
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: Role
  name: kube-rbac-proxy:my-app
subjects:
# All user certificates of Ingress controllers are issued for one specific group.
- kind: Group
  name: ingress-nginx:auth
```

For the Ingress resource, add parameters:

```
nginx.ingress.kubernetes.io/backend-protocol: HTTPS
nginx.ingress.kubernetes.io/configuration-snippet: |
  proxy_ssl_certificate /etc/nginx/ssl/client.crt;
  proxy_ssl_certificate_key /etc/nginx/ssl/client.key;
  proxy_ssl_protocols TLSv1.2;
  proxy_ssl_session_reuse on;
```

Here you can read more about how certificate authentication works.

How do I configure an external load balancer to check if IngressNginxController is available?

In case an Ingress NGINX Controller is deployed behind a load balancer, it is recommended that you configure your load balancer so that it would check the availability of the Ingress NGINX Controller’s endpoints via a health check mechanism, periodically sending either HTTP requests or TCP packets. While it is possible to test the endpoints simply by checking if a relevant TCP port is open, we recommend implementing HTTP checks with the following parameters:

- Protocol: `HTTP`
- Path: `/healthz`
- Port: `80` (or relevant httpPort value in case of using `HostPort` inlet).

How do I configure MetalLB to be accessible from the internal network only?

Below is an example of a MetalLB config with access from the internal network only:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: "nginx"
  inlet: "LoadBalancer"
  loadBalancer:
    sourceRanges:
    - 192.168.0.0/24
```

⚠ The `svcSourceRangeCheck` parameter should be enabled in the `cni-cilium` module for correct work.

How to add extra log fields to a nginx-controller?

Example of adding extra fields:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: "nginx"
  inlet: "LoadBalancer"
  additionalLogFields:
    my-cookie: "$cookie_MY_COOKIE"
```

How to enable HorizontalPodAutoscaling for IngressNginxController?

⚠ HPA mode is possible only for controllers with inlet: `LoadBalancer` or `LoadBalancerWithProxyProtocol`.

HPA mode is possible only for `minReplicas` != `maxReplicas` otherwise deployment `hpa-scaler` will not be created.

HPA is set with attributes `minReplicas` and `maxReplicas` in a IngressNginxController CR.

The IngressNginxController is deployed using DaemonSet. DaemonSet does not provide horizontal scaling capabilities, so `hpa-scaler` Deployment will be created with the HPA resource, which is observing custom metric `prometheus-metrics-adapter-d8-ingress-nginx-cpu-utilization-for-hpa`. If CPU utilization exceeds 50%, the HPA-controller scales `hpa-scaler` Deployment with a new replica (with respect to `minReplicas` and `maxReplicas`).

`hpa-scaler` Deployment has HardPodAntiAffinity, and it will order a new Node (inside its NodeGroup), where one more ingress-controller will be set.

Notes:

- The minimum actual number of IngressNginxController replicas cannot be less than the minimum number of nodes in the node group it is deployed to.
- The maximum actual number of IngressNginxController replicas cannot be greater than the maximum number of nodes in the node group it is deployed to.

How to use IngressClass with IngressClassParameters?

Since version 1.1 IngressNginxController Deckhouse creates an IngressClass object. If you want to use your own IngressClass with your customized IngressClassParameters, you need to add the label `ingress-class.deckhouse.io/external: "true"`:

```
apiVersion: networking.k8s.io/v1
kind: IngressClass
metadata:
  labels:
    ingress-class.deckhouse.io/external: "true"
  name: my-super-ingress
spec:
  controller: ingress-nginx.deckhouse.io/my-super-ingress
  parameters:
    apiGroup: elbv2.k8s.aws
    kind: IngressClassParams
    name: awesome-class-cfg
```

In this case Deckhouse will not create an IngressClass object and will use your own.

How to disable the collection of detailed Ingress resources statistics?

By default, Deckhouse collects detailed statistics from all Ingress resources in the cluster, which generates a high load on the monitoring system.

To disable statistics collection, add label `ingress.deckhouse.io/discard-metrics: "true"` to the corresponding Namespace or Ingress resource.

Example of disabling statistics (metrics) collection for all Ingress resources in the `review-1` namespace:

```
d8 k label ns review-1 ingress.deckhouse.io/discard-metrics=true
```

Example of disabling statistics (metrics) collection for all `test-site` Ingress resources in the `development` namespace:

```
d8 k label ingress test-site -n development ingress.deckhouse.io/discard-metrics=true
```

How do I correctly drain a node running an IngressNginxController's pods?

There are two ways to gracefully drain a node running IngressNginxController.

1. Using an annotation.

   The annotation will be automatically removed after the operation completes.

   ```
   d8 k annotate node <node_name> update.node.deckhouse.io/draining=user
   ```

2. Using d8 k drain.

   When using the standard d8 k drain command, you must specify the `--force` flag even if `--ignore-daemonsets` is present, since IngressNginxController is deployed using Advanced DaemonSet:

   ```
   d8 k drain <node_name> --delete-emptydir-data --ignore-daemonsets --force
   ```

How to enable Web Application Firewall (WAF)?

Software known as a Web Application Firewall (WAF) is used to protect web applications from Layer 7 attacks. Ingress-nginx controller has a built-in WAF called `ModSecurity' (The Open Worldwide Application Security Project).

ModSecurity is disabled by default.

Enabling ModSecurity

To enable ModSecurity, you must specify the following parameters in the `config` section of the CR IngressNginxController:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: <name_of_the_controller>
spec:
  config:
    enable-modsecurity: "true"
    modsecurity-snippet: |
      Include /etc/nginx/modsecurity/modsecurity.conf
```

After applying the settings, ModSecurity will start working for all traffic passing through this Ingress nginx controller. This uses the audit mode (`DetectionOnly`) and basic recommended configuration.

Setting up ModSecurity

You can configure ModSecurity in two ways:

1. For the entire ingress-nginx controller
   - the necessary directives are described in the section `config.modsecurity-snippet` in CR IngressNginxController, as in the example above.
2. For each CR Ingress separately
   - the necessary directives are described in the annotation `nginx.ingress.kubernetes.io/modsecurity-snippet : |` directly in Ingress manifests.

To enable the execution of rules (and not just logging), add the `SecRuleEngine On` directive as shown below:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: <name_of_the_controller>
spec:
  config:
    enable-modsecurity: "true"
    modsecurity-snippet: |
      Include /etc/nginx/modsecurity/modsecurity.conf
      SecRuleEngine On
```

Adding SecRules

An example of a rule to limit the number of arguments in a request URL. If the number of arguments exceeds 10, the server will reject the request with an error code 400 (Bad Request).

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: <name_of_the_controller>
spec:
  config:
    enable-modsecurity: "true"
    modsecurity-snippet: |
      Include /etc/nginx/modsecurity/modsecurity.conf
      SecRuleEngine On
      SecRule &ARGS "@gt 10" "id:100100,phase:2,deny,status:400,log,auditlog,severity:WARNING,msg:\"too many
args\""
```

A full list and description of the directives can be found in the official documentation.

Enabling OWASP Core Rule Set (CRS)

To enable OWASP Core Rule Set (CRS) add the `config.enable-owasp-modsecurity-crs` in CR IngressNginxController, as in the example below.

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: <name_of_the_controller>
spec:
  config:
    enable-modsecurity: "true"
    enable-owasp-modsecurity-crs: "true"
    modsecurity-snippet: |
      Include /etc/nginx/modsecurity/modsecurity.conf
      SecRuleEngine On
```

Examples

> **i** The module lifecycle stage: General Availability

An example for AWS (Network Load Balancer)

When creating a balancer, all zones available in the cluster are used.

In each zone, the balancer receives a public IP. If there is an instance with an Ingress controller in the zone, an A-record with the balancer's IP address from this zone is automatically added to the balancer's domain name.

When there are no instances with an Ingress controller in the zone, then the IP is automatically removed from the DNS.

If there is only one instance with an Ingress controller in a zone, when the pod is restarted, the IP address of the balancer of this zone will be temporarily excluded from DNS.

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
 name: main
spec:
  ingressClass: "nginx"
  inlet: "LoadBalancer"
  loadBalancer:
    annotations:
      service.beta.kubernetes.io/aws-load-balancer-type: "nlb"
```

An example for GCP / Yandex Cloud / Azure

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
 name: main
spec:
  ingressClass: "nginx"
  inlet: "LoadBalancer"
```

> ⚠ In **GCP**, nodes must have an annotation enabling them to accept connections to external addresses for the NodePort type services.

An example for OpenStack

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main-lbwpp
spec:
  inlet: LoadBalancerWithProxyProtocol
  ingressClass: nginx
  loadBalancerWithProxyProtocol:
    annotations:
      loadbalancer.openstack.org/proxy-protocol: "true"
      loadbalancer.openstack.org/timeout-member-connect: "2000"
```

An example for Bare metal

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: HostWithFailover
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
  - effect: NoExecute
    key: dedicated.deckhouse.io
    value: frontend
```

An example for Bare metal (Behind external load balancer, e.g. Cloudflare, Qrator, Nginx+, Citrix ADC, Kemp, etc.)

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: HostPort
  hostPort:
    httpPort: 80
    httpsPort: 443
    behindL7Proxy: true
```

An example for Bare metal (MetalLB BGP LoadBalancer)

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: LoadBalancer
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
  - effect: NoExecute
    key: dedicated.deckhouse.io
    value: frontend
```

In the case of using MetalLB, its speaker Pods must be run on the same Nodes as the Ingress controller Pods.

The controller must receive real IP addresses of clients — therefore its Service is created with the parameter `externalTrafficPolicy: Local` (disabling cross-node SNAT), and to accept this parameter the MetalLB speaker announce this Service only from those Nodes where the target Pods are running.

For this example, the configuration of the `metallb` module should be as follows:

```
metallb:
 speaker:
   nodeSelector:
     node-role.deckhouse.io/frontend: ""
   tolerations:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      value: frontend
```

An example for Bare metal (MetalLB L2 LoadBalancer)

1. Enable the `metallb` module:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: metallb
spec:
  enabled: true
  version: 2
```

2. Create a MetalLoadBalancerClass resource:

> **i** Metallb balancers should be placed on the same nodes as ingress controllers. In typical deployment scenarios, frontend nodes are used for this purpose (to deploy ingress controllers and Metallb load balancers on frontend nodes, use the annotation `node-role.deckhouse.io/frontend: ""` in their manifests).

```
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerClass
metadata:
  name: ingress
spec:
  addressPool:
    - 192.168.2.100-192.168.2.150
  isDefault: false
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  type: L2
```

3. Create a IngressNginxController resource:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: main
spec:
  ingressClass: nginx
  inlet: LoadBalancer
  loadBalancer:
    loadBalancerClass: ingress
    annotations:
    # The number of addresses that will be allocated from the pool declared in MetalLoadBalancerClass.
    network.deckhouse.io/l2-load-balancer-external-ips-count: "3"
  # Label selector and tolerations. Ingress-controller pods must be scheduled on same nodes as MetalLB
speaker pods.
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
  - effect: NoExecute
    key: dedicated.deckhouse.io
    value: frontend
    operator: Equal
```

> **i** When creating an ingress controller, you can also specify certain IP addresses from the pool that will be assigned to it. To specify the addresses that should be assigned to the service, use the annotation `network.deckhouse.io/load-balancer-ips`. If there is more than one desired address, there must also be an annotation `network.deckhouse.io/l2-load-balancer-external-ips-count`, which must specify the number of addresses allocated from the pool (it must not be less than the number of addresses listed in `network.deckhouse.io/load-balancer-ips`). Example of using annotations to assign specific addresses from the pool to the service.

4. The platform will create a service with the type `LoadBalancer`, to which a specified number of addresses will be assigned:

```
d8 k -n d8-ingress-nginx get svc
NAME                  TYPE           CLUSTER-IP      EXTERNAL-IP                                 PORT(S)                      AGE
main-load-balancer    LoadBalancer   10.222.130.11   192.168.2.100,192.168.2.101,192.168.2.102   80:30689/TCP,443:30668/TCP   11s
```

Example of segregating access between public and administrative zones

In many applications, the same backend serves both the public part and the administrative interface. For example:

- `https://example.com` is the public zone;
- `https://admin.example.com` is the administrative zone, access to which must be restricted (`ACL`, `mTLS`, `IP whitelist`, and so on).

For this scenario, we recommend offloading administrative traffic to a separate Ingress controller (with a dedicated Ingress class if necessary) and restricting access to it by using the `spec.acceptRequestsFrom` parameter.

Specifics of using a single Ingress controller

Consider an example where a single Ingress controller is used to serve requests from both the public zone and the administrative interface.

Example of Ingress resource configuration for this case:

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: admin-ingress
  annotations:
    nginx.ingress.kubernetes.io/whitelist-source-range: "1.2.3.4/32"
spec:
  ingressClassName: nginx # The Ingress resource for administrative traffic is associated with the same Ingress
controller as the Ingress resource for public traffic.
  rules:
    - host: admin.example.com
      http:
        paths:
          - path: /
            pathType: Prefix
            backend:
              service:
                name: backend
                port:
                  number: 80
---
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: public-ingress
spec:
  ingressClassName: nginx # The Ingress resource for public traffic is associated with the same Ingress
controller as the Ingress resource for administrative traffic.
  rules:
    - host: example.com
      http:
        paths:
          - path: /
            pathType: Prefix
            backend:
              service:
                name: backend
                port:
                  number: 80
```

With processing and forwarding of X-Forwarded-* headers enabled, the backend can rely on the `x-forwarded-host` header when making authorization decisions. In the example above, it is possible to reach the administrative zone through the Ingress resource that serves public traffic by using `x-forwarded-host`. Therefore, when using this option you must be sure that requests to the Ingress controller come only from trusted sources.

Using separate Ingress controllers

To avoid the situation described above (when, with processing and forwarding of X-Forwarded-* headers enabled it is possible, for example, to reach the administrative zone via the Ingress resource that serves public traffic by using `x-forwarded-host`), we recommend that you:

- configure access rules at the Ingress resource level,
- use separate Ingress controllers,
- restrict which source addresses are allowed to connect to the Ingress controllers.

Example of Ingress resource configuration for this case:

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: admin-ingress
  annotations:
    nginx.ingress.kubernetes.io/whitelist-source-range: "1.2.3.4/32"
spec:
  ingressClassName: admin-nginx # The Ingress resource for administrative traffic is associated with a separate
Ingress controller.
  rules:
    - host: admin.example.com
      http:
        paths:
          - path: /
            pathType: Prefix
            backend:
              service:
                name: backend
                port:
                  number: 80
---
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: public-ingress
spec:
  ingressClassName: public-nginx # The Ingress resource for public traffic is associated with a separate Ingress
controller.
  rules:
    - host: example.com
      http:
        paths:
          - path: /
            pathType: Prefix
            backend:
              service:
                name: backend
                port:
                  number: 80
```

Example of an Ingress controller that serves administrative Ingress resources and accepts connections only from specified subnets:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: admin
spec:
  ingressClass: admin-nginx
  inlet: HostPort
  acceptRequestsFrom:
    - 1.2.3.4/32
    - 10.0.0.0/16
  hostPort:
    httpPort: 80
    httpsPort: 443
    behindL7Proxy: true
```

In this example:

- The Ingress controller is exposed on node ports through the `HostPort` inlet.
- The `acceptRequestsFrom` parameter allows connections to the controller only from the listed subnets.
- Even if an external load balancer or client can set its own `X-Forwarded-*` header values, the decision whether to allow the connection to reach the controller is made based on the actual source address, not on headers.
- Administrative Ingress resources (in this example `admin-ingress`) are served by this controller according to the configured Ingress class.

Example of an Ingress controller that serves Ingress resources for public traffic:

```
apiVersion: deckhouse.io/v1
kind: IngressNginxController
metadata:
  name: public
spec:
  ingressClass: public-nginx
  inlet: HostPort
  hostPort:
    httpPort: 8080
    httpsPort: 8443
    behindL7Proxy: true
```

The istio module

i Available with limitations in: **CE, BE, SE, SE+, CSE Lite (1.73)**

Available without limitations in: **EE**

i The module lifecycle stage: General Availability

i Web interfaces associated with the module: istio

Compatibility table for supported versions

Istio version	K8S versions supported by Istio	Status in D8
1.25	1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35	Supported
1.21	1.26, 1.27, 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35	Deprecated and will be deleted

What issues does Istio help to resolve?

Istio is a framework for managing network traffic on a centralized basis that implements the Service Mesh approach.

Istio solves the tasks for applications:

- Using Mutual TLS.
- Access authorization between services.
- Request routing.
- Managing request balancing between service Endpoints.
- Improving Observability.
- Organizing a multi-datacenter cluster by joining clusters into a single Service Mesh (multicluster).
- Grouping isolated clusters into a federation with the ability to provide native (in the Service Mesh sense) access to selected services .

Mutual TLS

Mutual TLS is the main method of mutual service authentication. It is based on the fact that all outgoing requests are verified using the server certificate, and all incoming requests are verified using the client certificate. After the verification is complete, the sidecar-proxy can identify the remote node and use these data for authorization or auxiliary purposes.

Each service gets its own identifier of the following format: `<TrustDomain>/ns/<Namespace>/sa/<ServiceAccount>` where `TrustDomain` is the cluster domain in our case. You can assign your own ServiceAccount to each service or use the regular “default” one. The service ID can be used for authorization and other purposes. This is the identifier used as a name to validate against in TLS certificates.

You can redefine this settings at the Namespace level.

Authorization

The AuthorizationPolicy resource is responsible for managing authorization. Once this resource is created for the service, the following algorithm is used for determining the fate of the request:

- The request is denied if it falls under the DENY policy.
- The request is allowed if there are no ALLOW policies for the service.
- The request is allowed if it falls under the ALLOW policy.
- In all other cases, the request is denied.

In other words, if you explicitly deny something, then only this restrictive rule will work. On the other hand, if you explicitly allow something, only explicitly authorized requests would be allowed (however, restrictions will have precedence).

You can use the following arguments for defining authorization rules:

- Service IDs and wildcard expressions based on them (`mycluster.local/ns/myns/sa/myapp` or `mycluster.local/*`)
- Namespace
- IP ranges
- HTTP headers
- JWT tokens

Request routing

VirtualService is the main resource for routing control; it allows you to override the destination of an HTTP or TCP request. Routing decisions can be based on the following parameters:

- Host or other headers
- URI
- Method (GET, POST, etc.)
- Pod labels or the namespace of the request source
- dst-IP or dst-port for non-HTTP requests

Managing request balancing between service Endpoints

DestinationRule is the main resource for managing request balancing; it allows you to configure the details of requests leaving the Pods:

- Limits/timeouts for TCP
- Balancing algorithms between Endpoints
- Rules for detecting problems on the Endpoint side to take it out of balancing
- Encryption details

⚠ All customizable limits apply to each client Pod individually (on a per Pod basis)! Suppose you limited a service to one TCP connection. In this case, if you have three client Pods, the service will get three incoming connections.

Observability

Tracing

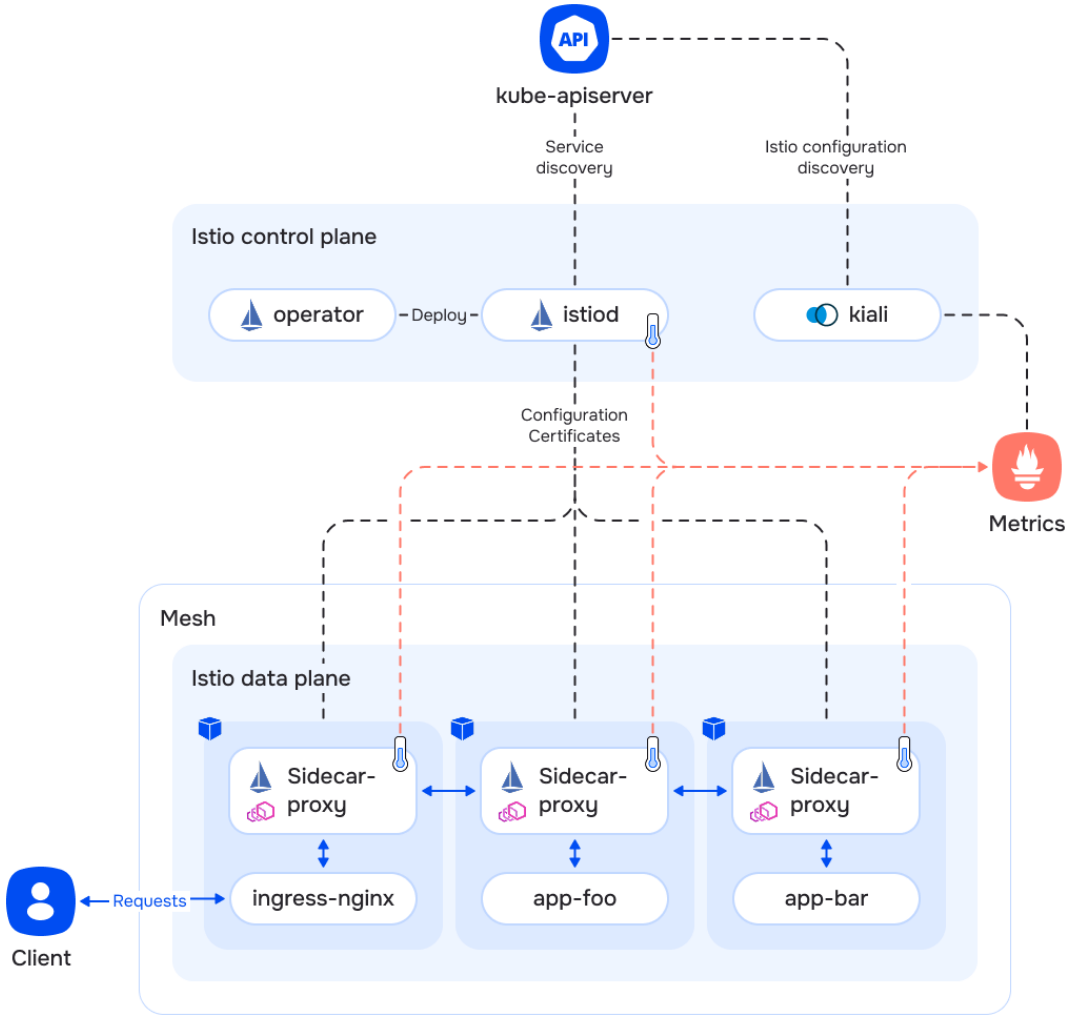
Istio makes it possible to collect application traces and inject trace headers if there are none. In doing so, however, you have to keep in mind the following:

- If a request initiates secondary requests for a service, they must inherit the trace headers by means of the application.
- You will need to install Jaeger to collect and display traces.

Grafana

The standard module bundle includes the following additional dashboards:

- Dashboard for evaluating the throughput and success of requests/responses between applications.
- Dashboard for evaluating control plane performance and load.



Kiali

Kiali is a tool for visualizing your application’s service tree. It allows you to quickly assess the situation in the network connectivity by visualizing the requests and their quantitative characteristics directly on the scheme.

Architecture of the cluster with Istio enabled

The cluster components are divided into two categories:

- Control plane — managing and maintaining services; “control-plane” usually refers to istiod Pods;
- Data plane — mediating and controlling all network communication between microservices, it is composed of a set of sidecar-proxy containers.

All data plane services are grouped into a mesh with the following features:

- It has a common namespace for generating service ID in the form `<TrustDomain>/ns/<Namespace>/sa/<ServiceAccount>`. Each mesh has a TrustDomain ID (in our case, it is the same as the cluster domain), e.g. `mycluster.local/ns/myns/sa/myapp`.
- Services within a single mesh can authenticate each other using trusted root certificates.

Control plane components:

- `istiod` — the main service with the following tasks:
  - Continuous connection to the Kubernetes API and collecting information about services.
  - Processing and validating all Istio-related Custom Resources using the Kubernetes Validating Webhook mechanism.
  - Configuring each sidecar proxy individually:

        - Generating authorization, routing, balancing rules, etc..
        - Distributing information about other application services in the cluster.
        - Issuing individual client certificates for implementing Mutual TLS. These certificates are unrelated to the certificates that Kubernetes uses for its own service needs.
    - Automatic tuning of manifests that describe application Pods via the Kubernetes Mutating Webhook mechanism:
        - Injecting an additional sidecar-proxy service container.
        - Injecting an additional init container for configuring the network subsystem (configuring DNAT to intercept application traffic).
        - Routing readiness and liveness probes through the sidecar-proxy.
- `operator` — installs all the resources required to operate a specific version of the control plane.
- `kiali` — dashboard for monitoring and controlling Istio resources as well as user services managed by Istio that allows you:
    - Visualize inter-service connections.
    - Diagnose problem inter-service connections.
    - Diagnose the control plane state.

The Ingress controller must be refined to receive user traffic:

- You need to add sidecar-proxy to the controller Pods. It only handles traffic from the controller to the application services (the `enableIstioSidecar` parameter of the `IngressNginxController` resource).
- Services not managed by Istio continue to function as before, requests to them are not intercepted by the controller sidecar.
- Requests to services running under Istio are intercepted by the sidecar and processed according to Istio rules (read more about activating Istio to work with the application).

The istiod controller and sidecar-proxy containers export their own metrics that the cluster-wide Prometheus collects.

Application service architecture with Istio enabled

Details

- Each service Pod gets a sidecar container — sidecar-proxy. From the technical standpoint, this container contains two applications:
    - **Envoy** proxies service traffic. It is responsible for implementing all the Istio functionality, including routing, authentication, authorization, etc.
    - **pilot-agent** is a part of Istio. It keeps the Envoy configurations up to date and has a built-in caching DNS server.
- Each Pod has a DNAT configured for incoming and outgoing service requests to the sidecar-proxy. The additional init container is used for that. Thus, the traffic is routed transparently for applications.
- Since incoming service traffic is redirected to the sidecar-proxy, this also applies to the readiness/liveness traffic. The Kubernetes subsystem that does this doesn't know how to probe containers under Mutual TLS. Thus, all the existing probes are automatically reconfigured to use a dedicated sidecar-proxy port that routes traffic to the application unchanged.
- You have to configure the Ingress controller to receive requests from outside the cluster:
    - The controller's Pods have additional sidecar-proxy containers.
    - Unlike application Pods, the Ingress controller's sidecar-proxy intercepts only outgoing traffic from the controller to the services. The incoming traffic from the users is handled directly by the controller itself;
- Ingress resources require refinement in the form of adding annotations:
    - `nginx.ingress.kubernetes.io/service-upstream: "true"` — the Ingress controller will use the service's ClusterIP as upstream instead of the Pod addresses. In this case, traffic balancing between the Pods is handled by the sidecar-proxy. Use this option only if your service has a ClusterIP.
    - `nginx.ingress.kubernetes.io/upstream-vhost: "myservice.myns.svc"` — the Ingress controller's sidecar-proxy makes routing decisions based on the Host header. If this annotation is omitted, the controller will leave a header with the site address (e.g. `Host: example.com`).
- Resources of the Service type do not require any adaptation and continue to function properly. Just like before, applications have access to service addresses like `servicename`, `servicename.myns.svc`, etc;
- DNS requests from within the Pods are transparently redirected to the sidecar-proxy for processing:
    - This way, domain names of the services in the neighboring clusters can be disassociated from their addresses.

User request lifecycle

Application with Istio turned off

Application with Istio turned on

Activating Istio to work with the application

The main purpose of the activation is to add a sidecar container to the application Pods so that Istio can manage the traffic.

The sidecar-injector is a recommended way to add sidecars. Istio can inject sidecar containers into user Pods using the Admission Webhook mechanism. You can configure it using labels and annotations:

- A label attached to a namespace allows the sidecar-injector to identify a group of Pods to inject sidecar containers into:
    - `istio-injection=enabled` — use the global version of Istio (`spec.settings.globalVersion` in `ModuleConfig`);
    - `istio.io/rev=v1x21` — use the specific Istio version for a given namespace;
    - `istio.io/rev=default` — use the global version of Istio (`spec.settings.globalVersion` in `ModuleConfig`).
- The `sidecar.istio.io/inject` (`"true"` or `"false"`) **Pod** annotation lets you redefine the `sidecarInjectorPolicy` policy locally. These annotations work only in namespaces to which the above labels are attached.

It is also possible to add the sidecar to an individual pod in namespace without the `istio-injection=enabled` or `istio.io/rev=vXxYZ` labels by setting the `sidecar.istio.io/inject=true` Pod label.

⚠ Istio-proxy, running as a sidecar container, consumes resources and adds overhead.

Overhead added by Istio-proxy:

- Any incoming DNAT request is forcibly intercepted by the Envoy proxy. Envoy analyzes the request and forwards it by establishing a new connection. On the receiver side, the process is identical: traffic first reaches the "receiving" Envoy and only then is passed to the application itself.
- Each Envoy instance stores information about all services in the cluster; therefore, scaling the cluster leads to a linear increase in Envoy's RAM consumption due to storing the full service map. Using the Sidecar CustomResource, the configuration is filtered, and only the necessary minimum of data is delivered to Envoy.

⚠ The EnvoyFilter interface can be controlled by Lua plugins, but it is an internal control mechanism for implementing the Istio functionality. It must not be used in a user configuration, as doing so would compromise the integrity of the system.

It is also important to get the Ingress controller and the application's Ingress resources ready:

- Enable `enableIstioSidecar` of the `IngressNginxController` resource.
- Add annotations to the application's Ingress resources:
  - `nginx.ingress.kubernetes.io/service-upstream: "true"` — the Ingress controller will use the service's ClusterIP as upstream instead of the Pod addresses. In this case, traffic balancing between the Pods is now handled by the sidecar-proxy. Use this option only if your service has a ClusterIP.
  - `nginx.ingress.kubernetes.io/upstream-vhost: "myservice.myns.svc"` — the Ingress controller's sidecar-proxy makes routing decisions based on the Host header. If this annotation is omitted, the controller will leave a header with the site address (e.g. `Host: example.com`).

Federation and multicluster

Deckhouse supports two schemes of inter-cluster interaction:

- federation
- multicluster

Below are their fundamental differences:

- The federation aggregates multiple sovereign (independent) clusters:
  - Each cluster has its own namespace (for Namespace, Service, etc.);
  - Access to individual services between clusters is clearly defined.
- The multicluster aggregates co-dependent clusters:
  - Cluster namespaces are shared — each service is available to neighboring clusters as if it were running in a local cluster (unless authorization rules prohibit that).

Federation

Requirements for clusters

- Each cluster must have a unique domain in the `clusterDomain` parameter of the resource ClusterConfiguration. The default value is `cluster.local`.
- Pod and Service subnets in the `podSubnetCIDR` and `serviceSubnetCIDR` parameters of the resource ClusterConfiguration can be the same.
- Each cluster must have a unique domain in the `clusterDomain` parameter of the resource ClusterConfiguration. Please note that none of the clusters should use the domain `cluster.local`, which is the default setting.

  > **i** `cluster.local` is an unmodified alias for the local cluster domain. When specifying `cluster.local` as a principals in the AuthorizationPolicy, it will always refer to the local cluster, even if there is another cluster in the mesh with `clusterDomain` explicitly defined as `cluster.local`. source

- There are no requirements for unique subnets of modules and services in the `podSubnetCIDR` and `serviceSubnetCIDR` parameters of the resource ClusterConfiguration when clusters are operating in a federation.
  - When analyzing HTTP and HTTPS traffic *(in Istio terminology)*, you can identify them and decide on further routing or blocking based on their headers.
  - At the same time, when analyzing TCP traffic *(in Istio terminology)*, it is possible to identify them and decide on further routing or blocking based only on their destination IP address or port number.

    > **i** Istio operates in the multi-network mode — pods from different clusters can only communicate with each other through the Istio ingress gateway. Direct communication between pods of different clusters is not supported.

General principles of federation

- Federation requires mutual trust between clusters. Thereby, to use federation, you have to make sure that both clusters (say, A and B) trust each other. This is achieved by a mutual exchange of root certificates.
- You also need to share information about government services to use the federation. You can do that using ServiceEntry resource. A service entry defines the public ingress-gateway address of the B cluster so that services of the A cluster can communicate with the bar service in the B cluster.

Enabling the federation

Enabling federation (via the `istio.federation.enabled = true` module parameter) results in the following activities:

- The `ingressgateway` service is added to the cluster. Its task is to proxy mTLS traffic coming from outside of the cluster to application services.
- A service gets added to the cluster that exports the following cluster metadata to the outside:
  - Istio root certificate (accessible without authentication).
  - List of public services in the cluster (available only for authenticated requests from neighboring clusters).
  - List of public addresses of the `ingressgateway` service (available only for authenticated requests from neighboring clusters).

Managing the federation

To establish a federation, you must:

- Create a set of `IstioFederation` resources in each cluster that describe all the other clusters.
  - After successful auto-negotiation between clusters, the status of `IstioFederation` resource will be filled with neighbour's public and private metadata (`status.metadataCache.public` and `status.metadataCache.private`).
- Add the `federation.istio.deckhouse.io/public-service: ""` label to each resource(`service`) that is considered public within the federation.
  - In the other federation clusters, a corresponding `ServiceEntry` will be created for each `service`, leading to the `ingressgateway` of the original cluster.

> ⚠ In the `.spec.ports` section of `services`, each port must have the `name` field filled.

Multicluster

Requirements for clusters

- Cluster domains in the `clusterDomain` parameter of the resource ClusterConfiguration must be the same for all multicluster members. The default value is `cluster.local`.
- Pod and Service subnets in the `podSubnetCIDR` and `serviceSubnetCIDR` parameters of the resource ClusterConfiguration must be unique for each multicluster member.
  - When analyzing HTTP and HTTPS traffic *(in Istio terminology)*, you can identify them and decide on further routing or blocking based on their headers.
  - At the same time, when analyzing TCP traffic *(in Istio terminology)*, it is possible to identify them and decide on further routing or blocking based only on their destination IP address or port number.

  > **i**
  >
  > If the IP addresses of services or pods in different clusters match, requests from other pods in other clusters may mistakenly fall under the Istio's rules. The intersection of subnets of services and pods is not recommended (source).
  >
  > Istio operates in the multi-network mode — pods from different clusters can only communicate with each other through the Istio ingress gateway. Direct communication between pods of different clusters is not supported.

General principles

- Multicluster requires mutual trust between clusters. Thereby, to use multiclustering, you have to make sure that both clusters (say, A and B) trust each other. From a technical point of view, this is achieved by a mutual exchange of root certificates.
- Istio connects directly to the API server of the neighboring cluster to gather information about its services. This Deckhouse module takes care of the corresponding communication channel.

Enabling the multicluster

Enabling the multicluster (via the `istio.multicluster.enabled = true` module parameter) results in the following activities:

- A proxy is added to the cluster to publish access to the API server via the standard Ingress resource:
  - Access through this public address is secured by authorization based on Bearer tokens signed with trusted keys. Deckhouse automatically exchanges trusted public keys during the mutual configuration of the multicluster.
  - The proxy itself has read-only access to a limited set of resources.
- A service gets added to the cluster that exports the following cluster metadata to the outside:
  - Istio root certificate (accessible without authentication).
  - The public API server address (available only for authenticated requests from neighboring clusters).
  - List of public addresses of the `ingressgateway` service (available only for authenticated requests from neighboring clusters).
  - Server public keys to authenticate requests to API server and to private metadata (see above).

Managing the multicluster

To create a multicluster, you need to create a set of `IstioMulticluster` resources in each cluster that describe all the other clusters.

In case of issues when working with a multi-cluster, it is necessary to check in each cluster:

1. The status of the `IstioMultiCluster` resources. To do this, run the command `d8 k describe istiomulticluster cluster-name`. It is important that the resource status shows `Root CA` and that the `Public Last Fetch Timestamp` field has a recent timestamp.
2. The `Ingress Gateways` field of the `IstioMultiCluster` resource should contain the IP address of the second cluster's `IngressGateway`.
3. Using the `istioctl` utility (how to install...):

```
istioctl remote-clusters -i d8-istio
NAME          SECRET                                    STATUS     ISTIOD
cluster-b     d8-istio/istio-remote-secret-cluster-b     synced     istiod-v1x21-5c57d85b54-k8pl7
```

Estimating overhead

Using Istio will incur additional resource costs for both **control-plane** (istiod controller) and **data-plane** (istio-sidecars).

control-plane

The istiod controller continuously monitors the cluster configuration, compiles the settings for the istio-sidecars and distributes them over the network. Accordingly, the more applications and their instances, the more services, and the more frequently this configuration changes, the more computational resources are required and the greater the load on the network. Two approaches are supported to reduce the load on controller instances:

- horizontal scaling (module configuration `controlPlane.replicasManagement`) — the more controller instances, the fewer instances of istio-sidecars to serve for each controller and the less CPU and network load.
- data-plane segmentation using the *Sidecar* resource (recommended approach) — the smaller the scope of an individual istio-sidecar, the less data in the data-plane needs to be updated and the less CPU and network overhead.

A rough estimate of overhead for a control-plane instance that serves 1000 services and 2000 istio-sidecars is 1 vCPU and 1.5 GB RAM.

data-plane

The consumption of data-plane resources (istio-sidecar) is affected by many factors:

- number of connections,
- the intensity of requests,
- size of requests and responses,
- protocol (HTTP/TCP),
- number of CPU cores,
- complexity of Service Mesh configuration.

A rough estimate of the overhead for an istio-sidecar instance is 0.5 vCPU for 1000 requests/sec and 50 MB RAM. istio-sidecars also increase latency in network requests — about 2.5ms per request.

Third-party components

List of third-party software used in the `istio` module:

- Istio 1.21.6

  License: Apache License 2.0

  An open platform to connect, manage, and secure microservices.

- Istio 1.25.2

  License: Apache License 2.0

  An open platform to connect, manage, and secure microservices.

- Kiali 1.81.0

  License: Apache License 2.0

  Visualisation tool for the istio service mesh topology, and features like circuit breakers or request rates.

- Kiali 2.7.1

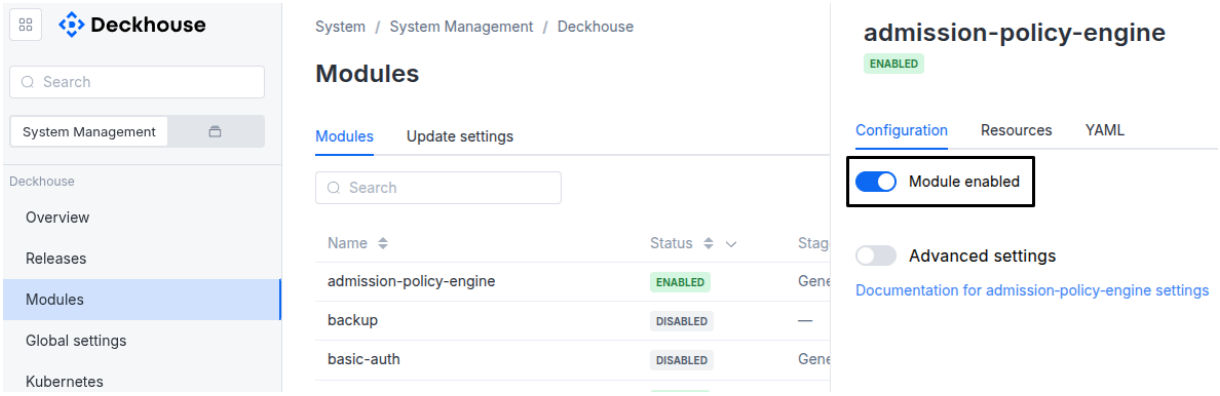
  License: Apache License 2.0

  Visualisation tool for the istio service mesh topology, and features like circuit breakers or request rates.

Configuration

> i Available with limitations in: **CE, BE, SE, SE+, CSE Lite (1.73)**
>
> Available without limitations in: **EE**

> i The module lifecycle stage: General Availability



The module has 17 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `istio` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

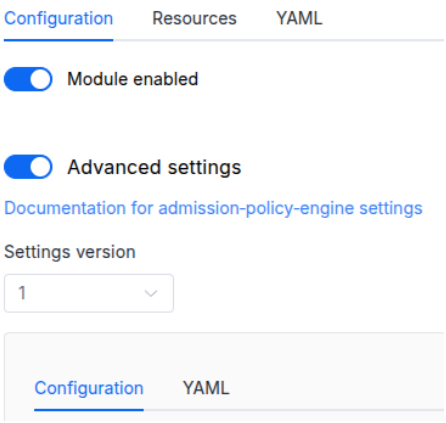
```
d8 system module enable istio
```

- **Using ModuleConfig `istio`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `istio` (create it if necessary);

  Example of a manifest to enable module `istio`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: istio
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `istio` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `istio` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `istio`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `istio` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc istio
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `istio` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `istio`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: istio
  spec:
    version: 3
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `.settings.auth.password`.

- Updates from version **2** to **3**:
  - Move `.settings.enableHTTP10` to `.settings.dataPlane.enableHTTP10`.
  - Move `.settings.proxyConfig` to `.settings.dataPlane.proxyConfig`.

Parameters

Schema version: 3

- **settings**
  object
  - **settings.additionalVersions**
    array of strings

    Additional versions of Istio control plane to install. You can use specific namespace labels (`istio.io/rev=`) to switch between installed revisions.

    Default: `[]`

    - **Element of the array**
      string

      Pattern: `^[0-9]+\.[0-9]+$`

  - **settings.alliance**
    object

Available in editions: EE

Common options both for federation and multicluster.

- **settings.alliance.ingressGateway**
  object

  Available in editions: EE

  ingressgateway settings.

  - **settings.alliance.ingressGateway.advertise**
    array of objects

    Available in editions: EE

    The actual addresses that will be announced to remote clusters for organizing intercluster application requests. If not specified, the addresses will be discovered automatically.

    Default: `[]`

    Examples:

    ```
    advertise:
    - address: 172.16.0.5
      port: 15443
    ```

    ```
    advertise:
    - address: somehost.example.com
      port: 15443
    ```

    - **settings.alliance.ingressGateway.advertise.address**
      string

      Required value

      Pattern: `^([a-z0-9]([a-z0-9-]{0,61}[a-z0-9])?\.)+[a-z]{2,}$`

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

      Examples:

      ```
      address: somehost.example.com
      ```

      ```
      address: 172.16.0.5
      ```

    - **settings.alliance.ingressGateway.advertise.port**
      integer

      Required value

      Allowed values: `1024 <= X <= 65535`

  - **settings.alliance.ingressGateway.gatewayPodAnnotations**
    object

    Available in editions: EE

    Additional annotations for ingressgateway DaemonSet pods.

    Example:

    ```
    gatewayPodAnnotations:
      checksum/config: xyz-123
    ```

  - **settings.alliance.ingressGateway.inlet**
    string

    Available in editions: EE

    The method for exposing ingressgateway.

    - `LoadBalancer` — is a recommended method if you have a cloud-based cluster and it supports Load Balancing.
    - `NodePort` — for installations that do not have the LB.

    Default: `LoadBalancer`

    Allowed values: `LoadBalancer`, `NodePort`

    Example:

    ```
    inlet: LoadBalancer
    ```

  - **settings.alliance.ingressGateway.nodePort**
    object

    Available in editions: EE

    Special settings for NodePort inlet.

    Examples:

    ```
    nodePort: {}
    ```

```
nodePort:
  port: 30001
```

- **settings.alliance.ingressGateway.nodePort.port**
  integer

  Static port number for NodePort-type Service. Must be in range, set by kube-apiserver –service-node-port-range argument (default is 30000-32767).

  Allowed values: `1024 <= X <= 65535`

- **settings.alliance.ingressGateway.nodeSelector**
  object

  Available in editions: EE

  ingressgateway DaemonSet nodeSelector.

  The same as the `spec.nodeSelector` pod parameter in Kubernetes.

  Example:

  ```
  nodeSelector:
    type: ingress
  ```

- **settings.alliance.ingressGateway.serviceAnnotations**
  object

  Available in editions: EE

  Additional service annotations. They can be used, e.g., for configuring a local LB in the Yandex Cloud (using the `yandex.cpi.flant.com/listener-subnet-id` annotation).

  Example:

  ```
  serviceAnnotations:
    yandex.cpi.flant.com/listener-subnet-id: xyz-123
  ```

- **settings.alliance.ingressGateway.tolerations**
  array of objects

  Available in editions: EE

  ingressgateway DaemonSet tolerations.

  The same as `spec.tolerations` for the Kubernetes pod.

  Example:

  ```
  tolerations:
  - operator: Exists
  ```

  - **settings.alliance.ingressGateway.tolerations.effect**
    string
  - **settings.alliance.ingressGateway.tolerations.key**
    string
  - **settings.alliance.ingressGateway.tolerations.operator**
    string
  - **settings.alliance.ingressGateway.tolerations.tolerationSeconds**
    integer
  - **settings.alliance.ingressGateway.tolerations.value**
    string

- **settings.auth**
  object

  Options related to authentication or authorization in the application.

  Example:

  ```
  auth:
    externalAuthentication:
      authURL: https://dex.d8.svc.cluster.local/dex/auth
      authSignInURL: https://example.com/dex/sign_in
    allowedUserGroups:
    - admins
  ```

  - **settings.auth.allowedUserEmails**
    array of strings

    An array of emails of users that can access module’s public web interfaces.

    This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

  - **settings.auth.allowedUserGroups**
    array of strings

    An array of user groups that can access module’s public web interfaces.

    This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

  - **settings.auth.externalAuthentication**
    object

Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

> **i** External authentication is enabled automatically if the user-authn module is enabled.

- **settings.auth.externalAuthentication.authSignInURL**
  string

  The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

  Example:

  ```
  authSignInURL: https://example.com/dex/sign_in
  ```

- **settings.auth.externalAuthentication.authURL**
  string

  The URL of the authentication service.

  If the user is authenticated, the service should return an HTTP 200 response code.

  Example:

  ```
  authURL: https://example.com/dex/auth
  ```

- **settings.auth.satisfyAny**
  boolean

  Enables single authentication.

  If used together with the whitelistSourceRanges parameter, it authorizes all the users from above networks (no need to enter a username and password).

  Default: `false`

  Example:

  ```
  satisfyAny: true
  ```

- **settings.auth.whitelistSourceRanges**
  array of strings

  An array if CIDRs that are allowed to authenticate in module's public web interfaces.

  Example:

  ```
  whitelistSourceRanges:
  - 1.1.1.1/32
  ```

- **settings.ca**
  object

  Explicitly specified root certificate. It signs individual service certificates to use in mutual TLS connections. To create a certificate, you can use the example, in which `basicConstraints = CA:FALSE` needs to be replaced with `basicConstraints = CA:TRUE`.

  - **settings.ca.cert**
    string

    The root or intermediate certificate in PEM format.

  - **settings.ca.chain**
    string

    A certificate chain in PEM format if `cert` is an intermediate certificate.

  - **settings.ca.key**
    string

    The key to the root certificate in PEM format.

  - **settings.ca.root**
    string

    The root certificate in PEM format if `cert` is an intermediate certificate.

- **settings.controlPlane**
  object

  istiod specific settings.

  - **settings.controlPlane.nodeSelector**
    object

    Optional `nodeSelector` for istiod. The same as the `spec.nodeSelector` pod parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.controlPlane.replicasManagement**
    object

    Replication management settings and scaling of istiod.

    Examples:

```
replicasManagement:
  mode: Standard
```

```
replicasManagement:
  mode: Static
  static:
    replicas: 3
```

```
replicasManagement:
  mode: HPA
  hpa:
    minReplicas: 2
    maxReplicas: 5
    metrics:
    - type: CPU
      targetAverageUtilization: 80
```

- **settings.controlPlane.replicasManagement.hpa**
  object

  Options for replicas management for the `HPA` mode.

  - **settings.controlPlane.replicasManagement.hpa.maxReplicas**
    number

    Required value

    The upper limit for the number of replicas to which the HPA can scale up. It cannot be less that `minReplicas`.

    Allowed values: `1 <= X`

  - **settings.controlPlane.replicasManagement.hpa.metrics**
    array of objects

    Required value

    The HPA will use these metrics to decide whether to increase or decrease the number of replicates.

    - **settings.controlPlane.replicasManagement.hpa.metrics.targetAverageUtilization**
      number

      Required value

      The target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

      Allowed values: `1 <= X <= 100`

    - **settings.controlPlane.replicasManagement.hpa.metrics.type**
      string

      Required value

      Metric type.

      Allowed values: `CPU`

  - **settings.controlPlane.replicasManagement.hpa.minReplicas**
    number

    Required value

    The lower limit for the number of replicas to which the HPA can scale down.

    Allowed values: `1 <= X`

- **settings.controlPlane.replicasManagement.mode**
  string

  Replicas management mode:

  - `Standard` — replicas management and scaling mode according to the global fault tolerance mode (the highAvailability parameter);
  - `Static` — the mode, where the number of replicas is specified explicitly (the static.replicas parameter);
  - `HPA` — the mode, where the number of replicas is calculated automatically using HPA based on CPU usage. You can configure this mode by modifying parameters in the hpa parameter section.

  Default: `Standard`

  Allowed values: `Standard`, `Static`, `HPA`

- **settings.controlPlane.replicasManagement.static**
  object

  Options for replicas management for the `Static` mode.

  - **settings.controlPlane.replicasManagement.static.replicas**
    number

    Required value

    Desired number of replicas.

    Allowed values: `1 <= X`

- **settings.controlPlane.resourcesManagement**
  object

Settings for CPU and memory requests and limits by istiod pods.

Examples:

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: InPlaceOrRecreate
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

```
resourcesManagement:
  mode: Static
  static:
    requests:
      cpu: 55m
      memory: 256Mi
    limits:
      cpu: '2'
      memory: 2Gi
```

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: Auto
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

- **settings.controlPlane.resourcesManagement.mode**
  string

  Resource management mode:

  - `Static` — allows you to specify requests/limits. The parameters of this mode are defined in the `static` parameter section;
  - `VPA` — uses VPA. You can configure this mode by modifying parameters in the `vpa` parameter section.

  Default: `VPA`

  Allowed values: `VPA`, `Static`

- **settings.controlPlane.resourcesManagement.static**
  object

  Resource management options for the `Static` mode.

  - **settings.controlPlane.resourcesManagement.static.limits**
    object

    Configuring CPU and memory limits.

    - **settings.controlPlane.resourcesManagement.static.limits.cpu**
      string

      Configuring CPU limits.

      Pattern: `^[0-9]+m?$`

    - **settings.controlPlane.resourcesManagement.static.limits.memory**
      string or number

      Configuring memory limits.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.controlPlane.resourcesManagement.static.requests**
    object

    Resource requests settings for pods.

    - **settings.controlPlane.resourcesManagement.static.requests.cpu**
      string

      Configuring CPU requests.

      Pattern: `^[0-9]+m?$`

    - **settings.controlPlane.resourcesManagement.static.requests.memory**
      string or number

      Configuring memory requests.

Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.controlPlane.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.controlPlane.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.controlPlane.resourcesManagement.vpa.cpu.limitRatio**
      number

      The CPU limits/requests ratio.

      This ratio is used for calculating the initial CPU limits for a pod.

      If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

    - **settings.controlPlane.resourcesManagement.vpa.cpu.max**
      string or number

      The maximum value that the VPA can set for the CPU requests.

      Default: `2`

      Pattern: `^[0-9]+m?$`

    - **settings.controlPlane.resourcesManagement.vpa.cpu.min**
      string or number

      The minimum value that the VPA can set for the CPU requests.

      Default: `50m`

      Pattern: `^[0-9]+m?$`

  - **settings.controlPlane.resourcesManagement.vpa.memory**
    object

    Memory-related VPA settings.

    - **settings.controlPlane.resourcesManagement.vpa.memory.limitRatio**
      number

      The memory limits/requests ratio.

      This ratio is used for calculating the initial memory limits for a pod.

      If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

    - **settings.controlPlane.resourcesManagement.vpa.memory.max**
      string or number

      The maximum memory requests the VPA can set.

      Default: `2Gi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.controlPlane.resourcesManagement.vpa.memory.min**
      string or number

      The minimum memory requests the VPA can set.

      Default: `256Mi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.controlPlane.resourcesManagement.vpa.mode**
    string

    VPA operating mode.

    - `Initial` — VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
    - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.
    - `Auto` — VPA automatically recreates pods to apply updated resource values.

      > **i** Starting from Deckhouse version 1.75, this mode is considered legacy. It is recommended to use `InPlaceOrRecreate` instead.

    Default: `InPlaceOrRecreate`

    Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **settings.controlPlane.tolerations**
  array of objects

  Optional `tolerations` for istiod. The same as `spec.tolerations` for the Kubernetes pod.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.controlPlane.tolerations.effect**
    string

        - **settings.controlPlane.tolerations.key**
          string
        - **settings.controlPlane.tolerations.operator**
          string
        - **settings.controlPlane.tolerations.tolerationSeconds**
          integer
        - **settings.controlPlane.tolerations.value**
          string
  - **settings.dataPlane**
    object
    - **settings.dataPlane.accessLog**
      object
      - **settings.dataPlane.accessLog.jsonLabels**
        object

        Structured access log format using key-value pairs. Template operators are described in envoy documentation.

        Default: `{"start time":"%START TIME%","method":"%REQ(:METHOD)%","path":"%REQ(X-ENVOY-ORIGINAL-PATH?:PATH)%","protocol":"%PROTOCOL%","response_code":"%RESPONSE_CODE%","response_flags":"%RESPONSE FLAGS%","bytes received":"%BYTES_RECEIVED%","bytes_sent":"%BYTES_SENT%","duration":"%DURATION%","user agent":"%REQ(USER-AGENT)%","authority":"%REQ(:AUTHORITY)%","upstream_host":"%UPSTREAM_HOST%"}`

      - **settings.dataPlane.accessLog.textFormat**
        string

        Sidecar's access log format template. Template operators are described in envoy documentation.

        Default: `[%START TIME%] "%REQ(:METHOD)% %REQ(X-ENVOY-ORIGINAL-PATH?:PATH)% %PROTOCOL%" %RESPONSE CODE% %RESPONSE FLAGS% %RESPONSE CODE DETAILS% %CONNECTION TERMINATION DETAILS% "%UPSTREAM TRANSPORT FAILURE REASON%" %BYTES RECEIVED% %BYTES SENT% %DURATION% %RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)% "%REQ(X-FORWARDED-FOR)%" "%REQ(USER-AGENT)%" "%REQ(X-REQUEST-ID)%" "%REQ(:AUTHORITY)%" "%UPSTREAM HOST%" %UPSTREAM LOCAL ADDRESS% %DOWNSTREAM_LOCAL_ADDRESS% %DOWNSTREAM_REMOTE_ADDRESS% %REQUESTED_SERVER_NAME% %ROUTE_NAME%`

      - **settings.dataPlane.accessLog.type**
        string

        Default: `Text`

        Allowed values: `Text`, `JSON`

    - **settings.dataPlane.enableHTTP10**
      boolean

      Whether to handle HTTP/1.0 requests in istio-sidecars or deny them with `426 Upgrade Required` response.

      Default: `false`

      Example:

      ```
      enableHTTP10: true
      ```

    - **settings.dataPlane.extensionProviders**
      array of objects

      Additional Istio extension providers to register in the mesh configuration.

      The provider name `main-access-log-format` is reserved by Deckhouse.

      Default: `[]`

      Example:

      ```
      extensionProviders:
      - name: authservice-grpc
        envoyExtAuthzGrpc:
          service: authservice.example.svc.cluster.local
          port: 10003
      ```

      - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc**
        object

        Required value

        External authorization provider that implements Envoy ext_authz gRPC API.

        - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.clearRouteCache**
          boolean

          Clear route cache to let the external authorization service affect routing decisions.

        - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.failOpen**
          boolean

          Allow requests when the authorization service is unavailable or returns a 5xx error.

        - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.port**
          integer

          Required value

          Service port.

          Allowed values: `1 <= X <= 65535`

        - **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.service**
          string

          Required value

Service that implements Envoy ext_authz gRPC API. The format is `[<hostname>]/[<namespace>]`.

- **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.statusOnError**
  string

  HTTP status returned to the client when communication with the authorization service fails.

- **settings.dataPlane.extensionProviders.envoyExtAuthzGrpc.timeout**
  string

  Maximum duration the proxy waits for the authorization service response.

- **settings.dataPlane.extensionProviders.name**
  string

  Required value

  Unique extension provider name.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

- **settings.dataPlane.proxyConfig**
  object

  Mesh-wide defaults for ProxyConfig configurations.

  - **settings.dataPlane.proxyConfig.holdApplicationUntilProxyStarts**
    boolean

    With this feature, the sidecar-injector injects the sidecar at the first place of Pod’s container list and adds a postStart hook to be sure if the Envoy proxy is initialized before the application. So the Envoy is able to handle requests without application network errors.

    This global flag can be overriden per Pod by an annotation — `proxy.istio.io/config: '{ "holdApplicationUntilProxyStarts": true }'`.

    Default: `false`

    Example:

    ```
    holdApplicationUntilProxyStarts: true
    ```

  - **settings.dataPlane.proxyConfig.idleTimeout**
    string

    Timeout for connections without application activity established between the client’s istio-sidecar and the service. When the timeout expires, the connection between the sidecar and the service is closed, but the connection between the application and the sidecar is not closed. If set to `0s`, the timeout is disabled.

    This global flag can be overriden per Pod by an annotation:

    ```
    proxy.istio.io/config: |-
      proxyMetadata:
        ISTIO_META_IDLE_TIMEOUT: "12h"
    ```

    > **Warning!** Disabling this timeout (setting the value to `0s`) is very likely to result in leaky connections due to TCP FIN packet loss, etc. **Warning!** After changing this setting, a restart of the client pods is required.

    Default: `1h`

    Pattern: `^[0-9]+(s|m|h)$`

    Example:

    ```
    idleTimeout: 24h
    ```

- **settings.dataPlane.trafficRedirectionSetupMode**
  string

  Managing the redirection mode of application traffic to be forwarded under Istio control in the Pod’s network namespace.

  - `CNIPlugin` — in this mode, the configuration is performed by a CNI plugin when creating a Pod on a node. This mode does not require additional permissions for Pods and is recommended. This mode has limitations when using application init-containers that perform network communication with other services.
  - `InitContainer` — classic mode, each application Pod is automatically injected with a special init-container that configures the network environment of the Pod. In order to perform this configuration, the init-container is given additional permissions, which may not meet the security requirements of individual installations.

  Default: `InitContainer`

  Allowed values: `CNIPlugin`, `InitContainer`

  Examples:

  ```
  trafficRedirectionSetupMode: CNIPlugin
  ```

  ```
  trafficRedirectionSetupMode: InitContainer
  ```

- **settings.dataPlane.ztunnel**
  object

  ztunnel specific settings.

  - **settings.dataPlane.ztunnel.resourcesManagement**
    object

Settings for CPU and memory requests and limits by istiod pods.

Examples:

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: InPlaceOrRecreate
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

```
resourcesManagement:
  mode: Static
  static:
    requests:
      cpu: 55m
      memory: 256Mi
    limits:
      cpu: '2'
      memory: 2Gi
```

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: Auto
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

- **settings.dataPlane.ztunnel.resourcesManagement.mode**
  string

  Resource management mode:

  - `Static` — allows you to specify requests/limits. The parameters of this mode are defined in the static parameter section;
  - `VPA` — uses VPA. You can configure this mode by modifying parameters in the vpa parameter section.

  Default: `VPA`

  Allowed values: `VPA`, `Static`

- **settings.dataPlane.ztunnel.resourcesManagement.static**
  object

  Resource management options for the `Static` mode.

  - **settings.dataPlane.ztunnel.resourcesManagement.static.limits**
    object

    Configuring CPU and memory limits.

    - **settings.dataPlane.ztunnel.resourcesManagement.static.limits.cpu**
      string

      Configuring CPU limits.

      Pattern: `^[0-9]+m?$`

    - **settings.dataPlane.ztunnel.resourcesManagement.static.limits.memory**
      string or number

      Configuring memory limits.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.dataPlane.ztunnel.resourcesManagement.static.requests**
    object

    Resource requests settings for pods.

    - **settings.dataPlane.ztunnel.resourcesManagement.static.requests.cpu**
      string

      Configuring CPU requests.

      Pattern: `^[0-9]+m?$`

    - **settings.dataPlane.ztunnel.resourcesManagement.static.requests.memory**
      string or number

      Configuring memory requests.

Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.dataPlane.ztunnel.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.dataPlane.ztunnel.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.dataPlane.ztunnel.resourcesManagement.vpa.cpu.limitRatio**
      number

      The CPU limits/requests ratio.

      This ratio is used for calculating the initial CPU limits for a pod.

      If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

    - **settings.dataPlane.ztunnel.resourcesManagement.vpa.cpu.max**
      string or number

      The maximum value that the VPA can set for the CPU requests.

      Default: `2`

      Pattern: `^[0-9]+m?$`

    - **settings.dataPlane.ztunnel.resourcesManagement.vpa.cpu.min**
      string or number

      The minimum value that the VPA can set for the CPU requests.

      Default: `50m`

      Pattern: `^[0-9]+m?$`

  - **settings.dataPlane.ztunnel.resourcesManagement.vpa.memory**
    object

    Memory-related VPA settings.

    - **settings.dataPlane.ztunnel.resourcesManagement.vpa.memory.limitRatio**
      number

      The memory limits/requests ratio.

      This ratio is used for calculating the initial memory limits for a pod.

      If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

    - **settings.dataPlane.ztunnel.resourcesManagement.vpa.memory.max**
      string or number

      The maximum memory requests the VPA can set.

      Default: `2Gi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.dataPlane.ztunnel.resourcesManagement.vpa.memory.min**
      string or number

      The minimum memory requests the VPA can set.

      Default: `256Mi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.dataPlane.ztunnel.resourcesManagement.vpa.mode**
    string

    VPA operating mode.

    - `Initial` — VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
    - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.
    - `Auto` — VPA automatically recreates pods to apply updated resource values.

      > **i** Starting from Deckhouse version 1.75, this mode is considered legacy. It is recommended to use `InPlaceOrRecreate` instead.

    Default: `InPlaceOrRecreate`

    Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **settings.federation**
  object

  Available in editions: EE

  Parameters for federating with other clusters.

  - **settings.federation.enabled**
    boolean

Designate this cluster as a federation member (see Enabling federation).

Default: `false`

Example:

```
enabled: true
```

- **settings.globalVersion**
  string

  Specific version of Istio control-plane which handles unspecific versions of data plane (namespaces with `istio-injection=enabled` label, not `istio.io/rev=`).

  Default: `1.25`

  Pattern: `^[0-9]+\.[0-9]+$`

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

  Example:

  ```
  highAvailability: true
  ```

- **settings.https**
  object

  What certificate type to use with module's public web interfaces.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object
    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy.

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.https.customCertificate**
    object
    - **settings.https.customCertificate.secretName**
      string

      The name of the secret in the `d8-system` namespace to use with Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy.

      This secret must have the kubernetes.io/tls format.

      Default: `false`

  - **settings.https.mode**
    string

    The HTTPS usage mode:

    - `CertManager` — Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy will use HTTPS and get a certificate from the clusterissuer defined in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate` — Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy will use HTTPS using the certificate from the `d8-system` namespace.
    - `OnlyInURI` — Kiali/metadata-exporter (including SPIFFE endpoint)/api-proxy will work over HTTP (thinking that there is an external HTTPS load balancer in front that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

    Caution! Unlike other modules, Istio doesn't support non-secured HTTP (`mode: Disabled`).

    Default: `CertManager`

    Allowed values: `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for Kiali, metadata-exporter and proxy-api.

  Optional. By default, the `modules.ingressClass` global value is used.

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.jwksResolverAdditionalRootCA**
  string

  An additional root certificate in PEM format. It is used by istiod when resolving JWKS URIs over HTTPS.

  Example: —–BEGIN CERTIFICATE—– ... —–END CERTIFICATE—–

- **settings.multicluster**
  object

  Available in editions: EE

  Multicluster parameters.

  - **settings.multicluster.enabled**
    boolean

    Designate this cluster as a multicluster member (see Enabling multicluster).

    Default: `false`

    Example:

    ```
    enabled: true
    ```

- **settings.nodeSelector**
  object

  Optional `nodeSelector` for istio-operator, metadata-exporter and Kiali. The same as the `spec.nodeSelector` pod parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.outboundTrafficPolicyMode**
  string

  How to handle requests directed to external services which aren’t registered in service mesh.

  - `AllowAny` — allow.
  - `RegistryOnly` — deny. In this case to work with external services you need to register them with ServiceEntry custom resource or to organize egressgateway.

  Default: `AllowAny`

  Allowed values: `AllowAny`, `RegistryOnly`

  Example:

  ```
  outboundTrafficPolicyMode: AllowAny
  ```

- **settings.sidecar**
  object

  Network settings for traffic capture by istio sidecar.

  - **settings.sidecar.excludeInboundPorts**
    array of strings

    The range of inbound ports whose traffic is guaranteed not to flow through Istio.

    You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/excludeInboundPorts` annotation.

    Default: `[]`

    Example:

    ```
    excludeInboundPorts:
    - '8080'
    - '8443'
    ```

    - **Element of the array**
      string

      Pattern: `^[0-9]{1,5}$`

  - **settings.sidecar.excludeOutboundIPRanges**
    array of strings

    Traffic to these IP ranges is guaranteed not to flow through Istio.

    You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/excludeOutboundIPRanges` annotation.

    Default: `[]`

    Example:

    ```
    excludeOutboundIPRanges:
    - 10.1.1.0/24
    ```

    - **Element of the array**
      string

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

  - **settings.sidecar.excludeOutboundPorts**
    array of strings

The range of outbound ports whose traffic is guaranteed not to flow through Istio.

You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/excludeOutboundPorts` annotation.

Default: `[]`

Example:

```
excludeOutboundPorts:
- '8080'
- '8443'
```

- **Element of the array**
  string

  Pattern: `^[0-9]{1,5}$`

- **settings.sidecar.includeOutboundIPRanges**
  array of strings

  Traffic to these IP ranges is forcibly routed through Istio.

  You can redefine this parameter for single Pod using the `traffic.sidecar.istio.io/includeOutboundIPRanges` annotation.

  Default: `["0.0.0.0/0"]`

  Example:

  ```
  includeOutboundIPRanges:
  - 10.1.1.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **settings.sidecar.resourcesManagement**
  object

  Manages Istio sidecar container resources.

  Caution! The setting only applies to new Pods with `istio-proxy`.

  Example:

  ```
  resourcesManagement:
    static:
      requests:
        cpu: 100m
        memory: 128Mi
      limits:
        cpu: 2000m
        memory: 1Gi
  ```

  - **settings.sidecar.resourcesManagement.mode**
    string

    Resource management mode:

    - `Static` — allows you to specify requests/limits. The parameters of this mode are defined in the static parameter section;

    Default: `Static`

    Allowed values: `Static`

  - **settings.sidecar.resourcesManagement.static**
    object

    Resource management options for the `Static` mode.

    - **settings.sidecar.resourcesManagement.static.limits**
      object

      Configuring CPU and memory limits.

      - **settings.sidecar.resourcesManagement.static.limits.cpu**
        string

        Configuring CPU limits.

        Default: `2000m`

        Pattern: `^[0-9]+m?$`

      - **settings.sidecar.resourcesManagement.static.limits.memory**
        string or number

        Configuring memory limits.

        Default: `1Gi`

        Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.sidecar.resourcesManagement.static.requests**
      object

Resource requests settings for pods.

- **settings.sidecar.resourcesManagement.static.requests.cpu**
  string

  Configuring CPU requests.

  Default: `100m`

  Pattern: `^[0-9]+m?$`

- **settings.sidecar.resourcesManagement.static.requests.memory**
  string or number

  Configuring memory requests.

  Default: `128Mi`

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.tolerations**
  array of objects

  Optional `tolerations` for istio-operator, metadata-exporter and Kiali. The same as `spec.tolerations` for the Kubernetes pod.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string
- **settings.tracing**
  object

  Tracing parameters.

  - **settings.tracing.collector**
    object

    Tracing collection settings.

    - **settings.tracing.collector.zipkin**
      object

      Zipkin protocol parameters used by Istio for sending traces. Jaeger supports this protocol.

      If tracing is enabled, this settings section is mandatory.

      - **settings.tracing.collector.zipkin.address**
        string

        Network address of zipkin collector in `<IP of FQDN>:<port>` format.

        Pattern: `[0-9a-zA-Z\.-]+`

        Example:

        ```
        address: zipkin.myjaeger.svc:9411
        ```
  - **settings.tracing.enabled**
    boolean

    Turn on or off tracing collection and displaying in Kiali.

    Default: `false`

    Example:

    ```
    enabled: true
    ```
  - **settings.tracing.kiali**
    object

    Span displaying settings for Kiali.

    When not configured, Kiali won’t show any tracing dashboards.

    Examples:

    ```
    kiali: {}
    ```

    ```
    kiali:
      jaegerURLForUsers: https://tracing-service:4443/jaeger
      jaegerGRPCEndpoint: http://tracing.myjaeger.svc:16685/
    ```

    - **settings.tracing.kiali.jaegerGRPCEndpoint**
      string

      Accessible from cluster address of jaeger GRPC interface for system queries by Kiali.

      When not configured, Kiali will only show external links using the `jaegerURLForUsers` config without interpretationing.

Example:

```
jaegerGRPCEndpoint: http://tracing.myjaeger.svc:16685/
```

- **settings.tracing.kiali.jaegerURLForUsers**
  string

  Jaeger UI address for users. Mandatory parameter if Kiali is enabled.

  Example:

  ```
  jaegerURLForUsers: https://tracing-service:4443/jaeger
  ```

- **settings.tracing.sampling**
  number

  The sampling rate option can be used to control what percentage of requests get reported to your tracing system.

  This should be configured depending upon your traffic in the mesh and the amount of tracing data you want to collect.

  It is possible to override this option with the following Pod annotation:

  ```
  proxy.istio.io/config: |
    tracing:
      sampling: 100.0
  ```

  Default: `1.0`

  Allowed values: `0.01 <= X <= 100.0`

  Example:

  ```
  sampling: 50.05
  ```

Authentication

user-authn module provides authentication by default. Also, externalAuthentication can be configured (see below). If these options are disabled, the module will use basic auth with the auto-generated password.

Use d8 k to see password:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values istio -o json | jq
'.istio.internal.auth.password'
```

Delete the Secret to re-generate password:

```
d8 k -n d8-istio delete secret/kiali-basic-auth
```

⚠ The `auth.password` parameter is deprecated.

Custom Resources

i The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

i The module lifecycle stage: General Availability

IngressIstioController

Scope: Cluster
Version: v1alpha1

- **spec**
  object

  Required value

  - **spec.hostPort**
    object

    `HostPort` inlet settings.

    - **spec.hostPort.httpPort**
      integer

      Port for insecure HTTP connections.

      If the parameter is not set, the connection over HTTP cannot be established.

      This parameter is mandatory if `httpsPort` is not set.

      Example:

      ```
      httpPort: 80
      ```

- **spec.hostPort.httpsPort**
  integer

  Port for secure HTTPS connections.

  If the parameter is not set, the connection over HTTPS cannot be established.

  This parameter is mandatory if `httpPort` is not set.

  Example:

  ```
  httpsPort: 443
  ```

- **spec.ingressGatewayClass**
  string

  Required value

  Ingress gateway class is used by application Gateway resources for identifying the right Ingress gateway setup.

  The identification is organized by setting the spec.selector: `istio.deckhouse.io/ingress-gateway-class: <ingressGatewayClass value>`.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

  Example:

  ```
  ingressGatewayClass: istio
  ```

- **spec.inlet**
  string

  Required value

  The way traffic goes to cluster from the outer network.

  - `LoadBalancer` — Ingress controller is deployed and the service of `LoadBalancer` type is provisioned.
  - `NodePort` — Ingress controller is deployed and available through nodes' ports via `nodePort`.
  - `HostPort` — Ingress controller is deployed and available through nodes' ports via `hostPort`.

    Caution! There can be only one controller with this inlet type on a host.

  Allowed values: `LoadBalancer`, `HostPort`, `NodePort`

- **spec.loadBalancer**
  object

  Not required value.

  A section of parameters of the `LoadBalancer` inlet.

  - **spec.loadBalancer.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

- **spec.nodePort**
  object

  `HostPort` inlet settings.

  - **spec.nodePort.httpPort**
    integer

    Port for insecure HTTP connections.

    If the parameter is not set, the connection over HTTP cannot be established.

    This parameter is mandatory if `httpsPort` is not set.

    Example:

    ```
    httpPort: 30080
    ```

  - **spec.nodePort.httpsPort**
    integer

    Port for secure HTTPS connections.

    If the parameter is not set, the connection over HTTPS cannot be established.

    This parameter is mandatory if `httpPort` is not set.

    Example:

    ```
    httpsPort: 30443
    ```

- **spec.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resourcesRequests**
  object

  Max amounts of CPU and memory resources that the pod can request when selecting a node (if the VPA is disabled, then these

values become the default ones).

- **spec.resourcesRequests.mode**
  string

  Required value

  The mode for managing resource requests.

  Default: `VPA`

  Allowed values: `VPA`, `Static`
- **spec.resourcesRequests.static**
  object

  Static mode settings.

  - **spec.resourcesRequests.static.cpu**
    string

    CPU requests.

    Default: `350m`
  - **spec.resourcesRequests.static.memory**
    string

    Memory requests.

    Default: `500Mi`
- **spec.resourcesRequests.vpa**
  object

  Parameters of the vpa mode.

  - **spec.resourcesRequests.vpa.cpu**
    object

    CPU-related parameters.

    - **spec.resourcesRequests.vpa.cpu.max**
      string

      Maximum allowed CPU requests.

      Default: `100m`
    - **spec.resourcesRequests.vpa.cpu.min**
      string

      Minimum allowed CPU requests.

      Default: `50m`
  - **spec.resourcesRequests.vpa.memory**
    object

    The amount of memory requested.

    - **spec.resourcesRequests.vpa.memory.max**
      string

      Maximum allowed memory requests.

      Default: `200Mi`
    - **spec.resourcesRequests.vpa.memory.min**
      string

      Minimum allowed memory requests.

      Default: `100Mi`
  - **spec.resourcesRequests.vpa.mode**
    string

    The VPA usage mode.

    Default: `Initial`

    Allowed values: `Initial`, `Auto`

- **spec.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`
  - **spec.tolerations.key**
    string
  - **spec.tolerations.operator**
    string

    Default: `Equal`

Allowed values: `Exists`, `Equal`

- **spec.tolerations.tolerationSeconds**
  integer
- **spec.tolerations.value**
  string

IstioFederation

Scope: Cluster
Version: v1alpha1

Custom resource for setting remote cluster as trusted one.

- **spec**
  object

  Required value

  Available in editions: EE

  - **spec.metadata**
    object
    - **spec.metadata.ca**
      string

      Available in editions: EE

      Certificate for validation HTTPS endpoint with remote cluster metadata.

      Example:

      ```
      ca: "-----BEGIN CERTIFICATE----- ..... -----END CERTIFICATE-----"
      ```
    - **spec.metadata.insecureSkipVerify**
      boolean

      Available in editions: EE

      Skip validation certificate on HTTPS endpoint with remote cluster metadata.

      Default: `false`

      Example:

      ```
      insecureSkipVerify: true
      ```
  - **spec.metadataEndpoint**
    string

    Required value

    Available in editions: EE

    HTTPS endpoint with remote cluster metadata.

    Example:

    ```
    metadataEndpoint: https://istio.k8s.example.com/metadata/
    ```
  - **spec.trustDomain**
    string

    Required value

    Available in editions: EE

    The TrustDomain of the remote cluster.

    A mandatory parameter, but it is not currently utilized, as Istio does not yet support mapping TrustDomain to a root Certificate Authority (CA).

    Pattern: `^[0-9a-zA-Z._-]+$`

    Example:

    ```
    trustDomain: cluster.local
    ```
- **status**
  object
  - **status.metadataCache**
    object
    - **status.metadataCache.private**
      object
      - **status.metadataCache.private.ingressGateways**
        array of objects
        - **status.metadataCache.private.ingressGateways.address**
          string
        - **status.metadataCache.private.ingressGateways.port**
          integer
      - **status.metadataCache.private.publicServices**
        array of objects
        - **status.metadataCache.private.publicServices.hostname**
          string
        - **status.metadataCache.private.publicServices.ports**
          array of objects
          - **status.metadataCache.private.publicServices.ports.name**
            string

                - **status.metadataCache.private.publicServices.ports.port**
                  integer
                - **status.metadataCache.private.publicServices.ports.protocol**
                  string
        - **status.metadataCache.privateLastFetchTimestamp**
          string
        - **status.metadataCache.public**
          object
            - **status.metadataCache.public.authnKeyPub**
              string
            - **status.metadataCache.public.clusterUUID**
              string
            - **status.metadataCache.public.rootCA**
              string
        - **status.metadataCache.publicLastFetchTimestamp**
          string

IstioMulticluster

Scope: Cluster
Version: v1alpha1

Custom resource for setting remote cluster as trusted one.

- **spec**
  object

  Required value

  Available in editions: EE

  - **spec.enableIngressGateway**
    boolean

    Available in editions: EE

    Using IngressGateway for accessing remote Pods.

    If remote Pods are accessible directly from our cluster (flat network), it is efficient not to use extra hop.

    Default: `true`

  - **spec.metadata**
    object
    - **spec.metadata.ca**
      string

      Available in editions: EE

      HTTPS certificate authority for remote cluster metadata.

    - **spec.metadata.insecureSkipVerify**
      boolean

      Available in editions: EE

      HTTPS check or not for remote cluster metadata.

      Default: `false`

      Example:

      ```
      insecureSkipVerify: true
      ```

  - **spec.metadataEndpoint**
    string

    Required value

    Available in editions: EE

    HTTPS endpoint with remote cluster metadata.

    Example:

    ```
    metadataEndpoint: https://istio.k8s.example.com/metadata/
    ```

- **status**
  object
  - **status.metadataCache**
    object
    - **status.metadataCache.private**
      object
      - **status.metadataCache.private.apiHost**
        string
      - **status.metadataCache.private.ca**
        string
      - **status.metadataCache.private.ingressGateways**
        array of objects
        - **status.metadataCache.private.ingressGateways.address**
          string
        - **status.metadataCache.private.ingressGateways.port**
          integer
      - **status.metadataCache.private.networkName**
        string
    - **status.metadataCache.privateLastFetchTimestamp**
      string
    - **status.metadataCache.public**

object
- **status.metadataCache.public.authnKeyPub**
  string
- **status.metadataCache.public.clusterUUID**
  string
- **status.metadataCache.public.rootCA**
  string

- **status.metadataCache.publicLastFetchTimestamp**
  string

Routing

DestinationRule

Reference.

Allows you to:

- Define a strategy for balancing traffic between service endpoints:
  - The balancing algorithm to use (LEAST_CONN, ROUND_ROBIN, ...);
  - Symptoms that an endpoint is unhealthy and rules for removing it from load balancing;
  - Limits for TCP connections and endpoint requests;
  - Sticky Sessions;
  - Circuit Breaker;
- Define alternative endpoint groups for traffic processing (suitable for Canary Deployments). Also, you can configure balancing strategies for each group;
- Configuring TLS for outgoing requests.

VirtualService

Reference.

Using VirtualService is optional; regular services fit just fine if their capabilities match your requirements.

Allows you to configure request routing:

- Arguments on which routing decisions are based on:
  - Host;
  - URI;
  - Weight;
- Parameters of the resulting directions:
  - The new host;
  - The new URI;
  - If the host is defined using DestinationRule, then requests can be sent to `subsets`;
  - Timeout and retry settings.

> **⚠** Istio must be aware of the `destination`; if you use an external API, register it via ServiceEntry.

ServiceEntry

Reference.

It is similar to Endpoints + Service in vanilla Kubernetes. Informs Istio about the existence of an external service and lets you redefine its address.

Authentication

Answers the question “Who has made the request?” Not to be confused with authorization - the latter determines what the authenticated subject can or cannot do.

There are two authentication methods:

- mTLS;
- JWT tokens;

PeerAuthentication

Reference.

Allows you to define the mTLS strategy for an individual namespace. Defines how traffic will be tunneled (or not) to the sidecar. Each mTLS request can automatically identify the source and allows you to use it in the authorization rules.

RequestAuthentication

Reference.

Allows you to configure JWT authentication for requests.

Authorization

⚠ Authorization without the use of mTLS or JWT authentication will not work fully. In this case, you will be able to use only basic arguments, such as `source.ip` and `request.headers`, for defining policies.

AuthorizationPolicy

Reference.

Enables and defines access control to the `workload`. The `AuthorizationPolicy` custom resource supports both ALLOW and DENY rules. The following decision-making algorithm is used if at least one policy is defined for a workload:

- The request is denied if it falls under the DENY policy.
- The request is allowed if there are no ALLOW policies for the service.
- The request is allowed if it falls under the ALLOW policy.
- In all other cases, the request is denied.

The following arguments are used in the decision-making algorithm:

- source:
  - namespace
  - principal (i.e., the ID the user has received after authentication)
  - IP
- destination:
  - method (GET, POST, ...)
  - Host
  - port
  - URI
- conditions:
  - HTTP-headers
  - source arguments
  - destination arguments
  - JWT-tokens

Sidecar

Reference

This resource limits the number of services for which information is transmitted to the `istio-proxy` sidecar.

Examples

ℹ The module lifecycle stage: General Availability

Circuit Breaker

The `outlierDetection` settings in the DestinationRule custom resource help to determine whether some endpoints do not behave as expected. Refer to the Envoy documentation for more details on the Outlier Detection algorithm.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: reviews-cb-policy
spec:
  host: reviews.prod.svc.cluster.local
  trafficPolicy:
    connectionPool:
      tcp:
        maxConnections: 100 # The maximum number of connections to the host (cumulative for all endpoints)
      http:
        maxRequestsPerConnection: 10 # The connection will be re-established after every 10 requests
    outlierDetection:
      consecutive5xxErrors: 7 # Seven consecutive errors are allowed (including 5XX, TCP and HTTP timeouts)
      interval: 5m          # over 5 minutes.
      baseEjectionTime: 15m  # Upon reaching the error limit, the endpoint will be excluded from balancing for 15
minutes.
```

Additionally, the VirtualService resource is used to configure the HTTP timeouts. These timeouts are also taken into account when calculating error statistics for endpoints.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: my-productpage-rule
  namespace: myns
spec:
  hosts:
  - productpage
  http:
  - timeout: 5s
    route:
    - destination:
       host: productpage
```

gRPC balancing

⚠ Assign a name with the `grpc` prefix or value to the port in the corresponding service to make gRPC service balancing start automatically.

Locality Failover

i Read the main documentation if you need.

Istio allows you to configure a priority-based locality (geographic location) failover between endpoints. Istio uses node labels with the appropriate hierarchy to define the zone:

- `topology.istio.io/subzone`
- `topology.kubernetes.io/zone`
- `topology.kubernetes.io/region`

This comes in handy for inter-cluster failover when used together with a multicluster.

⚠ The Locality Failover can be enabled using the DestinationRule CR. Note that you also have to configure the outlierDetection.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: helloworld
spec:
  host: helloworld
  trafficPolicy:
    loadBalancer:
      localityLbSetting:
        enabled: true # Locality Failover is enabled
    outlierDetection: # outlierDetection must be enabled
      consecutive5xxErrors: 1
      interval: 1s
      baseEjectionTime: 1m
```

Retry

You can use the VirtualService resource to configure Retry for requests.

⚠ All requests (including POST ones) are retried three times by default.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: ratings-route
spec:
  hosts:
  - ratings.prod.svc.cluster.local
  http:
  - route:
    - destination:
       host: ratings.prod.svc.cluster.local
    retries:
      attempts: 3
      perTryTimeout: 2s
      retryOn: gateway-error,connect-failure,refused-stream
```

Canary

⚠ Istio is only responsible for flexible request routing that relies on special request headers (such as cookies) or simply randomness. The CI/CD system is responsible for customizing this routing and “switching” between canary versions.

The idea is that two Deployments with different versions of the application are deployed in the same namespace. The Pods of different versions have different labels (`version: v1` and `version: v2`).

You have to configure two custom resources:

- A DestinationRule – defines how to identify different versions of your application (subsets);
- A VirtualService – defines how to balance traffic between different versions of your application.

Example:

```
apiVersion: networking.istio.io/v1beta1
kind: DestinationRule
metadata:
  name: productpage-canary
spec:
  host: productpage
  # subsets are only available when accessing the host via the VirtualService from a Pod managed by Istio.
  # These subsets must be defined in the routes.
  subsets:
  - name: v1
    labels:
      version: v1
  - name: v2
    labels:
      version: v2
```

Cookie-based routing

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: productpage-canary
spec:
  hosts:
  - productpage
  http:
  - match:
    - headers:
       cookie:
         regex: "^(.*;?)?(canary=yes)(;.*)?"
    route:
    - destination:
        host: productpage
        subset: v2 # The reference to the subset from the DestinationRule.
  - route:
    - destination:
        host: productpage
        subset: v1
```

Probability-based routing

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: productpage-canary
spec:
  hosts:
  - productpage
  http:
  - route:
    - destination:
        host: productpage
        subset: v1 # The reference to the subset from the DestinationRule.
      weight: 90 # Percentage of traffic that the Pods with the version: v1 label will be getting.
  - route:
    - destination:
        host: productpage
        subset: v2
      weight: 10
```

Ingress to publish applications

Istio Ingress Gateway

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: IngressIstioController
metadata:
 name: main
spec:
  # ingressGatewayClass contains the label selector value used to create the Gateway resource
  ingressGatewayClass: istio-hp
  inlet: HostPort
  hostPort:
    httpPort: 80
    httpsPort: 443
  nodeSelector:
    node-role.deckhouse.io/frontend: ""
  tolerations:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      operator: Equal
      value: frontend
  resourcesRequests:
    mode: VPA
```

```
apiVersion: v1
kind: Secret
metadata:
  name: app-tls-secret
  namespace: d8-ingress-istio # note the namespace isn't app-ns
type: kubernetes.io/tls
data:
  tls.crt: |
    <tls.crt data>
  tls.key: |
    <tls.key data>
```

```
apiVersion: networking.istio.io/v1beta1
kind: Gateway
metadata:
  name: gateway-app
  namespace: app-ns
spec:
  selector:
    # label selector for using the Istio Ingress Gateway main-hp
    istio.deckhouse.io/ingress-gateway-class: istio-hp
  servers:
    - port:
        # standard template for using the HTTP protocol
        number: 80
        name: http
        protocol: HTTP
      hosts:
        - app.example.com
    - port:
        # standard template for using the HTTPS protocol
        number: 443
        name: https
        protocol: HTTPS
      tls:
        mode: SIMPLE
        # a secret with a certificate and a key, which must be created in the d8-ingress-istio namespace
        # supported secret formats can be found at https://istio.io/latest/docs/tasks/traffic-
management/ingress/secure-ingress/#key-formats
        credentialName: app-tls-secret
      hosts:
        - app.example.com
```

```
apiVersion: networking.istio.io/v1beta1
kind: VirtualService
metadata:
  name: vs-app
  namespace: app-ns
spec:
  gateways:
    - gateway-app
  hosts:
    - app.example.com
  http:
    - route:
        - destination:
            host: app-svc
```

Ingress NGINX

To use Ingress, you need to:

- Configure the Ingress controller by adding Istio sidecar to it. In our case, you need to enable the `enableIstioSidecar` parameter in the ingress-nginx module's IngressNginxController custom resource.
- Set up an Ingress that refers to the Service. The following annotations are mandatory for Ingress:
  - `nginx.ingress.kubernetes.io/service-upstream: "true"` — using this annotation, the Ingress controller sends requests to a single ClusterIP (from Service CIDR) while envoy load balances them. Ingress controller's sidecar is only catching traffic directed to Service CIDR.
  - `nginx.ingress.kubernetes.io/upstream-vhost: myservice.myns.svc` — using this annotation, the sidecar container can identify the application service that serves requests.

Examples:

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: productpage
  namespace: bookinfo
  annotations:
    # Nginx proxies traffic to the ClusterIP instead of pods' own IPs.
    nginx.ingress.kubernetes.io/service-upstream: "true"
    # In Istio, all routing is carried out based on the `Host:` headers.
    # Instead of letting Istio know about the `productpage.example.com` external domain,
    # we use the internal domain of which Istio is aware.
    nginx.ingress.kubernetes.io/upstream-vhost: productpage.bookinfo.svc
spec:
  rules:
    - host: productpage.example.com
      http:
        paths:
        - path: /
          pathType: Prefix
          backend:
            service:
              name: productpage
              port:
                number: 9080
```

```
apiVersion: v1
kind: Service
metadata:
  name: productpage
  namespace: bookinfo
spec:
  ports:
  - name: http
    port: 9080
  selector:
    app: productpage
  type: ClusterIP
```

Authorization configuration examples

Decision-making algorithm

The following algorithm for deciding the fate of a request becomes active after `AuthorizationPolicy` is created for the application:

- The request is denied if it falls under the DENY policy;
- The request is allowed if there are no ALLOW policies for the application;
- The request is allowed if it falls under the ALLOW policy.
- All other requests are denied.

In other words, if you explicitly deny something, then only this restrictive rule will work. If you explicitly allow something, only explicitly authorized requests will be allowed (however, restrictions will stay in force and have precedence).

⚠ The policies based on high-level parameters like namespace or principal require enabling Istio for all involved applications. Also, there must be organized Mutual TLS between applications.

Examples:

- Let's deny POST requests for the myapp application. Since a policy is defined, only POST requests to the application are denied (as per the algorithm above).

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-post-requests
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  action: DENY
  rules:
  - to:
    - operation:
        methods: ["POST"]
```

- Below, the ALLOW policy is defined for the application. It only allows requests from the `bar` namespace (other requests are denied).

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  action: ALLOW # The default value, can be skipped.
  rules:
  - from:
    - source:
        namespaces: ["bar"]
```

- Below, the ALLOW policy is defined for the application. Note that it does not have any rules, so not a single request matches it (still, the policy exists). Thus, our decision-making algorithm suggests that if something is allowed, then everything else is denied. In this case, “everything else” includes all the requests.

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  action: ALLOW # The default value, can be skipped.
  rules: []
```

- Below, the (default) ALLOW policy is defined for the application. Note that it has an empty rule. Any request matches this rule, so it is naturally approved.

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: allow-all
  namespace: foo
spec:
  selector:
    matchLabels:
      app: myapp
  rules:
  - {}
```

Deny all actions for the foo namespace

There are two ways you can do that:

- Explicitly. Here, the DENY policy is created. It has a single `{}` rule that covers all the requests:

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec:
  action: DENY
  rules:
  - {}
```

- Implicitly. Here, the (default) ALLOW policy is created that does not have any rules. Thus, no requests will match it, and the policy will deny all of them.

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
  name: deny-all
  namespace: foo
spec: {}
```

Deny requests from the foo NS only

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: deny-from-ns-foo
 namespace: myns
spec:
 action: DENY
 rules:
 - from:
   - source:
      namespaces: ["foo"]
```

Allow requests for the foo NS only

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-intra-namespace-only
 namespace: foo
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      namespaces: ["foo"]
```

Allow requests from anywhere in the cluster

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-my-cluster
 namespace: myns
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      principals: ["mycluster.local/*"]
```

Allow any requests for foo or bar clusters

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-foo-or-bar-clusters-to-ns-baz
 namespace: baz
spec:
 action: ALLOW
 rules:
 - from:
   - source:
      principals: ["foo.local/*", "bar.local/*"]
```

Allow any requests only from entities in the baz namespace of the foo or bar clusters

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-foo-or-bar-clusters-to-ns-baz
 namespace: baz
spec:
 action: ALLOW
 rules:
 - from:
   - source: # Logical conjunction is used for the rules below.
       namespaces: ["baz"]
       principals: ["foo.local/*", "bar.local/*"]
```

Allow from any cluster (via mTLS)

⚠ The denying rules (if they exist) have priority over any other rules. See the algorithm.

Example:

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-any-cluster-with-mtls
 namespace: myns
spec:
 action: ALLOW
 rules:
 - from:
   - source:
       principals: ["*"] # To force the mTLS usage.
```

Allow all requests from anywhere (including no mTLS - plain text traffic)

```
apiVersion: security.istio.io/v1beta1
kind: AuthorizationPolicy
metadata:
 name: allow-all-from-any
 namespace: myns
spec:
 action: ALLOW
 rules: [{}]
```

Setting up federation for two clusters using the IstioFederation CR

Cluster A:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioFederation
metadata:
  name: cluster-b
spec:
  metadataEndpoint: https://istio.k8s-b.example.com/metadata/
  trustDomain: cluster-b.local
```

Cluster B:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioFederation
metadata:
  name: cluster-a
spec:
  metadataEndpoint: https://istio.k8s-a.example.com/metadata/
  trustDomain: cluster-a.local
```

Setting up multicluster for two clusters using the IstioMulticluster CR

Cluster A:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioMulticluster
metadata:
  name: cluster-b
spec:
  metadataEndpoint: https://istio.k8s-b.example.com/metadata/
```

Cluster B:

```
apiVersion: deckhouse.io/v1alpha1
kind: IstioMulticluster
metadata:
  name: cluster-a
spec:
  metadataEndpoint: https://istio.k8s-a.example.com/metadata/
```

Control the data-plane behavior

Prevent istio-proxy from terminating before the main application's connections are closed

By default, during termination, all containers in a Pod, including istio-proxy one, receive SIGTERM signal simultaneously. But some applications need time to properly handle the termination and sometimes they need to do some network requests. It isn't possible when the istio-proxy stops before the application do. The solution is to add a preStop hook which evaluates the application's activity via discovering application's network sockets and let the sidecar stop when they aren't in the network namespace.

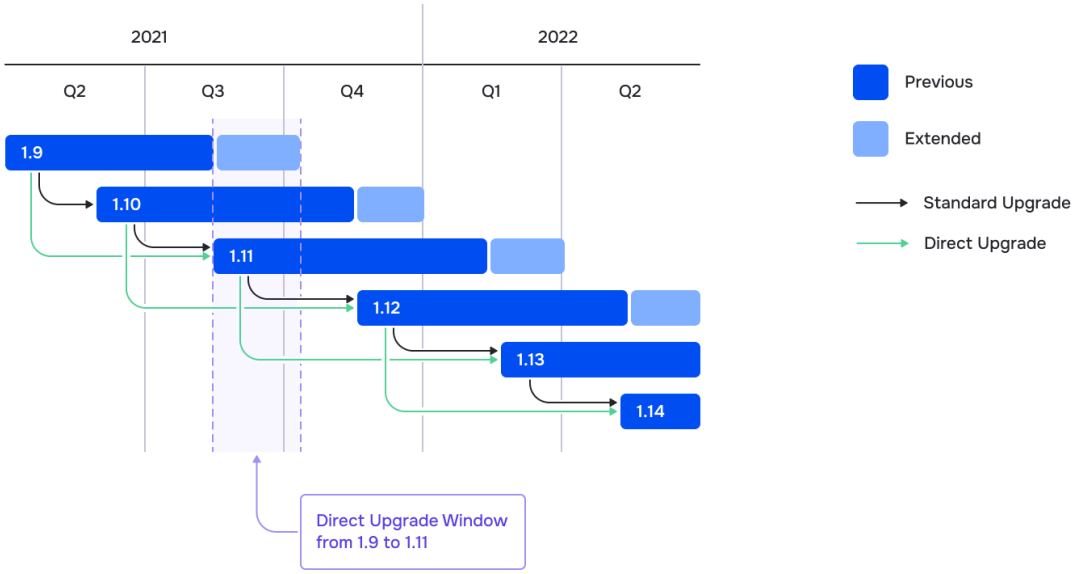
The annotation below adds the preStop hook to istio-proxy container in application's Pod:

```
annotations:
  inject.istio.io/templates: "sidecar,d8-hold-istio-proxy-termination-until-application-stops"
```

`CNIPlugin` application traffic redirection mode restrictions

Unlike the `InitContainer` mode, the redirection setting is done at the moment of Pod creating, not at the moment of triggering the `istio-init` init-container. This means that application init-containers will not be able to interact with other services because all traffic will be redirected to the `istio-proxy` sidecar container, which is not yet running. Workarounds:

- Run the application init container from the user with uid `1337`. Requests from this user are not intercepted under Istio control.
- Exclude a service IP address or port from Istio control using the `traffic.sidecar.istio.io/excludeOutboundIPRanges` or `traffic.sidecar.istio.io/excludeOutboundPorts` annotations.



⚠ Each of the workarounds removes traffic from Istio's control, which in turn removes encryption of traffic between application services.

⚠ UID `1337` is reserved by Istio for the `istio-proxy` sidecar container. Do not run your application containers with this UID — their traffic will bypass Istio completely (no routing rules, mTLS, or telemetry will be applied). Use UID `1337` only in init containers when you need to perform network requests before the sidecar is ready.

Upgrading Istio

Upgrading Istio control-plane

- Deckhouse allows you to install different control-plane versions simultaneously:
  - A single global version to handle namespaces or Pods with indifferent version (namespace label `istio-injection: enabled`). It is configured by the globalVersion parameter.
  - Additional versions handle namespaces or Pods with explicitly configured versions (`istio.io/rev: v1x25` label for namespace or Pod). They are configured by the `additionalVersions` parameter.
- Istio declares backward compatibility between data-plane and control-plane in the range of two minor versions:

- Upgrade algorithm (i.e. from `1.21` to `1.25`):
  - Configure additional version in the additionalVersions parameter (`additionalVersions: ["1.25"]`).
- Wait for the corresponding pod `istiod-v1x25-xxx-yyy` to appear in `d8-istio` namespace.
- For every application namespase with istio enabled:
  - Change `istio-injection: enabled` label to `istio.io/rev: v1x25`.
  - Recreate the Pods in namespace (one at a time), simultaneously monitoring the application's workability.
- Reconfigure `globalVersion` to `1.25` and remove the `additionalVersions` configuration.
- Make sure, the old `istiod` pod has gone.

- Change application namespace labels to `istio-injection: enabled`.

To find all Pods with old Istio revision (in the example — version 21), execute the command:

```
d8 k get pods -A -o json | jq --arg revision "v1x21" \
  '.items[] | select(.metadata.annotations."sidecar.istio.io/status" // "{}" | fromjson |
   .revision == $revision) | .metadata.namespace + "/" + .metadata.name'
```

⚠ Upgrading to Istio 1.25 is only possible from version 1.21.

Auto upgrading istio data-plane

To automate istio-sidecar upgrading, set a label `istio.deckhouse.io/auto-upgrade="true"` on the application `Namespace` or on the individual resources — `Deployment`, `DaemonSet` or `StatefulSet`.

Customizing istio-proxy sidecar resource management

You can override the global istio-proxy sidecar resource limits for specific workloads by adding annotations to your application Pods.

Supported annotations

Use these Pod annotations to customize sidecar resources:

Annotation	Description	Example Value
`sidecar.istio.io/proxyCPU`	CPU request for sidecar	`200m`
`sidecar.istio.io/proxyCPULimit`	CPU limit for sidecar	`"1"`
`sidecar.istio.io/proxyMemory`	Memory request for sidecar	`128Mi`
`sidecar.istio.io/proxyMemoryLimit`	Memory limit for sidecar	`512Mi`

Configuration Examples

For Deployments:

```
apiVersion: apps/v1
kind: Deployment
metadata:
# ...
spec:
  template:
    metadata:
      annotations:
         sidecar.istio.io/proxyCPU: 200m
         sidecar.istio.io/proxyCPULimit: "1"
         sidecar.istio.io/proxyMemory: 128Mi
         sidecar.istio.io/proxyMemoryLimit: 512Mi
# ... rest of your deployment spec
```

For ReplicaSets:

```
apiVersion: apps/v1
kind: ReplicaSet
metadata:
# ...
spec:
  template:
    metadata:
      annotations:
         sidecar.istio.io/proxyCPU: 200m
         sidecar.istio.io/proxyCPULimit: "1"
         sidecar.istio.io/proxyMemory: 128Mi
         sidecar.istio.io/proxyMemoryLimit: 512Mi
# ... rest of your deployment spec
```

For Pod:

```
apiVersion: v1
kind: Pod
metadata:
  annotations:
    sidecar.istio.io/proxyCPU: 200m
    sidecar.istio.io/proxyCPULimit: "1"
    sidecar.istio.io/proxyMemory: 128Mi
    sidecar.istio.io/proxyMemoryLimit: 512Mi
# ... rest of your pod spec
```

⚠ All four parameters must be defined together - if you set any of these annotations, you must specify all four (`sidecar.istio.io/proxyCPU`, `sidecar.istio.io/proxyCPULimit`, `sidecar.istio.io/proxyMemory`, and `sidecar.istio.io/proxyMemoryLimit`).

The keepalived module

i The module lifecycle stage: General Availability

⚠ This module does not work with the cilium module.

This module (managed via custom resources) is intended for configuring keepalived clusters on nodes.

Third-party components

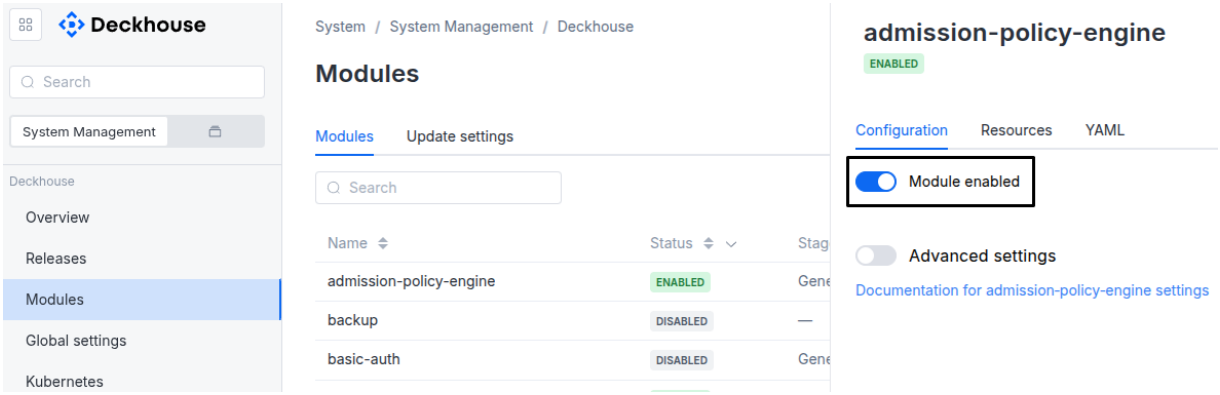
List of third-party software used in the `keepalived` module:

- keepalived 2.2.7

  License: GNU General Public License v2.0

  Provides simple and robust facilities for loadbalancing and high-availability to Linux system and Linux based infrastructures.

Configuration



i The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `keepalived` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

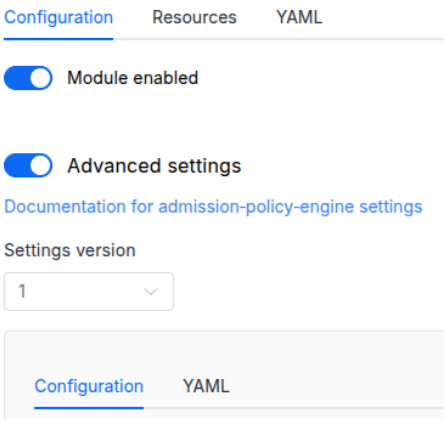
```
d8 system module enable keepalived
```

- **Using ModuleConfig `keepalived`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `keepalived` (create it if necessary);

  Example of a manifest to enable module `keepalived`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: keepalived
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `keepalived` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `keepalived` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `keepalived`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `keepalived` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc keepalived
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `keepalived` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `keepalived`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: keepalived
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Keepalived clusters are configured using the custom resource.

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

KeepalivedInstance

Scope: Cluster
Version: v1alpha1

The custom resource for configuring keepalived clusters.

Each `KeepalivedInstance` custom resource defines a single keepalived cluster.

`metadata.name` — the name of the cluster (used in pod names).

- **spec**
  object

  Required value

  - **spec.nodeSelector**
    object

    Required value

    Defines the `nodeSelector` parameter for keepalived pods.

    Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

  - **spec.tolerations**
    array of objects

Defines `tolerations` for keepalived pods.

Format: the standard toleration list. Instance pods inherit this field as is.

- **spec.tolerations.effect**
  string

  Defines the taint's effect this toleration is associated with (it matches any effect if empty).

  Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

- **spec.tolerations.key**
  string

  Defines the taint's key this toleration is associated with (it matches any key if empty).

  If the key is omitted (emplty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

- **spec.tolerations.operator**
  string

  Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

  Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

  Default: `Equal`

  Allowed values: `Exists`, `Equal`

- **spec.tolerations.tolerationSeconds**
  integer

  Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

  If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

  The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the operator parameter is set to `Exists`.

- **spec.vrrpInstances**
  array of objects

  Required value

  A list of VRRP instances in the keepalived cluster. Essentially, it is a list of address groups that migrate between servers simultaneously and cannot work separately.

  Do not confuse `vrrpInstance` with `KeepalivedInstance`. `vrrpInstance` is a component of `KeepalivedInstance`.

  The `keepalived` module configures VRRP instances so that all addresses (all groups) are evenly distributed across all servers (instead of gathering together on the same node).

  - **spec.vrrpInstances.id**
    integer

    Required value

    A unique **cluster-wide** identifier of a VRRP group.

    Do not use the same ID in different `KeepalivedInstance` instances unless you have a perfect reason to do so.

    Allowed values: `1 <= X <= 255`

  - **spec.vrrpInstances.interface**
    object

    Required value

    Defines the strategy of detecting interface for the service VRRP traffic on the node.

    - **spec.vrrpInstances.interface.detectionStrategy**
      string

      You can select one of the following three interface detecting strategis:

      - `Name` — set the interface name explicitly using the `spec.vrrpInstances[].interface.name` parameter. In this case, all nodes must have the same interface that serves the correct network (e.g., eth0).
      - `NetworkAddress` — find an interface with an IP from this subnet on the node and use it.
      - `DefaultRoute` — use the interface for the default route on the node (254 "main" in the table).
    - **spec.vrrpInstances.interface.name**
      string

      The name of the interface for the service VRRP traffic if the `Name` `detectionStrategy` is used.

      A mandatory parameter if `detectionStrategy` = `Name`.

    - **spec.vrrpInstances.interface.networkAddress**
      string

      The address of the subnet to use for determining an interface if `detectionStrategy` = `NetworkAddress`.

      A mandatory parameter if `detectionStrategy` = `NetworkAddress`.

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

      Example:

```
networkAddress: 192.168.42.0/24
```

- **spec.vrrpInstances.preempt**
  boolean

  Defines if the IP is passed to a node after its recovery from a failure.

  It makes sense not to pass the IP if you have just one `vrrpInstance` to preserve connections. If you have a lot of groups and a lot of traffic, it is better to pass it to prevent the concentration of all groups on one node.

  The default is — `true`, that is, the IP will passed to a node after its recovery.

- **spec.vrrpInstances.virtualIPAddresses**
  array of objects

  Required value

  A list of IP addresses that will “jump” between the servers **in tandem**

  - **spec.vrrpInstances.virtualIPAddresses.address**
    string

    Required value

    One of the group addresses.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

    Example:

    ```
    address: 192.168.42.15/32
    ```

  - **spec.vrrpInstances.virtualIPAddresses.interface**
    object

    Not required value.

    An interface for binding a virtual IP address on a node (similar to `spec.vrrpInstances[].interface`).

    If omitted, the main service interface defined in `spec.vrrpInstances[].interface` will be used.

    - **spec.vrrpInstances.virtualIPAddresses.interface.detectionStrategy**
      string

      You can select one of the following three interface detecting strategis ti bind an IP address:

      - `Name` — set the interface name explicitly using the `spec.vrrpInstances[].virtualIPAddresses[].interface.name` parameter. In this case, all nodes must have the same interface that serves the correct network (e.g., eth0).
      - `NetworkAddress` — find an interface with an IP from this subnet on the node and use it.
      - `DefaultRoute` — use the interface for the default route on the node (254 “main” in the table).
    - **spec.vrrpInstances.virtualIPAddresses.interface.name**
      string

      A name of the interface to bind a virtual IP address if `virtualIPaddresses[].detectionStrategy = Name` is used.

      A mandatory parameter if `virtualIPaddresses[].detectionStrategy = Name`.

    - **spec.vrrpInstances.virtualIPAddresses.interface.networkAddress**
      string

      The address of the subnet to use for determining an interface if `virtualIPaddresses[].detectionStrategy = NetworkAddress`.

      A mandatory parameter if `virtualIPaddresses[].detectionStrategy = NetworkAddress`.

      Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

      Example:

      ```
      networkAddress: 192.168.42.0/24
      ```

keepalived: FAQ

> **i** The module lifecycle stage: General Availability

How to manually switch keepalived?

1. Enter the desired pod using a debug container with a shared process namespace: `d8 k debug -n d8-keepalived -it keepalived-<name> --profile=general --target keepalived`.
2. Edit the configuration file `vim /proc/1/root/etc/keepalived/keepalived.conf`, replace the value in the `priority` line with <number of keepalived pods + 1> or set a value higher than the current VRRP master (e.g., `255`).
3. Apply settings – send a signal to reload the configuration: `kill -HUP 1`.

Examples

> **i** The module lifecycle stage: General Availability

Three public IP addresses

Suppose there are three public IP addresses on three front nodes. Each virtual IP address is placed in a separate VRRP group. Thus, each

address “jumps” independently of the others, and if there are three nodes in the cluster with the `node-role.deckhouse.io/frontend: ""` labels, then each IP gets its own MASTER node.

```
apiVersion: deckhouse.io/v1alpha1
kind: KeepalivedInstance
metadata:
  name: front
spec:
  nodeSelector: # Mandatory.
    node-role.deckhouse.io/frontend: ""
  tolerations:  # Optional.
  - key: dedicated.deckhouse.io
    operator: Equal
    value: frontend
  vrrpInstances:
  - id: 1 # The unique cluster ID.
    interface:
      detectionStrategy: DefaultRoute # The card with the default route is used as a service network one.
    virtualIPAddresses:
    - address: 42.43.44.101/32
      # The interface parameter is omitted since IP addresses are based on the cards that service VRRP traffic.
  - id: 2
    interface:
      detectionStrategy: DefaultRoute
    virtualIPAddresses:
    - address: 42.43.44.102/32
  - id: 3
    interface:
      detectionStrategy: DefaultRoute
    virtualIPAddresses:
    - address: 42.43.44.103/32
```

Suppose there is a gateway with a pair of IP addresses for LAN and WAN. In the case of the gateway, the private and public IPs are bind together, and they will “jump” between the nodes in tandem. In the below example, the VRRP traffic is routed through the LAN interface. It can be detected using the NetworkAddress method (assuming that each node has an IP belonging to this subnet).

```
apiVersion: deckhouse.io/v1alpha1
kind: KeepalivedInstance
metadata:
  name: mygateway
spec:
  nodeSelector:
    node-role.deckhouse.io/mygateway: ""
  tolerations:
  - key: node-role.deckhouse.io/mygateway
    operator: Exists
  vrrpInstances:
  - id: 4 # Since "1", "2", "3" IDs are used in the "front" KeepalivedInstance above.
    interface:
      detectionStrategy: NetworkAddress
      networkAddress: 192.168.42.0/24
    virtualIPAddresses:
    - address: 192.168.42.1/24
      # In this case, we have already detected the local network (above); thus, the interface parameter can be
safely omitted.
    - address: 42.43.44.1/28
      interface:
        detectionStrategy: Name
        name: ens7 # we use the fact that an interface for public IPs is called "ens7" on all nodes
```

The kube-dns module

> **i** The module lifecycle stage: General Availability

The module installs CoreDNS components for managing DNS in the Kubernetes cluster.

> **i** **Caution.** The module deletes all the previously installed kubeadm Deployments, ConfigMaps as well as RBAC for CoreDNS. When deploying your own CoreDNS, avoid using the names `coredns` or `system:coredns` for any resources (Deployment, Service, ConfigMap, ServiceAccount, ClusterRole, ClusterRoleBinding). Use alternative names like `infra-dns` to prevent automatic removal by Deckhouse Kubernetes Platform.

Third-party components

List of third-party software used in the `kube-dns` module:

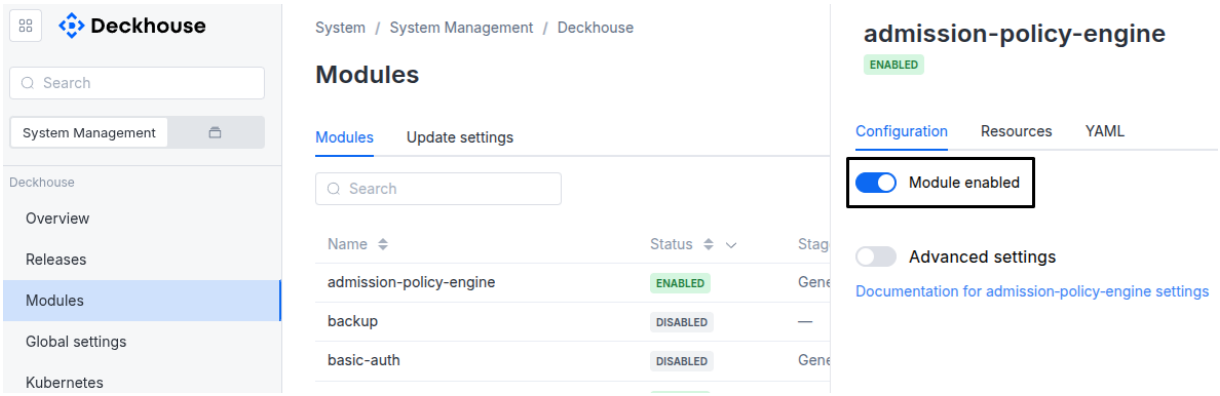
- CoreDNS

  License: Apache License 2.0

  A DNS server/forwarder that chains plugins.

Configuration

> The module lifecycle stage: General Availability



The module has 1 alert.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `kube-dns` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

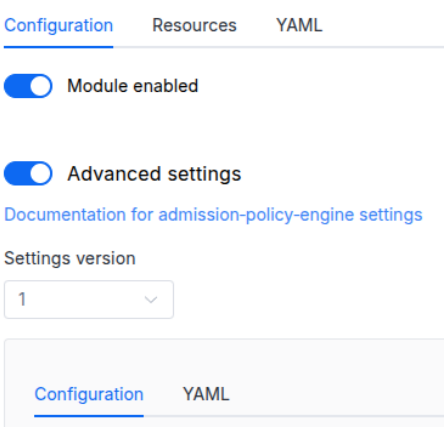
```
d8 system module enable kube-dns
```

- **Using ModuleConfig `kube-dns`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `kube-dns` (create it if necessary);

  Example of a manifest to enable module `kube-dns`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: kube-dns
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `kube-dns` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `kube-dns` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `kube-dns`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `kube-dns` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc kube-dns
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `kube-dns` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `kube-dns`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: kube-dns
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.clusterDomainAliases**
    array of strings

    A list of cluster domain aliases; these are resolved on par with `global.discovery.clusterDomain`.

    Please note: the domain alias must not match the domain used in the DNS name template in the publicDomainTemplate parameter.

    - **Element of the array**
      string

      Pattern: `^[0-9a-zA-Z\.-]+$`
  - **settings.enableLogs**
    boolean

    Enable CoreDNS logging.

    Default: `false`
  - **settings.hosts**
    array of objects

    Not required value.

    A static list of hosts similar to that of `/etc/hosts`.

    - **settings.hosts.domain**
      string

      Pattern: `^[0-9a-zA-Z\.-]+$`
    - **settings.hosts.ip**
      string

      Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}$`
  - **settings.stubZones**
    array of objects

    A list of additional zones CoreDNS should be authoritative for.

    Default: `[]`

    Example:

    ```
    stubZones:
    - zone: example.com
      upstreamNameservers:
      - 8.8.8.8
      cacheTTLSeconds: 3600
      transportProtocolMode: PreferUDP
    ```

    - **settings.stubZones.cacheTTLSeconds**
      integer

      Max TTL in seconds for NOERROR responses.

      Default: `30`

      Allowed values: `1 <= X <= 3600`

- **settings.stubZones.transportProtocolMode**
  string

  The mode of the transport protocol for communicating with the upstream DNS server:

  - `PreferUDP` — UDP is used, even if the original request came over TCP. Note that if the DNS response from the upstream DNS server exceeds 512 bytes and has been truncated and marked with the TC bit (RFC 1035), then it will be resent over TCP (RFC 5966). The request will not be resent over TCP if there are other UDP issues.
  - `ForceTCP` — Always uses TCP, even if the original request is over UDP.
  - `KeepOriginal` — Uses the same protocol (TCP or UDP) as the original request.

  Default: `PreferUDP`

  Allowed values: `PreferUDP`, `ForceTCP`, `KeepOriginal`

- **settings.stubZones.upstreamNameservers**
  array of strings

  Required value

  A list of IP addresses of recursive DNS servers that CoreDNS will use to resolve domains in this zone.

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}(:[0-9]{1,})?$`

- **settings.stubZones.zone**
  string

  Required value

  The CoreDNS zone.

  Pattern: `^[0-9a-zA-Z\.\-_]+$`

  Example:

  ```
  zone: consul.local
  ```

- **settings.transportProtocolMode**
  string

  The mode of the transport protocol for communicating with the upstream DNS server:

  - `PreferUDP` — UDP is used, even if the original request came over TCP. Note that if the DNS response from the upstream DNS server exceeds 512 bytes and has been truncated and marked with the TC bit (RFC 1035), then it will be resent over TCP (RFC 5966). The request will not be resent over TCP if there are other UDP issues.
  - `ForceTCP` — Always uses TCP, even if the original request is over UDP.
  - `KeepOriginal` — Uses the same protocol (TCP or UDP) as the original request.

  Default: `PreferUDP`

  Allowed values: `PreferUDP`, `ForceTCP`, `KeepOriginal`

- **settings.upstreamNameservers**
  array of strings

  A list of IP addresses of recursive DNS servers that CoreDNS will use to resolve external domains.

  By default, the `/etc/resolv.conf` list is used.

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}\.[0-9]{1,}(:[0-9]{1,})?$`

FAQ

> **i** The module lifecycle stage: General Availability

How to change cluster domain with minimal downtime?

Add a new domain and retain the previous one. To do this, modify the configuration parameters:

1. In the controlPlaneManager.apiserver:
   - controlPlaneManager.apiserver.certSANs,
   - apiserver.serviceAccount.additionalAPIAudiences,
   - apiserver.serviceAccount.additionalAPIIssuers.

   Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: control-plane-manager
spec:
  enabled: true
  version: 1
  settings:
    apiserver:
      certSANs:
       - kubernetes.default.svc.<old clusterDomain>
       - kubernetes.default.svc.<new clusterDomain>
      serviceAccount:
        additionalAPIAudiences:
        - https://kubernetes.default.svc.<old clusterDomain>
        - https://kubernetes.default.svc.<new clusterDomain>
        additionalAPIIssuers:
        - https://kubernetes.default.svc.<old clusterDomain>
        - https://kubernetes.default.svc.<new clusterDomain>
```

2. In the kubeDns.clusterDomainAliases:

   Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: kube-dns
spec:
  version: 1
  enabled: true
  settings:
    clusterDomainAliases:
      - <old clusterDomain>
      - <new clusterDomain>
```

3. Wait until the `kube-apiserver` has restarted.

```
d8 k -n kube-system get pods -l component=kube-apiserver
```

4. Replace the previous `clusterDomain` with the new one. Run this command to edit cluster configuration:

```
d8 system edit cluster-configuration
```

5. Restart deckhouse pods:

```
kubectl -n d8-system rollout restart deployment deckhouse
```

⚠ **Important.** In kubernetes, controllers in the cluster use advanced ServiceAccount tokens to interact with API server. These tokens have extra fields `iss:` and `aud:` that contain `clusterDomain` (e.g. `"iss": "https://kubernetes.default.svc.cluster.local"`). After changing the clusterDomain, the API server will start issuing tokens with the new service-account-issuer, but thanks to the configuration of additionalAPIAudiences and additionalAPIIssuers, the apiserver will continue to accept the old tokens. After 48 minutes (80% of 3607 seconds), Kubernetes will begin to refresh the issued tokens, and the new service-account-issuer will be used for the updated tokens. After 90 minutes (3607 seconds plus a short buffer) following the kube-apiserver restart, you can remove the serviceAccount configuration from the control-plane-manager configuration.

⚠ **Important.** In case you need to remove old domain from `clusterDomainAliases` in kube-dns configuration, recreation of all pods in cluster is required, so new pods will have correct search domain in `/etc/resolv.conf` file. This will lead to service downtime until pods are restarted.

```
d8 k delete pods --all-namespaces --all
```

⚠ **Important!** If you use istio module, you have to restart all the application pods under istio control after changing `clusterDomain`.

How to scale-up kube-dns replicas?

Deckhouse distributes kube-dns pods based on the following principles. It searches for nodes with the labels `node-role.deckhouse.io/` and `node-role.kubernetes.io/`, then applies the following rules:

- If there are nodes with the `kube-dns` role in the cluster, the number of replicas is calculated as the sum of these nodes and the master nodes, but not more than masters count plus 2.
- If kube-dns nodes are absent, the system searches for nodes with the `system` role, and the number of replicas is then determined as the sum of system nodes and master nodes, but not more than masters count plus 2.
- If only master nodes are present in the cluster, the number of kube-dns replicas will be equal to the number of masters.

Examples

> The module lifecycle stage: General Availability

Configuration example

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: kube-dns
spec:
  version: 1
  enabled: true
  settings:
    upstreamNameservers:
    - 8.8.8.8
    - 8.8.4.4
    hosts:
    - domain: one.example.com
      ip: 192.168.0.1
    - domain: two.another.example.com
      ip: 10.10.0.128
    stubZones:
    - zone: consul.local
      upstreamNameservers:
      - 10.150.0.1
    enableLogs: true
    clusterDomainAliases:
    - foo.bar
    - baz.qux
```

The kube-proxy module

> The module lifecycle stage: General Availability

The module deletes the entire `kubeadm` kube-proxy set (`DaemonSet`, `ConfigMap`, `RBAC`) and installs its own.

For security reasons, for NodePort services, connections are only allowed to the nodes' InternalIP by default. You can lift this restriction using the `node.deckhouse.io/nodeport-bind-internal-ip: "false"` annotation.

Here is an example of a NodeGroup annotation:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: myng
spec:
  nodeTemplate:
    annotations:
      node.deckhouse.io/nodeport-bind-internal-ip: "false"
...
```

> **Note!** Following the addition, deletion, or changing the annotation, you have to restart kube-proxy Pods manually.
>
> **Note!** The kube-proxy module is automatically disabled when the cni-cilium module is enabled.

The local-path-provisioner module

> The module lifecycle stage: General Availability

Local Path Provisioner provides a way for the Kubernetes users to utilize the local storage on each node.

How does it work?

For each custom resource LocalPathProvisioner, a corresponding `StorageClass` is created.

The allowed topology for `StorageClass` is calculated based on the list of `nodeGroup` names from the CR. The topology is used for scheduling Pods.

When a Pod orders a disk:

- a `HostPath` PV is created
- the `Provisioner` creates a local disk folder on the desired node along the path consisting of the `path` custom resource parameter, the PV name and the PVC name.

  Example of a path:

  ```
  /opt/local-path-provisioner/pvc-d9bd3878-f710-417b-a4b3-38811aa8aac1_d8-monitoring_prometheus-main-db-prometheus-main-0
  ```

Limitations

- The disk size limit is not supported for the local path provisioned volumes.

Third-party components

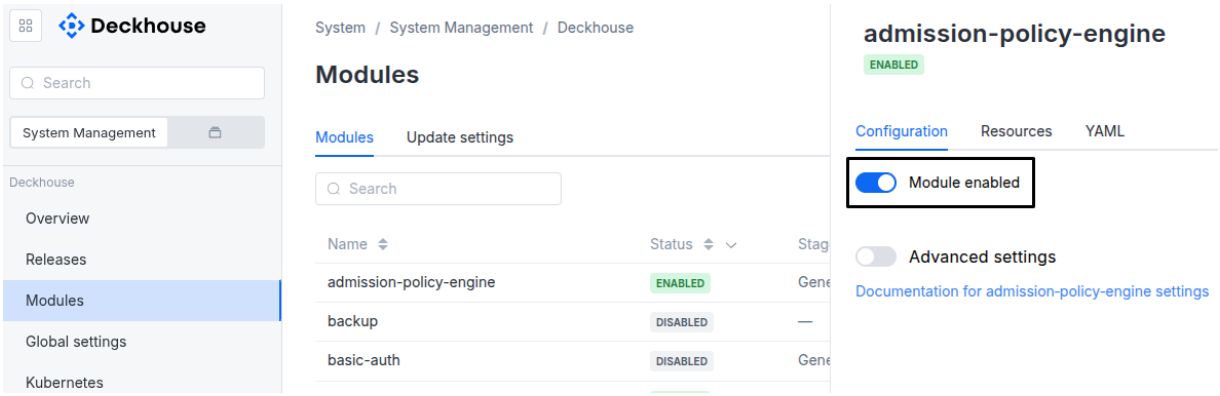
List of third-party software used in the `local-path-provisioner` module:

- Local-path-provisioner

  License: Apache License 2.0

  Local Path Provisioner provides a way for the Kubernetes users to utilize the local storage in each node by creating hostPath based persistent volume on the node automatically.

Configuration



> i The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `local-path-provisioner` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

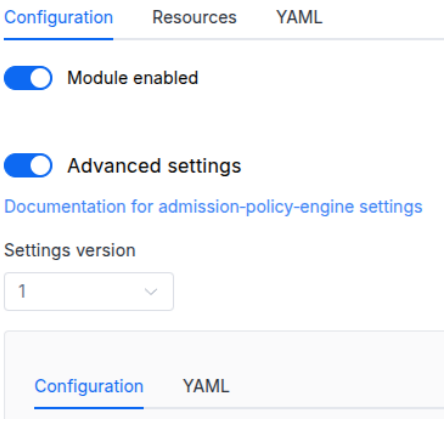
```
d8 system module enable local-path-provisioner
```

- **Using ModuleConfig `local-path-provisioner`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `local-path-provisioner` (create it if necessary);

  Example of a manifest to enable module `local-path-provisioner`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: local-path-provisioner
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `local-path-provisioner` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `local-path-provisioner` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `local-path-provisioner`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `local-path-provisioner` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc local-path-provisioner
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `local-path-provisioner` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `local-path-provisioner`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: local-path-provisioner
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

The module does not require any configuration.

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

LocalPathProvisioner

Scope: Cluster
Version: v1alpha1

Parameters of the `local-path-provisioner` instance.

- **spec**
  object
  - **spec.nodeGroups**
    array of strings

    Select nodeGroups for storageClass allowedTopologies.

    Example:

    ```
    nodeGroups:
    - master
    - worker
    ```

  - **spec.path**
    string

    Required value

Node root path for PV's.

Example:

```
path: "/opt/local-path-provisioner"
```

- **spec.reclaimPolicy**
  string

  Retain policy for PV's.

  Default: `Retain`

  Allowed values: `Retain`, `Delete`

FAQ

> **i** The module lifecycle stage: General Availability

How to configure Prometheus to use local storage for storing data?

Deploy custom resource `LocalPathProvisioner`:

```
apiVersion: deckhouse.io/v1alpha1
kind: LocalPathProvisioner
metadata:
  name: localpath-system
spec:
  nodeGroups:
  - system
  path: "/opt/local-path-provisioner"
```

- `spec.nodeGroups` must match NodeGroup where prometheus Pods run.
- `spec.path` - node data path.

Add to the following parameters to the `prometheus` module configuration:

```
longtermStorageClass: localpath-system
storageClass: localpath-system
```

Wait for the restart of Prometheus Pods.

Examples

> **i** The module lifecycle stage: General Availability

Example of a `LocalPathProvisioner` custom resource

Reclaim policy set by default to `Retain`.

```
apiVersion: deckhouse.io/v1alpha1
kind: LocalPathProvisioner
metadata:
  name: localpath-system
spec:
  nodeGroups:
  - system
  path: "/opt/local-path-provisioner"
```

Example of a `LocalPathProvisioner` custom resource with `reclaimPolicy` set

Reclaim policy set to `Delete`.

```
apiVersion: deckhouse.io/v1alpha1
kind: LocalPathProvisioner
metadata:
  name: localpath-system
spec:
  nodeGroups:
  - system
  path: "/opt/local-path-provisioner"
  reclaimPolicy: "Delete"
```

The log-shipper module

> **i** The module lifecycle stage: General Availability

The `log-shipper` module simplifies the configuration of log collection in Kubernetes. It allows you to quickly collect logs from both applications running in the cluster and from the nodes themselves, and then send them to any storage system, internal or external (for

example, Loki, Elasticsearch, S3, and others).

Module features:

- centrally collects and transmits logs from the cluster;
- filters, transforms, and enriches logs before sending;
- configures routing of logs between different sources and receivers.

1. Deckhouse Kubernetes Platform (DKP) is watching ClusterLoggingConfig, ClusterLogDestination and PodLoggingConfig custom resources. The combination of a logging source and log destination is called `pipeline`.
2. DKP generates a configuration file and stores it into Kubernetes `Secret`.
3. `Secret` is mounted to all log-shipper agent Pods and the configuration is reloaded on changes by the `reloader` sidecar container.

Deployment topologies

This module deploys only agents on nodes. It is implied that logs are sent from the cluster using one of the following topologies.

Distributed

Agents send logs directly to the storage, e.g., Loki, Elasticsearch.

- Less complicated scheme to use.
- Available out of the box without any external dependency besides storage.
- Complicated transformations consume more resources.

Centralized

All logs are aggregated by one of the available aggregation destinations, e.g., Logstash, Vector. Agents on nodes do minimal transformations and try to send logs from nodes faster with less resource consumption. Complicated mappings are applied on the aggregator’s side.

- Lower resource consumption for applications on nodes.
- Users can configure any possible mappings for aggregators and send logs to many more storages.
- Dedicated nodes for aggregates can be scaled up and down on the loading changes.

Stream

The main goal of this architecture is to send messages to the queue system as quickly as possible, then other workers will read them and deliver them to the long-term storage for later analysis.

- The same pros and cons as for centralized architecture, yet one more middle layer storage is added.
- Increased durability. Suites for all infrastructures where logs delivery is crucial.

Metadata

On collecting, all sources enrich logs with metadata. The enrichment takes place at the `Source` stage.

Kubernetes

The following metadata fields will be exposed:

Label	Pod spec path
`pod`	metadata.name
`namespace`	metadata.namespace
`pod_labels`	metadata.labels
`pod_ip`	status.podIP
`image`	spec.containers[].image
`container`	spec.containers[].name
`node`	spec.nodeName
`pod_owner`	metadata.ownerRef[0]
Label	**Node spec path**
`node_group`	metadata.labels[].node.deckhouse.io/group

i For Splunk, the `pod_labels` fields are not exported because it is a nested object, which is not supported by Splunk.

File

The following metadata fields will be exposed:

Label	Pod spec path
`host`	spec.nodeName
`host_ip`	status.hostIP
`file`	Path to the log file being read

Log filters

There are two filters for reducing the number of messages sent to storage, `log filter` and `label filter`.

They are executed right after concatenating lines together with the multiline log parser.

1. `label filter` - rules are run on message metadata. The metadata (or label) fields are populated based on the log source, and different sources will have different sets of fields. These rules are needed, for example, to discard messages from a specific container or pod with/without a label.
2. `log filter` - rules are run on the original message. It is possible to discard a message based on a JSON field, or, if the message is not in JSON format, use a regular expression to search the string.

Both filters have the same structured configuration:

- `field` — the source of data to filter (most of the time it is a value of a label or a JSON parameter).
- `operator` — action to apply to a value of the field. Possible options are In, NotIn, Regex, NotRegex, Exists, DoesNotExist.
- `values` — defines different values for different operators:
  - DoesNotExist, Exists — not supported;
  - In, NotIn — a value of a field must / mustn't be in the list of provided values;
  - Regex, NotRegex — a value of a field must match any or mustn't match all the provided regexes (values).

More examples can be found in the Examples section of the documentation.

⚠ Extra labels are added on the `Destination` stage of the pipeline, so it is impossible to run queries against them.

Third-party components

List of third-party software used in the `log-shipper` module:

- Vector

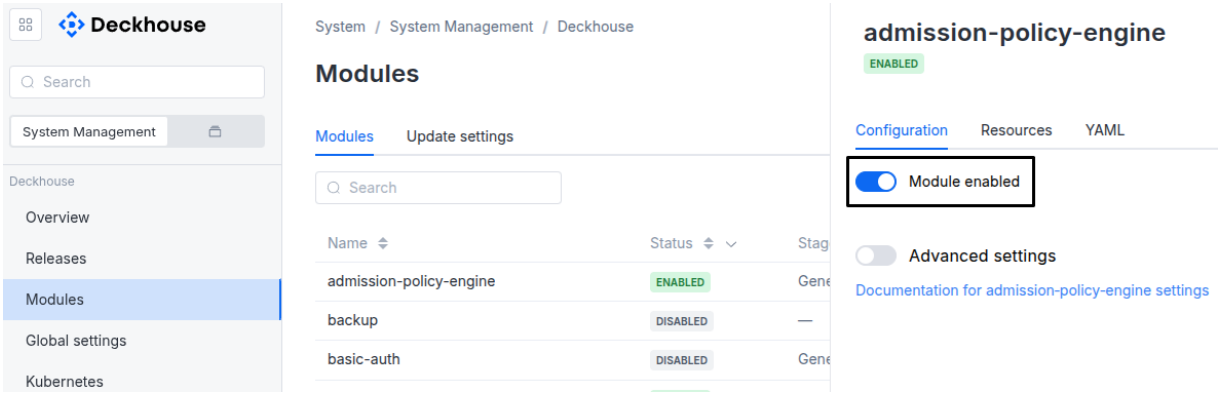
  License: Mozilla Public License, version 2.0

  Vector is a high-performance, observability data pipeline for logs and metrics

Configuration

i The module lifecycle stage: General Availability

The module starts reading logs only if log-pipeline is created. Log-pipeline consists of ClusterLoggingConfig/PodLoggingConfig connected to ClusterLogDestination.



The module has 6 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `log-shipper` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

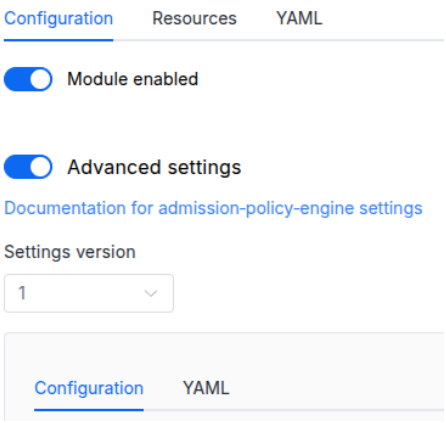
```
d8 system module enable log-shipper
```

- **Using ModuleConfig `log-shipper`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `log-shipper` (create it if necessary);

  Example of a manifest to enable module `log-shipper`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: log-shipper
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `log-shipper` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `log-shipper` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `log-shipper`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `log-shipper` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc log-shipper
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `log-shipper` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `log-shipper`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: log-shipper
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Move `.settings.resourcesRequests.static.cpu` and `.settings.resourcesRequests.static.memory` to `.settings.resourcesRequests.static.requests`.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.debug**
    boolean

Enable or disable agent debug logging. Default: `false`.

Default: `false`

- **settings.nodeSelector**
  object

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, `nodeSelector` will be determined automatically.

- **settings.resourcesRequests**
  object

  Max amounts of CPU and memory resources that the pod can request when selecting a node.

  If the `vertical-pod-autoscaler` module is disabled, then these values become the default ones.

  Examples:

```
resourcesRequests:
  mode: VPA
  vpa:
    mode: Auto
    cpu:
      min: 50m
      max: 2
    memory:
      min: 256Mi
      max: 2Gi
```

```
resourcesRequests:
  mode: VPA
  vpa:
    mode: Initial
    cpu:
      min: 1
      max: 3000m
    memory:
      min: 1024
      max: 4096
```

```
resourcesRequests:
  mode: Static
  static:
    requests:
      cpu: 55m
      memory: 256Mi
    limits:
      cpu: 2
      memory: 2Gi
```

  - **settings.resourcesRequests.mode**
    string

    Required value

    Resource request management mode:

    - `Static` is a classic one. In it, you explicitly specify requests. The parameters of this mode are defined in the static parameter section;
    - `VPA` mode uses VPA. You can configure this mode by modifying parameters in the vpa parameter section.

    Default: `VPA`

    Allowed values: `VPA`, `Static`

  - **settings.resourcesRequests.static**
    object

    Resource request management options for the `Static` mode.

    - **settings.resourcesRequests.static.limits**
      object

      Configuring CPU and memory limits.

      - **settings.resourcesRequests.static.limits.cpu**
        string or number

        Configuring CPU limits.

        Pattern: `^[0-9]+m?$`

      - **settings.resourcesRequests.static.limits.memory**
        string or number

        Configuring memory limits.

        Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.resourcesRequests.static.requests**
      object

Resource requests settings for pods.

- **settings.resourcesRequests.static.requests.cpu**
  string or number

  Configuring CPU requests.

  Pattern: `^[0-9]+m?$`

- **settings.resourcesRequests.static.requests.memory**
  string or number

  Configuring memory requests.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesRequests.vpa**
  object

  Resource request management options for the VPA mode.

  - **settings.resourcesRequests.vpa.cpu**
    object

    Required value

    CPU-related parameters.

    - **settings.resourcesRequests.vpa.cpu.max**
      string or number

      The maximum value that the VPA can set for the CPU requests.

      Default: `500m`

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesRequests.vpa.cpu.min**
      string or number

      The minimum value that the VPA can set for the CPU requests.

      Default: `50m`

      Pattern: `^[0-9]+m?$`

  - **settings.resourcesRequests.vpa.memory**
    object

    Required value

    The amount of memory requested.

    - **settings.resourcesRequests.vpa.memory.max**
      string or number

      The maximum memory requests the VPA can set.

      Default: `2048Mi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    - **settings.resourcesRequests.vpa.memory.min**
      string or number

      The minimum memory requests the VPA can set.

      Default: `64Mi`

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.resourcesRequests.vpa.mode**
    string

    Required value

    The VPA usage mode.

    Default: `Initial`

    Allowed values: `Initial`, `Auto`

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, `tolerations` will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

ClusterLogDestination

Scope: Cluster

- v1alpha2
- v1alpha1

Describes setting for a log storage, which you can use in many log sources.

`metadata.name` — is an upstream name, which you should use in custom resource ClusterLoggingConfig.

- **spec**
  object

  Required value

  - **spec.buffer**
    object

    Buffer parameters.

    - **spec.buffer.disk**
      object

      Disk buffer parameters.

      - **spec.buffer.disk.maxSize**
        integer or string

        The maximum size of the buffer on disk. Must be at least ~256MB (268435488 bytes).

        You can express size as a plain integer or as a fixed-point number using one of these quantity suffixes: `E`, `P`, `T`, `G`, `M`, `k`, `Ei`, `Pi`, `Ti`, `Gi`, `Mi`, `Ki`.

        More about resource quantity:

        - kubernetes quantity
        - memory resource units

        Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

        Examples:

        ```
        maxSize: 512Mi
        ```

        ```
        maxSize: 268435488
        ```

    - **spec.buffer.memory**
      object
      - **spec.buffer.memory.maxEvents**
        number

        The maximum number of events allowed in the buffer.

    - **spec.buffer.type**
      string

      Required value

      The type of buffer to use.

      Allowed values: `Disk`, `Memory`

    - **spec.buffer.whenFull**
      string

      Event handling behavior when a buffer is full.

      Default: `Block`

      Allowed values: `DropNewest`, `Block`

  - **spec.elasticsearch**
    object
    - **spec.elasticsearch.auth**
      object
      - **spec.elasticsearch.auth.awsAccessKey**

string

Base64-encoded AWS `ACCESS_KEY`.

- **spec.elasticsearch.auth.awsAssumeRole**
  string

  The ARN of an IAM role to assume at startup.

- **spec.elasticsearch.auth.awsRegion**
  string

  AWS region for authentication.

- **spec.elasticsearch.auth.awsSecretKey**
  string

  Base64-encoded AWS `SECRET_KEY`.

- **spec.elasticsearch.auth.password**
  string

  Base64-encoded Basic authentication password.

- **spec.elasticsearch.auth.strategy**
  string

  The authentication strategy to use.

  Default: `Basic`

  Allowed values: `Basic`, `AWS`

- **spec.elasticsearch.auth.user**
  string

  The Basic authentication user name.

- **spec.elasticsearch.dataStreamEnabled**
  boolean

  Use for storage indexes or datastreams (https://www.elastic.co/guide/en/elasticsearch/reference/master/data-streams.html).

  Datastream usage is better for logs and metrics storage but they works only for Elasticsearch >= 7.16.X.

  Default: `false`

- **spec.elasticsearch.docType**
  string

  The `doc_type` for your index data. This is only relevant for Elasticsearch <= 6.X.

  - For Elasticsearch >= 7.X you do not need this option since this version has removed `doc_type` mapping;
  - For Elasticsearch >= 6.X the recommended value is `_doc`, because using it will make it easy to upgrade to 7.X;
  - For Elasticsearch < 6.X you can't use a value starting with `_` or empty string. Use, for example, values like `logs`.

- **spec.elasticsearch.endpoint**
  string

  Required value

  Base URL of the Elasticsearch instance.

- **spec.elasticsearch.index**
  string

  Index name to write events to.

- **spec.elasticsearch.pipeline**
  string

  Name of the pipeline to apply.

- **spec.elasticsearch.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.elasticsearch.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.elasticsearch.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.elasticsearch.tls.clientCrt.crtFile**
      string

Required value

Base64-encoded certificate in PEM format.

You must also set the `keyFile` parameter.

- **spec.elasticsearch.tls.clientCrt.keyFile**
  string

  Required value

  Base64-encoded private key in PEM format (PKCS#8).

  You must also set the `crtFile` parameter.

- **spec.elasticsearch.tls.clientCrt.keyPass**
  string

  Base64-encoded pass phrase used to unlock the encrypted key file.

- **spec.elasticsearch.tls.secretRef**
  object

  Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

  - **spec.elasticsearch.tls.secretRef.name**
    string

    Name of the Secret with TLS certificates.

- **spec.elasticsearch.tls.verifyCertificate**
  boolean

  Validate the TLS certificate of the remote host. Specifically the issuer is checked but not CRLs (Certificate Revocation Lists).

  Default: `true`

- **spec.elasticsearch.tls.verifyHostname**
  boolean

  Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

  Default: `true`

- **spec.extraLabels**
  object

  A set of labels that will be attached to each batch of events.

  You can use simple templating here: `{{ app }}`.

  There are some reserved keys:

  - parsed_data
  - pod
  - pod_labels_*
  - pod_ip
  - namespace
  - image
  - container
  - node
  - pod_owner

  More about field path notation…

  Example:

  ```
  extraLabels:
    forwarder: vector
    key: value
    app_info: "{{ app }}"
    array_member: "{{ array[0] }}"
    symbol_escating_value: "{{ pay\\.day }}"
  ```

- **spec.kafka**
  object
  - **spec.kafka.bootstrapServers**
    array of strings

    Required value

    A list of host and port pairs that are the addresses of the Kafka brokers in a "bootstrap" Kafka cluster that a Kafka client connects to initially to bootstrap itself.

    Default: `[]`

Example:

```
bootstrapServers:
- 10.14.22.123:9092
- 10.14.23.332:9092
```

- **Element of the array**
  string

  Pattern: `^(.+)\:\d{1,5}$`

- **spec.kafka.encoding**
  object

  How to encode the message.

  - **spec.kafka.encoding.cef**
    object

    CEF-specific configuration fields. Only applicable when codec is set to `CEF`.

    - **spec.kafka.encoding.cef.deviceProduct**
      string

      Default: `log-shipper-agent`

    - **spec.kafka.encoding.cef.deviceVendor**
      string

      Default: `Deckhouse`

    - **spec.kafka.encoding.cef.deviceVersion**
      string

      Default: `1`

  - **spec.kafka.encoding.codec**
    string

    Available encoding formats.

    Default: `JSON`

    Allowed values: `JSON`, `CEF`

- **spec.kafka.keyField**
  string

  Allows to set the key_field.

  Examples:

  ```
  keyField: host
  ```

  ```
  keyField: node
  ```

  ```
  keyField: namespace
  ```

  ```
  keyField: parsed_data.app_info
  ```

- **spec.kafka.sasl**
  object

  Configuration for SASL authentication when interacting with Kafka.

  - **spec.kafka.sasl.mechanism**
    string

    Required value

    The SASL mechanism to use. Only PLAIN and SCRAM-based mechanisms are supported.

    Allowed values: `PLAIN`, `SCRAM-SHA-256`, `SCRAM-SHA-512`

  - **spec.kafka.sasl.password**
    string

    Required value

    The SASL password.

    Example:

    ```
    password: qwerty
    ```

  - **spec.kafka.sasl.username**
    string

Required value

The SASL username.

Example:

```
username: username
```

- **spec.kafka.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.kafka.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.kafka.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.kafka.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.kafka.tls.clientCrt.keyFile**
      string

      Required value

      Base64-encoded private key in PEM format (PKCS#8).

      You must also set the `crtFile` parameter.

    - **spec.kafka.tls.clientCrt.keyPass**
      string

      Base64-encoded pass phrase used to unlock the encrypted key file.

  - **spec.kafka.tls.secretRef**
    object

    Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

    - **spec.kafka.tls.secretRef.name**
      string

      Name of the Secret with TLS certificates.

  - **spec.kafka.tls.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    Default: `true`

  - **spec.kafka.tls.verifyHostname**
    boolean

    Verifies that the name of the remote host matches the name specified in the remote host’s TLS certificate.

    Default: `true`

- **spec.kafka.topic**
  string

  Required value

  The Kafka topic name to write events to. This parameter supports template syntax, which enables you to use dynamic per-event values.

  Examples:

  ```
  topic: logs
  ```

  ```
  topic: logs-{{unit}}-%Y-%m-%d
  ```

- **spec.logstash**
  object
  - **spec.logstash.endpoint**

string

Required value

Base URL of the Logstash instance.

- **spec.logstash.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.logstash.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.logstash.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.logstash.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.logstash.tls.clientCrt.keyFile**
      string

      Required value

      Base64-encoded private key in PEM format (PKCS#8).

      You must also set the `crtFile` parameter.

    - **spec.logstash.tls.clientCrt.keyPass**
      string

      Base64-encoded pass phrase used to unlock the encrypted key file.

  - **spec.logstash.tls.secretRef**
    object

    Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

    - **spec.logstash.tls.secretRef.name**
      string

      Name of the Secret with TLS certificates.

  - **spec.logstash.tls.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    Default: `true`

  - **spec.logstash.tls.verifyHostname**
    boolean

    Verifies that the name of the remote host matches the name specified in the remote host’s TLS certificate.

    Default: `true`

- **spec.loki**
  object
  - **spec.loki.auth**
    object
    - **spec.loki.auth.password**
      string

      Base64-encoded Basic authentication password.

    - **spec.loki.auth.strategy**
      string

      The authentication strategy to use.

      Default: `Basic`

      Allowed values: `Basic`, `Bearer`

    - **spec.loki.auth.token**
      string

      The token to use for Bearer authentication.

- **spec.loki.auth.user**
  string

  The Basic authentication user name.

- **spec.loki.endpoint**
  string

  Required value

  Base URL of the Loki instance.

  > **i** Agent automatically adds `/loki/api/v1/push` into URL during data transmission.

- **spec.loki.tenantID**
  string

  ID of a tenant.

  This option is used only for GrafanaCloud. When running Loki locally, a tenant ID is not required.

- **spec.loki.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.loki.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.loki.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.loki.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.loki.tls.clientCrt.keyFile**
      string

      Required value

      Base64-encoded private key in PEM format (PKCS#8).

      You must also set the `crtFile` parameter.

    - **spec.loki.tls.clientCrt.keyPass**
      string

      Base64-encoded pass phrase used to unlock the encrypted key file.

  - **spec.loki.tls.secretRef**
    object

    Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

    - **spec.loki.tls.secretRef.name**
      string

      Name of the Secret with TLS certificates.

  - **spec.loki.tls.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    If set to `false`, the certificate is not checked in the Certificate Revocation Lists.

    Default: `true`

  - **spec.loki.tls.verifyHostname**
    boolean

    Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

    Default: `true`

- **spec.rateLimit**
  object

Parameter for limiting the flow of events.

- **spec.rateLimit.excludes**
  array of objects

  List of excludes for keyField.

  Only NOT matched log entries would be rate limited.

  Examples:

  ```
  excludes:
    field: tier
    operator: Exists
  ```

  ```
  excludes:
    field: foo
    operator: NotIn
    values:
    - dev
    - 42
    - 'true'
    - '3.14'
  ```

  ```
  excludes:
    field: bar
    operator: Regex
    values:
    - "^abc"
    - "^\\d.+$"
  ```

  - **spec.rateLimit.excludes.field**
    string

    Required value

    Field name for filtering.

  - **spec.rateLimit.excludes.operator**
    string

    Required value

    Operator for log field comparations:

    - `In` — finds a substring in a string.
    - `NotIn` — is a negative version of the `In` operator.
    - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
    - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
    - `Exists` — drops log event if it contains some fields.
    - `DoesNotExist` — drops log event if it does not contain some fields.

    Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

  - **spec.rateLimit.excludes.values**
    array

    Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

    Fields a with float or boolean values will be converted to strings during comparison.

- **spec.rateLimit.keyField**
  string

  The name of the log field whose value will be hashed to determine if the event should be rate limited.

- **spec.rateLimit.linesPerMinute**
  number

  Required value

  The number of records per minute.

- **spec.socket**
  object
  - **spec.socket.address**
    string

    Required value

    Address of the socket.

    Pattern: `^.*:[1-9][0-9]+$`

  - **spec.socket.encoding**

object

How to encode the message.

- **spec.socket.encoding.cef**
  object

  CEF-specific configuration fields. Only applicable when codec is set to `CEF`.

  - **spec.socket.encoding.cef.deviceProduct**
    string

    Default: `log-shipper-agent`

  - **spec.socket.encoding.cef.deviceVendor**
    string

    Default: `Deckhouse`

  - **spec.socket.encoding.cef.deviceVersion**
    string

    Default: `1`

- **spec.socket.encoding.codec**
  string

  Available encoding formats.

  Default: `JSON`

  Allowed values: `Text`, `JSON`, `Syslog`, `CEF`, `GELF`

- **spec.socket.mode**
  string

  Required value

  Allowed values: `TCP`, `UDP`

- **spec.socket.tcp**
  object
  - **spec.socket.tcp.tls**
    object

    Configures the TLS options for outgoing connections.

    - **spec.socket.tcp.tls.caFile**
      string

      Base64-encoded CA certificate in PEM format.

    - **spec.socket.tcp.tls.clientCrt**
      object

      Configures the client certificate for outgoing connections.

      - **spec.socket.tcp.tls.clientCrt.crtFile**
        string

        Required value

        Base64-encoded certificate in PEM format.

        You must also set the `keyFile` parameter.

      - **spec.socket.tcp.tls.clientCrt.keyFile**
        string

        Required value

        Base64-encoded private key in PEM format (PKCS#8).

        You must also set the `crtFile` parameter.

      - **spec.socket.tcp.tls.clientCrt.keyPass**
        string

        Base64-encoded pass phrase used to unlock the encrypted key file.

    - **spec.socket.tcp.tls.secretRef**
      object

      Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

      - **spec.socket.tcp.tls.secretRef.name**
        string

        Name of the Secret with TLS certificates.

  - **spec.socket.tcp.verifyCertificate**

boolean

Validate the TLS certificate of the remote host.

If set to `false`, the certificate is not checked in the Certificate Revocation Lists.

Default: `true`

- **spec.socket.tcp.verifyHostname**
  boolean

  Verifies that the name of the remote host matches the name specified in the remote host’s TLS certificate.

  Default: `true`

- **spec.splunk**
  object
  - **spec.splunk.endpoint**
    string

    Required value

    Base URL of the Splunk instance.

    Example:

    ```
    endpoint: https://http-inputs-hec.splunkcloud.com
    ```

  - **spec.splunk.index**
    string

    Index name to write events to.

  - **spec.splunk.tls**
    object

    Configures the TLS options for outgoing connections.

    - **spec.splunk.tls.caFile**
      string

      Base64-encoded CA certificate in PEM format.

    - **spec.splunk.tls.clientCrt**
      object

      Configures the client certificate for outgoing connections.

      - **spec.splunk.tls.clientCrt.crtFile**
        string

        Required value

        Base64-encoded certificate in PEM format.

        You must also set the `keyFile` parameter.

      - **spec.splunk.tls.clientCrt.keyFile**
        string

        Required value

        Base64-encoded private key in PEM format (PKCS#8).

        You must also set the `crtFile` parameter.

      - **spec.splunk.tls.clientCrt.keyPass**
        string

        Base64-encoded pass phrase used to unlock the encrypted key file.

    - **spec.splunk.tls.secretRef**
      object

      Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

      - **spec.splunk.tls.secretRef.name**
        string

        Name of the Secret with TLS certificates.

    - **spec.splunk.tls.verifyCertificate**
      boolean

      Validate the TLS certificate of the remote host.

      Default: `true`

    - **spec.splunk.tls.verifyHostname**

boolean

Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

Default: `true`

- **spec.splunk.token**
  string

  Required value

  Default Splunk HEC token. If an event has a token set in its metadata, it will have priority over the one set here.

- **spec.transformations**
  array of objects

  Ordered list of transformations applied to each log event before it is sent to the destination. Items are executed in array order.

  `AddLabels` runs after `extraLabels` when both are configured.

  Available actions:

  - `ReplaceKeys` — recursively replace matches of the `source` pattern with `target` in the given paths.
  - `ParseMessage` — parse the `message` field using `sourceFormat` and write the result to `targetLabel` (default `.message`; the lone `.` merges into the event root). On parse failure the original `message` is left unchanged.
  - `DropLabels` — remove the value at each `label` path, or if `keepKeys` is set on an item, keep only those child key names inside the object at `label`.
  - `AddLabels` — add labels (literals, `{{ .path }}` templates, optional `when`). Runs after `extraLabels`; on key name conflicts `AddLabels` wins.
  - `ReplaceValue` — replace substrings in scalar string fields using the `source` regex; `target` may reference named groups as `{{ group_name }}`.

  Examples:

  ```
  transformations:
    action: ReplaceKeys
    replaceKeys:
      source: "."
      target: _
      labels:
      - ".pod_labels"
  ```

  ```
  transformations:
    action: ParseMessage
    parseMessage:
      sourceFormat: String
      string:
        regex: "^(?P<msg>.*)$"
        setLabels:
          msg: "{{ msg }}"
  ```

  ```
  transformations:
    action: ParseMessage
    parseMessage:
      sourceFormat: Klog
  ```

  ```
  transformations:
    action: ParseMessage
    parseMessage:
      sourceFormat: JSON
      json:
        depth: 1
  ```

  ```
  transformations:
    action: DropLabels
    dropLabels:
      labels:
      - label: ".first"
      - label: ".second"
      - label: ".pod_labels"
        keepKeys:
        - app
        - team
  ```

```
transformations:
  action: AddLabels
  addLabels:
    when:
    - .namespace == "production"
    setLabels:
      ".env": prod
      ".source_app": "{{ .pod_labels.app }}"
```

```
transformations:
  action: ReplaceValue
  replaceValue:
    source: "\\d+"
    target: REDACTED
    labels:
    - ".message"
```

- **spec.transformations.action**
  string

  Transformation type; selects which parameter block is used.

  Allowed values: `ReplaceKeys`, `ParseMessage`, `DropLabels`, `AddLabels`, `ReplaceValue`

- **spec.transformations.addLabels**
  object

  Adds fields to the event from `setLabels` (literals and `{{ .path }}` templates). Runs after `extraLabels` when both are set; on path conflicts values from this transform win. Optional `when` filter.

  - **spec.transformations.addLabels.setLabels**
    object

    Required value

    Keys are destination label paths in Vector notation: each key starts with `.` relative to the event root (e.g. `.env`, `.source_app`). Values are literals or `{{ .path }}` templates where `path` in the template is a source field path with a leading `.`.

    Examples:

    ```
    setLabels:
      ".tier": backend
    ```

    ```
    setLabels:
      ".source_app": "{{ .pod_labels.app }}"
    ```

  - **spec.transformations.addLabels.when**
    array of strings

    Optional list of conditions combined with logical AND. In comparisons, the field path is a leading dot and dot-separated segments (e.g. `.namespace`, `.pod_labels.app`). Each item is either: a comparison `path ==|!=|=~|!=~ value` (regular expression for `=~` / `!=~`), a `path` with no operator or right-hand side (field exists), or `!.path` (field does not exist).

    Examples:

    ```
    when: .namespace == "production"
    ```

    ```
    when: .pod_labels.app =~ "^api-"
    ```

    ```
    when: .level != "debug"
    ```

    ```
    when: ".pod_labels.team"
    ```

    ```
    when: "!.pod_labels.legacy"
    ```

    - **Element of the array**
      string

      Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'"|<>~#/@]+$`

- **spec.transformations.dropLabels**
  object

  Removes field paths, or narrows objects by keeping only selected child keys at each `label` when `keepKeys` is set.

  - **spec.transformations.dropLabels.labels**
    array of objects

Required value

Each item has a required Vector path `label` and optional `keepKeys`. If `keepKeys` is omitted, the subtree at `label` is removed. If `keepKeys` is set, only those child key names are kept in the object at `label`.

- **spec.transformations.dropLabels.labels.keepKeys**
  array of strings

  Child key names (no leading dot) to keep inside the object at `label`; all other child keys are removed.

  - **Element of the array**
    string

    Pattern: `^[a-zA-Z0-9_.\-/]+$`

- **spec.transformations.dropLabels.labels.label**
  string

  Required value

  Vector path to a field or subtree; when `keepKeys` is set, must resolve to an object.

  Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-"/:]+$`

- **spec.transformations.parseMessage**
  object

  Parses the string in the `message` field (format from `sourceFormat`) and writes the result to `targetLabel` as a Vector path with a leading `.` (default `.message`; the lone `.` merges the parsed object into the event root). On parse failure the original `message` field is left unchanged.

  - **spec.transformations.parseMessage.json**
    object
    - **spec.transformations.parseMessage.json.depth**
      integer

      Depth for JSON parsing.

      Allowed values: `1 <= X <= 128`

  - **spec.transformations.parseMessage.sourceFormat**
    string

    Required value

    Message format for converting into an object.

    Allowed values: `String`, `JSON`, `Klog`, `SysLog`, `CLF`, `Logfmt`

  - **spec.transformations.parseMessage.string**
    object

    Settings for `sourceFormat: String`. `regex` and `setLabels` are required.

    - **spec.transformations.parseMessage.string.regex**
      string

      Required value

      Regular expression with named capture groups; requires `setLabels`.

      Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'\"|<>~#/@]+$`

    - **spec.transformations.parseMessage.string.setLabels**
      object

      Required value

      Maps output keys to literals or `{{ group_name }}` templates.

  - **spec.transformations.parseMessage.targetLabel**
    string

    Destination path for the parsed value (default `.message`). The lone value `.` merges into the event root. Must not be `.parsed_data`.

    Default: `.message`

    Pattern: `^(\.|\.[a-zA-Z0-9_\[\]\\\.\-"/:']+)$`

    Examples:

    ```
    targetLabel: ".message"
    ```

    ```
    targetLabel: "."
    ```

    ```
    targetLabel: ".tmp"
    ```

- **spec.transformations.replaceKeys**

object

Recursively replaces matches of the `source` pattern with the `target` value in the listed paths (`labels`). Paths use Vector notation with a leading `.` on each list item.

- **spec.transformations.replaceKeys.labels**
  array of strings

  Required value

  Label paths where the replacement runs. Each item must start with `.` (Vector field path notation, e.g. `.pod_labels`, `.parsed_data`).

  Examples:

  ```
  labels: ".pod_labels"
  ```

  ```
  labels: ".annotations"
  ```

  - **Element of the array**
    string

    Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-"/:']+$`

- **spec.transformations.replaceKeys.source**
  string

  Required value

  Pattern used to find matches. Can be a static string or a regular expression (same character set as other regex fields in transformations).

  Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'"|<>~#/@]+$`

  Examples:

  ```
  source: "."
  ```

  ```
  source: "^old\\."
  ```

- **spec.transformations.replaceKeys.target**
  string

  Literal replacement string for matched substrings (not a regex).

  Default:

  Examples:

  ```
  target: _
  ```

  ```
  target: ''
  ```

- **spec.transformations.replaceValue**
  object

  Replace matches of `source` in each listed scalar string field with `target`.

  - **spec.transformations.replaceValue.labels**
    array of strings

    Required value

    Paths to scalar string fields where replacement runs. Each item must start with `.` (Vector path, e.g. `.message`, `.parsed_data.token`).

    Examples:

    ```
    labels: ".message"
    ```

    ```
    labels: ".parsed_data.line"
    ```

    - **Element of the array**
      string

      Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-"/:']+$`

  - **spec.transformations.replaceValue.source**
    string

    Required value

    Regular expression to search in each scalar field value.

    Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'"|<>~#/@]+$`

Examples:

```
source: "\\d+"
```

```
source: "(?P<tok>token=[^\\s]+)"
```

- **spec.transformations.replaceValue.target**
  string

  Required value

  Replacement string; may use `{{name}}` for named capture groups.

  Examples:

```
target: REDACTED
```

```
target: "{{tok}}"
```

- **spec.type**
  string

  Type of a log storage backend.

  Allowed values: `Loki`, `Elasticsearch`, `Logstash`, `Vector`, `Kafka`, `Splunk`, `Socket`

- **spec.vector**
  object
  - **spec.vector.endpoint**
    string

    Required value

    An address of the Vector instance. API v2 must be used for communication between instances.

    Pattern: `^(.+):([0-9]{1,5})$`

  - **spec.vector.tls**
    object

    Configures the TLS options for outgoing connections.

    - **spec.vector.tls.caFile**
      string

      Base64-encoded CA certificate in PEM format.

    - **spec.vector.tls.clientCrt**
      object

      Configures the client certificate for outgoing connections.

      - **spec.vector.tls.clientCrt.crtFile**
        string

        Required value

        Base64-encoded certificate in PEM format.

        You must also set the `keyFile` parameter.

      - **spec.vector.tls.clientCrt.keyFile**
        string

        Required value

        Base64-encoded private key in PEM format (PKCS#8).

        You must also set the `crtFile` parameter.

      - **spec.vector.tls.clientCrt.keyPass**
        string

        Base64-encoded passphrase used to unlock the encrypted key file.

    - **spec.vector.tls.secretRef**
      object

      Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

      - **spec.vector.tls.secretRef.name**
        string

        Name of the Secret with TLS certificates.

    - **spec.vector.tls.verifyCertificate**
      boolean

Validate the TLS certificate of the remote host.

Default: `true`

- **spec.vector.tls.verifyHostname**
  boolean

  Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

  Default: `true`

Deprecated resource. Support for the resource might be removed in a later release.

Describes setting for a log storage, which you can use in many log sources.

`metadata.name` — is an upstream name, which you should use in custom resource ClusterLoggingConfig.

- **spec**
  object

  Required value

  - **spec.buffer**
    object

    Buffer parameters.

    - **spec.buffer.disk**
      object

      Disk buffer parameters.

      - **spec.buffer.disk.maxSize**
        integer or string

        The maximum size of the buffer on disk. Must be at least ~256MB (268435488 bytes).

        You can express size as a plain integer or as a fixed-point number using one of these quantity suffixes: `E`, `P`, `T`, `G`, `M`, `k`, `Ei`, `Pi`, `Ti`, `Gi`, `Mi`, `Ki`.

        More about resource quantity:

        - kubernetes quantity
        - memory resource units

        Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

        Examples:

        ```
        maxSize: 512Mi
        ```

        ```
        maxSize: 268435488
        ```

    - **spec.buffer.memory**
      object
      - **spec.buffer.memory.maxEvents**
        number

        The maximum number of events allowed in the buffer.

    - **spec.buffer.type**
      string

      Required value

      The type of buffer to use.

      Allowed values: `Disk`, `Memory`

    - **spec.buffer.whenFull**
      string

      Event handling behavior when a buffer is full.

      Default: `Block`

      Allowed values: `DropNewest`, `Block`

  - **spec.elasticsearch**
    object
    - **spec.elasticsearch.auth**
      object
      - **spec.elasticsearch.auth.awsAccessKey**
        string

        Base64-encoded AWS `ACCESS_KEY`.

      - **spec.elasticsearch.auth.awsAssumeRole**
        string

The ARN of an IAM role to assume at startup.

- **spec.elasticsearch.auth.awsRegion**
  string

  AWS region for authentication.

- **spec.elasticsearch.auth.awsSecretKey**
  string

  Base64-encoded AWS `SECRET_KEY`.

- **spec.elasticsearch.auth.password**
  string

  Base64-encoded Basic authentication password.

- **spec.elasticsearch.auth.strategy**
  string

  The authentication strategy to use.

  Default: `Basic`

  Allowed values: `Basic`, `AWS`

- **spec.elasticsearch.auth.user**
  string

  The Basic authentication user name.

- **spec.elasticsearch.dataStreamEnabled**
  boolean

  Use for storage indexes or datastreams (https://www.elastic.co/guide/en/elasticsearch/reference/master/data-streams.html).

  Datastream usage is better for logs and metrics storage but they works only for Elasticsearch >= 7.16.X.

  Default: `false`

- **spec.elasticsearch.docType**
  string

  The `doc_type` for your index data. This is only relevant for Elasticsearch <= 6.X.

  - For Elasticsearch >= 7.X you do not need this option since this version has removed `doc_type` mapping;
  - For Elasticsearch >= 6.X the recommended value is `_doc`, because using it will make it easy to upgrade to 7.X;
  - For Elasticsearch < 6.X you can't use a value starting with `_` or empty string. Use, for example, values like `logs`.

- **spec.elasticsearch.endpoint**
  string

  Required value

  Base URL of the Elasticsearch instance.

- **spec.elasticsearch.index**
  string

  Index name to write events to.

- **spec.elasticsearch.pipeline**
  string

  Name of the pipeline to apply.

- **spec.elasticsearch.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.elasticsearch.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.elasticsearch.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.elasticsearch.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.elasticsearch.tls.clientCrt.keyFile**

string

Required value

Base64-encoded private key in PEM format (PKCS#8).

You must also set the `crtFile` parameter.

- **spec.elasticsearch.tls.clientCrt.keyPass**
  string

  Base64-encoded pass phrase used to unlock the encrypted key file.

- **spec.elasticsearch.tls.secretRef**
  object

  Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

  - **spec.elasticsearch.tls.secretRef.name**
    string

    Name of the Secret with TLS certificates.

- **spec.elasticsearch.tls.verifyCertificate**
  boolean

  Validate the TLS certificate of the remote host. Specifically the issuer is checked but not CRLs (Certificate Revocation Lists).

  Default: `true`

- **spec.elasticsearch.tls.verifyHostname**
  boolean

  Verifies that the name of the remote host matches the name specified in the remote host’s TLS certificate.

  Default: `true`

- **spec.extraLabels**
  object

  A set of labels that will be attached to each batch of events.

  You can use simple templating here: `{{ app }}`.

  There are some reserved keys:

  - parsed_data
  - pod
  - pod_labels_*
  - pod_ip
  - namespace
  - image
  - container
  - node
  - pod_owner

  More about field path notation…

  Example:

  ```
  extraLabels:
    forwarder: vector
    key: value
    app_info: "{{ app }}"
    array_member: "{{ array[0] }}"
    symbol_escating_value: "{{ pay\\.day }}"
  ```

- **spec.kafka**
  object
  - **spec.kafka.bootstrapServers**
    array of strings

    Required value

    A list of host and port pairs that are the addresses of the Kafka brokers in a “bootstrap” Kafka cluster that a Kafka client connects to initially to bootstrap itself.

    Default: `[]`

    Example:

    ```
    bootstrapServers:
    - 10.14.22.123:9092
    - 10.14.23.332:9092
    ```

- **Element of the array**
  string

  Pattern: `^(.+)\:\d{1,5}$`

- **spec.kafka.encoding**
  object

  How to encode the message.

  - **spec.kafka.encoding.cef**
    object

    CEF-specific configuration fields. Only applicable when codec is set to `CEF`.

    - **spec.kafka.encoding.cef.deviceProduct**
      string

      Default: `log-shipper-agent`

    - **spec.kafka.encoding.cef.deviceVendor**
      string

      Default: `Deckhouse`

    - **spec.kafka.encoding.cef.deviceVersion**
      string

      Default: `1`

  - **spec.kafka.encoding.codec**
    string

    Available encoding formats.

    Default: `JSON`

    Allowed values: `JSON`, `CEF`

- **spec.kafka.keyField**
  string

  Allows to set the key_field.

  Examples:

  ```
  keyField: host
  ```

  ```
  keyField: node
  ```

  ```
  keyField: namespace
  ```

  ```
  keyField: parsed_data.app_info
  ```

- **spec.kafka.sasl**
  object

  Configuration for SASL authentication when interacting with Kafka.

  - **spec.kafka.sasl.mechanism**
    string

    Required value

    The SASL mechanism to use. Only PLAIN and SCRAM-based mechanisms are supported.

    Allowed values: `PLAIN`, `SCRAM-SHA-256`, `SCRAM-SHA-512`

  - **spec.kafka.sasl.password**
    string

    Required value

    The SASL password.

    Example:

    ```
    password: qwerty
    ```

  - **spec.kafka.sasl.username**
    string

    Required value

    The SASL username.

    Example:

```
username: username
```

- **spec.kafka.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.kafka.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.kafka.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.kafka.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.kafka.tls.clientCrt.keyFile**
      string

      Required value

      Base64-encoded private key in PEM format (PKCS#8).

      You must also set the `crtFile` parameter.

    - **spec.kafka.tls.clientCrt.keyPass**
      string

      Base64-encoded pass phrase used to unlock the encrypted key file.

  - **spec.kafka.tls.secretRef**
    object

    Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

    - **spec.kafka.tls.secretRef.name**
      string

      Name of the Secret with TLS certificates.

  - **spec.kafka.tls.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    Default: `true`

  - **spec.kafka.tls.verifyHostname**
    boolean

    Verifies that the name of the remote host matches the name specified in the remote host’s TLS certificate.

    Default: `true`

- **spec.kafka.topic**
  string

  Required value

  The Kafka topic name to write events to. This parameter supports template syntax, which enables you to use dynamic per-event values.

  Examples:

  ```
  topic: logs
  ```

  ```
  topic: logs-{{unit}}-%Y-%m-%d
  ```

- **spec.logstash**
  object
  - **spec.logstash.endpoint**
    string

    Required value

    Base URL of the Logstash instance.

- **spec.logstash.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.logstash.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.logstash.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.logstash.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.logstash.tls.clientCrt.keyFile**
      string

      Required value

      Base64-encoded private key in PEM format (PKCS#8).

      You must also set the `crtFile` parameter.

    - **spec.logstash.tls.clientCrt.keyPass**
      string

      Base64-encoded pass phrase used to unlock the encrypted key file.

  - **spec.logstash.tls.secretRef**
    object

    Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

    - **spec.logstash.tls.secretRef.name**
      string

      Name of the Secret with TLS certificates.

  - **spec.logstash.tls.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    Default: `true`

  - **spec.logstash.tls.verifyHostname**
    boolean

    Verifies that the name of the remote host matches the name specified in the remote host’s TLS certificate.

    Default: `true`

- **spec.loki**
  object
  - **spec.loki.auth**
    object
    - **spec.loki.auth.password**
      string

      Base64-encoded Basic authentication password.

    - **spec.loki.auth.strategy**
      string

      The authentication strategy to use.

      Default: `Basic`

      Allowed values: `Basic`, `Bearer`

    - **spec.loki.auth.token**
      string

      The token to use for Bearer authentication.

    - **spec.loki.auth.user**
      string

      The Basic authentication user name.

- **spec.loki.endpoint**
  string

  Required value

  Base URL of the Loki instance.

  > **i** Agent automatically adds `/loki/api/v1/push` into URL during data transmission.

- **spec.loki.tenantID**
  string

  ID of a tenant.

  This option is used only for GrafanaCloud. When running Loki locally, a tenant ID is not required.

- **spec.loki.tls**
  object

  Configures the TLS options for outgoing connections.

  - **spec.loki.tls.caFile**
    string

    Base64-encoded CA certificate in PEM format.

  - **spec.loki.tls.clientCrt**
    object

    Configures the client certificate for outgoing connections.

    - **spec.loki.tls.clientCrt.crtFile**
      string

      Required value

      Base64-encoded certificate in PEM format.

      You must also set the `keyFile` parameter.

    - **spec.loki.tls.clientCrt.keyFile**
      string

      Required value

      Base64-encoded private key in PEM format (PKCS#8).

      You must also set the `crtFile` parameter.

    - **spec.loki.tls.clientCrt.keyPass**
      string

      Base64-encoded pass phrase used to unlock the encrypted key file.

  - **spec.loki.tls.secretRef**
    object

    Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

    - **spec.loki.tls.secretRef.name**
      string

      Name of the Secret with TLS certificates.

  - **spec.loki.tls.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    If set to `false`, the certificate is not checked in the Certificate Revocation Lists.

    Default: `true`

  - **spec.loki.tls.verifyHostname**
    boolean

    Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

    Default: `true`

- **spec.rateLimit**
  object

  Parameter for limiting the flow of events.

  - **spec.rateLimit.excludes**
    array of objects

List of excludes for keyField.

Only NOT matched log entries would be rate limited.

Examples:

```
excludes:
  field: tier
  operator: Exists
```

```
excludes:
  field: foo
  operator: NotIn
  values:
  - dev
  - 42
  - 'true'
  - '3.14'
```

```
excludes:
  field: bar
  operator: Regex
  values:
  - "^abc"
  - "^\\d.+$"
```

- **spec.rateLimit.excludes.field**
  string

  Required value

  Field name for filtering.

- **spec.rateLimit.excludes.operator**
  string

  Required value

  Operator for log field comparations:

  - `In` — finds a substring in a string.
  - `NotIn` — is a negative version of the `In` operator.
  - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
  - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
  - `Exists` — drops log event if it contains some fields.
  - `DoesNotExist` — drops log event if it does not contain some fields.

  Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

- **spec.rateLimit.excludes.values**
  array

  Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

  Fields a with float or boolean values will be converted to strings during comparison.

- **spec.rateLimit.keyField**
  string

  The name of the log field whose value will be hashed to determine if the event should be rate limited.

- **spec.rateLimit.linesPerMinute**
  number

  Required value

  The number of records per minute.

- **spec.socket**
  object
  - **spec.socket.address**
    string

    Required value

    Address of the socket.

    Pattern: `^.*:[1-9][0-9]+$`

  - **spec.socket.encoding**
    object

    How to encode the message.

    - **spec.socket.encoding.cef**

object

CEF-specific configuration fields. Only applicable when codec is set to `CEF`.

- **spec.socket.encoding.cef.deviceProduct**
  string

  Default: `log-shipper-agent`

- **spec.socket.encoding.cef.deviceVendor**
  string

  Default: `Deckhouse`

- **spec.socket.encoding.cef.deviceVersion**
  string

  Default: `1`

- **spec.socket.encoding.codec**
  string

  Available encoding formats.

  Default: `JSON`

  Allowed values: `Text`, `JSON`, `Syslog`, `CEF`, `GELF`

- **spec.socket.mode**
  string

  Required value

  Allowed values: `TCP`, `UDP`

- **spec.socket.tcp**
  object
  - **spec.socket.tcp.tls**
    object

    Configures the TLS options for outgoing connections.

    - **spec.socket.tcp.tls.caFile**
      string

      Base64-encoded CA certificate in PEM format.

    - **spec.socket.tcp.tls.clientCrt**
      object

      Configures the client certificate for outgoing connections.

      - **spec.socket.tcp.tls.clientCrt.crtFile**
        string

        Required value

        Base64-encoded certificate in PEM format.

        You must also set the `keyFile` parameter.

      - **spec.socket.tcp.tls.clientCrt.keyFile**
        string

        Required value

        Base64-encoded private key in PEM format (PKCS#8).

        You must also set the `crtFile` parameter.

      - **spec.socket.tcp.tls.clientCrt.keyPass**
        string

        Base64-encoded pass phrase used to unlock the encrypted key file.

    - **spec.socket.tcp.tls.secretRef**
      object

      Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

      - **spec.socket.tcp.tls.secretRef.name**
        string

        Name of the Secret with TLS certificates.

  - **spec.socket.tcp.verifyCertificate**
    boolean

    Validate the TLS certificate of the remote host.

    If set to `false`, the certificate is not checked in the Certificate Revocation Lists.

Default: `true`

- **spec.socket.tcp.verifyHostname**
  boolean

  Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

  Default: `true`

- **spec.splunk**
  object
  - **spec.splunk.endpoint**
    string

    Required value

    Base URL of the Splunk instance.

    Example:

    ```
    endpoint: https://http-inputs-hec.splunkcloud.com
    ```

  - **spec.splunk.index**
    string

    Index name to write events to.

  - **spec.splunk.tls**
    object

    Configures the TLS options for outgoing connections.

    - **spec.splunk.tls.caFile**
      string

      Base64-encoded CA certificate in PEM format.

    - **spec.splunk.tls.clientCrt**
      object

      Configures the client certificate for outgoing connections.

      - **spec.splunk.tls.clientCrt.crtFile**
        string

        Required value

        Base64-encoded certificate in PEM format.

        You must also set the `keyFile` parameter.

      - **spec.splunk.tls.clientCrt.keyFile**
        string

        Required value

        Base64-encoded private key in PEM format (PKCS#8).

        You must also set the `crtFile` parameter.

      - **spec.splunk.tls.clientCrt.keyPass**
        string

        Base64-encoded pass phrase used to unlock the encrypted key file.

    - **spec.splunk.tls.secretRef**
      object

      Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

      - **spec.splunk.tls.secretRef.name**
        string

        Name of the Secret with TLS certificates.

    - **spec.splunk.tls.verifyCertificate**
      boolean

      Validate the TLS certificate of the remote host.

      Default: `true`

    - **spec.splunk.tls.verifyHostname**
      boolean

      Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

      Default: `true`

- **spec.splunk.token**
  string

  Required value

  Default Splunk HEC token. If an event has a token set in its metadata, it will have priority over the one set here.

- **spec.transformations**
  array of objects

  List of transformations that can be applied to logs before sending them to the destination.

  Available options:

  - `ReplaceKeys`: Replaces `source` with `target` in the specified label keys.

    Example:

    ```
    transformations:
    - action: ReplaceKeys
      replaceKeys:
        source: "."
        target: "_"
        labels:
          - .pod_labels
    ```

  - `ParseMessage`: Converts the `message` field from the format specified in `sourceFormat` into an object. If conversion fails, the `message` field remains unchanged.

    Examples:

    ```
    transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: String
        string:
          regex: "^(?P<msg>.*)$"
          setLabels:
            msg: "{{ msg }}"
    ```

    ```
    transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: Klog
    - action: ParseMessage
      parseMessage:
        sourceFormat: JSON
        json:
          depth: 1
    - action: ParseMessage
      parseMessage:
        sourceFormat: String
        string:
          regex: "^(?P<msg>.*)$"
          setLabels:
            msg: "{{ msg }}"
    ```

  - `DropLabels`: Removes the specified labels.

    Example:

    ```
    transformations:
    - action: DropLabels
      dropLabels:
        labels:
          - .first
          - .second
    ```

  - **spec.transformations.action**
    string

    Type of a transformation.

    Allowed values: `ReplaceKeys`, `ParseMessage`, `DropLabels`, `AddLabels`, `ReplaceValue`

  - **spec.transformations.addLabels**
    object
    - **spec.transformations.addLabels.setLabels**
      object

Required value

- **spec.transformations.addLabels.when**
  array of strings
  - **Element of the array**
    string

    Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'"|<>~#/@]+$`

- **spec.transformations.dropLabels**
  object

  Removes the specified labels.

  - **spec.transformations.dropLabels.labels**
    array of strings

    List of labels to remove.

    - **Element of the array**
      string

      Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-]+$`

  - **spec.transformations.dropLabels.paths**
    array of objects

    List of path entries matching v1alpha2 dropLabels.labels.

    - **spec.transformations.dropLabels.paths.keepKeys**
      array of strings
      - **Element of the array**
        string

        Pattern: `^[a-zA-Z0-9_.\-/]+$`

    - **spec.transformations.dropLabels.paths.label**
      string

      Required value

      Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-]+$`

- **spec.transformations.parseMessage**
  object

  Converts the `message` field into an object.

  - **spec.transformations.parseMessage.json**
    object
    - **spec.transformations.parseMessage.json.depth**
      integer

      Depth for JSON parsing.

      Allowed values: `1 <= X <= 128`

  - **spec.transformations.parseMessage.sourceFormat**
    string

    Required value

    Message format for converting into an object.

    Allowed values: `String`, `JSON`, `Klog`, `SysLog`, `CLF`, `Logfmt`

  - **spec.transformations.parseMessage.string**
    object
    - **spec.transformations.parseMessage.string.regex**
      string

      Regular expression with named capture groups.

      Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'\"|<>~#/@]+$`

    - **spec.transformations.parseMessage.string.setLabels**
      object

      Maps output keys to literals or `{{ group_name }}` templates.

    - **spec.transformations.parseMessage.string.targetField**
      string

      Target field where the structured message is placed.

      Pattern: `^[a-zA-Z0-9_\\\.\-]+$`

  - **spec.transformations.parseMessage.targetLabel**
    string

    Destination path for the parsed value.

    Default: `.message`

Pattern: `^(\.|\.[a-zA-Z0-9_\[\]\\\.\-"/:']+)$`

- **spec.transformations.replaceKeys**
  object

  Recursive replacement of all matches of the `source` pattern with the `target` value in the specified labels.

  - **spec.transformations.replaceKeys.labels**
    array of strings

    Required value

    List of labels in which the recursive replacement will be performed.

    - **Element of the array**
      string

      Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-]+$`

  - **spec.transformations.replaceKeys.source**
    string

    Required value

    Pattern used to find matches. Can be a static string or a regular expression.

  - **spec.transformations.replaceKeys.target**
    string

    Value that replaces all matches of the pattern.

    Default:

- **spec.transformations.replaceValue**
  object
  - **spec.transformations.replaceValue.labels**
    array of strings

    Required value

    - **Element of the array**
      string

      Pattern: `^\.[a-zA-Z0-9_\[\]\\\.\-"/:']+$`

  - **spec.transformations.replaceValue.source**
    string

    Required value

    Pattern: `^[a-zA-Z0-9_\s\\\[\](){}?*+.^$\-=!:,'"|<>~#/@]+$`

  - **spec.transformations.replaceValue.target**
    string

    Required value

- **spec.type**
  string

  Type of a log storage backend.

  Allowed values: `Loki`, `Elasticsearch`, `Logstash`, `Vector`, `Kafka`, `Splunk`, `Socket`

- **spec.vector**
  object
  - **spec.vector.endpoint**
    string

    Required value

    An address of the Vector instance. API v2 must be used for communication between instances.

    Pattern: `^(.+):([0-9]{1,5})$`

  - **spec.vector.tls**
    object

    Configures the TLS options for outgoing connections.

    - **spec.vector.tls.caFile**
      string

      Base64-encoded CA certificate in PEM format.

    - **spec.vector.tls.clientCrt**
      object

      Configures the client certificate for outgoing connections.

      - **spec.vector.tls.clientCrt.crtFile**
        string

        Required value

Base64-encoded certificate in PEM format.

You must also set the `keyFile` parameter.

- **spec.vector.tls.clientCrt.keyFile**
  string

  Required value

  Base64-encoded private key in PEM format (PKCS#8).

  You must also set the `crtFile` parameter.

- **spec.vector.tls.clientCrt.keyPass**
  string

  Base64-encoded passphrase used to unlock the encrypted key file.

- **spec.vector.tls.secretRef**
  object

  Reference to a Kubernetes Secret containing the CA certificate (ca.pem), client certificate (crt.pem), private key (key.pem) and key pass (keyPass) in Base64-encoded PEM format. If specified, TLS settings are overridden with values from the secret. Secret should be located in d8-log-shipper namespace and have `log-shipper.deckhouse.io/watch-secret: true` label.

  - **spec.vector.tls.secretRef.name**
    string

    Name of the Secret with TLS certificates.

- **spec.vector.tls.verifyCertificate**
  boolean

  Validate the TLS certificate of the remote host.

  Default: `true`

- **spec.vector.tls.verifyHostname**
  boolean

  Verifies that the name of the remote host matches the name specified in the remote host's TLS certificate.

  Default: `true`

ClusterLoggingConfig

Scope: Cluster

- v1alpha2
- v1alpha1

Describes a log source in log-pipeline.

Each custom resource `ClusterLoggingConfig` describes rules for log fetching from cluster.

- **spec**
  object

  Required value

  - **spec.destinationRefs**
    array of strings

    Required value

    Array of `ClusterLogDestination` custom resource names which this source will output with.

    Fields with float or boolean values will be converted to strings.

  - **spec.file**
    object

    Describes a rule for collecting logs from files on a node.

    - **spec.file.exclude**
      array of strings

      Array of file patterns to exclude when collecting logs.

      Wildcards are supported.

      Examples:

      ```
      exclude: "/var/log/nginx/error.log"
      ```

      ```
      exclude: "/var/log/audit.log"
      ```

    - **spec.file.include**
      array of strings

Array of file patterns to include.

Wildcards are supported

Examples:

```
include: "/var/log/*.log"
```

```
include: "/var/log/nginx/*.log"
```

- **spec.file.lineDelimiter**
  string

  String sequence used to separate one file line from another.

  Example:

  ```
  lineDelimiter: "\\r\\n"
  ```

- **spec.kubernetesPods**
  object

  Describes a rule for collecting logs from the cluster’s pods.

  - **spec.kubernetesPods.keepDeletedFilesOpenedFor**
    string

    Specifies the time to keep deleted files opened for reading. Vector will keep pods metadata for this time as well to read logs from deleted pods. This option is useful in cases of a log storage unavailability or a network partition. Vector will keep log files opened until finally sending them to the destination.

    Enabling this option may affect the resource consumption of the Vector and also flood a disk with deleted logs. Use it with caution.

    The format is a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

  - **spec.kubernetesPods.labelSelector**
    object

    Specifies the label selector to filter Pods with.

    You can get more into here.

    - **spec.kubernetesPods.labelSelector.matchExpressions**
      array of objects

      List of label expressions for Pods.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      - key: tier
        operator: NotIn
        values:
        - production
      ```

      - **spec.kubernetesPods.labelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.kubernetesPods.labelSelector.matchExpressions.operator**
        string

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.kubernetesPods.labelSelector.matchExpressions.values**
        array of strings

        A label value.

        - **Element of the array**
          string

          Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

          Length: `1..63`

    - **spec.kubernetesPods.labelSelector.matchLabels**

object

List of labels which Pod should have.

Example:

```
matchLabels:
  foo: bar
  baz: who
```

- **spec.kubernetesPods.namespaceSelector**
  object

  Specifies the namespace selector to filter Pods with.

  The filter uses the `labelSelector` parameter to determine the namespaces from which logs should be collected.

  - **spec.kubernetesPods.namespaceSelector.labelSelector**
    object

    Specifies the label selector to filter namespaces from which logs should be collected.

    You can get more into here.

    - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions**
      array of objects

      List of label expressions that a namespace should have to qualify for the filter condition.

      Example:

      ```
      matchExpressions:
      - key: tier
        operator: In
        values:
        - production
        - staging
      ```

      - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions.key**
        string

        Required value

        A label name.

      - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions.operator**
        string

        Required value

        A comparison operator.

        Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

      - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions.values**
        array of strings

        A label value.

        - **Element of the array**
          string

          Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

          Length: `1..63`

    - **spec.kubernetesPods.namespaceSelector.labelSelector.matchLabels**
      object

      List of labels that a namespace should have to qualify for the filter condition.

      Example:

      ```
      matchLabels:
        foo: bar
        baz: who
      ```

- **spec.labelFilter**
  array of objects

  Rules to filter log lines by their metadata labels.

  Example:

```
labelFilter:
- field: container
  operator: In
  values:
  - nginx
- field: pod_labels.tier
  operator: Regex
  values:
  - prod-.+
  - stage-.+
```

- **spec.labelFilter.field**
  string

  Required value

  Label name for filtering.

  Must not be empty.

  Pattern: `.+`

- **spec.labelFilter.operator**
  string

  Required value

  Operator for log field comparations:

  - `In` — finds a substring in a string.
  - `NotIn` — is a negative version of the `In` operator.
  - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
  - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
  - `Exists` — drops log event if it contains some fields.
  - `DoesNotExist` — drops log event if it does not contain some fields.

  Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

- **spec.labelFilter.values**
  array

  Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

  Fields a with float or boolean values will be converted to strings during comparison.

- **spec.logFilter**
  array of objects

  A list of filters for logs that are applied to messages in JSON format.

  Only matched lines would be stored to log destination.

  Example:

```
logFilter:
- field: tier
  operator: Exists
- field: foo
  operator: NotIn
  values:
  - dev
  - 42
  - 'true'
  - '3.14'
- field: bar
  operator: Regex
  values:
  - "^abc"
  - "^\\d.+$"
```

  - **spec.logFilter.field**
    string

    Required value

    Field name for filtering. It should be empty for non-JSON messages.

  - **spec.logFilter.operator**
    string

    Required value

    Operator for log field comparations:

- `In` — finds a substring in a string.
- `NotIn` — is a negative version of the `In` operator.
- `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
- `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
- `Exists` — drops log event if it contains some fields.
- `DoesNotExist` — drops log event if it does not contain some fields.

Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

- **spec.logFilter.values**
  array

  Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

  Fields a with float or boolean values will be converted to strings during comparison.

- **spec.multilineParser**
  object

  Multiline parser for different patterns.

  - **spec.multilineParser.custom**
    object

    Multiline parser custom regex rules.

    - **spec.multilineParser.custom.endsWhen**
      object

      It’s a condition to distinguish the last log line of multiline log.

      - **spec.multilineParser.custom.endsWhen.notRegex**
        string

        Regex string, which treats as match only strings that DOESN’T match regex.

      - **spec.multilineParser.custom.endsWhen.regex**
        string

        Regex string, which treats as match only strings that match regex.

    - **spec.multilineParser.custom.startsWhen**
      object

      It’s a condition to distinguish the first log line of multiline log.

      - **spec.multilineParser.custom.startsWhen.notRegex**
        string

        Regex string, which treats as match only strings that DOESN’T match regex.

      - **spec.multilineParser.custom.startsWhen.regex**
        string

        Regex string, which treats as match only strings that match regex.

  - **spec.multilineParser.type**
    string

    Required value

    Parser types:

    - `None` — do not parse logs.
    - `General` — tries to match general multiline logs with space or tabulation on extra lines.
    - `Backslash` — tries to match bash style logs with backslash on all lines except the last event line.
    - `LogWithTime` — tries to detect events by timestamp.
    - `MultilineJSON` — tries to match JSON logs, assuming the event starts with the `{` symbol.
    - `Custom` - tries to match logs with the user provided regex in `spec.multilineParser.custom` field.

    Default: `None`

    Allowed values: `None`, `General`, `Backslash`, `LogWithTime`, `MultilineJSON`, `Custom`

- **spec.type**
  string

  Required value

  Set on of possible input sources.

  `KubernetesPods` source reads logs from Kubernetes Pods.

  `File` source reads local file from node filesystem.

  Allowed values: `KubernetesPods`, `File`

Deprecated resource. Support for the resource might be removed in a later release.

Describes a log source in log-pipeline.

Each custom resource `ClusterLoggingConfig` describes rules for log fetching from cluster.

- **spec**
  object

  Required value

  - **spec.destinationRefs**
    array of strings

    Required value

    Array of `ClusterLogDestination` custom resource names which this source will output with.

    Fields with float or boolean values will be converted to strings.

  - **spec.file**
    object

    Describes a rule for collecting logs from files on a node.

    - **spec.file.exclude**
      array of strings

      Array of file patterns to exclude when collecting logs.

      Wildcards are supported.

      Examples:

      ```
      exclude: "/var/log/nginx/error.log"
      ```

      ```
      exclude: "/var/log/audit.log"
      ```

    - **spec.file.include**
      array of strings

      Array of file patterns to include.

      Wildcards are supported

      Examples:

      ```
      include: "/var/log/*.log"
      ```

      ```
      include: "/var/log/nginx/*.log"
      ```

    - **spec.file.lineDelimiter**
      string

      String sequence used to separate one file line from another.

      Example:

      ```
      lineDelimiter: "\\r\\n"
      ```

  - **spec.kubernetesPods**
    object

    Describes a rule for collecting logs from the cluster’s pods.

    - **spec.kubernetesPods.keepDeletedFilesOpenedFor**
      string

      Specifies the time to keep deleted files opened for reading. Vector will keep pods metadata for this time as well to read logs from deleted pods. This option is useful in cases of a log storage unavailability or a network partition. Vector will keep log files opened until finally sending them to the destination.

      Enabling this option may affect the resource consumption of the Vector and also flood a disk with deleted logs. Use it with caution.

      The format is a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

      Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

    - **spec.kubernetesPods.labelSelector**
      object

      Specifies the label selector to filter Pods with.

      You can get more into here.

      - **spec.kubernetesPods.labelSelector.matchExpressions**
        array of objects

        List of label expressions for Pods.

        Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.kubernetesPods.labelSelector.matchExpressions.key**
  string

  A label name.

- **spec.kubernetesPods.labelSelector.matchExpressions.operator**
  string

  A comparison operator.

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.kubernetesPods.labelSelector.matchExpressions.values**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Length: `1..63`

- **spec.kubernetesPods.labelSelector.matchLabels**
  object

  List of labels which Pod should have.

  Example:

```
matchLabels:
  foo: bar
  baz: who
```

- **spec.kubernetesPods.namespaceSelector**
  object

  Specifies the namespace selector to filter Pods with.

  The filter can use one of the three available ways to set the condition (parameters `matchNames`, `excludeNames`, `labelSelector`)

  - **spec.kubernetesPods.namespaceSelector.excludeNames**
    array of strings

    A list of namespaces, from the pods of which you need to exclude the collection of logs, but collect from the rest.

  - **spec.kubernetesPods.namespaceSelector.labelSelector**
    object

    Specifies the label selector to filter namespaces from which logs should be collected.

    You can get more into here.

    - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions**
      array of objects

      List of label expressions that a namespace should have to qualify for the filter condition.

      Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
```

      - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions.key**
        string

        A label name.

      - **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions.operator**

string

A comparison operator.

Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.kubernetesPods.namespaceSelector.labelSelector.matchExpressions.values**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Length: `1..63`

- **spec.kubernetesPods.namespaceSelector.labelSelector.matchLabels**
  object

  List of labels that a namespace should have to qualify for the filter condition.

  Example:

  ```
  matchLabels:
    foo: bar
    baz: who
  ```

- **spec.kubernetesPods.namespaceSelector.matchNames**
  array of strings

  A list of namespaces from whose pods logs should be collected.

- **spec.labelFilter**
  array of objects

  Rules to filter log lines by their metadata labels.

  Example:

  ```
  labelFilter:
  - field: container
    operator: In
    values:
    - nginx
  - field: pod_labels.tier
    operator: Regex
    values:
    - prod-.+
    - stage-.+
  ```

  - **spec.labelFilter.field**
    string

    Required value

    Label name for filtering.

    Must not be empty.

    Pattern: `.+`

  - **spec.labelFilter.operator**
    string

    Required value

    Operator for log field comparations:

    - `In` — finds a substring in a string.
    - `NotIn` — is a negative version of the `In` operator.
    - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
    - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
    - `Exists` — drops log event if it contains some fields.
    - `DoesNotExist` — drops log event if it does not contain some fields.

    Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

  - **spec.labelFilter.values**
    array

    Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

    Fields a with float or boolean values will be converted to strings during comparison.

- **spec.logFilter**

array of objects

A list of filters for logs that are applied to messages in JSON format.

Only matched lines would be stored to log destination.

Example:

```
logFilter:
- field: tier
  operator: Exists
- field: foo
  operator: NotIn
  values:
  - dev
  - 42
  - 'true'
  - '3.14'
- field: bar
  operator: Regex
  values:
  - "^abc"
  - "^\\d.+$"
```

- **spec.logFilter.field**
  string

  Required value

  Field name for filtering. It should be empty for non-JSON messages.

- **spec.logFilter.operator**
  string

  Required value

  Operator for log field comparations:

  - `In` — finds a substring in a string.
  - `NotIn` — is a negative version of the `In` operator.
  - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
  - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
  - `Exists` — drops log event if it contains some fields.
  - `DoesNotExist` — drops log event if it does not contain some fields.

  Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

- **spec.logFilter.values**
  array

  Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

  Fields a with float or boolean values will be converted to strings during comparison.

- **spec.multilineParser**
  object

  Multiline parser for different patterns.

  - **spec.multilineParser.custom**
    object

    Multiline parser custom regex rules.

    - **spec.multilineParser.custom.endsWhen**
      object

      It’s a condition to distinguish the last log line of multiline log.

      - **spec.multilineParser.custom.endsWhen.notRegex**
        string

        Regex string, which treats as match only strings that DOESN’T match regex.

      - **spec.multilineParser.custom.endsWhen.regex**
        string

        Regex string, which treats as match only strings that match regex.

    - **spec.multilineParser.custom.startsWhen**
      object

      It’s a condition to distinguish the first log line of multiline log.

      - **spec.multilineParser.custom.startsWhen.notRegex**
        string

Regex string, which treats as match only strings that DOESN’T match regex.

- **spec.multilineParser.custom.startsWhen.regex**
  string

  Regex string, which treats as match only strings that match regex.

- **spec.multilineParser.type**
  string

  Required value

  Parser types:

  - `None` — do not parse logs.
  - `General` — tries to match general multiline logs with space or tabulation on extra lines.
  - `Backslash` — tries to match bash style logs with backslash on all lines except the last event line.
  - `LogWithTime` — tries to detect events by timestamp.
  - `MultilineJSON` — tries to match JSON logs, assuming the event starts with the `{` symbol.
  - `Custom` - tries to match logs with the user provided regex in `spec.multilineParser.custom` field.

  Default: `None`

  Allowed values: `None`, `General`, `Backslash`, `LogWithTime`, `MultilineJSON`, `Custom`

- **spec.type**
  string

  Required value

  Set on of possible input sources.

  `KubernetesPods` source reads logs from Kubernetes Pods.

  `File` source reads local file from node filesystem.

  Allowed values: `KubernetesPods`, `File`

PodLoggingConfig

Scope: Namespaced
Version: v1alpha1

Custom resource for namespaced Kubernetes source.

Each custom resource `PodLoggingConfig` describes rules for log fetching from specified namespace.

- **spec**
  object

  Required value

  - **spec.clusterDestinationRefs**
    array of strings

    Required value

    Array of `ClusterLogDestination` custom resource names which this source will output with.

  - **spec.keepDeletedFilesOpenedFor**
    string

    Specifies the time to keep deleted files opened for reading. Vector will keep pods metadata for this time as well to read logs from deleted pods. This option is useful in cases of a log storage unavailability or a network partition. Vector will keep log files opened until finally sending them to the destination.

    Enabling this option may affect the resource consumption of the Vector and also flood a disk with deleted logs. Use it with caution.

    The format is a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

  - **spec.labelFilter**
    array of objects

    Rules to filter log lines by their metadata labels.

    Example:

```
labelFilter:
- field: container
  operator: In
  values:
  - nginx
- field: pod_labels.tier
  operator: Regex
  values:
  - prod-.+
  - stage-.+
- field: message
  operator: Regex
  values:
  - ".*search_text.*"
```

- **spec.labelFilter.field**
  string

  Required value

  Label name for filtering.

  Must not be empty.

  Pattern: `.+`

- **spec.labelFilter.operator**
  string

  Required value

  Operator for log field comparations:

  - `In` — finds a substring in a string.
  - `NotIn` — is a negative version of the `In` operator.
  - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
  - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
  - `Exists` — drops log event if it contains some fields.
  - `DoesNotExist` — drops log event if it does not contain some fields.

  Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

- **spec.labelFilter.values**
  array

  Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

  Fields with a float or boolean values will be converted to strings during comparison.

- **spec.labelSelector**
  object

  Specifies the label selector to filter Pods.

  For more information, see the Kubernetes documentation.

  - **spec.labelSelector.matchExpressions**
    array of objects

    List of label expressions for Pods.

    Example:

    ```
    matchExpressions:
    - key: tier
      operator: In
      values:
      - production
      - staging
    ```

    - **spec.labelSelector.matchExpressions.key**
      string

      A label name.

    - **spec.labelSelector.matchExpressions.operator**
      string

      A comparison operator.

      Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

    - **spec.labelSelector.matchExpressions.values**
      array of strings

A label value.

- **Element of the array**
  string

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

- **spec.labelSelector.matchLabels**
  object

  List of labels which Pod should have.

  Example:

  ```
  matchLabels:
    foo: bar
    baz: who
  ```

- **spec.logFilter**
  array of objects

  A list of filters for logs that are applied to messages in JSON format.

  Only matched lines would be stored to log destination.

  Example:

  ```
  logFilter:
  - field: tier
    operator: Exists
  - field: foo
    operator: NotIn
    values:
    - dev
    - 42
    - 'true'
    - '3.14'
  - field: bar
    operator: Regex
    values:
    - "^abc"
    - "^\\d.+$"
  ```

  - **spec.logFilter.field**
    string

    Required value

    Field name for filtering. It should be empty for non-JSON messages.

  - **spec.logFilter.operator**
    string

    Required value

    Operator for log field comparations:

    - `In` — finds a substring in a string.
    - `NotIn` — is a negative version of the `In` operator.
    - `Regex` — is trying to match regexp over the field; only log events with matching fields will pass.
    - `NotRegex` — is a negative version of the `Regex` operator; log events without fields or with not matched fields will pass.
    - `Exists` — drops log event if it contains some fields.
    - `DoesNotExist` — drops log event if it does not contain some fields.

    Allowed values: `In`, `NotIn`, `Regex`, `NotRegex`, `Exists`, `DoesNotExist`

  - **spec.logFilter.values**
    array

    Array of values or regexes for corresponding operations. Does not work for `Exists` and `DoesNotExist` operations.

    Fields a with float or boolean values will be converted to strings during comparison.

- **spec.multilineParser**
  object

  Multiline parser for different patterns.

  - **spec.multilineParser.custom**
    object

    Multiline parser custom regex rules.

    - **spec.multilineParser.custom.endsWhen**

object

It’s a condition to distinguish the last log line of the multiline log.

- **spec.multilineParser.custom.endsWhen.notRegex**
  string

  Regex string, which treats as match only strings that DON’T match the regex.

- **spec.multilineParser.custom.endsWhen.regex**
  string

  Regex string, which treats as match only strings that match the regex.

- **spec.multilineParser.custom.startsWhen**
  object

  It’s a condition to distinguish the first log line of multiline log.

  - **spec.multilineParser.custom.startsWhen.notRegex**
    string

    Regex string, which treats as match only strings that DON’T match the regex.

  - **spec.multilineParser.custom.startsWhen.regex**
    string

    Regex string, which treats as match only strings that match the regex.

- **spec.multilineParser.type**
  string

  Required value

  Parser types:

  - `None` — do not parse logs.
  - `General` — tries to match general multiline logs with space or tabulation on extra lines.
  - `Backslash` — tries to match bash style logs with backslash on all lines except the last event line.
  - `LogWithTime` — tries to detect events by timestamp.
  - `MultilineJSON` — tries to match JSON logs, assuming the event starts with the `{` symbol.
  - `Custom` - tries to match logs with the user provided regex in `spec.multilineParser.custom` field.

  Default: `None`

  Allowed values: `None`, `General`, `Backslash`, `LogWithTime`, `MultilineJSON`, `Custom`

FAQ

> **i** The module lifecycle stage: General Availability

How to add authorization to the *ClusterLogDestination* resource?

To add authorization parameters to the ClusterLogDestination resource, you need to:

- change the connection protocol to Loki to HTTPS
- add the auth section, in which:
  - the strategy parameter should be set to `Bearer`;
  - the token parameter should contain the `log-shipper-token` token from the `d8-log-shipper` namespace.

For example:

- ClusterLogDestination resource without authorization:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki
spec:
  type: Loki
  loki:
    endpoint: "http://loki.d8-monitoring:3100"
```

- Get the `log-shipper-token` token from the `d8-log-shipper` namespace:

```
d8 k -n d8-log-shipper get secret log-shipper-token -o jsonpath='{.data.token}' | base64 -d
```

- ClusterLogDestination resource with authorization:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki
spec:
  type: Loki
  loki:
    endpoint: "https://loki.d8-monitoring:3100"
    auth:
      strategy: "Bearer"
      token: <log-shipper-token>
    tls:
      verifyHostname: false
      verifyCertificate: false
```

Advanced usage

> **i** The module lifecycle stage: General Availability

How to enable debugging logs?

Enable the debug parameter of the module.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: log-shipper
spec:
  version: 1
  enabled: true
  settings:
    debug: true
```

Then in logs, you will find a lot of helpful information about HTTP requests, connects reusing, detailed traces, and so on.

How to get aware of logs pipelines?

To begin with, retrieve the list of pods on the desired node.

```
d8 k -n d8-log-shipper get pods -o wide | grep $node
```

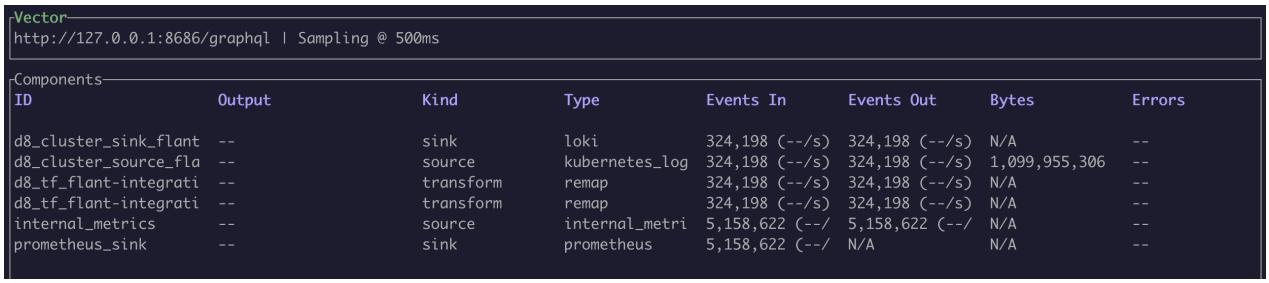
Select the appropriate pod and execute commands directly from the container.

```
d8 k -n d8-log-shipper exec $pod -c vector -- COMMAND_NAME
```

All subsequent commands are assumed to be executed within the container.

See pipelines as a graph

- Execute the `vector graph` command to get the output of logs pipelines topology in the DOT format.
- Put the output to webgraphviz os similar service to render the graph.



Example of the graph output for a single pipeline in ASCII format:

```
+-----------------------------------------------+
|  d8_cluster_source_flant-integration-d8-logs  |
+-----------------------------------------------+
  |
  |
  v
+-----------------------------------------------+
|      d8_tf_flant-integration-d8-logs_0        |
+-----------------------------------------------+
  |
  |
  v
+-----------------------------------------------+
|      d8_tf_flant-integration-d8-logs_1        |
+-----------------------------------------------+
  |
  |
  v
+-----------------------------------------------+
| d8_cluster_sink_flant-integration-loki-storage |
+-----------------------------------------------+
```

Investigate data processing

There is the `vector top` command to help you see how much data is going through all checkpoints of the pipeline.

Example of the output:

Get raw log samples

You may use the `vector tap` command to get input data for any channel components. The only argument to be set is the ID of the processing stage. Patterns in a glob format are also supported for selections (e.g., `d8_cluster_source_*`).

By using the following command, you can see the log's before applying the transformation rules (`d8_cluster_source_*` is the first stage of processing according to the output of the `vector graph` command):

```
vector tap 'cluster_logging_config/*'
```

Transformed logs that are received at the input of the next channel components in the chain:

```
vector tap 'transform/*'
```

You can then use the `vector vrl` interactive console to debug VRL message remap rules.

Example of a program on VRL:

```
. = {"test1": "lynx", "test2": "fox"}
del(.test2)
.
```

How to add a new source/sink support for log-shipper?

Vector in the `log-shipper` module has been built with the limited number of enabled features (to improve building speed and decrease the size of the final binary).

You can see a list of all supported features by executing the `vector list` command.

If supporting a new source/sink is required, you need to add the corresponding feature to the list of enabled features in the Dockerfile.

Examples

> **i** The module lifecycle stage: General Availability

Getting logs from all cluster Pods and sending them to Loki

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: all-logs
spec:
  type: KubernetesPods
  destinationRefs:
  - loki-storage
---
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
```

Specify `d8-loki` in the ClusterLoggingConfig destinationRefs field to send logs to the loki cluster module. More examples in the documentation.

Reading Pod logs from a specified namespace with a specified label and redirecting to Loki and Elasticsearch

Reading logs from `namespace=whispers` with label `app=booking` and storing them into Loki and Elasticsearch:

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: whispers-booking-logs
spec:
  type: KubernetesPods
  kubernetesPods:
    namespaceSelector:
      labelSelector:
        matchExpressions:
        - key: "kubernetes.io/metadata.name"
          operator: In
          values: [whispers]
    labelSelector:
      matchLabels:
        app: booking
  destinationRefs:
  - loki-storage
  - es-storage
---
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
---
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: es-storage
spec:
  type: Elasticsearch
  elasticsearch:
    endpoint: http://192.168.1.1:9200
    index: logs-%F
    auth:
      strategy: Basic
      user: elastic
      password: c2VjcmV0IC1uCg==
```

Creating a source in namespace and reading logs of all Pods in that NS with forwarding them to Loki

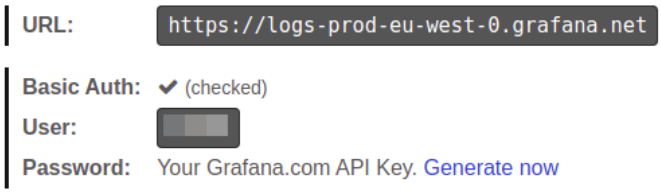
Namespaced pipeline - reading logs from `test-whispers` namespace (all Pods):

```
apiVersion: deckhouse.io/v1alpha1
kind: PodLoggingConfig
metadata:
  name: whispers-logs
  namespace: tests-whispers
spec:
  clusterDestinationRefs:
    - loki-storage
---
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
```

Reading only Pods in the specified namespace and having a certain label

Read logs from Pods with label `app=booking` in namespace `test-whispers`:

```
apiVersion: deckhouse.io/v1alpha1
kind: PodLoggingConfig
metadata:
  name: whispers-logs
  namespace: tests-whispers
spec:
  labelSelector:
    matchLabels:
      app: booking
  clusterDestinationRefs:
    - loki-storage
---
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
```



Migration from Promtail to Log-Shipper

Path `/loki/api/v1/push` has to be removed from the previously used Loki URL.

Vector will add this PATH automatically during working with Loki destination.

Working with Grafana Cloud

This documentation expects that you have created API key.

Firstly you should encode your token with base64.

```
echo -n "<YOUR-GRAFANACLOUD-TOKEN>" | base64 -w0
```

Then you can create **ClusterLogDestination**

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  loki:
    auth:
      password: PFlPVVItR1JBRkFOQUNMT1VELVRPS0VOPg==
      strategy: Basic
      user: "<YOUR-GRAFANACLOUD-USER>"
    endpoint: <YOUR-GRAFANACLOUD-URL> # For example https://logs-prod-us-central1.grafana.net or
https://logs-prod-eu-west-0.grafana.net
  type: Loki
```

Now you can create PodLogginConfig or ClusterPodLoggingConfig and send logs to **Grafana Cloud**.

Adding Loki source to Deckhouse Grafana

You can work with Loki from embedded to deckhouse Grafana. Just add **GrafanaAdditionalDatasource**

```
apiVersion: deckhouse.io/v1
kind: GrafanaAdditionalDatasource
metadata:
  name: loki
spec:
  access: Proxy
  basicAuth: false
  jsonData:
    maxLines: 5000
    timeInterval: 30s
  type: loki
  url: http://loki.loki:3100
```

Elasticsearch < 6.X usage

For Elasticsearch < 6.0 doc_type indexing should be set. Config should look like this:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: es-storage
spec:
  type: Elasticsearch
  elasticsearch:
    endpoint: http://192.168.1.1:9200
    docType: "myDocType" # Set any string here. It should not start with '_'
    auth:
      strategy: Basic
      user: elastic
      password: c2VjcmV0IC1uCg==
```

Index template for Elasticsearch

It is possible to route logs to particular indexes based on metadata using index templating:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: es-storage
spec:
  type: Elasticsearch
  elasticsearch:
    endpoint: http://192.168.1.1:9200
    index: "k8s-{{ namespace }}-%F"
```

For the above example for each Kubernetes namespace a dedicated index in Elasticsearch will be created.

This feature works well combining with `extraLabels`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: es-storage
spec:
  type: Elasticsearch
  elasticsearch:
    endpoint: http://192.168.1.1:9200
    index: "k8s-{{ service }}-{{ namespace }}-%F"
  extraLabels:
    service: "{{ service_name }}"
```

1. If a log message is in JSON format, the `service_name` field of this JSON document is moved to the metadata level.
2. The new metadata field `service` is used for the index template.

Splunk integration

It is possible to send logs from Deckhouse to Splunk.

1. Endpoint must be equal to the Splunk instance name with the `8088` port and no path provided, e.g. `https://prd-p-xxxxxx.splunkcloud.com:8088`.
2. To add a token to ingest logs, go to `Setting -> Data inputs`, add a new `HTTP Event Collector` and copy a token.
3. Provide a Splunk index to store logs, e.g., `logs`.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: splunk
spec:
  type: Splunk
  splunk:
    endpoint: https://prd-p-xxxxxx.splunkcloud.com:8088
    token: xxxx-xxxx-xxxx
    index: logs
    tls:
      verifyCertificate: false
      verifyHostname: false
```

> **i** Splunk destination doesn't support pod labels for indexes. Consider exporting necessary labels with the `extraLabels` option.

```
extraLabels:
  pod_label_app: '{{ pod_labels.app }}'
```

Simple Logstash example

To send logs to Logstash, the `tcp` input should be configured on the Logstash instance side, and its codec should be set to `json`.

An example of the minimal Logstash configuration:

```
input {
  tcp {
    port => 12345
    codec => json
  }
}
output {
  stdout { codec => json }
}
```

An example of the `ClusterLogDestination` manifest:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: logstash
spec:
  type: Logstash
  logstash:
    endpoint: logstash.default:12345
```

Syslog

The following examples sets severity for the syslog messages and uses the socket destination:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: rsyslog
spec:
  type: Socket
  socket:
    mode: TCP
    address: 192.168.0.1:3000
    encoding:
      codec: Syslog
  extraLabels:
    syslog.severity: "alert"
    # the request_id field should be present in the log message
    syslog.message_id: "{{ request_id }}"
```

Graylog integration

Make sure that an incoming stream is configured in Graylog to receive messages over the TCP protocol on the specified port.

Example manifest for integration with Graylog:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: test-socket2-dest
spec:
  type: Socket
  socket:
    address: graylog.svc.cluster.local:9200
    mode: TCP
    encoding:
      codec: GELF
```

Logs in CEF Format

There is a way to format logs in CEF format using `codec: CEF`, with overriding `cef.name` and `cef.severity` based on values from the `message` field (application log) in JSON format.

In the example below, `app` and `log_level` are keys containing values for overriding:

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: siem-kafka
spec:
  extraLabels:
    cef.name: '{{ app }}'
    cef.severity: '{{ log_level }}'
  type: Kafka
  kafka:
    bootstrapServers:
      - my-cluster-kafka-brokers.kafka:9092
    encoding:
      codec: CEF
    tls:
      verifyCertificate: false
      verifyHostname: true
    topic: logs
```

You can also manually set your own values:

```
extraLabels:
  cef.name: 'TestName'
  cef.severity: '1'
```

Collect Kubernetes Events

Kubernetes Events can be collected by log-shipper if `events-exporter` is enabled in the extended-monitoring module configuration.

Enable `events-exporter` by adjusting `extended-monitoring` settings:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: extended-monitoring
spec:
  version: 1
  settings:
    events:
      exporterEnabled: true
```

Apply the following `ClusterLoggingConfig` to collect logs from the `events-exporter` Pod:

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: kubernetes-events
spec:
  type: KubernetesPods
  kubernetesPods:
    labelSelector:
      matchLabels:
        app: events-exporter
    namespaceSelector:
      labelSelector:
        matchExpressions:
        - key: "kubernetes.io/metadata.name"
          operator: In
          values: [d8-monitoring]
  destinationRefs:
  - loki-storage
```

Log filters

Users can filter logs by applying two filters:

- `labelFilter` — applies to the top-level metadata, e.g., container, namespace, or Pod name.
- `logFilter` — applies to fields of a message if it is in JSON format.

Collect only logs of the `nginx` container

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: nginx-logs
spec:
  type: KubernetesPods
  labelFilter:
  - field: container
    operator: In
    values: [nginx]
  destinationRefs:
  - loki-storage
```

Collect logs without strings `GET /status" 200`

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: all-logs
spec:
  type: KubernetesPods
  destinationRefs:
  - loki-storage
  labelFilter:
  - field: message
    operator: NotRegex
    values:
    - .*GET /status" 200$
```

Audit of kubelet actions

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: kubelet-audit-logs
spec:
  type: File
  file:
    include:
    - /var/log/kube-audit/audit.log
  logFilter:
  - field: userAgent
    operator: Regex
    values: ["kubelet.*"]
  destinationRefs:
  - loki-storage
```

Deckhouse system logs

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: system-logs
spec:
  type: File
  file:
    include:
    - /var/log/syslog
  labelFilter:
  - field: message
    operator: Regex
    values:
    - .*d8-kubelet-forker.*
    - .*containerd.*
    - .*bashible.*
    - .*kernel.*
  destinationRefs:
  - loki-storage
```

> **i** If you need logs from only one or from a small group of a Pods, try to use the kubernetesPods settings to reduce the number of reading filed. Do not use highly grained filters to read logs from a single pod.

Log transformations

In a ClusterLogDestination resource, you can chain transformations in order. The following actions are supported: `ParseMessage`, `ReplaceKeys`, `ReplaceValue`, `AddLabels`, and `DropLabels`.

Transforming logs into a structured object

You can use the `ParseMessage` transformation to convert a string in the `message` field into a structured object. For `sourceFormat: String`, provide a regular expression with named capture groups and a `setLabels` map. Output keys are filled from `{{ group_name }}` templates. If multiple `ParseMessage` transformations are used, the one that parses the string must be applied last.

You cannot set `parseMessage.targetLabel` to `.parsed_data`.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: string-to-json
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: String
        string:
          regex: "^(?P<msg>.*)$"
          setLabels:
            msg: "{{ msg }}"
```

Example original log entry:

```
/docker-entrypoint.sh: Configuration complete; ready for start up
```

Transformed result:

```
{... "message": {
  "msg": "/docker-entrypoint.sh: Configuration complete; ready for start up"
  }
}
```

Transforming logs in Klog format into a structured object

You can use the `ParseMessage` transformation to parse logs in Klog format and convert them into a structured object.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: klog-to-json
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: Klog
```

Example original log entry:

```
I0505 17:59:40.692994   28133 klog.go:70] hello from klog
```

Transformed result:

```
{... "message": {
  "file":"klog.go",
  "id":28133,
  "level":"info",
  "line":70,
  "message":"hello from klog",
  "timestamp":"2025-05-05T17:59:40.692994Z"
  }
}
```

Transforming logs in Syslog format into a structured object

You can use the `ParseMessage` transformation to parse logs in Syslog format and convert them into a structured object.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: syslog-to-json
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: SysLog
```

Example original log entry:

```
<13>1 2020-03-13T20:45:38.119Z dynamicwireless.name non 2426 ID931 [exampleSDID@32473 iut="3" eventSource= "Application"
eventID="1011"] Try to override the THX port, maybe it will reboot the neural interface!
```

Transformed result:

```
{... "message": {
  "appname": "non",
  "exampleSDID@32473": {
    "eventID": "1011",
    "eventSource": "Application",
    "iut": "3"
  },
  "facility": "user",
  "hostname": "dynamicwireless.name",
  "message": "Try to override the THX port, maybe it will reboot the neural interface!",
  "msgid": "ID931",
  "procid": 2426,
  "severity": "notice",
  "timestamp": "2020-03-13T20:45:38.119Z",
  "version": 1
  }
}
```

Transforming logs in CLF format into a structured object

You can use the `ParseMessage` transformation to parse logs in CLF format and convert them into a structured object.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: clf-to-json
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: CLF
```

Example original log entry:

```
127.0.0.1 bob frank [10/Oct/2000:13:55:36 -0700] \"GET /apache_pb.gif HTTP/1.0\" 200 2326
```

Transformed result:

```
{... "message": {
  "host": "127.0.0.1",
  "identity": "bob",
  "message": "GET /apache_pb.gif HTTP/1.0",
  "method": "GET",
  "path": "/apache_pb.gif",
  "protocol": "HTTP/1.0",
  "size": 2326,
  "status": 200,
  "timestamp": "2000-10-10T20:55:36Z",
  "user": "frank"
  }
}
```

Transforming logs in logfmt format into a structured object

You can use the `ParseMessage` transformation to parse logs in logfmt format and convert them into a structured object.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: logfmt-to-json
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: Logfmt
```

Example original log entry:

```
@timestamp=\"Sun Jan 10 16:47:39 EST 2021\" level=info msg=\"Stopping all fetchers\" tag#production=stopping_fetchers
id=ConsumerFetcherManager-1382721708341 module=kafka.consumer.ConsumerFetcherManager
```

Transformed result:

```
{... "message": {
  "@timestamp": "Sun Jan 10 16:47:39 EST 2021",
  "id": "ConsumerFetcherManager-1382721708341",
  "level": "info",
  "module": "kafka.consumer.ConsumerFetcherManager",
  "msg": "Stopping all fetchers",
  "tag#production": "stopping_fetchers"
  }
}
```

Parsing JSON and reducing the nesting depth

You can use the `ParseMessage` transformation to parse log entries in JSON format. Using the `depth` parameter, you can control the nesting depth.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: parse-json
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: JSON
        json:
          depth: 1
```

Example original log entry:

```
{"level" : { "severity": "info" },"msg" : "fetching.module.release"}
```

Transformed result:

```
{... "message": {
  "level" : "{ \"severity\": \"info\" }",
  "msg" : "fetching.module.release"
  }
}
```

Example of parsing mixed-format entries into a structured object

The string transformation must be applied last.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: parse-json
spec:
  ...
  transformations:
  - action: ParseMessage
    parseMessage:
      sourceFormat: JSON
  - action: ParseMessage
    parseMessage:
      sourceFormat: Klog
  - action: ParseMessage
    parseMessage:
      sourceFormat: String
      string:
        regex: "^(?P<text>.*)$"
        setLabels:
          text: "{{ text }}"
```

Example original log entry:

```
/docker-entrypoint.sh: Configuration complete; ready for start up
{"level" : { "severity": "info" },"msg" : "fetching.module.release"}
I0505 17:59:40.692994   28133 klog.go:70] hello from klog
```

Transformed result:

```
{... "message": {
  "text": "/docker-entrypoint.sh: Configuration complete; ready for start up"
  }
}
{... "message": {
  "level" : "{ "severity": "info" }",
  "msg" : "fetching.module.release"
  }
}
{... "message": {
  "file":"klog.go",
  "id":28133,
  "level":"info",
  "line":70,
  "message":"hello from klog",
  "timestamp":"2025-05-05T17:59:40.692994Z"
  }
}
```

Replacing labels

You can use the `ReplaceKeys` transformation to replace `source` with `target` in the specified label keys.

{% alert level=”info” %} To apply the `ReplaceKeys` transformation to the `message` field or its nested fields, the log entry must first be parsed into a structured object using the `ParseMessage` transformation. {% endalert %}

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: replace-dot
spec:
  ...
  transformations:
    - action: ReplaceKeys
      replaceKeys:
        source: "."
        target: "_"
        labels:
          - .pod_labels
```

Example original log entry:

```
{"msg" : "fetching.module.release"} # Pod label pod.app=test
```

Transformed result:

```
{... "message": {
  "msg" : "fetching.module.release"
  },
  "pod_labels": {
    "pod_app": "test"
  }
}
```

Replacing substrings in string fields

You can use the `ReplaceValue` transformation to replace matches of a regular expression (`source`) in scalar string fields. The `target` string can be a literal or use `{{ name }}` for named capture groups from `source`.

{% alert level=”info” %} Apply `ParseMessage` first if you need to run replacement on a field inside a structured `message`. {% endalert %}

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: redact-digits
spec:
  ...
  transformations:
    - action: ReplaceValue
      replaceValue:
        source: \d+
        target: REDACTED
        labels:
          - .message
```

Example original log entry:

```
user id 12345 connected from 10.0.0.1
```

Transformed result:

```
{... "message": "user id REDACTED connected from REDACTED"
}
```

Adding labels from literals and templates

You can use the `AddLabels` transformation to add fields using static values or templates such as `{{ .pod_labels.app }}`. Transformations run after applying `extraLabels`. If label names overlap, the value from `AddLabels` has priority.

The `when` field is an optional list of conditions combined with logical AND. The left-hand side of a condition is a path to a field on the log event: a leading dot and dot-separated segments (for example, `.namespace`, `.pod_labels.app`, `.message.level`). Each list item can be one of the following types:

- Value comparison: `.namespace == "production"`. Supported operators are `==`, `!=`, `=~`, and `!=~`.
- Field existence check: Only a path with no operator, for example, `.pod_labels.team` (the field must exist).
- Field absence check: `!.pod_labels.legacy`.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: add-env-from-pod
spec:
  ...
  transformations:
    - action: AddLabels
      addLabels:
        when:
          - '.namespace == "production"'
        setLabels:
          .env: prod
          .source_app: "{{ .pod_labels.app }}"
```

Transformed result for an event in namespace `production` with pod label `app=api`:

```
{..."namespace": "production", "pod_labels": { "app": "api" } "env": "prod", "source_app": "api", ...
}
```

Removing labels

You can use the `DropLabels` transformation to remove specific labels from log records. Each item under `dropLabels.labels` has a `label` field (the path) and optional `keepKeys`. If `keepKeys` is set for an item, `label` must point to an **object**; inside it, every nested key not listed in `keepKeys` is removed (key names without a leading dot). If `keepKeys` is unset for that item, the path in `label` is removed entirely.

{% alert level=”info” %} To apply the `DropLabels` transformation to the `message` field or its nested fields, the log entry must first be parsed into a structured object using the `ParseMessage` transformation. {% endalert %}

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: drop-label
spec:
  ...
  transformations:
    - action: DropLabels
      dropLabels:
        labels:
          - label: .example
```

Example of removing a specific label from a structured message

The following example shows how you can remove a label from a structured JSON message. The `ParseMessage` transformation is applied first to parse the message, followed by `DropLabels` to remove the specified label.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: drop-label
spec:
  ...
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: JSON
    - action: DropLabels
      dropLabels:
        labels:
          - label: .message.example
```

Example original log entry:

```
{"msg" : "fetching.module.release", "example": "test"}
```

Transformed result:

```
{... "message": {
  "msg" : "fetching.module.release"
  }
}
```

Sending logs to Elasticsearch with transformations

The following is an example of a ClusterLogDestination resource for sending logs to Elasticsearch.

In this example:

- JSON from the `message` field is parsed and moved into the event root (`targetLabel: "."`).
- Dots are replaced with underscores in `pod_labels` key names.
- The source `message` field is deleted.

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: es-storage
spec:
  type: Elasticsearch
  elasticsearch:
    endpoint: http://elasticsearch:9200
    index: logs-%F
  transformations:
    - action: ParseMessage
      parseMessage:
        sourceFormat: JSON
        targetLabel: "."
    - action: ReplaceKeys
      replaceKeys:
        source: "."
        target: "_"
        labels:
          - .pod_labels
    - action: DropLabels
      dropLabels:
        labels:
          - label: .message
```

Example source log line: a Java app emits structured JSON to stdout, therefore the JSON line is stored in the `message` field of the event. The `msg` field inside that line holds the program log text.

```
{... "namespace": "prod", "pod_labels": {"app.kubernetes.io/name": "orders", "app": "api"}, "message": "
{\"@timestamp\":\"2025-03-25T10:15:00.123Z\",\"level\":\"INFO\",\"logger\":\"com.example.OrderService\",\"msg\":\"Order id=42
created; user=1001\"}"}
```

Transformation result:

- JSON fields are moved into the event root.
- Dots in `pod_labels` key names are replaced with underscores.
- The `message` field is removed.

```
{... "namespace": "prod",
  "pod_labels": {
    "app_kubernetes_io/name": "orders",
    "app": "api"
  },
  "@timestamp": "2025-03-25T10:15:00.123Z",
  "level": "INFO",
  "logger": "com.example.OrderService",
  "msg": "Order id=42 created; user=1001"
}
```

Collect logs from production namespaces using the namespace label selector option

```
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: production-logs
spec:
  type: KubernetesPods
  kubernetesPods:
    namespaceSelector:
      labelSelector:
        matchLabels:
          environment: production
  destinationRefs:
  - loki-storage
```

Exclude Pods or namespaces with a label

There is a preconfigured label to exclude particular namespaces or Pods: `log-shipper.deckhouse.io/exclude=true`. It can help to stop collecting logs from a namespace or Pod without changing global configurations.

```
---
apiVersion: v1
kind: Namespace
metadata:
  name: test-namespace
  labels:
    log-shipper.deckhouse.io/exclude: "true"
---
apiVersion: apps/v1
kind: Deployment
metadata:
  name: test-deployment
spec:
  ...
  template:
    metadata:
      labels:
        log-shipper.deckhouse.io/exclude: "true"
```

Enable Buffering

The log buffering configuration is essential for improving the reliability and performance of the log collection system. Buffering can be useful in the following cases:

1. Temporary connectivity disruptions. If there are temporary disruptions or instability in the connection to the log storage system (such as Elasticsearch), a buffer allows logs to be temporarily stored and sent when the connection is restored.
2. Smoothing out load peaks. During sudden spikes in log volume, a buffer helps smooth out peak loads on the log storage system, preventing it from becoming overloaded and potentially losing data.
3. Performance optimization. Buffering helps optimize the performance of the log collection system by accumulating logs and sending them in batches, which reduces the number of network requests and improves overall throughput.

Example of enabling in-memory buffering

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  buffer:
    memory:
      maxEvents: 4096
    type: Memory
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
```

Example of enabling disk buffering

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  buffer:
    disk:
      maxSize: 1Gi
    type: Disk
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
```

Example of defining behavior when the buffer is full

```
apiVersion: deckhouse.io/v1alpha1
kind: ClusterLogDestination
metadata:
  name: loki-storage
spec:
  buffer:
    disk:
      maxSize: 1Gi
    type: Disk
    whenFull: DropNewest
  type: Loki
  loki:
    endpoint: http://loki.loki:3100
```

More detailed description of the parameters is available in the ClusterLogDestination resource.

The loki module

⚠ The module lifecycle stage: Preview

In Kubernetes, the system logs on the nodes do not last long and may be lost during a restart or update. This module deploys its own operational log storage based on Grafana Loki in the cluster..

Module features:

- system logs are automatically logged into Loki without additional configuration.;
- access to the logs is implemented via Grafana and the Deckhouse Kubernetes Platform web interface (console);
- the module is designed to store logs for a short time. For long-term storage or archiving, it is recommended to use external systems supported via log-shipper.

Third-party components

List of third-party software used in the `loki` module:

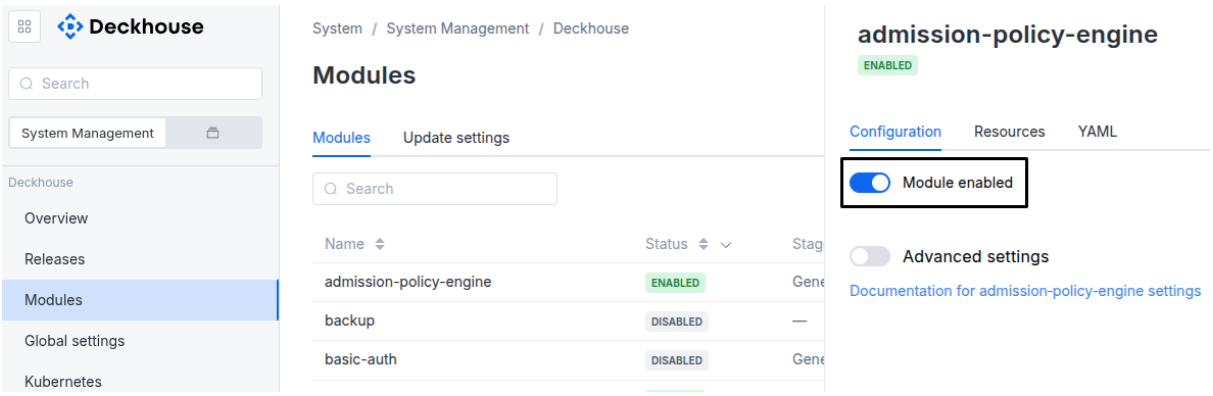
- Loki

  License: GNU Affero General Public License v3.0

  Loki: like Prometheus, but for logs.

Configuration

⚠ The module lifecycle stage: Preview



The module has 2 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `loki` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

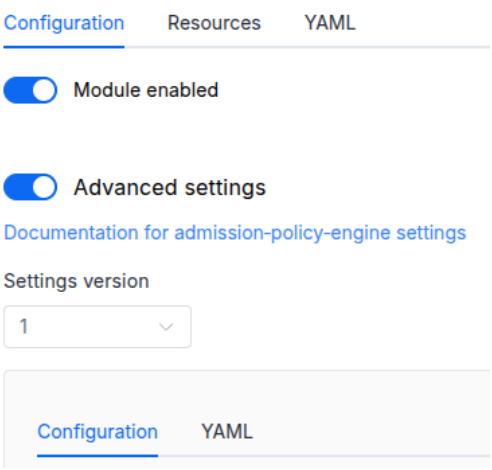
```
d8 system module enable loki
```

- **Using ModuleConfig `loki`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `loki` (create it if necessary);

  Example of a manifest to enable module `loki`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: loki
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `loki` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `loki` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `loki`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `loki` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc loki
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `loki` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

  Example of a manifest for ModuleConfig `loki`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: loki
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.allowDeleteLogs**
    boolean

    Allow logs deletion using /loki/api/v1/delete endpoints.

    Default: `false`
  - **settings.diskSizeGigabytes**
    integer

    Initial disk size for log storage or PVC size when specifying the storageClass parameters. You should manually specify the required disk size for storing logs for the period defined by the `retentionPeriodHours` parameter. The extended-monitoring module automatically monitors the percentage of used disk space.

    Default: `2`
  - **settings.lokiConfig**
    object

    Loki configuration options available for tuning.

    See Loki documentation for more information.

    > **i** Caution! Incorrect settings may lead to the malfunction of Loki.

    - **settings.lokiConfig.grpcServerMaxConcurrentStreams**
      integer

      Limit on the number of concurrent streams for gRPC calls.

      Default: `100`
    - **settings.lokiConfig.grpcServerMaxRecvMsgSize**
      integer

      Limit on the size of a gRPC message this server can receive in bytes.

      Default: `104857600`
    - **settings.lokiConfig.grpcServerMaxSendMsgSize**
      integer

      Limit on the size of a gRPC message this server can send in bytes.

      Default: `4194304`
    - **settings.lokiConfig.ingestionBurstSizeMB**
      number

      Overall ingestion burst size in megabytes. E.g., maximum push request size.

      Default: `6`
    - **settings.lokiConfig.ingestionRateMB**
      number

      Overall ingestion rate limit in megabytes per second.

      Default: `4`
    - **settings.lokiConfig.maxChunksPerQuery**
      integer

      The maximum number of chunks that can be fetched per query.

      Default: `2000000`
    - **settings.lokiConfig.maxEntriesLimitPerQuery**
      integer

      The maximum number of entries returned for the query.

      Default: `5000`
    - **settings.lokiConfig.maxLabelNamesPerSeries**
      integer

      The maximum number of unique label names per series (log stream).

      Default: `32`
    - **settings.lokiConfig.maxStreamsPerUser**
      integer

      The maximum total number of streams for the Loki instance.

      Each stream has unique labels. The number of streams is the number of unique label sets. E. g. `{job="my-app", instance="kube-node-1", namespace="production", pod_name="backend-79dbf6fcb7-v5gs7",`

`app="backend"}`.

0 means unlimited.

Default: `0`

- **settings.lokiConfig.perStreamRateLimit**
  string or number

  Maximum byte rate per second per stream. Can be either a number or a string with a unit (KB, MB, GB).

  Default: `3MB`

  Pattern: `^[0-9]+(KB|MB|GB)?$`

- **settings.lokiConfig.perStreamRateLimitBurst**
  string or number

  Maximum burst size per stream. Can be either a number or a string with a unit (KB, MB, GB).

  Default: `15MB`

  Pattern: `^[0-9]+(KB|MB|GB)?$`

- **settings.nodeSelector**
  object

  The same as the Pods' `spec.nodeSelector` parameter in Kubernetes. If the parameter is omitted or `false`, `nodeSelector` will be determined automatically.

- **settings.resourcesManagement**

  Settings for CPU and memory requests and limits by Loki pods.

  Examples:

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: InPlaceOrRecreate
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

```
resourcesManagement:
  mode: Static
  static:
    requests:
      cpu: 55m
      memory: 256Mi
    limits:
      cpu: 2
      memory: 2Gi
```

```
resourcesManagement:
  mode: VPA
  vpa:
    mode: Auto
    cpu:
      min: 50m
      max: 2
      limitRatio: 1.5
    memory:
      min: 256Mi
      max: 2Gi
      limitRatio: 1.5
```

  - **settings.resourcesManagement.mode**
    string

    Resource management mode:

    - `Static` is a classic one. In it, you specify requests/limits. The parameters of this mode are defined in the static parameter section;
    - `VPA` mode uses VPA. You can configure this mode by modifying parameters in the vpa parameter section.

    Default: `VPA`

Allowed values: `VPA`, `Static`

- **settings.resourcesManagement.static**
  object

  Resource management options for the `Static` mode.

  - **settings.resourcesManagement.static.limits**
    object

    Configuring CPU and memory limits.

    - **settings.resourcesManagement.static.limits.cpu**
      string or number

      Configuring CPU limits.

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.static.limits.memory**
      string or number

      Configuring memory limits.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  - **settings.resourcesManagement.static.requests**
    object

    Resource requests settings for pods.

    - **settings.resourcesManagement.static.requests.cpu**
      string or number

      Configuring CPU requests.

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.static.requests.memory**
      string or number

      Configuring memory requests.

      Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa**
  object

  Resource management options for the `VPA` mode.

  - **settings.resourcesManagement.vpa.cpu**
    object

    CPU-related VPA settings.

    - **settings.resourcesManagement.vpa.cpu.limitRatio**
      number

      The CPU limits/requests ratio.

      This ratio is used for calculating the initial CPU limits for a pod.

      If this parameter is set, the VPA will recalculate the CPU limits while maintaining the specified limits/requests ratio.

    - **settings.resourcesManagement.vpa.cpu.max**
      string or number

      The maximum value that the VPA can set for the CPU requests.

      Default: `2`

      Pattern: `^[0-9]+m?$`

    - **settings.resourcesManagement.vpa.cpu.min**
      string or number

      The minimum value that the VPA can set for the CPU requests.

      Default: `50m`

      Pattern: `^[0-9]+m?$`

  - **settings.resourcesManagement.vpa.memory**
    object

    Memory-related VPA settings.

    - **settings.resourcesManagement.vpa.memory.limitRatio**
      number

      The memory limits/requests ratio.

      This ratio is used for calculating the initial memory limits for a pod.

If this parameter is set, the VPA will recalculate the memory limits while maintaining the specified limits/requests ratio.

- **settings.resourcesManagement.vpa.memory.max**
  string or number

  The maximum memory requests the VPA can set.

  Default: `2Gi`

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa.memory.min**
  string or number

  The minimum memory requests the VPA can set.

  Default: `256Mi`

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **settings.resourcesManagement.vpa.mode**
  string

  VPA operating mode.

  - `Initial` — VPA sets initial values for pod resource requests and limits at pod creation time. Resource values are not changed automatically afterwards.
  - `InPlaceOrRecreate` — VPA attempts to update pod resources in place when supported by the cluster. If in-place updates are not possible, the pod will be recreated.
  - `Auto` — VPA automatically recreates pods to apply updated resource values.

    > **i** Starting from Deckhouse version 1.75, this mode is considered legacy. It is recommended to use `InPlaceOrRecreate` instead.

  Default: `InPlaceOrRecreate`

  Allowed values: `Initial`, `InPlaceOrRecreate`, `Auto`

- **settings.retentionPeriodHours**
  integer

  The desired minimum log retention period in hours.

  This parameter does not affect the log retention depth, since Loki only deletes old data when the disk is full.

  If Loki deletes data that has not yet reached the specified retention period, you will receive a `LokiInsufficientDiskForRetention` alert. In this case, you should either increase the disk size or decrease the value of this parameter.

  Default: `168`

- **settings.storageClass**
  string or boolean

  The name of the StorageClass for storing Loki logs (PVC).

  If omitted, the StorageClass of the existing Loki PVC is used. If there is no PVC yet, the StorageClass will be used according to the global storageClass parameter setting.

  The global `storageClass` parameter is only considered when the module is enabled. Changing the global `storageClass` parameter while the module is enabled will not trigger disk re-provisioning.

  Warning. Specifying a value different from the one currently used (in the existing PVC) will result in disk re-provisioning and all data will be deleted.

  Allowed values: `false`

  Examples:

  ```
  storageClass: false
  ```

  ```
  storageClass: default
  ```

- **settings.storeSystemLogs**
  boolean

  Save logs from the `d8-*` namespaces to loki.

  The log-shipper module must be enabled.

  Default: `true`

- **settings.tolerations**
  array of objects

  The same as the Pods' `spec.tolerations` parameter in Kubernetes. If the parameter is omitted or `false`, `tolerations` will be determined automatically.

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

An example of the configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: loki
spec:
  settings:
    storageClass: ceph-csi-rbd
    diskSizeGigabytes: 10
    retentionPeriodHours: 48
  enabled: true
  version: 1
```

FAQ

⚠ The module lifecycle stage: Preview

Why is LokiDiscardedSamplesWarning alert triggered?

The `LokiDiscardedSamplesWarning` alert is triggered when Loki discards logs during data ingestion because they fail validation or exceed configured limits.

In other words, `log-shipper` is trying to send data that Loki rejects.

Possible causes

Most likely, a limit on the size or number of streams has been exceeded.

Loki enforces limits on:

- The number of unique labels per stream
- The length of label names and values
- The number of streams per client
- The batch size during ingestion

For a detailed description of each limit, refer to the official Loki documentation.

Resolving the issue

1. Check the reason in the alert description.

   ```
   Samples are being discarded because of "{{ $labels.reason }}"...
   ```

   The `{{ $labels.reason }}` field indicates which limit was exceeded and why Loki is rejecting logs.

2. Adjust the corresponding limit in the `loki` module configuration.

   For a description of configurable parameters, refer to the module documentation.

   For example, if the reason is `rate_limited`, increase the `ingestionRateMB` or `ingestionBurstSizeMB` values if temporary ingestion spikes are expected. Alternatively, you can limit the amount of logs sent on the application side.

Module loki: examples

⚠ The module lifecycle stage: Preview

Reading Pod logs from a specified namespace and sending them to Loki

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: loki
spec:
  settings:
    storageClass: ceph-csi-rbd
    diskSizeGigabytes: 30
    retentionPeriodHours: 168
  enabled: true
  version: 1
---
apiVersion: deckhouse.io/v1alpha2
kind: ClusterLoggingConfig
metadata:
  name: development-logs
spec:
  type: KubernetesPods
  kubernetesPods:
    namespaceSelector:
      labelSelector:
        matchExpressions:
        - key: "kubernetes.io/metadata.name"
          operator: In
          values: [development]
  destinationRefs:
    - d8-loki
```

For more examples, see the log-shipper module page.

The metallb module

> **i** Available with limitations in: **SE, SE+, CSE Lite (1.73)**
>
> Available without limitations in: **EE**

> **i** The module lifecycle stage: General Availability

This module implements the `LoadBalancer` mechanism for services in bare metal clusters.

Supports the following operating modes:

- **Layer 2 Mode** – introduces an improved load-balancing mechanism for bare metal clusters (compared to the standard L2 mode in MetalLB), enabling the use of multiple “public” IP addresses for cluster services.
- **BGP Mode** – fully based on the MetalLB solution.

Layer 2 mode

In Layer 2 mode, one or more nodes take responsibility for providing the service within the “public” network. From the network’s perspective, it appears as if each of these nodes has multiple IP addresses assigned to its network interface. Technically, this is achieved by the module responding to ARP requests for IPv4 services and NDP requests for IPv6 services. The primary advantage of Layer 2 mode is its versatility: it works in any Ethernet network without requiring specialized hardware.

Advantages of the module over the classic MetalLB

MetalLB in L2 mode allows ordering Service with `LoadBalancer` type, the operation of which is based on the fact that balancing nodes simulate ARP-responses from the “public” IP in a peering network. This mode has a significant limitation — only one balancing node handles all the incoming traffic of this service at a time. Therefore:

- The node selected as the leader for the “public” IP becomes a “bottleneck”, with no possibility of horizontal scaling.
- If the balancer node fails, all current connections will be dropped while switching to a new balancing node that will be selected as the leader.

This module helps to overcome these limitations. It introduces a new resource, MetalLoadBalancerClass, which allows associating a group of nodes with an IP address pool using a `nodeSelector`. Afterward, a standard Service resource of type `LoadBalancer` can be created, specifying the name of the corresponding MetalLoadBalancerClass. Additionally, annotations can be used to define the required number of IP addresses for L2 advertisement.

Thus:

- The application will receive not a single, but several (according to the number of balancer nodes) “public” IPs. These IPs will need to be configured as A-records for the application’s public domain. For further horizontal scaling, additional balancer nodes will need to be added, the corresponding Service will be created automatically, you just need to add them to the list of A-records for the application domain.
- If one of the balancer nodes fails, only part of the connections will fail over to the healthy node.

BGP Mode

Metallb in BGP mode provides an efficient and scalable way to expose `LoadBalancer` type Services in Kubernetes clusters running on bare metal. By utilizing the standardized BGP protocol, metallb seamlessly integrates into existing network infrastructure and ensures high availability of Services.

How metallb Works in BGP Mode

In BGP mode, metallb establishes BGP sessions with routers (or Top-of-Rack switches) and announces the IP addresses of `LoadBalancer` type services to them. This is accomplished as follows:

Configuration.

- Metallb is configured with a pool of IP addresses that it can assign to Services.
- BGP session parameters are defined: the Autonomous System (AS) number of the Kubernetes cluster, the IP addresses of the routers (peers), the AS number of the peers, and optionally, authentication passwords.
- For each IP address pool, specific announcement parameters can be set, such as community strings.

Establishing BGP Sessions.

- On each node of the Kubernetes cluster where metallb is running, the speaker component establishes BGP sessions with the specified routers.
- Routing information is exchanged between metallb and the routers.

Assigning IP Addresses to Services.

- When a Service of type `LoadBalancer` is created, metallb selects a free IP address from the configured pool and assigns it to the Service.
- The controller component tracks changes to Services and manages IP address assignments.

Announcing IP Addresses.

- After an IP address is assigned, the speaker on the node elected as the leader for that Service begins announcing the IP address over the established BGP sessions.
- The routers receive this announcement and update their routing tables, directing traffic for that IP address to the node that announced it.

Traffic Distribution.

- Routers use Equal-Cost Multi-Path (ECMP) or other load balancing algorithms to distribute traffic among nodes announcing the same Service IP address.
- Inside the Kubernetes cluster, traffic arriving at a node is forwarded to the Service’s pods using the mechanisms of the employed CNI (iptables/IPVS, eBPF programs, etc.).

Advantages of Using BGP

- **Standardized Protocol:** BGP is a widely used and well-established routing protocol.
- **Flexibility and Scalability:** BGP allows you to integrate your Kubernetes cluster into your existing network infrastructure and scale your services.
- **Load Distribution:** Using ECMP allows for efficient load distribution across cluster nodes.
- **Fault Tolerance:** If a node announcing an IP address fails, routers automatically redirect traffic to other nodes announcing the same IP.

Disadvantages of Using BGP

- **Configuration Complexity:** Configuring BGP can be more complex than configuring ARP/NDP announcements (in Layer 2 mode).
- **Network Equipment Requirements:** Routers must support BGP and ECMP.

Third-party components

List of third-party software used in the `metallb` module:

- MetalLB 0.15.2

  License: Apache License 2.0

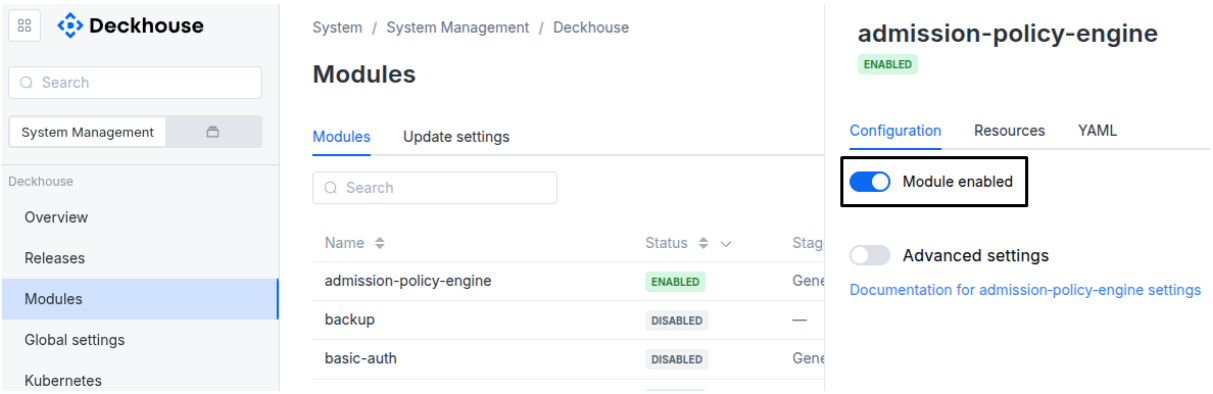
  A load-balancer implementation for bare metal Kubernetes clusters, using standard routing protocols.

Configuration

> **i** Available with limitations in: **SE, SE+, CSE Lite (1.73)**
>
> Available without limitations in: **EE**

> **i** The module lifecycle stage: General Availability

The module has 7 alerts.



The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the

`metallb` module and enable (or disable) the “Module enabled” toggle. Save changes.

Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

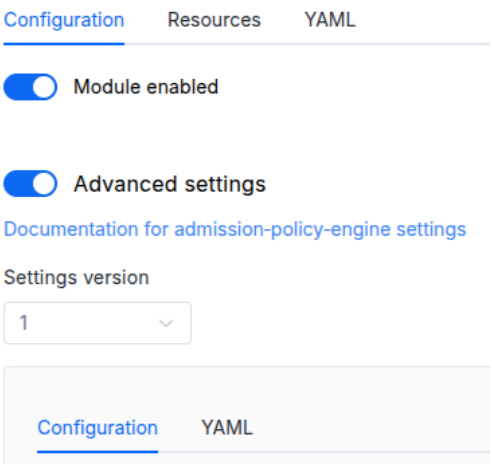
  ```
  d8 system module enable metallb
  ```

- **Using ModuleConfig `metallb`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `metallb` (create it if necessary);

  Example of a manifest to enable module `metallb`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: metallb
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `metallb` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `metallb` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `metallb`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `metallb` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc metallb
  ```

Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `metallb` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `metallb`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: metallb
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Remove all `addressPool` elements with the `layer2` protocol.

Parameters

Schema version: 2

Example:

```
bgpPeers:
- peer-address: 192.168.1.1
  peer-asn: 1111
  my-asn: 2222
  source-address: 192.168.1.2
  hold-time: 10s
  node-selector:
    matchLabels:
      node: test
addressPools:
- name: my-pool-bgp
  protocol: bgp
  addresses:
  - 192.168.100.1-192.168.100.10
  - 192.168.101.0/24
  bgp-advertisements:
  - aggregation-length: 32
    localpref: 100
    communities:
    - no-advertise
bgpCommunities:
  no-advertise: 65535:65282
speaker:
  nodeSelector:
    mylabel: speaker
```

- **settings**
  object
  - **settings.addressPools**
    array of objects

    Required value

    A list of IP ranges to assign to services.

    Format — a data array similar to that of MetalLB's.

    Default: `[]`

    - **settings.addressPools.addresses**
      array of strings

Required value

A list of ranges, where each range can look like a subnet/mask or a numeric address range (with “-“ as a delimiter).

- **settings.addressPools.auto-assign**
  boolean

  Auto-assign flag used to prevent metallb from automatic allocation for a pool.

  Default: `true`

- **settings.addressPools.avoid-buggy-ips**
  boolean

  Prevents addresses ending with `.0` and `.255` to be used by a pool.

  Default: `false`

- **settings.addressPools.bgp-advertisements**
  array of objects

  Defines BGP advertisements.

  - **settings.addressPools.bgp-advertisements.aggregation-length**
    integer

    The aggregation-length advertisement option lets you “roll up” prefix into a larger one.

    Works for IPv4 addresses.

    Default: `32`

    Allowed values: `1 <= X`

  - **settings.addressPools.bgp-advertisements.communities**
    array of strings

    Keys from the bgpCommunities parameter to be associated with the announcement.

    Example:

    ```
    communities:
    - no-advertise
    ```

  - **settings.addressPools.bgp-advertisements.localpref**
    integer

    The `BGP LOCAL_PREF` attribute which is used by BGP best path algorithm.

    Path with higher localpref is preferred over one with lower localpref.

- **settings.addressPools.name**
  string

  Required value

  The name of the pool. It should conform to RFC 1123: dot-separated parts in lowercase, consists of alphanumeric characters, ‘-‘. Each part must start and end with an alphanumeric character.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.addressPools.protocol**
  string

  Required value

  The protocol used by the speaker to announce services.

  Allowed values: `bgp`, `layer2`

- **settings.bgpCommunities**
  object

  Available in editions: EE

  The BGP communities list.

  Example:

  ```
  bgpCommunities:
    no-advertise: 65535:65282
  ```

- **settings.bgpPeers**
  array of objects

  Available in editions: EE

  A list of external BGP routers to use with the module.

  Format — a data array similar to that of MetalLB’s.

Default: `[]`

- **settings.bgpPeers.hold-time**
  integer or string

  The timeout after which the neighboring BGP peer is considered dead. This value is divided by three to get the keep-alive interval.

  The recommended value is `3s` (i.e., keep-alive packets are sent once per second). Note that the BGP protocol does not support values lower than this. By default, the parameter is set to `90s` (i.e., keep-alive packets are sent every 30 seconds).

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **settings.bgpPeers.my-asn**
  integer

  Required value

  The AS number in the cluster.

  Allowed values: `0 <= X <= 4294967295`

- **settings.bgpPeers.node-selector**
  object

  The additional pseudo-selector implemented by the speaker application. It selects nodes that are allowed to connect to external BGP routers. Do not confuse it with `speaker.nodeSelector` and `nodeSelector`.

  An optional parameter.

  The format is `matchLabels` or `matchExpressions`.

  - **settings.bgpPeers.node-selector.matchExpressions**
    array of objects
    - **settings.bgpPeers.node-selector.matchExpressions.key**
      string
    - **settings.bgpPeers.node-selector.matchExpressions.operator**
      string
    - **settings.bgpPeers.node-selector.matchExpressions.values**
      array of strings
  - **settings.bgpPeers.node-selector.matchLabels**
    object
- **settings.bgpPeers.password**
  string

  Authentication password for BGP-routers enforcing TCP MD5 authenticated sessions.

- **settings.bgpPeers.peer-address**
  string

  Required value

  The IP address of the external BGP router.

  Pattern: `^([0-9]{1,3}\.){3}[0-9]{1,3}$`

- **settings.bgpPeers.peer-asn**
  integer

  Required value

  The AS number on the external BGP router.

  Allowed values: `0 <= X <= 4294967295`

- **settings.bgpPeers.peer-port**
  integer

  Port to dial when establishing the session.

  Default: `179`

  Allowed values: `0 <= X <= 16384`

- **settings.bgpPeers.router-id**
  string

  BGP router ID to advertise to the peer.

- **settings.bgpPeers.source-address**
  string

  The source IP address for outbound connections.

  Pattern: `^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$`

- **settings.loadBalancerClass**
  string

  An optional field describing the LoadBalancer class. The LoadBalancerClass field should be used in L2 LoadBalancer mode to specify the MetalLoadBalancerClass that defines the balancer parameters for the Service.

- **settings.nodeSelector**
  object

  A selector for the main controller. It is the same as the Pod's `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.speaker**
  object

  Settings for the `speaker` component that implements the LoadBalancer's IPs publishing protocol for external infrastructure.

  - **settings.speaker.nodeSelector**
    object

    Required value

    A selector for the speaker DaemonSet. It is the same as the Pod's `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.speaker.tolerations**
    array of objects

    Tolerations for the speaker DaemonSet. They are the same as the Pod's `spec.tolerations` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

    - **settings.speaker.tolerations.effect**
      string
    - **settings.speaker.tolerations.key**
      string
    - **settings.speaker.tolerations.operator**
      string
    - **settings.speaker.tolerations.tolerationSeconds**
      integer
    - **settings.speaker.tolerations.value**
      string

- **settings.tolerations**
  array of objects

  Tolerations for the main controller. They are the same as the Pod's `spec.tolerations` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

MetalLoadBalancerClass

Short names: mlbc

Scope: Cluster
Version: v1alpha1

MetalLoadBalancerClass is the Schema for the metalloadbalancerclasses API

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object
  - **spec.addressPool**
    array of strings

An array of public IP address ranges. Each range can be specified using a CIDR notation or by directly specifying the range, for example, `10.10.10.1-10.10.10.100`.

Examples:

```
addressPool: 10.42.0.0/24
```

```
addressPool: 10.33.5.100-10.33.5.106
```

- **spec.isDefault**
  boolean

  Whether MetalLoadBalancerClass is selected for all services by default.

  Example:

  ```
  isDefault: true
  ```

- **spec.l2**
  object

  Available in editions: SE, SE+, EE

  - **spec.l2.interfaces**
    array of strings

    Available in editions: SE, SE+, EE

    A list of network interfaces from which the assigned IP addresses will be announced. If this field is not filled in or an empty array is specified, the announcement will occur from all interfaces on the node. It is highly recommended to configure this parameter to prevent the announcement of addresses from all node interfaces.

    Example:

    ```
    interfaces:
    - eth1
    - eth2
    ```

- **spec.nodeSelector**
  object

  Allows restricting the list of nodes from which the announcement will occur. Specified as a set of labels for filtering nodes.

- **spec.type**
  string

  Selecting the load balancer operating mode.

  Example:

  ```
  type: L2
  ```

- **status**
  object

Examples

> **i** The module lifecycle stage: General Availability

Metallb can be used in Static (bare metal) clusters when there is no option to use cloud load balancers. Metallb can work in L2 LoadBalancer or BGP modes LoadBalancer.

Example of metallb usage in L2 LoadBalancer mode

Enable the module:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: metallb
spec:
  enabled: true
  version: 2
```

Prepare the application to publish:

```
d8 k create deploy nginx --image=nginx
```

Create the MetalLoadBalancerClass resource:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: MetalLoadBalancerClass
metadata:
  name: ingress
spec:
  addressPool:
    - 192.168.2.100-192.168.2.150
  isDefault: false
  nodeSelector:
    node-role.kubernetes.io/loadbalancer: "" # node-balancer selector
  type: L2
```

Create standard resource Service with special annotation and MetalLoadBalancerClass name:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-deployment
  annotations:
    network.deckhouse.io/l2-load-balancer-external-ips-count: "3"
spec:
  type: LoadBalancer
  loadBalancerClass: ingress # MetalLoadBalancerClass name
  ports:
  - port: 8000
    protocol: TCP
    targetPort: 80
  selector:
    app: nginx
```

As a result, the created Service with the type `LoadBalancer` will be assigned the specified number of addresses:

```
d8 k get svc
```

Output example:

```
NAME                TYPE           CLUSTER-IP      EXTERNAL-IP                                 PORT(S)        AGE
nginx-deployment    LoadBalancer   10.222.130.11   192.168.2.100,192.168.2.101,192.168.2.102   80:30544/TCP   11s
```

> **i** When creating a service, you can also specify certain IP addresses from the pool that will be assigned to it.

The resulting EXTERNAL-IP are ready to use in application DNS-domain:

```
$ curl -s -o /dev/null -w "%{http_code}" 192.168.2.100:8000
200
$ curl -s -o /dev/null -w "%{http_code}" 192.168.2.101:8000
200
$ curl -s -o /dev/null -w "%{http_code}" 192.168.2.102:8000
200
```

Example of metallb usage in BGP LoadBalancer mode

Enable the module and configure all the necessary parameters*:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: metallb
spec:
  enabled: true
  settings:
    addressPools:
    - addresses:
      - 192.168.219.100-192.168.219.200
      name: mypool
      protocol: bgp
    bgpPeers:
    - hold-time: 3s
      my-asn: 64600
      peer-address: 172.18.18.10
      peer-asn: 64601
    speaker:
      nodeSelector:
        node-role.deckhouse.io/metallb: ""
  version: 2
```

* — in future versions, BGP mode settings will be set via the MetalLoadBalancerClass resource.

Configure BGP peering on the network equipment.

Additional configuration examples for Service

Creating a service and assigning it specific IP addresses from the pool

> **i** To specify the addresses that should be assigned to the service, use the annotation `network.deckhouse.io/load-balancer-ips`. If there is more than one desired address, there must also be an annotation `network.deckhouse.io/l2-load-balancer-external-ips-count`, which must specify the number of addresses allocated from the pool (it must not be less than the number of addresses listed in `network.deckhouse.io/load-balancer-ips`).

```
apiVersion: v1
kind: Service
metadata:
  name: nginx-deployment
  annotations:
    # The number of addresses that will be allocated from the pool declared in MetalLoadBalancerClass.
    network.deckhouse.io/l2-load-balancer-external-ips-count: "3"
    # A list of addresses from the pool declared in MetalLoadBalancerClass that will be allocated to
the service.
    network.deckhouse.io/load-balancer-ips: "192.168.2.102,192.168.2.103,192.168.2.104"
spec:
  type: LoadBalancer
  loadBalancerClass: ingress # MetalLoadBalancerClass name
  ports:
  - port: 8000
    protocol: TCP
    targetPort: 80
  selector:
    app: nginx
```

As a result, the created Service with the type `LoadBalancer` will be assigned the specified number of addresses:

```
d8 k get svc
```

Output example:

```
NAME                TYPE           CLUSTER-IP      EXTERNAL-IP                                 PORT(S)        AGE
nginx-deployment    LoadBalancer   10.222.130.11   192.168.2.102,192.168.2.103,192.168.2.104   80:30544/TCP   11s
```

Creating a service with a single, forcibly selected address

To create a Service with a forcibly selected address, you need to add the annotation `network.deckhouse.io/load-balancer-ips`:

```
apiVersion: v1
kind: Service
metadata:
  name: nginx
  annotations:
    network.deckhouse.io/load-balancer-ips: 192.168.217.217
spec:
  ports:
  - port: 80
    targetPort: 80
  selector:
    app: nginx
  type: LoadBalancer
```

Creating services with shared IP addresses

To create a Services with shared IP addresses, you need to add the annotation `network.deckhouse.io/load-balancer-shared-ip-key`. The value of the annotation is a “sharing key”. Services can share an IP address under the following conditions:

- They have the same sharing key.
- They request the use of different ports (e.g. tcp/80 for one and tcp/443 for the other).
- They use the Cluster external traffic policy, or they both point to the exact same set of pods (i.e. the pod selectors are identical).

If these conditions are satisfied, MetalLB may colocate the two services on the same IP, but **does not have to**! If you want to ensure that they share a specific address, use the `network.deckhouse.io/load-balancer-ips` annotation described above.

Here is an example configuration of two services that share the same ip address:

```
apiVersion: v1
kind: Service
metadata:
  name: dns-service-tcp
  namespace: default
  annotations:
    network.deckhouse.io/load-balancer-shared-ip-key: "key-to-share-1.2.3.4"
spec:
  type: LoadBalancer
  ports:
    - name: dnstcp
      protocol: TCP
      port: 53
      targetPort: 53
  selector:
    app: dns
---
apiVersion: v1
kind: Service
metadata:
  name: dns-service-udp
  namespace: default
  annotations:
    network.deckhouse.io/load-balancer-shared-ip-key: "key-to-share-1.2.3.4"
spec:
  type: LoadBalancer
  ports:
    - name: dnsudp
      protocol: UDP
      port: 53
      targetPort: 53
  selector:
    app: dns
```

Creating a service and assigning IPAddressPools to it when using mettalb in BGP LoadBalancer mode

Creating a Service and assigning it IPAddressPools is possible in BGP LoadBalancer mode using the annotation `metallb.universe.tf`. For L2 LoadBalancer mode, you need to use the MetalLoadBalancerClass settings (see above).

```
apiVersion: v1
kind: Service
metadata:
  name: nginx
  annotations:
    metallb.universe.tf/address-pool: production-public-ips
spec:
  ports:
  - port: 80
    targetPort: 80
  selector:
    app: nginx
  type: LoadBalancer
```

Automatic configuration of the monitoring system to collect metrics from user applications

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

Additional configuration is required to monitor user applications running in the cluster. This module simplifies the setup process by reducing it to specifying a specific label for the desired application.

To enable the `monitoring-custom` module to collect application metrics, you must:

- Attach the `prometheus.deckhouse.io/custom-target` label to a Service or a Pod. The label value defines the name in the Prometheus list of targets.
  - You should use the application's name (in lowercase, separated by a hyphen "-") as the value of the `prometheus.deckhouse.io/custom-target` label. This way, the application will be uniquely identified in the cluster.

    Suppose the application is deployed in the cluster more than once (in staging, testing, etc.) or even has several copies in the same namespace. In that case, you still only need to specify its name since all metrics have `namespace`, `pod` labels anyway (and the `service` label if it is accessed via the Service). In other words, the application's name uniquely identifies the application in the cluster (and not a specific installation of it).
- Set the `http-metrics` or `https-metrics` name to the port that will be used for collecting metrics to connect to it over HTTP or HTTPS, respectively.

  If it is not feasible for some reason (e.g., the port is already defined and has a different name), you can use the `prometheus.deckhouse.io/port: port number` annotation to set the port number and `prometheus.deckhouse.io/tls: "true"` if metrics are collected over HTTPS.

  > **i** When annotating a Service, you must use `targetPort` as the port value. I.e., the port that is open and listening by your application, not the Service port.

  - Example No. 1:

    ```
    ports:
    - name: https-metrics
      containerPort: 443
    ```

  - Example No. 2:

    ```
    annotations:
      prometheus.deckhouse.io/port: "443"
      prometheus.deckhouse.io/tls: "true"  # you don't need to specify this annotation if metrics
    are sent over HTTP
    ```
- When using service mesh Istio in mTLS STRICT mode, add the following Service or Pod annotation to force collecting metrics with proper mTLS certificate: `prometheus.deckhouse.io/istio-mtls: "true"`. Note that the application metrics must be exported via pure HTTP without TLS.
- *(Optional)* Attach the following annotations to fine-tune the monitoring:
  - `prometheus.deckhouse.io/path` — the path to collect metrics (default: `/metrics`);
  - `prometheus.deckhouse.io/query-param-$name` — GET parameters; they will be converted to a map of the following form: `$name=$value` ('' by default);
    - you can specify several such annotations;

      For example, `prometheus.deckhouse.io/query-param-foo=bar` & `prometheus.deckhouse.io/query-param-bar=zxc` annotations will be converted to the `http://...?foo=bar&bar=zxc` query;
  - `prometheus.deckhouse.io/allow-unready-pod` — enables collecting metrics for Pods in any state (by default, Prometheus scrapes metrics from the Ready Pods only). Note that this option is rarely helpful. For example, it can come in handy if it takes a long time to start your application (e.g., some data are loaded into the database at

startup or some caching activity occurs), but valuable metrics are supplied during the startup process, helping to monitor it;
- `prometheus.deckhouse.io/sample-limit` — sample limit for a Pod (5000 by default). The default value prevents a situation when the application suddenly starts to supply too many metrics, disrupting the entire monitoring process. This annotation must be attached to the resource with the `prometheus.deckhouse.io/custom-target` label;

An example: Service

```
apiVersion: v1
kind: Service
metadata:
  name: my-app
  namespace: my-namespace
  labels:
    prometheus.deckhouse.io/custom-target: my-app
  annotations:
    prometheus.deckhouse.io/port: "8061"                 # by default, either the http-metrics or
https-metrics service port is used
    prometheus.deckhouse.io/path: "/my_app/metrics"         # /metrics by default
    prometheus.deckhouse.io/query-param-format: "prometheus"  # '' by default
    prometheus.deckhouse.io/allow-unready-pod: "true"       # by default, NON-ready Pods are ignored
    prometheus.deckhouse.io/sample-limit: "5000"           # by default, the sample is limited to 5000
metrics for a single Pod
spec:
  ports:
  - name: my-app
    port: 8060
  - name: http-metrics
    port: 8061
    targetPort: 8061
  selector:
    app: my-app
```

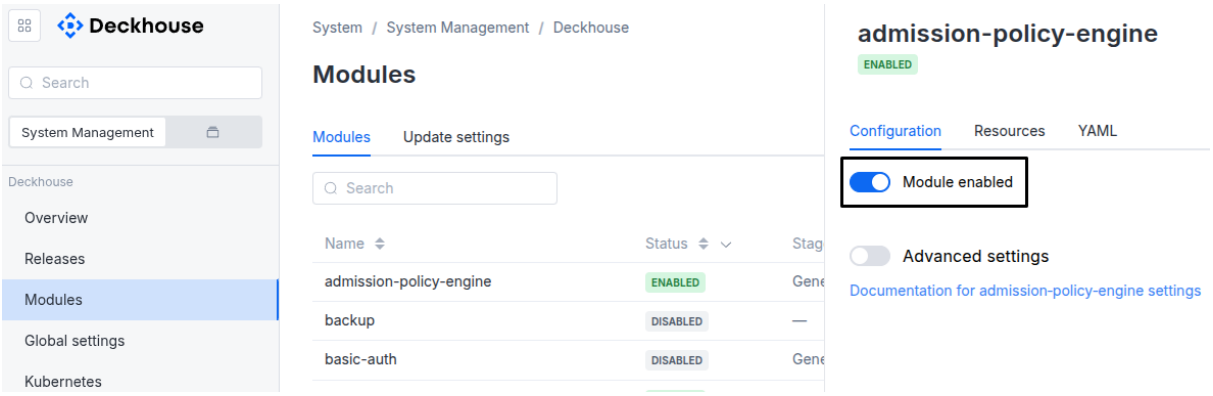
An example: Deployment

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-app
  labels:
    app: my-app
spec:
  selector:
    matchLabels:
      app: my-app
  template:
    metadata:
      labels:
        app: my-app
        prometheus.deckhouse.io/custom-target: my-app
      annotations:
        prometheus.deckhouse.io/sample-limit: "5000"  # by default, the sample is limited to 5000
metrics for a single Pod
    spec:
      containers:
      - name: my-app
        image: my-app:1.7.9
        ports:
        - name: https-metrics
          containerPort: 443
```

Configuration

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

The module works if the `prometheus` module is enabled and does not have any parameters to configure.



The module has 5 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-custom` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

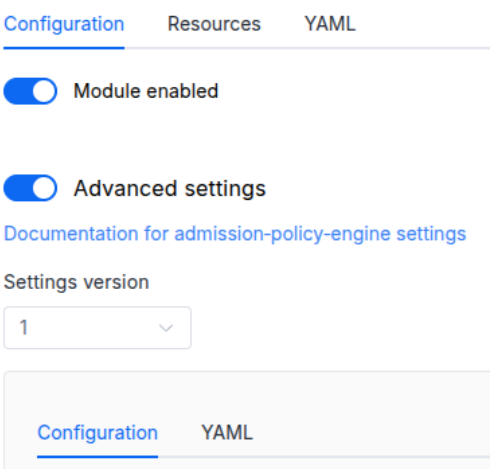
```
d8 system module enable monitoring-custom
```

- **Using ModuleConfig `monitoring-custom`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `monitoring-custom` (create it if necessary);

  Example of a manifest to enable module `monitoring-custom`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-custom
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-custom` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `monitoring-custom` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `monitoring-custom`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `monitoring-custom` (for more details on configuring Deckhouse, see the

documentation) by executing the following command:

```
d8 k edit mc monitoring-custom
```

Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `monitoring-custom` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `monitoring-custom`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-custom
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Requirements

To the versions of other modules:

- `prometheus`: any version.

The monitoring-deckhouse module

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

The `monitoring-deckhouse` module provides comprehensive monitoring, alerting, and observability for the Deckhouse Kubernetes Platform itself. It monitors the health, performance, and proper operation of DKP core components to ensure platform stability and reliability.

This module is a critical observability component that works in conjunction with the `prometheus` module to provide insights into DKP operational state.

The module deploys monitoring resources that:

- **Collect Deckhouse metrics**: Module scrapes metrics from the Deckhouse pod using PodMonitor resources, including:
  - Self metrics on port `4222` via `/metrics` endpoint.
  - Custom hook-generated metrics via `/metrics/hooks` endpoint.
  - Module execution metrics, hook performance, and system health indicators.
- **Define alerting rules**: Module provides comprehensive Prometheus alerting rules organized into several categories:
  - **DKP availability**: Monitors pod health, readiness, and uptime.
  - **DKP malfunctioning**: Detects excessive restarts, registry access issues, hung processes.
  - **Release management**: Tracks release channel subscriptions, pending updates, and manual approvals.
  - **Module management**: Monitors module state, validation errors, and deprecated configurations.
  - **CNI checks**: Detects multiple CNI configurations and misconfigurations.
  - **OS requirements**: Identifies nodes running deprecated operating system versions.
- **Provide Grafana dashboards**: Includes pre-built Grafana dashboards for visualizing:
  - DKP performance metrics.
  - Module execution statistics.
  - Hook run times and resource usage.
  - Queue processing and convergence status.

Metrics collection

The module configures a PodMonitor that scrapes two endpoints from the Deckhouse pod:

1. **DKP metrics** (`/metrics`): Core DKP operational metrics:
   - `deckhouse_live_ticks`: Health indicator incrementing every 10 seconds.
   - `deckhouse_registry_errors`: Registry connectivity issues.
   - `deckhouse_module_hook_run_seconds`: Module hook execution duration.
   - `deckhouse_tasks_queue_action_duration_seconds`: Task queue processing times.
   - And many more operational metrics.
2. **Hook metrics** (`/metrics/hooks`): Custom metrics generated by DKP hooks with `honorLabels: true` to preserve hook-specific labels.

Integration with Observability module

When the `observability` module is enabled, this module automatically creates:

- ClusterObservabilityMetricsRulesGroup resources for Prometheus rules.

- ClusterObservabilityDashboard resources for Grafana dashboards.

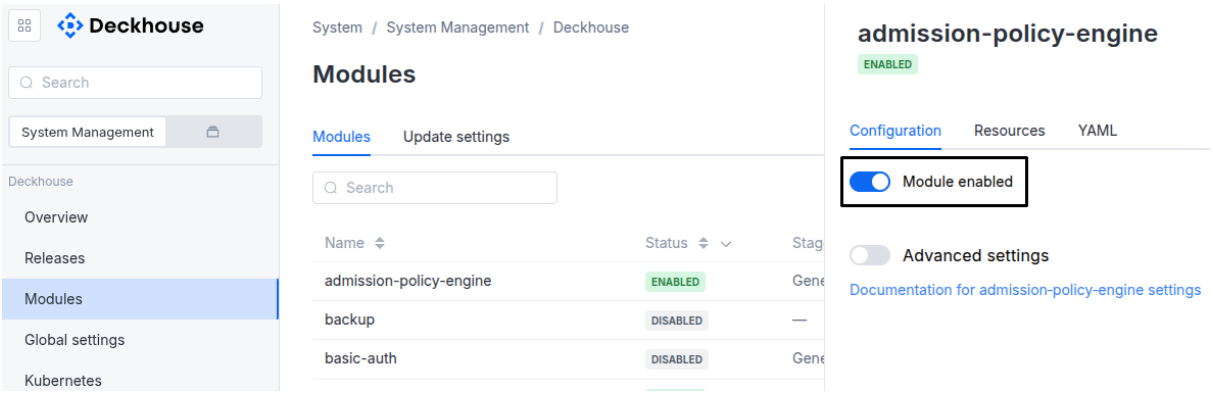
This enables centralized management and multi-tenancy support for monitoring resources.

Requirements

- `prometheus` module must be enabled (automatic dependency).
- `operator-prometheus` module should be enabled for PodMonitor support.

Configuration

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation



The module has 51 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-deckhouse` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

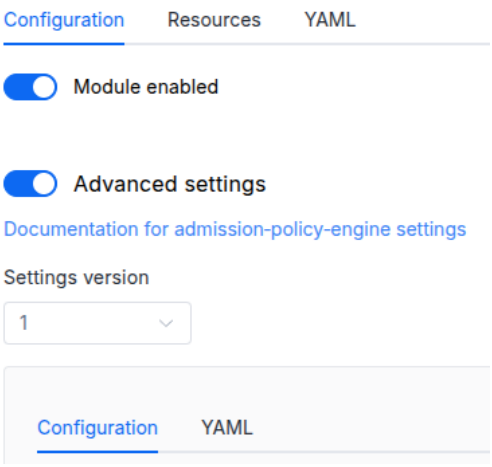
```
d8 system module enable monitoring-deckhouse
```

- **Using ModuleConfig `monitoring-deckhouse`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `monitoring-deckhouse` (create it if necessary);

  Example of a manifest to enable module `monitoring-deckhouse`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-deckhouse
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-deckhouse` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `monitoring-deckhouse` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `monitoring-deckhouse`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `monitoring-deckhouse` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc monitoring-deckhouse
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `monitoring-deckhouse` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `monitoring-deckhouse`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: monitoring-deckhouse
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `prometheus`: any version.

The module does not have any settings.

The monitoring-kubernetes module

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

The `monitoring-kubernetes` module provides transparent and timely monitoring of the status of all cluster nodes and key infrastructure components.

Module features:

- provides an opportunity to plan infrastructure resources (Capacity planning);
- monitors the container runtime version (docker, containerd) on each node and checks it for compliance with the allowed versions;
- monitors the performance of the cluster monitoring subsystem itself (Dead man’s switch);
- gets metrics about the availability of file descriptors, sockets, free space, and inodes on each node;
- monitors the correct operation of key monitoring components: kube-state-metrics, node-exporter, kube-dns;
- checks the status of all nodes (`NotReady`, `drain`, `cordon`) and promptly reports problems;
- monitors time synchronization and notifies about deviations;
- detects cases of prolonged CPU steal overrun (when the node does not receive the required CPU time);

- controls the status of the Conntrack table on the nodes;
- shows pods with incorrect statuses, for example, if kubelet failed to do its job;
- allows you to export metrics to external monitoring systems for a single point of control.

Third-party components

List of third-party software used in the `monitoring-kubernetes` module:

- Node exporter

  License: Apache License 2.0

  Prometheus exporter for hardware and OS metrics exposed by *NIX kernels, written in Go with pluggable metric collectors.

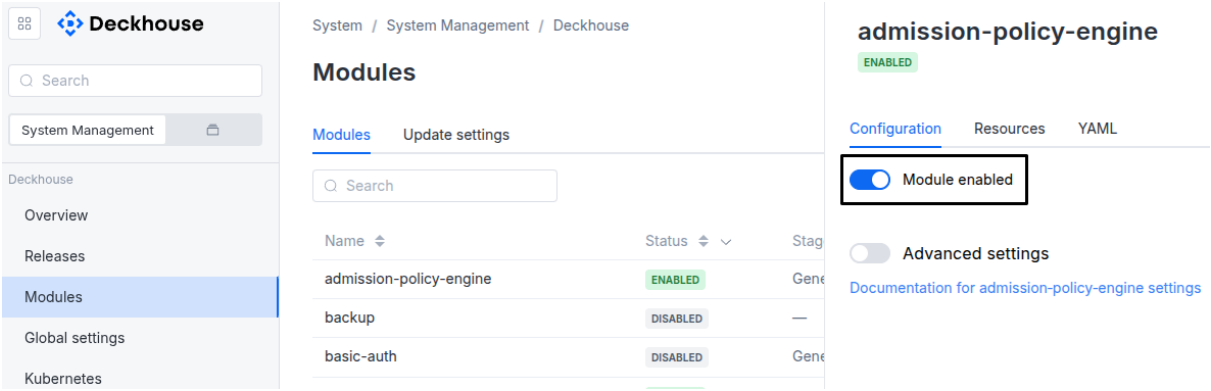
- kube-state-metrics

  License: Apache License 2.0

  A simple service that listens to the Kubernetes API server and generates metrics about the state of the objects.

Configuration

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation



The module has 47 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-kubernetes` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

```
d8 system module enable monitoring-kubernetes
```

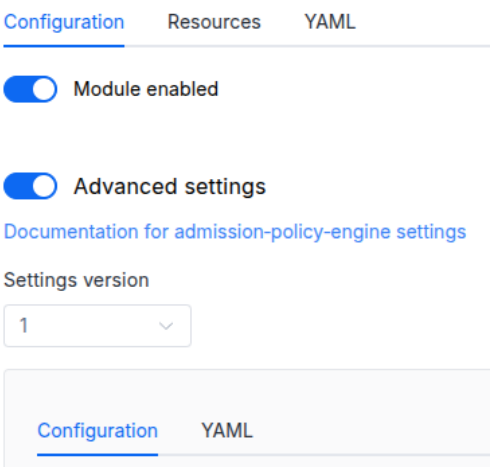
- **Using ModuleConfig `monitoring-kubernetes`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `monitoring-kubernetes` (create it if necessary);

  Example of a manifest to enable module `monitoring-kubernetes`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-kubernetes
spec:
  enabled: true
```

How to configure the module...



You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-kubernetes` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the

module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `monitoring-kubernetes` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `monitoring-kubernetes`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `monitoring-kubernetes` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc monitoring-kubernetes
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `monitoring-kubernetes` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `monitoring-kubernetes`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: monitoring-kubernetes
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `prometheus`: any version.

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  If the `.ebpfExporterEnabled` field is set to `true`, add `.oomKillsExporterEnabled=true`. Then, delete the `.ebpfExporterEnabled` field from the object.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.highAvailability**
    boolean

Manually enable the high availability mode.

By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

Examples:

```
highAvailability: true
```

```
highAvailability: false
```

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.oomKillsExporterEnabled**
  boolean

  Set to 'false' to disable oom-kills-exporter in case it behaves incorrectly.

  Default: `true`

  Example:

  ```
  oomKillsExporterEnabled: false
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

- **settings.vpa**
  object

  VPA settings for `kube-state-metrics` pods.

  Example:

  ```
  vpa:
    kubeStateMetricsMaxCPU: 130m
    kubeStateMetricsMaxMemory: 115Mi
  ```

  - **settings.vpa.kubeStateMetricsMaxCPU**
    string or number

    The maximum value that the VPA can set for the CPU requests.

    Pattern: `^[0-9]+m?$`

    Examples:

    ```
    kubeStateMetricsMaxCPU: 3
    ```

    ```
    kubeStateMetricsMaxCPU: 1000m
    ```

- **settings.vpa.kubeStateMetricsMaxMemory**
  string or number

  The maximum memory requests the VPA can set.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

  ```
  kubeStateMetricsMaxMemory: 3Mi
  ```

Monitoring the control plane

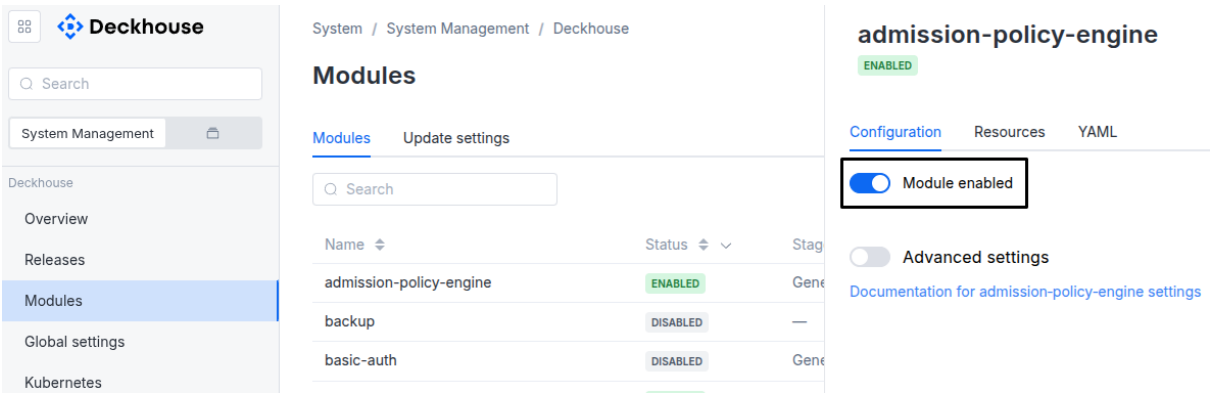
> The module lifecycle stage: General Availability
> The module has requirements for installation

The `monitoring-kubernetes-control-plane` module is responsible for monitoring the Kubernetes control plane. It safely scrapes metrics and provides a basic set of rules for monitoring the following cluster components:

- kube-apiserver
- kube-controller-manager
- kube-scheduler
- kube-etcd

Configuration

> The module lifecycle stage: General Availability
> The module has requirements for installation



The module has 11 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-kubernetes-control-plane` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

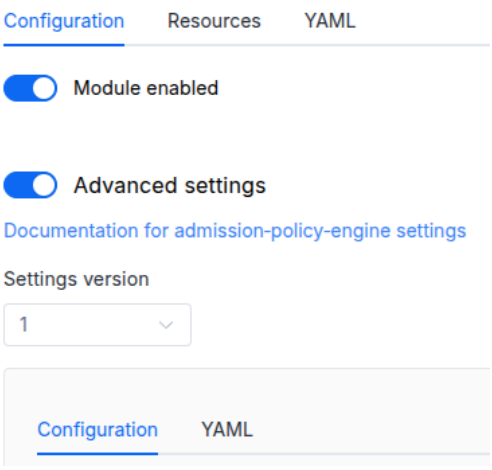
  ```
  d8 system module enable monitoring-kubernetes-control-plane
  ```

- **Using ModuleConfig `monitoring-kubernetes-control-plane`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `monitoring-kubernetes-control-plane` (create it if necessary);

  Example of a manifest to enable module `monitoring-kubernetes-control-plane`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-kubernetes-control-plane
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-kubernetes-control-plane` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `monitoring-kubernetes-control-plane` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `monitoring-kubernetes-control-plane`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `monitoring-kubernetes-control-plane` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc monitoring-kubernetes-control-plane
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `monitoring-kubernetes-control-plane` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `monitoring-kubernetes-control-plane`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: monitoring-kubernetes-control-plane
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the Kubernetes version: 1.22.0 and above.

To the Deckhouse version: 1.22.0 and above.

To the versions of other modules:

- `prometheus`: any version.
- `control-plane-manager`: any version.

Monitoring network interaction between all cluster nodes, as well as (optionally) up to additional external nodes

> The module lifecycle stage: General Availability
> The module has requirements for installation

Description

The network communication monitoring module provides continuous connectivity verification between all the main and, if necessary, external nodes of the cluster.

Module features:

- automatically checks the availability of all cluster nodes (and, optionally, external systems) using ICMP (ping) — testing is started every two seconds;
- all results are exported in metrics format to the Prometheus monitoring system.;
- included is a ready—made dashboard for Grafana, where current availability, delay schedules, and potential network connectivity issues are visualized in real time;
- allows you to quickly identify nodes with degraded connectivity and speeds up the response to incidents.

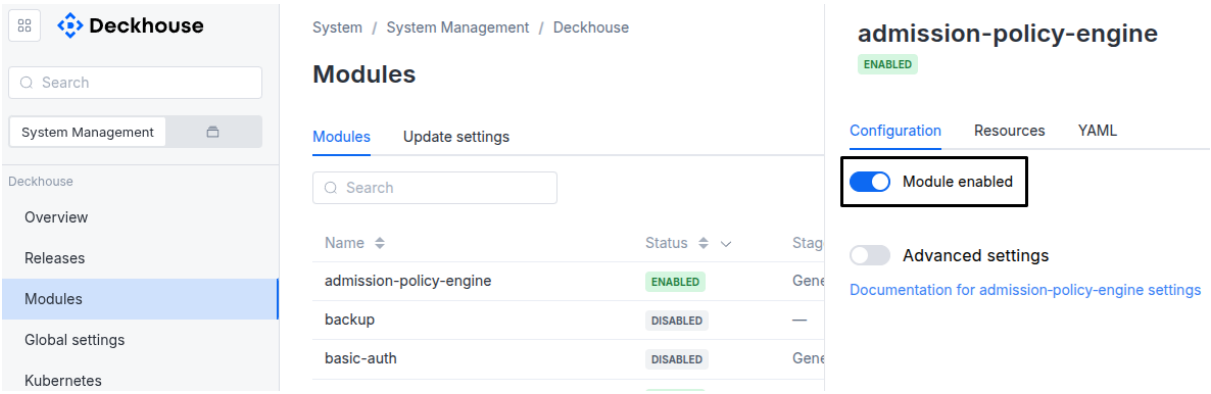
How does it work?

The module tracks the node's `.status.addresses` field for changes. Upon detecting changes, it invokes a hook that collects a complete list of node names/addresses and passes it to a DaemonSet (the latter recreates the Pods). As a result, ping checks the always up-to-date list of nodes.

The monitoring-ping module: configuration

> The module lifecycle stage: General Availability
> The module has requirements for installation

The module does not have any mandatory parameters.



The module has 1 alert.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `monitoring-ping` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

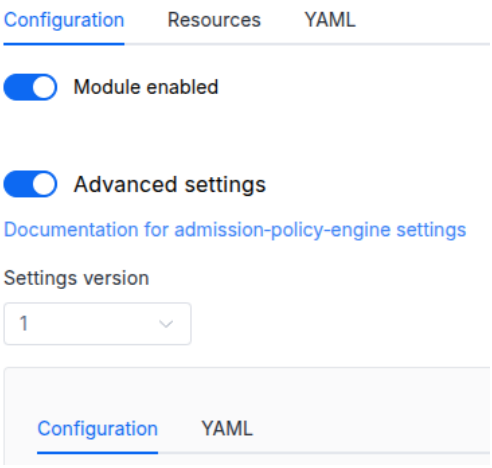
```
d8 system module enable monitoring-ping
```

- **Using ModuleConfig `monitoring-ping`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `monitoring-ping` (create it if necessary);

  Example of a manifest to enable module `monitoring-ping`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-ping
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `monitoring-ping` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `monitoring-ping` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `monitoring-ping`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `monitoring-ping` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc monitoring-ping
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `monitoring-ping` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `monitoring-ping`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: monitoring-ping
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `monitoring-kubernetes`: any version.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.externalTargets**
    array of objects

    A list of additional hosts to monitor.

    Example:

    ```
    - name: google-primary
      host: 8.8.8.8
    - name: yaru
      host: ya.ru
    - host: youtube.com
    ```

    - **settings.externalTargets.host**
      string

      Required value

      IP address or host name to monitor.

    - **settings.externalTargets.name**
      string

      Monitoring record name.

The monitoring-ping module: usage

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

Adding extra IP addresses to monitor

To monitor additional IP addresses, use the externalTargets parameters:

Module configuration example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: monitoring-ping

Module multitenancy-manager

> ⚠ The module lifecycle stage: Preview

Description

The module enables the creation of projects in a Kubernetes cluster. **Project** is an isolated environment where applications can be deployed.

Why is this needed?

The standard `Namespace` resource, used for logical resource separation in Kubernetes, does not provide necessary functionalities, hence it is not an isolated environment:

- Resource consumption by pods is not limited by default;
- Network communication with other pods works by default from any point in the cluster;
- Unrestricted access to node resources: address space, network space, mounted host directories.

The configuration capabilities of `Namespace` do not fully meet modern development requirements. By default, the following features are not included for `Namespace`:

- Log collection;
- Audit;
- Vulnerability scanning.

The functionality of projects allows addressing these issues.

⚠ The `secret-copier` module cannot be used together with `multitenancy-manager` module.

Advantages of the module

For platform administrators:

- **Consistency**: Administrators can create projects using the same template, ensuring consistency and simplifying management.
- **Security**: Projects provide isolation of resources and access policies between different projects, supporting a secure multitenant environment.
- **Resource Consumption**: Administrators can easily set quotas on resources and limitations for each project, preventing excessive resource usage.

For platform users:

- **Quick Start**: Developers can request projects created from ready-made templates from administrators, allowing for a quick start to developing a new application.
- **Isolation**: Each project provides an isolated environment where developers can deploy and test their applications without impacting other projects.

Limitations

The module works only within the limits below:

- Creating more than one namespace within a project is not supported. If you need multiple namespaces, create a separate project for each of them.
- Template resources are applied only to a single namespace whose name matches the project name.

Internal Logic

Creating a project

To create projects, the following Custom Resources are used:

- ProjectTemplate — a resource that describes the project template. It defines a list of resources to be created in the project and a schema for parameters that can be passed when creating the project;
- Project — a resource that describes a specific project.

When creating a Project resource from a specific ProjectTemplate, the following happens:

1. The parameters passed are validated against the OpenAPI specification (the `parametersSchema.openAPIV3Schema` field of ProjectTemplate);
2. Rendering of the resources template is performed using Helm. Values for rendering are taken from the `parameters` field of the Project resource;
3. A `Namespace` is created with a name matching the name of Project;
4. All resources described in the template are created in sequence.

ℹ **Attention!** When changing the project template, all created projects will be updated according to the new template.

Isolating a project

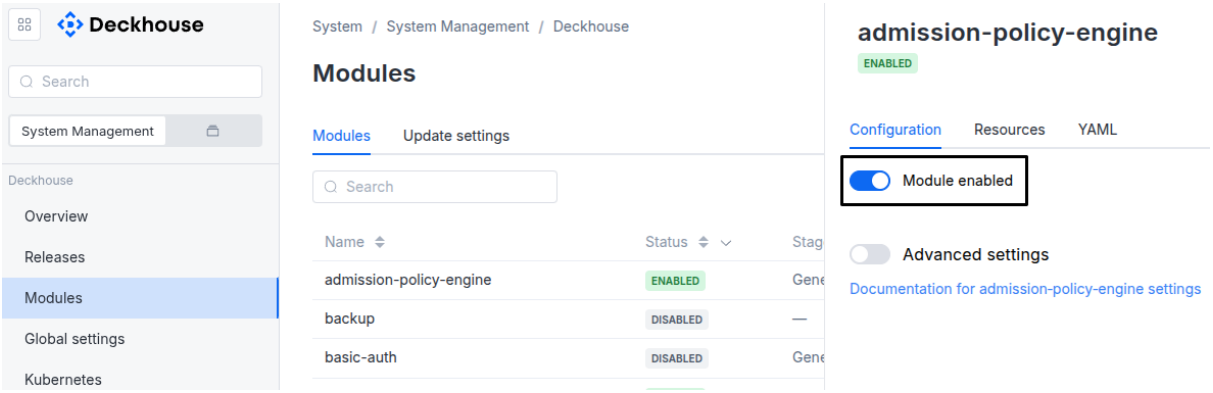
The project is based on the `Namespace` resource mechanism. Namespaces group pods, services, secrets, and other objects but do not provide complete isolation. The project functionality enhances namespaces by offering additional tools to improve control and security levels. To manage project isolation, Kubernetes features can be leveraged, such as:

- Access control resources (`AuthorizationRule` / `RoleBinding`) — manage interaction with objects within a `Namespace`. Define rules and assign roles to precisely control who can perform actions in your project.
- Resource quotas (`ResourceQuota`) — set limits on resource usage, such as CPU time, RAM, and object counts within a `Namespace`. These quotas help prevent excessive load and maintain control over applications within the project.
- Network connectivity control resources (`NetworkPolicy`) — control incoming and outgoing network traffic within a `Namespace`. Configure allowed connections between pods to enhance security and manage network interactions effectively.

These tools can be combined to configure the project according to the requirements of your application.

The multitenancy-manager module: configuration

⚠ The module lifecycle stage: Preview



The module does not have any mandatory parameters.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `multitenancy-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

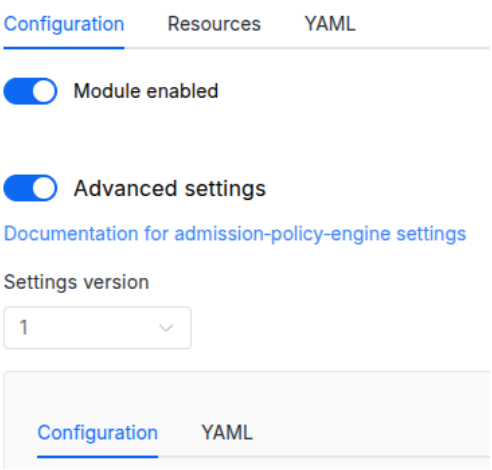
```
d8 system module enable multitenancy-manager
```

- **Using ModuleConfig `multitenancy-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `multitenancy-manager` (create it if necessary);

  Example of a manifest to enable module `multitenancy-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: multitenancy-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `multitenancy-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `multitenancy-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `multitenancy-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `multitenancy-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc multitenancy-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `multitenancy-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `multitenancy-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: multitenancy-manager
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.allowNamespacesWithoutProjects**
    boolean

    If this option is disabled - prohibit to create a namespace which is not a part of a Project.

    Default: `true`
  - **settings.highAvailability**
    boolean

    Manually enable the high availability mode.

    By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

    Example:

    ```
    highAvailability: true
    ```

The multitenancy-manager module: Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> ⚠ The module lifecycle stage: Preview

Project

Scope: Cluster

- v1alpha2
- v1alpha1

- **spec**
  object
  - **spec.description**
    string

    Arbitrary description of the project’s purpose. Specify an empty string if no description is required.
  - **spec.parameters**
    object

    Parameters passed to the resources template when creating the project.

Before creation, the values are validated against the schema of the template’s input parameters.

- **spec.projectTemplateName**
  string

  The name of the ProjectTemplate resource that defines which resources will be created in the project.

- **status**
  object
  - **status.conditions**
    array of objects
    - **status.conditions.lastProbeTime**
      string
    - **status.conditions.lastTransitionTime**
      string
    - **status.conditions.message**
      string
    - **status.conditions.status**
      string
    - **status.conditions.type**
      string
  - **status.namespaces**
    array of strings

    Used namespaces.

  - **status.observedGeneration**
    integer

    The last observed project`s generation

  - **status.resources**
    object

    Rendered and skipped resources.

  - **status.state**
    string

    Brief description of the project status, such as Error, Deploying, Deployed, etc.

  - **status.templateGeneration**
    integer

    The last observed template`s generation

Deprecated resource. Support for the resource might be removed in a later release.

- **spec**
  object
  - **spec.description**
    string

    Arbitrary description of the project’s purpose. Specify an empty string if no description is required.

  - **spec.projectTypeName**
    string

    The name of the ProjectType resource that defines which resources will be created in the project.

  - **spec.template**
    object

    Values passed to the resources template when creating the project. Before creation, the values are validated against the schema of the template’s input parameters.

- **status**
  object
  - **status.message**
    string

    Message indicating the cause of the current status.

  - **status.state**
    string

    Brief description of the project status, such as Ready, Error, Pending, etc.

  - **status.sync**
    boolean

    Indicates that the project parameters have been successfully applied after creation or modification.

ProjectTemplate

Scope: Cluster
Version: v1alpha1

Describes the project template.

This resource is referenced by the Project custom resource.

- **spec**
  object
  - **spec.description**
    string

    Arbitrary description of the template's purpose. Specify an empty string if no description is required.

  - **spec.parametersSchema**
    object

    Required value

    One of parameters schema to validate parameters of a project.

    For now only OpenAPI v3 schema is supported.

    - **spec.parametersSchema.openAPIV3Schema**
      object

      Required value

      OpenAPI specification for parameters.

      This is used to check the validity of the parameters that are passed when creating a new project.

  - **spec.resourcesTemplate**
    string

    Required value

    A template that defines resources in the `go template` format to be created when setting up a new project.

    Templates are fully compatible with all `helm` functions.

    Read more about creating an isolated Environment...

    The following parameters are available in templates:

    - `{{ .projectName }}` — the name of the `Project` for which the template is being rendered.
    - `{{ .projectTemplateName }}` — the name of the `ProjectTemplate`.
    - `{{ .parameters }}` — a dictionary of custom values, described in the .spec.parametersSchema and defined in the .spec.parameters.

    > **Note!** Specifying `.metadata.namespace` fields for objects is optional, as this field is automatically set with the name of the created project.

- **status**
  object
  - **status.message**
    string

    Message indicating the cause of the current status.

  - **status.ready**
    boolean

    Whether the template is ready to use. Indicates that the template has been successfully validated.

The multitenancy-manager module: usage examples

> ⚠ The module lifecycle stage: Preview

Default project templates

The following project templates are included in the Deckhouse Kubernetes Platform:

- `default` — a template that covers basic project use cases:
  - resource limitation
  - network isolation
  - automatic alerts and log collection
  - choice of security profile
  - project administrators setup

  Template description on GitHub.

- `secure` — includes all the capabilities of the `default` template and additional features:
  - setting up permissible UID/GID for the project
  - audit rules for project users' access to the Linux kernel
  - scanning of launched container images for CVE presence

  Template description on GitHub.

- `secure-with-dedicated-nodes` — includes all the capabilities of the `secure` template and additional features:
  - defining the node selector for all the pods in the project: if a pod is created, the node selector pod will be **substituted** with the project's node selector automatically.
  - defining the default toleration for all the pods in the project: if a pod is created, the default toleration will be **added** to the pod automatically.

Template description on GitHub.

To list all available parameters for a project template, execute the command:

```
d8 k get projecttemplates <PROJECT_TEMPLATE_NAME> -o jsonpath='{.spec.parametersSchema.openAPIV3Schema}' | jq
```

Creating a project

1. To create a project, create the Project resource by specifying the name of the project template in .spec.projectTemplateName field.
2. In the .spec.parameters field of the Project resource, specify the parameter values suitable for the ProjectTemplate .spec.parametersSchema.openAPIV3Schema.

   Example of creating a project using the Project resource from the `default` ProjectTemplate:

   ```
   apiVersion: deckhouse.io/v1alpha2
   kind: Project
   metadata:
     name: my-project
   spec:
     description: This is an example from the Deckhouse documentation.
     projectTemplateName: default
     parameters:
       resourceQuota:
         requests:
           cpu: 5
           memory: 5Gi
           storage: 1Gi
         limits:
           cpu: 5
           memory: 5Gi
       networkPolicy: Isolated
       podSecurityProfile: Restricted
       extendedMonitoringEnabled: true
       administrators:
       - subject: Group
         name: k8s-admins
   ```

3. To check the status of the project, execute the command:

   ```
   d8 k get projects my-project
   ```

   A successfully created project should be in the `Deployed` state. If the state equals `Error`, add the `-o yaml` argument to the command (e.g., `d8 k get projects my-project -o yaml`) to get more detailed information about the error.

Creating a project automatically for a namespace

You can create a new project for a namespace. To do this, add the `projects.deckhouse.io/adopt` annotation to the namespace. For example:

1. Create a new namespace:

   ```
   d8 k create ns test
   ```

2. Add the annotation:

   ```
   d8 k annotate ns test projects.deckhouse.io/adopt=""
   ```

3. Make sure that the project was created:

   ```
   d8 k get projects
   ```

   A new project corresponding to the namespace will appear in the project list:

   ```
   NAME        STATE      PROJECT TEMPLATE   DESCRIPTION                                          AGE
   deckhouse   Deployed   virtual            This is a virtual project                            181d
   default     Deployed   virtual            This is a virtual project                            181d
   test          Deployed   empty                                                                   1m
   ```

You can change the template of the created project to the existing one.

⚠ Note that changing the template may cause a resource conflict. If the template chart contains resources that are already present in the namespace, you will not be able to apply the template.

Creating your own project template

Default templates cover basic project use cases and serve as a good example of template capabilities.

To create your own template:

1. Take one of the default templates as a basis, for example, `default`.
2. Copy it to a separate file, for example, `my-project-template.yaml` using the command:

   ```
   d8 k get projecttemplates default -o yaml > my-project-template.yaml
   ```

3. Edit the `my-project-template.yaml` file, make the necessary changes.

   {% alert level=”info” %} You must update not only the template itself, but also the input parameters schema to match it.

   Project templates support all Helm templating functions. {% endalert %}

4. Change the template name in the `.metadata.name` field.
5. Apply your new template with the command:

   ```
   d8 k apply -f my-project-template.yaml
   ```

6. Check the availability of the new template with the command:

   ```
   d8 k get projecttemplates <NEW_TEMPLATE_NAME>
   ```

Using labels to manage resources

When creating resources in `ProjectTemplate`, you can use special labels to control how the `multitenancy-manager` processes these resources.

Skipping creation of the `heritage: multitenancy-manager` label

By default, all resources created from `ProjectTemplate` receive the label `heritage: multitenancy-manager`.
This label prohibits changes to resources by users or any other controller except `multitenancy-manager`.
If you need to allow resource modification (for example, for compatibility with other systems, or if implementing your own control over the created objects), add the label `projects.deckhouse.io/skip-heritage-label` to the resource.

Example:

```
---
apiVersion: v1
kind: ConfigMap
metadata:
  name: my-config
  namespace: {{ .projectName }}
  labels:
    projects.deckhouse.io/skip-heritage-label: "true"
    app: my-app
data:
  key: value
```

In this case, the resource will receive the labels `projects.deckhouse.io/project` and `projects.deckhouse.io/project-template`, but will not receive the label `heritage: multitenancy-manager`.

Excluding resources from management by multitenancy-manager

If you need to exclude a resource from management by `multitenancy-manager` (for example, if the resource should be managed manually or by another controller), add the label `projects.deckhouse.io/unmanaged` to the resource.

Example:

```
---
apiVersion: v1
kind: Secret
metadata:
  name: external-secret
  namespace: {{ .projectName }}
  labels:
    projects.deckhouse.io/unmanaged: "true"
type: Opaque
data:
  token: <base64-encoded-value>
```

Resources with the label `projects.deckhouse.io/unmanaged`:

- Will be created **only once** when the project is created;
- **Will not be updated** with subsequent template changes or updates;
- Will not be monitored in the project's status;
- Will receive the labels `projects.deckhouse.io/project` and `projects.deckhouse.io/project-template` but **will not receive** the label `heritage: multitenancy-manager`.

⚠ Once a resource is marked as `unmanaged`, it will be created on initial installation but not updated when the `ProjectTemplate` is changed.
After creation, the resource becomes fully independent and must be managed manually.

Implementing validation of object changes with a custom label

The `multitenancy-manager` module uses `ValidatingAdmissionPolicy` to protect resources labeled `heritage: multitenancy-manager` from manual changes.
You can implement similar validation for resources with any label.

How validation works in multitenancy-manager

Validation occurs for objects labeled `heritage: multitenancy-manager`.
The following components are used for this:

1. `ValidatingAdmissionPolicy`: Defines validation rules:
   - Operations: `UPDATE` and `DELETE`.
   - Check: only operations on behalf of the controller's service account are allowed.
   - Applies to all resources and API groups.
2. `ValidatingAdmissionPolicyBinding`: Defines which objects the validation applies to:
   - Uses `namespaceSelector` and `objectSelector` to select resources by the label `heritage: multitenancy-manager`.

Creating your own validation

To implement validation for resources with a different label (for example, `heritage: my-custom-label`):

1. Create a file with the ValidatingAdmissionPolicy and ValidatingAdmissionPolicyBinding resource manifests:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
  name: my-custom-label-validation
spec:
  failurePolicy: Fail
  matchConstraints:
    resourceRules:
      - apiGroups:   ["*"]
        apiVersions: ["*"]
        operations:  ["UPDATE", "DELETE"]
        resources:   ["*"]
        scope: "*"
  validations:
    - expression: 'request.userInfo.username == "system:serviceaccount:my-namespace:my-service-
account"' # Replace with your service account
      reason: Forbidden
      messageExpression: 'object.kind == ''Namespace'' ? ''This resource is managed by '' +
object.metadata.name + '' system. Manual modification is forbidden.''
        : ''This resource is managed by '' + object.metadata.namespace + '' system. Manual
modification is forbidden.'''
---
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicyBinding
metadata:
  name: my-custom-label-validation
spec:
  policyName: my-custom-label-validation
  validationActions: [Deny, Audit]
  matchResources:
    namespaceSelector:
      matchLabels:
        heritage: my-custom-label
    objectSelector:
      matchLabels:
        heritage: my-custom-label
```

2. Configure the validation parameters:
   - `policyName`: Unique policy name (must match in Policy and Binding).
   - `request.userInfo.username`: The name of the service account allowed to change resources (replace with your

service account).
  - `heritage: my-custom-label`: The value of the `heritage` label for your resources (replace with your value). The use of the values `multitenancy-manager`, `deckhouse` is prohibited.
  - `failurePolicy: Fail`: Policy on validation failure.
    - `Fail`: Reject the request on validation failure.
    - `Ignore`: Ignore validation errors.
  - `validationActions`: Validation actions:
    - `Deny`: Deny unauthorized operations.
    - `Audit`: Record operations in the audit log.

3. Apply the policy:

```
d8 k apply -f my-validation-policy.yaml
```

4. Ensure your resources have the corresponding `heritage` label:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: my-resource
  labels:
    heritage: my-custom-label
```

The namespace-configurator module

> **i** The module lifecycle stage: General Availability

The `namespace-configurator` module allows to assign annotations and labels to namespaces automatically.

It facilitates to enable new namespaces to monitoring system by adding `extended-monitoring.deckhouse.io/enabled=true` label.

How does it work?

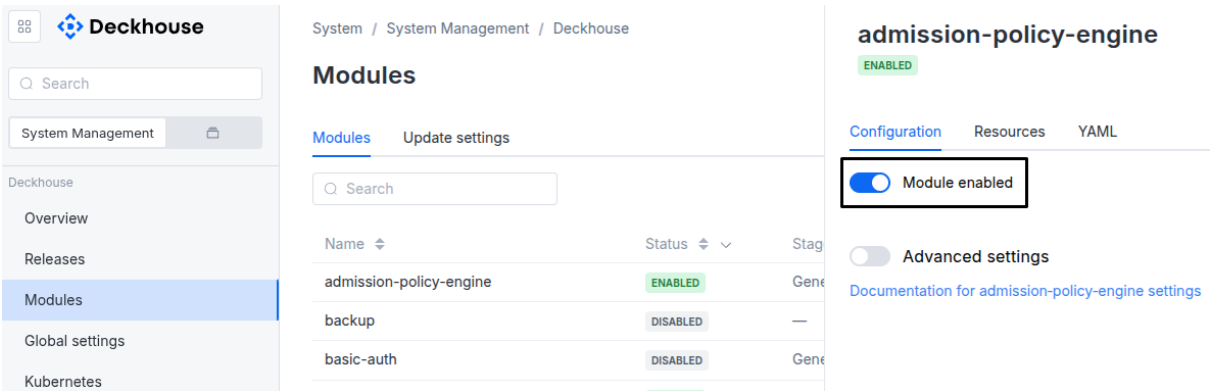
This module monitors the namespaces and configuration:

- It assigns labels and annotations from the configuration to all namespaces that match the `includeNames` pattern and do not match the `excludeNames` pattern.
- Namespaces labeled `heritage` with one of the values `upmeter`, `deckhouse` or `multitenancy-manager` are ignored;
- When changing the module configuration, namespace labels and annotations will be reassigned according to the configuration.

What do I need to configure?

All you need to do is to specify list of desired labels and annotations and matching patterns for namespaces in the module configuration.

Configuration



> **i** The module lifecycle stage: General Availability

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `namespace-configurator` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

Example of enabling the module:

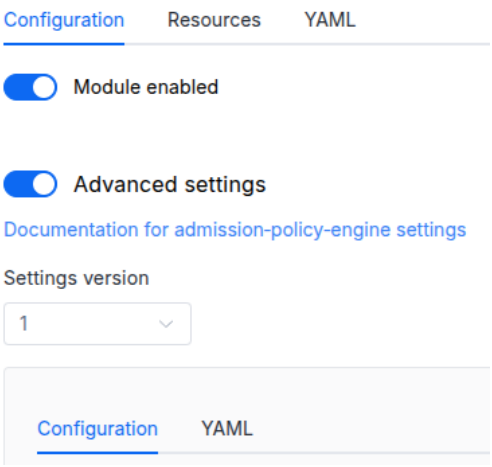
```
d8 system module enable namespace-configurator
```

- **Using ModuleConfig `namespace-configurator`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `namespace-configurator` (create it if necessary);

  Example of a manifest to enable module `namespace-configurator`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: namespace-configurator
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `namespace-configurator` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `namespace-configurator` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `namespace-configurator`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `namespace-configurator` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc namespace-configurator
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `namespace-configurator` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

  Example of a manifest for ModuleConfig `namespace-configurator`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: namespace-configurator
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.configurations**
    array of objects
    - **settings.configurations.annotations**
      object

      A list of annotations in the `key: "value"` format.

      Example:

      ```
      annotations:
        example: 'true'
      ```

    - **settings.configurations.excludeNames**
      array of strings

      A list of namespace patterns to exclude.

      Default: `[]`

      Example:

      ```
      excludeNames:
      - infra-test
      ```

    - **settings.configurations.includeNames**
      array of strings

      Required value

      A list of namespace patterns to include.

      Default: `[]`

      Example:

      ```
      includeNames:
      - prod-.*
      - infra-.*
      ```

    - **settings.configurations.labels**
      object

      A list of labels in the `key: "value"` format.

      Example:

      ```
      labels:
        istio-injection: 'true'
      ```

Examples

> **i** The module lifecycle stage: General Availability

Example

Add the label `extended-monitoring.deckhouse.io/enabled=true` and the annotation `foo=bar` to every namespace starting with `prod-` and `infra-`, except `infra-test`.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: namespace-configurator
spec:
  version: 1
  enabled: true
  settings:
    configurations:
    - annotations:
        foo: bar
      labels:
        extended-monitoring.deckhouse.io/enabled: "true"
      includeNames:
      - "^prod"
      - "^infra"
      excludeNames:

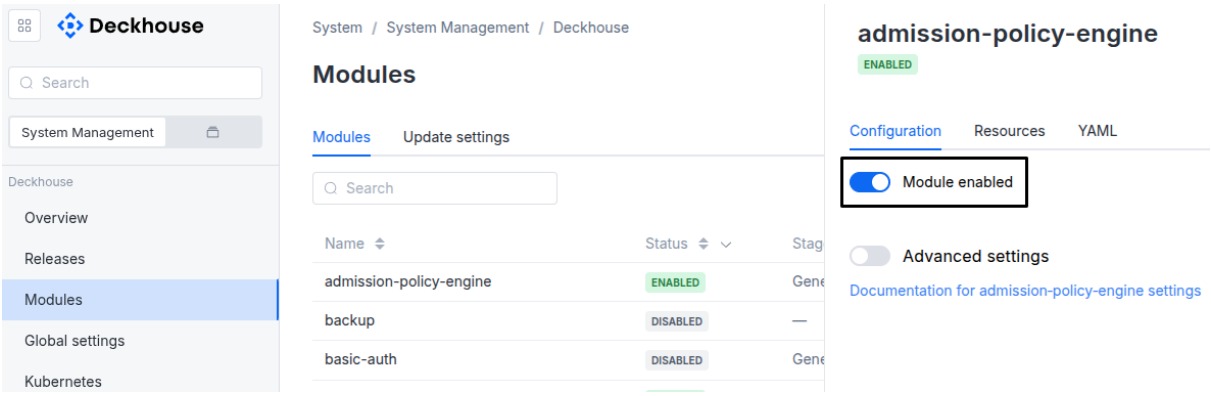
The network-gateway module

> **i** The module lifecycle stage: General Availability

This module creates a network gateway using Kubernetes nodes. It contains a DHCP server and a SNAT manager.

Configuration



> **i** The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-gateway` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

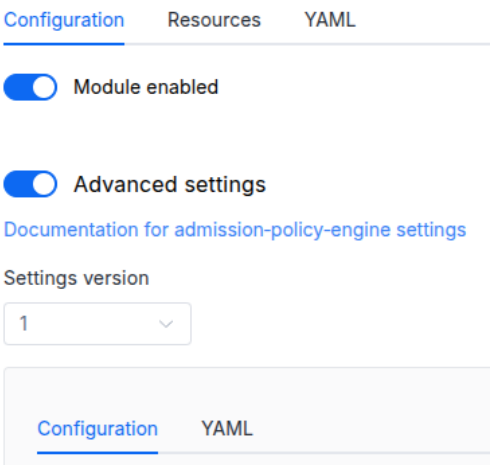
  ```
  d8 system module enable network-gateway
  ```

- **Using ModuleConfig `network-gateway`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `network-gateway` (create it if necessary);

  Example of a manifest to enable module `network-gateway`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: network-gateway
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-gateway` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `network-gateway` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `network-gateway`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `network-gateway` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc network-gateway
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `network-gateway` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `network-gateway`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: network-gateway
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.disableDHCP**
    boolean

    Disables the DHCP server.

    Default: `false`
  - **settings.dns**
    object

    Settings to pass to clients via DHCP.

    - **settings.dns.search**

array of strings

List of search domains.

Example:

```
search:
- office.example.com
- srv.example.com
```

- **settings.dns.servers**
  array of strings

  List of DNS servers.

  Example:

  ```
  servers:
  - 4.2.2.2
  - 8.8.8.8
  ```

- **settings.nodeSelector**
  object

  Required value

  Selects nodes that will be used to configure iptables rules and to run the DHCP server.

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes. Instance Pods inherit this field as is.

  Example:

  ```
  nodeSelector:
    type: network-gateway
  ```

- **settings.publicAddress**
  string

  Required value

  Replaces the src of the packets outgoing from the LAN.

  Pattern: `^([0-9]{1,3}\.){3}[0-9]{1,3}$`

  Example:

  ```
  publicAddress: 10.220.203.240
  ```

- **settings.storageClass**
  string

  The name of the StorageClass to use for storing the DHCP lease.

  If omitted, the StorageClass of the existing PVC is used. If there is no PVC yet, the StorageClass will be used according to the global storageClass parameter setting.

  The global `storageClass` parameter is only considered when the module is enabled. Changing the global `storageClass` parameter while the module is enabled will not trigger disk re-provisioning.

  *Warning.** Specifying a value different from the one currently used (in the existing PVC) will result in disk re-provisioning and all data will be deleted.

  If `false` is specified, emptyDir will be forced to be used.

  Dnsmasq (underlies our DHCP server) has its own mechanisms for protecting against the duplication of IP addresses if the lease database is lost (but it is better not to lose it).

- **settings.subnet**
  string

  Required value

  The address of a local subnet that gateway serves.

  The DHCP options to pass to clients are generated based on this address:

  - Address pool — numbers starting with 50 and up to the last one.
  - Router — the subnet's first address.

  Pattern: `^([0-9]{1,3}\.){3}[0-9]{1,3}(\/([0-9]|[1-2][0-9]|3[0-2]))$`

  Example:

  ```
  subnet: 192.168.42.0/24
  ```

- **settings.tolerations**
  array of objects

Tolerations for DHCP Pods and iptables managers.

The same as in the Pods' `spec.tolerations` parameter in Kubernetes. The instance's Pods inherit this field as is.

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

The network-policy-engine module

> **i** The module lifecycle stage: General Availability

> ⚠ Do not use the module if the cilium module is enabled because it already has network policy management.

This module manages network policies.

Deckhouse implements a conservative approach to organizing the network based on elementary network backends, such as *"pure"* CNI or flannel in the `host-gw` mode. This approach is simple and reliable, and has proven itself to be the best.

The `NetworkPolicy` implementation in Deckhouse is also simple and reliable. It is based on `kube-router` in the *Network Policy Controller* mode (`--run-firewall`). In this case, `kube-router` transforms `NetworkPolicy` network policies into `iptables` rules that work in any installations (regardless of the cloud or the CNI used).

The `network-policy-engine` module deploys a `d8-system` DaemonSet in the namespace with kube-router in the Network Policy Controller mode. As a result, the Kubernetes cluster fully supports Network Policies.

The following policy description formats are supported:

- *networking.k8s.io/NetworkPolicy API*
- *network policy V1/GA semantics*
- *network policy beta semantics*

Example recipes are available here.

Third-party components

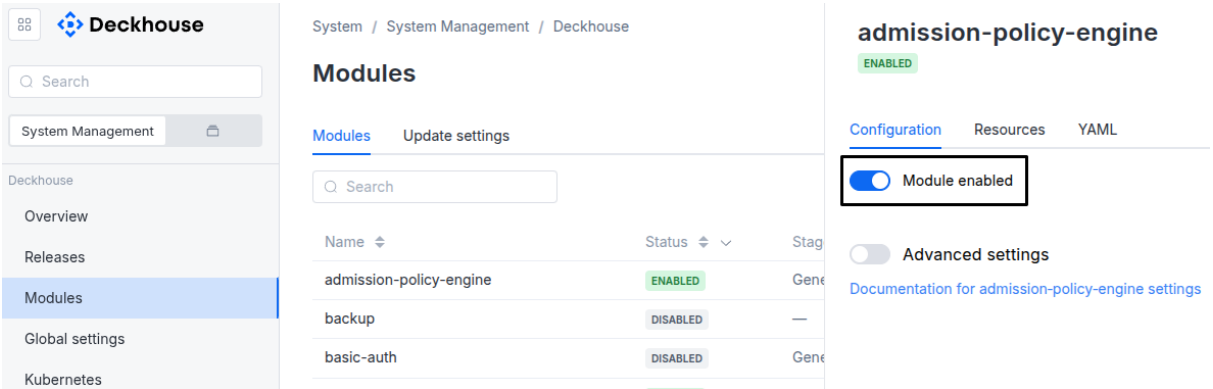
List of third-party software used in the `network-policy-engine` module:

- Kube-router 2.0.1

  License: Apache License 2.0

  A turnkey solution for Kubernetes networking with aim to provide operational simplicity and high performance.

Configuration



> **i** The module lifecycle stage: General Availability

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `network-policy-engine` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

Example of enabling the module:

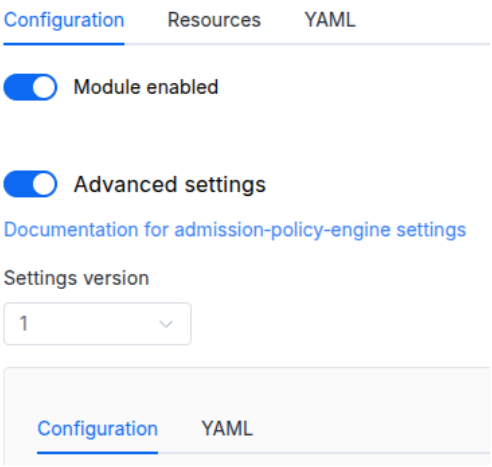
```
d8 system module enable network-policy-engine
```

- **Using ModuleConfig `network-policy-engine`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `network-policy-engine` (create it if necessary);

  Example of a manifest to enable module `network-policy-engine`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: network-policy-engine
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `network-policy-engine` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `network-policy-engine` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `network-policy-engine`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `network-policy-engine` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc network-policy-engine
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `network-policy-engine` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

  Example of a manifest for ModuleConfig `network-policy-engine`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: network-policy-engine
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Examples

> **i** The module lifecycle stage: General Availability

Examples of network policies

Deny external traffic to Pods in the namespace, but allow traffic to external resources from within the namespace

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: delete
spec:
  podSelector: {}
  egress:
  - {}
  ingress:
  - from:
    - podSelector: {}
  policyTypes:
  - Ingress
  - Egress
```

More examples are available in this repository.

The node-local-dns module

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

Module Description

This module deploys a caching DNS server on each cluster node and exports data to `Prometheus` for easy analysis of the cluster's DNS performance using the Grafana board.

The module runs the standard `CoreDNS` server (as part of a DaemonSet) on all nodes supplemented by the algorithm for configuring network and iptables rules.

Purpose

The regular DNS usage in Kubernetes poses some problems that may lead to unnecessary degradation of the service's performance:

- No request caching (in Linux, there is no caching right out-of-the-box; thus, Pods also lack it out-of-the-box).
- All the container-originated DNS requests result in a network request to the cluster DNS. Thus, even requests to resources within the same node result in network requests.
- The Pod request is first resolved in the cluster DNS zones and only then channeled to external DNS servers. For example, the request to `ya.ru` is first resolved in cluster zones such as `cluster.local`, `svc.cluster.local`, `<namespace>.svc.cluster.local`, receives negative responses, and gets appropriately resolved only on the "second" attempt.

Thus, even slight network delays may result in significant service performance degradation due to above problems.

One solution is to deploy a DNS server on each node (which is what this module does).

Outside requests (non-cached ones) are also first resolved in internal zones. Under high load (when a large number of requests are made to the same records simultaneously, as is often the case), such behavior can significantly improve the performance of DNS resolving.

Grafana dashboard

The `Kubernetes / DNS (node local)` dashboard displays:

- General graphs that allow you to evaluate the overall DNS performance.

- Graphs grouped by the node that let you analyze node data in more details if the general charts suggest that this node is unhealthy.
- Upstream-related graphs that allow you to evaluate the performance of the cluster DNS as well as the node servers specified in `/etc/resolv.conf`.

How does it work?

The module performs the following settings on each node:

- Configures an interface with the ClusterIP IP address of the `kube-dns` service.
- Starts a caching CoreDNS server that listens on this address.
- Adds a sophisticated iptables rule that uses a socket if it is open and ordinary Kubernetes magic for clusterIP if it is not.

And here is the rule itself that allows for an easy fallback:

```
-A PREROUTING -d <kube-dns IP address> -m socket --nowildcard -j NOTRACK
```

Aspects of CoreDNS configuration

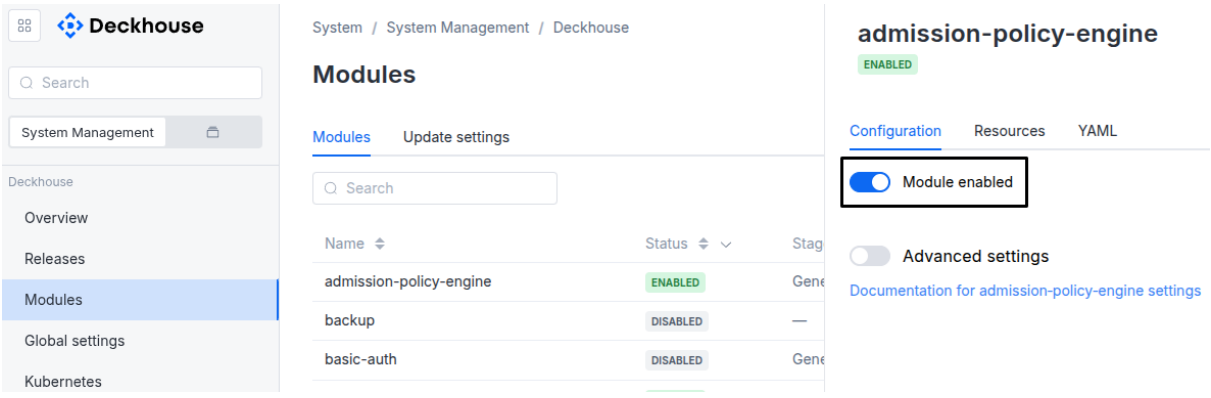
Main features of the CoreDNS config:

- caching of all requests;
- forwarding all DNS requests to ClusterIP of the cluster DNS.

Configuration

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

> **⚠**
> - The module works with all `CNIs`, but in order to work correctly with `cni-cilium`, a number of conditions must be met.
> - By default, when used together with the `cni-simple-bridge` or `cni-flannel` modules, the `node-local-dns` module **does not work** for requests from `hostNetwork`. In this case, all requests go to the `kube-dns` module. You can specify the address `169.254.20.10` in the pod configuration, but if `node-local-dns` module crashes, there will be no *fallback* to the `kube-dns` module.



The module has 5 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-local-dns` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

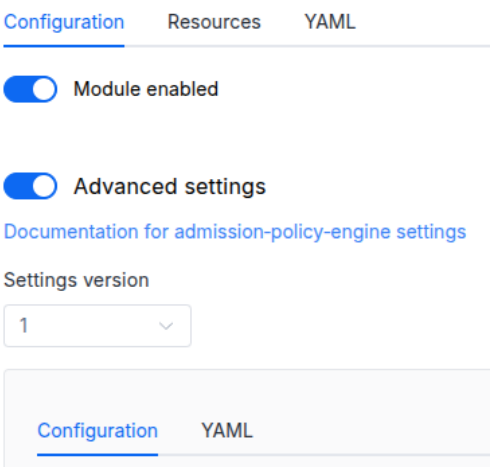
  ```
  d8 system module enable node-local-dns
  ```

- **Using ModuleConfig `node-local-dns`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `node-local-dns` (create it if necessary);

  Example of a manifest to enable module `node-local-dns`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: node-local-dns
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-local-dns` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `node-local-dns` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `node-local-dns`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `node-local-dns` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc node-local-dns
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `node-local-dns` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `node-local-dns`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: node-local-dns
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `kube-dns`: any version.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.disableIPv6**
    boolean

    Disables DNS resolution over IPv6 by returning empty responses for `AAAA` queries and `NXDOMAIN` for reverse IPv6 lookup requests in the `ip6.arpa` zone.

    Default: `false`
  - **settings.enableLogs**
    boolean

    Enables query logging for node-local-dns instances.

    Default: `false`
  - **settings.highAvailability**
    boolean

    Manual failover mode management. Within this module, the option affects the DNS records caching mechanism on nodes:

    - `true`: upon the expiration of the TTL for an individual DNS record, node-local-dns will continue to return the “stale” value immediately while simultaneously requesting a fresh value from the upstream kube-dns. Thus, in the event of issues with the nodes where kube-dns is running, applications will continue to receive responses to DNS queries with expired TTL, but without delay.
    - `false`: upon the expiration of the TTL for an individual DNS record, node-local-dns will continue to return the “stale” value, but only after querying the upstream kube-dns. Thus, in the event of issues with the nodes where kube-dns is running, applications will continue to receive DNS responses with expired TTL, but with potentially significant delay. This approach is suitable in highly dynamic environments where Services and Namespaces are frequently recreated.

    By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

    Example:

    ```
    highAvailability: true
    ```

Examples

> **i**
> The module lifecycle stage: General Availability
> The module has requirements for installation

An example of configuring a custom DNS for a Pod

```
apiVersion: v1
kind: Pod
metadata:
  name: dns-example
spec:
  dnsPolicy: "None"
  dnsConfig:
    nameservers:
      - 169.254.20.10
  containers:
    - name: test
      image: nginx
```

Here you can learn more about DNS configuring.

Configuration example

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: node-local-dns
spec:
  version: 1
  enabled: true
  settings:
    enableLogs: true
```

Managing nodes

> **i** The module lifecycle stage: General Availability

Primary functions

The `node-manager` module is responsible for managing nodes and has the following primary functions:

1. Managing multiple nodes as a related group (**NodeGroup**):
   - The ability to define metadata that are inherited by all nodes in the group.
   - Monitoring of a group as a single entity (grouping nodes on graphs by groups, grouping alerts about node unavailability, alerts about the unavailability of N or N% of nodes in a group).
2. **Chaos monkey** — the systemic termination of nodes. This feature tests the resilience of cluster elements and running applications.
3. Delaying the reboot or shutdown of a node while critical pods are running on it.
4. Installing, updating, and configuring the node software (containerd, kubelet, etc.), connecting the node to the cluster:
   - Installing operating system (see the list of supported OS) regardless of the infrastructure used (any cloud/any hardware).
   - The operating system's basic setup (disabling auto-update, installing the necessary packages, configuring logging parameters, etc.).
   - Configuring kubernetes-api-proxy (and the system for automatically updating the list of upstreams) to balance node (kubelet) requests over API servers.
   - Installing and configuring CRI containerd and Kubernetes, adding the node to the cluster.
   - Managing node updates and their downtime (disruptions):
     - Automatic determination of a valid minor Kubernetes version for a node group based on its settings (the kubernetesVersion parameter specified for a group), the default version for the whole cluster, and the current control-plane version (no nodes can be updated ahead of the control-plane update).
     - Only one node of a group can be updated at a time, and only if all the nodes in the group are available.
     - There are two types of node updates:
       - regular updates – always performed automatically;
       - disruption-involving updates (such as updating the kernel, switching docker versions, major change of the kubelet versions, etc.) – you can choose manual or automatic mode. If automatic disruptive updates are enabled, the node is drained before the update (this functionality can be disabled).
   - Monitoring the status and progress of the update.
5. Cluster scaling.

   - Autoscaling.

     Available with supported cloud providers (learn more); not available for static nodes. Cloud providers support automatic creation or deletion of virtual machines, joining them to or disjoining them from the cluster.

   - Maintaining the desired number of nodes in a group.

     Available for both cloud providers and static nodes (when using Cluster API Provider Static).

6. Managing Linux users on nodes.
7. Managing GPU resources on nodes:
   - Automatic detection and enablement of NVIDIA GPU.
   - Configurable GPU sharing modes per NodeGroup: Exclusive, TimeSlicing, MIG.
   - Monitoring integration — ready-made Grafana dashboards are available to visualize key GPU metrics.

Nodes are managed through the NodeGroup resource, and each node group performs specific tasks. Below are examples of node groups pooled by their tasks performed:

- a group of master nodes;
- a group of nodes for routing HTTP(s) traffic (front nodes);
- a group of monitoring-related nodes;
- a group of application nodes (the so-called worker nodes), etc.

The nodes belonging to the group have common parameters and are configured automatically according to the group's parameters. Deckhouse scales groups by adding, excluding, and updating their nodes. Both Static nodes deployed in the cloud and static (bare-metal or virtual machine) nodes can be combined into a single group. It paves the way for the hybrid clusters, in which you can scale nodes on physical servers via cloud nodes.

Operations on the cloud infrastructure are performed by means provided by supported cloud providers. If there is no support for the desired cloud platform, you can use its resources as static nodes.

The static nodes (e.g., bare metal servers) are handled by the Cluster API Provider Static (CAPS).

The following Managed Kubernetes services are supported (note that some service functionality may be unavailable):

- Google Kubernetes Engine (GKE);
- Elastic Kubernetes Service (EKS).

Node types

The following node types that can be worked with within a node group (resource NodeGroup) are supported:

- `CloudEphemeral` — the nodes are automatically ordered, created, and deleted in the configured cloud provider.
- `CloudPermanent` — the nodes differ in that their configuration is not taken from the custom resource nodeGroup, but from a special resource `<PROVIDER>ClusterConfiguration` (for example, AWSClusterConfiguration for AWS). Also, an important difference is that to apply node configuration, you need to run `dhctl converge` (by running Deckhouse installer). An example of a CloudPermanent node of a cloud cluster is a cluster master node.
- `CloudStatic` — a static node (created manually) hosted in the cloud integrated with one of the cloud providers. This node has the CSI running, and it is managed by the cloud-controller-manager. The `Node` object automatically gets the information about the cloud zone and region. Also, if a node gets deleted from the cloud, its corresponding Node object will be deleted in a cluster.
- `Static` — a static node hosted on a bare metal or virtual machine. In the case of a cloud environment, the `cloud-`

`controller-manager` does not manage the node even if one of the cloud providers is enabled. Learn more about working with static nodes...

Node grouping and group management

Grouping and managing nodes as a related group mean that all nodes in the group will have the same metadata derived from the `NodeGroup` custom resource.

The following monitoring patterns are available for node groups:

- with grouping of node parameters on the graphs for the group;
- with grouping of alerts about node unavailability;
- with alerts about unavailability of N nodes or N% of nodes in the group, etc.

Delaying node reboot or shutdown while critical pods are running

The `d8-shutdown-inhibitor` service in `node-manager` delays node shutdown or reboot if stateful applications or virtual machines (VMs) are running on the node. The delay is triggered if pods with the label `pod.deckhouse.io/inhibit-node-shutdown` are running on the node. DKP delays the shutdown or reboot of the node so that the user can migrate critical pods or terminate them in a controlled manner. This is useful, for example, for stateful workloads and other scenarios where data loss must be avoided.

How it works and key features

The `d8-shutdown-inhibitor` service prevents a node from shutting down as long as there are pods on it with the `Running` status that are labeled `pod.deckhouse.io/inhibit-node-shutdown`. The `GracefulShutdownPostpone` condition is used for this blocking. Additionally, the node is cordoned off during the blocking period to prevent the scheduler from scheduling new pods on it. The kubelet reads the node's `GracefulShutdownPostpone` condition and does not begin evicting pods marked with this label as long as the condition's `status` is `True` and `reason` is `PodsWithLabelAreRunningOnNode`. If there are pods on the node with the label `pod.deckhouse.io/inhibit-node-shutdown`, a corresponding message is displayed in the node console (wall).

Delaying mechanism features in DKP

The delay in restarting or shutting down a node while critical pods are running on it has the following features in DKP:

- A label must be explicitly set on each pod that is to block shutdown. If pods are created via a Deployment, the label is specified in the pod template.
- This mechanism works only with a modified kubelet version included in DKP. The regular Kubernetes does not support this behavior.
- The maximum block duration (`InhibitDelayMaxSec`) is `3` days. After this period expires, the shutdown may proceed regardless of whether there are pods on the node with the label `pod.deckhouse.io/inhibit-node-shutdown`.
- This mechanism does not cancel the scheduling of disruptive updates in `node-manager`. It only delays the actual reboot of the node at the time of shutdown.

> ⚠ To decide whether to block a node shutdown, DKP additionally queries the NodeGroup. If the current node belongs to the `master` group and it is the only master node in the cluster, the shutdown block will not be applied to it.

For information on enabling the delay mechanism, refer to the section "How to delay a node reboot while critical pods are running on it".

Automatic deploying, configuring and updating Kubernetes nodes

Automatic deployment (partially supported for *static/hybrid* nodes/clusters), configuration, and continuing software updates are supported for all cluster types (cloud or bare metal based).

Deploying Kubernetes nodes

Deckhouse automatically deploys cluster nodes by performing the following **idempotent** operations:

- Configuring the OS and optimizing it for containerd and Kubernetes:
  - Installing the needed packages from the distribution's repository.
  - Configuring kernel parameters, logging, log rotation, and other system parameters.
- Installing the appropriate versions of containerd and kubelet; adding the node to the Kubernetes cluster.
- Configuring kubernetes-api-proxy and updating the list of upstream resources for balancing node requests to the Kubernetes API.

Keeping nodes up-to-date

Two types of updates can be applied to keep cluster nodes up to date:

- **Regular**. These updates are always applied automatically and do not cause the node to stop or reboot.
- **Disruptive**. An example of such updates is a kernel or containerd version update, a major kubelet version change, etc. For this type of updates you can choose manual or automatic mode (disruptions parameter section). In automatic mode, the node is gracefully drained before the update.

Only one node of the group is updated at a time, and only if all the nodes in the group are available.

The `node-manager` module has a set of built-in metrics for monitoring the update process, alerting about issues with the update, or when a decision to proceed needs to be made by an administrator.

Working with nodes on supported cloud platforms

Each supported cloud provider can provision nodes in an automated manner. For this, you have to specify the required parameters for each node or a group of nodes.

Depending on the provider, these parameters can include:

- type of a node, the number of processor cores, the amount of RAM;
- disk size;
- security settings;
- connected networks;
- other parameters.

Creating, starting, and connecting virtual machines to the cluster are performed automatically.

Scaling nodes in the cloud

Two methods of scaling nodes in a group are supported:

- **Automatic scaling**

  If there is a resource shortage or pods in the `Pending` state are present, nodes will be added to the group. If there is no load on one or more nodes, they will be removed from the cluster. Autoscaling takes into account the group priority (the group with the highest priority will be scaled first).

  To enable automatic node scaling, specify *different* non-zero values for the minimum and maximum number of nodes in the group.

- **Fixed number of nodes**

  In this case, Deckhouse will maintain the specified number of nodes (e.g., by provisioning new nodes when nodes fail).

  To set a fixed number of nodes in a group and disable automatic scaling, specify the *same* values for minPerZone and maxPerZone.

Working with static nodes

When working with static nodes, some features of the `node-manager` module are limited:

- **No node provisioning.** Resources (bare metal servers, virtual machines, linked resources) are provisioned manually. Subsequent configuration of resources (connecting a node to the cluster, setting up monitoring, etc.) is performed either fully (similar to nodes in the cloud) or partly automatically.
- **No node autoscaling.** Maintaining the specified number of nodes in a group is supported when using Cluster API Provider Static (parameter staticInstances.count). That is, Deckhouse will attempt to maintain the specified number of nodes in the group, cleaning up unnecessary nodes and setting up new ones as needed (by picking them from StaticInstance resources that are in *Pending* state).

Configuring/clearing up a node, joining it to a cluster, and disjoining it can be done in the following ways:

- **Manually** using the pre-made scripts.

  To configure the server (VM) and join a node to the cluster, a special bootstrap script must be downloaded and run. This script is generated for each group of static nodes (each `NodeGroup` resource). It is located in the `d8-cloud-instance-manager/manual-bootstrap-for-<NAME-NODEGROUP>` secret. See an example of how to add a static node to a cluster.

  To disjoin a cluster node and clean up the server (virtual machine), you need to run the `/var/lib/bashible/cleanup_static_node.sh` script (it is present on each static node). An example of decommissioning a cluster node and cleaning up the server can be found in FAQ.

- **Automatically** using Cluster API Provider Static.

  Cluster API Provider Static (CAPS) connects to the server (VM) using StaticInstance and SSHCredentials resources, configures, and joins the node into the cluster.

  If necessary (for example, if the StaticInstance resource associated with the server is deleted or the number of group nodes is reduced), the Cluster API Provider Static connects to the cluster node, clears it, and disconnects it from the cluster.

- **Manually with subsequent transfer of the Node under automatic control** of Cluster API Provider Static.

  > **i** This feature is available starting with Deckhouse 1.63.

  To transfer an existing cluster node under CAPS management, it is necessary to prepare the StaticInstance and SSHCredentials resources for this node, as with automatic management in the point above, however the StaticInstance resource must additionally be annotated as `static.node.deckhouse.io/skip-bootstrap-phase: ""`.

Cluster API Provider Static

Cluster API Provider Static (CAPS) is an implementation of a declarative management provider for static nodes (bare metal servers or virtual machines) for the Kubernetes Cluster API. Essentially, CAPS is an additional layer of abstraction to the existing Deckhouse functionality that provides automatic static node configuration and cleanup using scripts generated for each node group (see Working with Static Nodes).

CAPS features are as follows:

- configuring a bare metal server (or virtual machine) to join a Kubernetes cluster;
- joining a node to the Kubernetes cluster;
- disjoining the node from the Kubernetes cluster;
- cleaning the bare metal server (or virtual machine) after disjoining the node from the Kubernetes cluster.

CAPS uses the following CustomResource when operating:

- **StaticInstance.** Each `StaticInstance` resource details a specific host (server, VM) that is managed using CAPS.
- **SSHCredentials**. Contains the SSH credentials required to connect to the host (`SSHCredentials` data is specified in the credentialsRef parameter of the `StaticInstance` resource).
- **NodeGroup**. The staticInstances parameter section defines the required number of nodes in the group and the filter for the `StaticInstance` resources that can be used in the group.

CAPS is enabled automatically if the NodeGroup has the staticInstances parameter section filled in. If the `staticInstances` parameter section in the `NodeGroup` is empty, then setting up and cleaning up nodes for that group is done *manually* rather than using CAPS (see adding a static node to a cluster and cleaning up a node).

The workflow for dealing with static nodes when using Cluster API Provider Static (CAPS) (see the adding a node example) is as follows:

1. **Preparing resources.**

   Before bringing a bare metal server or virtual machine under CAPS control, some preliminary steps may be necessary:

   - Preparing the storage system, adding mount points, and so on.
   - Installing the OS-specific packages.
   - Configuring the network. For example, configuring the network between the server and the cluster nodes.
   - Configuring SSH access to the server, creating a user that is a member of sudoers group. A good practice is to create a separate user and unique keys for each server.

2. **Creating a SSHCredentials resource.**

   The `SSHCredentials` resource contains the parameters required by CAPS to connect to a server via SSH. A single `SSHCredentials` resource can be used to connect to multiple servers, but it is a good practice to create unique users and access keys to connect to each server. In this case, the `SSHCredentials` resource will also be unique for each server.

3. **Creating a StaticInstance resource.**

   For every server (VM) in the cluster, an individual `StaticInstance` resource is created. It contains the IP address for connecting and a link to the `SSHCredentials` resource with the data to be used for connecting.

   The following is a list of possible `StaticInstance` states and its associated servers (VMs) and cluster nodes:

   - `Pending`. The server is not configured and there is no associated node in the cluster.
   - `Bootstrapping`. The procedure for configuring the server (VM) and connecting the node to the cluster is in progress.
   - `Running`. The server is configured and the associated node is added to the cluster.
   - `Cleaning`. The procedure of cleaning up the server and disconnecting the node from the cluster is in progress.

   > **i** You can transfer the existing manually-bootstrapped cluster node under CAPS management by annotating its StaticInstance with `static.node.deckhouse.io/skip-bootstrap-phase: ""`.

4. **Creating a NodeGroup resource.**

   When using CAPS, you have to focus on the nodeType parameter (must be `Static`) of the `NodeGroup` resource as well as the staticInstances parameter section.

   The staticInstances.labelSelector parameter section defines a filter that CAPS applies to select the `StaticInstance` resources to be used for a group. The filter allows only certain `StaticInstance` to be used for specific node groups, and also allows a single `StaticInstance` to be used in different node groups. You can choose not to define a filter to use any available `StaticInstance` for a node group.

   The staticInstances.count parameter specifies the desired number of nodes in the group. When the parameter changes, CAPS starts adding or removing the desired number of nodes (this process runs in parallel).

Using the data in the staticInstances parameter section, CAPS attempts to maintain the specified number of nodes in the group (count parameter). If a node needs to be added to the group, CAPS selects the resource StaticInstance that matches the filter and is in the `Pending` state, configures the server (VM), and joins the node to the cluster. If a node needs to be removed from the group, CAPS selects the StaticInstance that is in the `Running` state, cleans up the server (VM) and disconnects the node from the cluster (the corresponding `StaticInstance` then goes to the `Pending` state and can be reused).

Custom node settings

The NodeGroupConfiguration resource allows you to automate actions on group nodes. It supports running bash scripts on nodes (you can use the bashbooster command set) as well as the Go Template templating engine, and is a great way to automate operations such as:

- Installing and configuring additional OS packages.

  Examples:

  - installing the plugin for kubectl;
  - installing containerd with Nvidia GPU support.

- Updating the OS kernel to a specific version.

  Examples:

  - Debian kernel update;
  - CentOS kernel update.

- Modifying OS parameters.

Examples:

  - customizing the sysctl parameter;
  - adding a root certificate.

- Collecting information on a node and carrying out other similar tasks.

The `NodeGroupConfiguration` resource allows you to assign priority to scripts being run or limit them to running on specific node groups and OS types.

The script code is stored in the content of the resource. When a script is created on a node, the contents of the `content` parameter are fed into the Go Template templating engine. The latter embeds an extra layer of logic when generating a script. When parsed by the templating engine, a context with a set of dynamic variables becomes available.

The following variables are supported by the templating engine:

- `.cloudProvider` (for node groups of nodeType `CloudEphemeral` or `CloudPermanent`) — cloud provider dataset.

  Example of data...

  ```
  cloudProvider:
    instanceClassKind: OpenStackInstanceClass
    machineClassKind: OpenStackMachineClass
    openstack:
      connection:
        authURL: https://cloud.provider.com/v3/
        domainName: Default
        password: p@ssw0rd
        region: region2
        tenantName: mytenantname
        username: mytenantusername
      externalNetworkNames:
      - public
      instances:
        imageName: ubuntu-24-04-cloud-amd64
        mainNetwork: kube
        securityGroups:
        - kube
        sshKeyPairName: kube
      internalNetworkNames:
      - kube
      podNetworkMode: DirectRoutingWithPortSecurityEnabled
    region: region2
    type: openstack
    zones:
    - nova
  ```

- `.cri` — the CRI in use (starting with Deckhouse 1.49, only `Containerd` is supported).
- `.kubernetesVersion` — the Kubernetes version in use.
- `.nodeUsers` — the dataset with information about node users added via the NodeUser.

  Example of data...

  ```
  nodeUsers:
  - name: user1
    spec:
      isSudoer: true
      nodeGroups:
      - '*'
      passwordHash: PASSWORD_HASH
      sshPublicKey: SSH_PUBLIC_KEY
      uid: 1050
  ```

- `.nodeGroup` — node group dataset.

  Example of data...

```
nodeGroup:
  cri:
    type: Containerd
  disruptions:
    approvalMode: Automatic
  kubelet:
    containerLogMaxFiles: 4
    containerLogMaxSize: 50Mi
    resourceReservation:
      mode: "Off"
  kubernetesVersion: "1.31"
  manualRolloutID: ""
  name: master
  nodeTemplate:
    labels:
      node-role.kubernetes.io/control-plane: ""
      node-role.kubernetes.io/master: ""
    taints:
    - effect: NoSchedule
      key: node-role.kubernetes.io/master
  nodeType: CloudPermanent
  updateEpoch: "1699879470"
```

An example of using variables in a template:

```
{{- range .nodeUsers }}
echo 'Tuning environment for user {{ .name }}'
# Some code for tuning user environment
{{- end }}
```

An example of using bashbooster commands:

```
bb-event-on 'bb-package-installed' 'post-install'
post-install() {
  bb-log-info "Setting reboot flag due to kernel was updated"
  bb-flag-set reboot
}
```

The progress of script execution can be seen on the node in the bashible service log using the command:

```
journalctl -u bashible.service
```

The scripts themselves are located on the node in the directory `/var/lib/bashible/bundle_steps/`.

The service decides to re-run the scripts by comparing the single checksum of all files located at `/var/lib/bashible/configuration_checksum` with the checksum located in the `kubernetes` cluster in the `configuration-checksums` secret namespace `d8-cloud-instance-manager`.

You can see the checksum using the following command:

```
d8 k -n d8-cloud-instance-manager get secret configuration-checksums -o yaml
```

The service compares checksums every minute.

The checksum in the cluster changes every 4 hours, thereby re-running the scripts on all nodes. Forcing the execution of bashible on a node can be done by deleting the file with the script checksum using the following command:

```
rm /var/lib/bashible/configuration_checksum
```

Features of writing scripts

When writing your own scripts, it is important to consider the following features of their use in Deckhouse:

1. Scripts in deckhouse are executed once every 4 hours or more often based on external triggers. Therefore, it is important to write scripts in such a way that they check the need for their changes in the system before performing actions, thereby not making changes every time they are launched.
2. There are built-in scripts that perform various actions, including installing and configuring services. This is important to consider when choosing the priority of custom scripts. For example, if a script is planned to restart a service, then this script should be called after the service installation script, since otherwise it will not be able to execute when deploying a new node.

Useful features of some scripts:

- `032_configure_containerd.sh`: Merges the containerd configuration files and **restarts** the service. The location of the configuration files depends on the CRI used on the cluster nodes:
  - `/etc/containerd/conf.d/*.toml`: For containerd v1.

- `/etc/containerd/conf2.d/*.toml`: For containerd v2.

Note that directories containing configuration files are not created automatically. Files must be added to these directories in scripts with a priority of less than `32`.

Chaos Monkey

The instrument (you can enable it for each `NodeGroup` individually) for unexpected and random termination of nodes in a systemic manner. Chaos Monkey tests the resilience of cluster elements, applications, and infrastructure components.

Monitoring

DKP exports the group availability Prometheus metrics for each `NodeGroup`.

What information does Prometheus collect and in what form?

Metrics have the `d8_node_group_` prefix.

All the collected metrics have a label that allow you to identify the node group: `node_group_name`.

The following metrics are collected for each node group:

- `d8 node group ready` — the number of Kubernetes nodes in the group that are `Ready`.
- `d8 node group nodes` — the number of Kubernetes nodes (in any state) in the group.
- `d8 node group instances` — the number of instances (in any state) in the group.
- `d8 node group desired` — the number of desired `Machines` in the group.
- `d8 node group min` — the minimum number of instances in the group.
- `d8 node group max` — the maximum number of instances in the group.
- `d8 node group up to date` — the number of up-to-date nodes in the group.
- `d8 node group standby` — the number of over provisioned instances (see the standby parameter) in the group.
- `d8_node_group_has_errors` — equals to 1 if there are errors in the group.

Third-party components

List of third-party software used in the `node-manager` module:

- Gardener Machine Controller Manager v0.36.0

  License: Apache License 2.0

  An operator that manages VMs as a kubernetes custom resource.

- Cluster API 1.11.3

  License: Apache License 2.0

  Kubernetes Cluster API for declarative cluster lifecycle management.

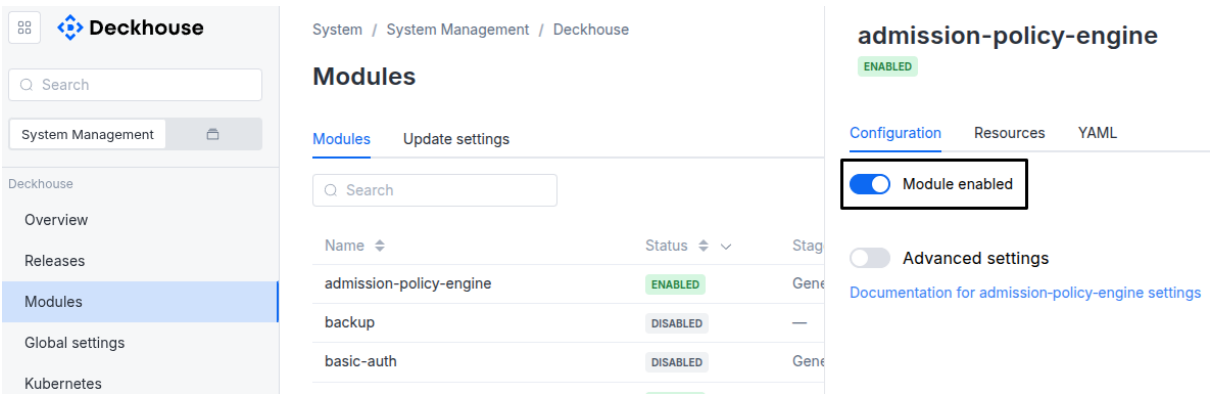
- Cluster Autoscaler

  License: Apache License 2.0

  Kubernetes autoscaler that automatically adjusts the size of the cluster.

Configuration

> **i** The module lifecycle stage: General Availability



The module has 37 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

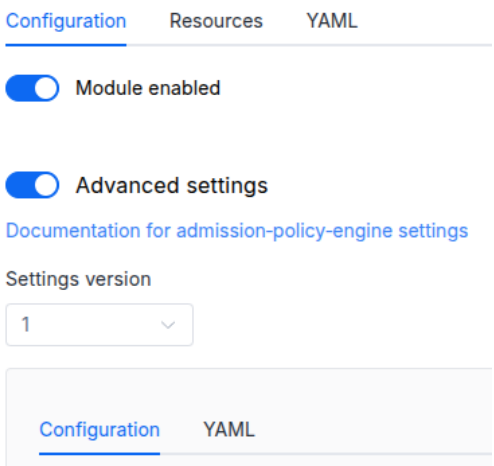
  ```
  d8 system module enable node-manager
  ```

- **Using ModuleConfig `node-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `node-manager` (create it if necessary);

  Example of a manifest to enable module `node-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: node-manager
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `node-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `node-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `node-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `node-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc node-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `node-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `node-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: node-manager
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Delete `allowedKubernetesVersions` and `allowedBundles`.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.capiEmergencyBrake**
    boolean

    Set to ‘true’ to disable CAPI in case of potentially cluster-damaging changes.

    > **Warning.** Use this flag only if you know why you are doing it and clearly understand the consequences.

    Default: `false`

    Example:

    ```
    capiEmergencyBrake: false
    ```
  - **settings.earlyOomEnabled**
    boolean

    Set to ‘false’ to disable early OOM killer in case it behaves incorrectly.

    Default: `true`

    Example:

    ```
    earlyOomEnabled: false
    ```
  - **settings.instancePrefix**
    string

    The prefix to use when creating instances via the corresponding cloud provider module.

    The default value can be calculated based on the `ClusterConfiguration` struct if the cluster is installed via the Deckhouse installer.

    Example:

    ```
    instancePrefix: kube
    ```
  - **settings.mcmEmergencyBrake**
    boolean

    Set to ‘true’ to disable machine-controller-manager in case of potentially cluster-damaging changes.

    > **Warning!** Use this flag only if you know what you are doing and clearly understand the consequences.

    Default: `false`

    Example:

    ```
    mcmEmergencyBrake: false
    ```

Custom resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

Instance

Scope: Cluster
Version: v1alpha1

Describes an implementation-independent ephemeral machine resource.

- **status**
  object
  - **status.bootstrapStatus**
    object

    Information about instance bootstrapping process.

    - **status.bootstrapStatus.description**
      string

      Description about getting logs.

    - **status.bootstrapStatus.logsEndpoint**
      string

      http endpoint for getting bootstrap logs.

  - **status.classReference**
    object

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

    - **status.classReference.kind**
      string

      The object type (e.g., `OpenStackInstanceClass`). The object type is specified in the documentation of the corresponding `cloud-provider-` module.

      Allowed values: `OpenStackInstanceClass`, `GCPInstanceClass`, `VsphereInstanceClass`, `AWSInstanceClass`, `YandexInstanceClass`, `AzureInstanceClass`, `VCDInstanceClass`, `ZvirtInstanceClass`, `DynamixInstanceClass`, `HuaweiCloudInstanceClass`, `DVPInstanceClass`

    - **status.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

  - **status.currentStatus**
    object

    Current status of the instance object.

    - **status.currentStatus.lastUpdateTime**
      string

      Last update time of current status.

    - **status.currentStatus.phase**
      string

      InstancePhase is a label for the condition of a instance at the current time.

  - **status.lastOperation**
    object

    Last operation refers to the status of the last operation performed.

    - **status.lastOperation.description**
      string

      Description of the current operation.

        - **status.lastOperation.lastUpdateTime**
          string

          Last update time of current operation.

        - **status.lastOperation.state**
          string

          State of operation.

        - **status.lastOperation.type**
          string

          Type of operation.

    - **status.machineRef**
      object

      Reference to instance in the cloud.

        - **status.machineRef.apiVersion**
          string

          APIVersion defines the versioned schema of this representation of an reference object.

        - **status.machineRef.kind**
          string

          Kind is a string value representing the REST resource referenced object represents.

        - **status.machineRef.name**
          string

          Name of referenced object.

        - **status.machineRef.namespace**
          string

          Namespace of referenced object.

    - **status.nodeRef**
      object

      Reference to the kubernetes node object.

        - **status.nodeRef.name**
          string

          Node name

InstanceTypesCatalog

Scope: Cluster
Version: v1alpha1

Contains information about discovered data from cloud.

- **instanceTypes**
  array of objects

  Required value

  List of available instance types.

    - **instanceTypes.cpu**
      integer or string

      Required value

      The number of CPUs for the instance type.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

    - **instanceTypes.memory**
      integer or string

      Required value

      The amount of RAM a instance type has.

      Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

- **instanceTypes.name**
  string

  Instance type name.

- **instanceTypes.rootDisk**
  integer or string

  Root disk size.

  Pattern: `^(\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))(([KMGTPE]i)|[numkMGTPE]|([eE](\+|-)?(([0-9]+(\.[0-9]*)?)|(\.[0-9]+))))?$`

NodeGroup

Short names: ng

Scope: Cluster

- v1
- v1alpha2
- v1alpha1

Describes the runtime parameters of the node group.

Example:

```
# NodeGroup for cloud nodes in AWS.
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: test
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    zones:
      - eu-west-1a
      - eu-west-1b
    minPerZone: 1
    maxPerZone: 2
    classReference:
      kind: AWSInstanceClass
      name: test
  nodeTemplate:
    labels:
      tier: test
---
# NodeGroup for static nodes on bare metal servers (or VMs).
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
```

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `42`

- **status**
  object
  - **status.conditionSummary**
    object
    - **status.conditionSummary.ready**
      string

      Status of the condition summary.

Allowed values: `True`, `False`

- **status.conditionSummary.statusMessage**
  string

  Status message about group handling.

- **status.conditions**
  array of objects
  - **status.conditions.lastTransitionTime**
    string

    Last time the condition transit from one status to another.

  - **status.conditions.message**
    string

    Human readable message indicating details about last transition.

  - **status.conditions.status**
    string

    Required value

    Status of the condition, one of True, False.

  - **status.conditions.type**
    string

    Required value

    Type of node group condition.

- **status.deckhouse**
  object
  - **status.deckhouse.observed**
    object

    Contains last timestamp when the resource change was noted by the operator and its checksum.

    - **status.deckhouse.observed.checkSum**
      string

      The checksum of the last observed resource.

    - **status.deckhouse.observed.lastTimestamp**
      string

      Last timestamp when a change of the resource was noted by the operator.

  - **status.deckhouse.processed**
    object

    Contains last timestamp when the resource was applied in the cluster by the operator and its checksum.

    - **status.deckhouse.processed.checkSum**
      string

      The checksum of the last applied resource.

    - **status.deckhouse.processed.lastTimestamp**
      string

      Last timestamp when the resource was applied in the cluster.

  - **status.deckhouse.synced**
    string

    True if last observed version of the resource was successfully applied in the cluster.

- **status.desired**
  integer

  Number of desired machines in the group.

- **status.error**
  string

  Error message about possible problems with the group handling.

- **status.instances**

integer

Number of instances (in any state) in the group.

- **status.kubernetesVersion**
  string

  The current version of kubernetes on the nodes, or the version to which the nodes will be upgraded.

- **status.lastMachineFailures**
  array of objects
  - **status.lastMachineFailures.lastOperation**
    object
    - **status.lastMachineFailures.lastOperation.description**
      string

      Last operation’s description.

    - **status.lastMachineFailures.lastOperation.lastUpdateTime**
      string

      Timestamp of last status update for operation.

    - **status.lastMachineFailures.lastOperation.state**
      string

      Machine’s operation state.

    - **status.lastMachineFailures.lastOperation.type**
      string

      Type of operation.

  - **status.lastMachineFailures.name**
    string

    Machine’s name.

  - **status.lastMachineFailures.ownerRef**
    string

    Machine owner’s name.

  - **status.lastMachineFailures.providerID**
    string

    Machine’s ProviderID.

- **status.max**
  integer

  Maximum amount of instances in the group.

- **status.min**
  integer

  Minimal amount of instances in the group.

- **status.nodes**
  integer

  Number of Kubernetes nodes (in any state) in the group.

- **status.ready**
  integer

  Number of ready Kubernetes nodes in the group.

- **status.standby**
  integer

  Number of overprovisioned instances in the group.

- **status.upToDate**
  integer

  Number of up-to-date nodes in the group.

- **spec**
  object

  Required value

- **spec.chaos**
  object

  Chaos monkey settings.

  Example:

  ```
  chaos:
    mode: DrainAndDelete
    period: 24h
  ```

  - **spec.chaos.mode**
    string

    The chaos monkey mode:

    - `DrainAndDelete` — drains and deletes a node when triggered;
    - `Disabled` — leaves this NodeGroup intact.

    Default: `Disabled`

    Allowed values: `Disabled`, `DrainAndDelete`

  - **spec.chaos.period**
    string

    The time interval to use for the chaos monkey.

    It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    Default: `6h`

    Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

- **spec.cloudInstances**
  object

  Parameter for provisioning the cloud-based VMs.

  > **i** **Caution!** Can only be used together with `nodeType: CloudEphemeral`.

  - **spec.cloudInstances.classReference**
    object

    Required value

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

    - **spec.cloudInstances.classReference.kind**
      string

      The object type (e.g., `OpenStackInstanceClass`). The object type is specified in the documentation of the corresponding `cloud-provider-` module.

      Allowed values: `OpenStackInstanceClass`, `GCPInstanceClass`, `VsphereInstanceClass`, `AWSInstanceClass`, `YandexInstanceClass`, `AzureInstanceClass`, `VCDInstanceClass`, `ZvirtInstanceClass`, `DynamixInstanceClass`, `HuaweiCloudInstanceClass`, `DVPInstanceClass`

    - **spec.cloudInstances.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

  - **spec.cloudInstances.maxPerZone**
    integer

    Required value

    The maximum number of instances for the group in each zone.

    This value is used as the upper bound in cluster-autoscaler.

    Allowed values: `0 <= X`

  - **spec.cloudInstances.maxSurgePerZone**
    integer

The maximum number of instances to rollout simultaneously in the group in each zone.

Default: `1`

Allowed values: `0 <= X`

- **spec.cloudInstances.maxUnavailablePerZone**
  integer

  The maximum number of unavailable instances (during rollout) in the group in each zone.

  Default: `0`

  Allowed values: `0 <= X`

- **spec.cloudInstances.minPerZone**
  integer

  Required value

  The minimum number of instances for the group in each zone.

  This value is used in the `MachineDeployment` object and as a lower bound in cluster-autoscaler.

  Allowed values: `0 <= X`

- **spec.cloudInstances.priority**
  integer

  Priority of the node group.

  When scaling a cluster, the autoscaler will first select node groups with a higher priority set. If several node groups have the same priority, the autoscaler randomly selects a group of them. You can control the rate at which nodes are switched to lower-priority groups on demand (for more details, see the FAQ).

  Using priorities can be convenient to prefer ordering cheaper nodes (for example, spot instances) over more expensive ones.

- **spec.cloudInstances.quickShutdown**
  Deprecated
  boolean

  Lowers CloudEphemeral machine drain timeout to 5 minutes.

- **spec.cloudInstances.standby**
  integer or string

  The summary number of overprovisioned nodes for this `NodeGroup` in all zones.

  An overprovisioned node is a cluster node on which resources are reserved that are available at any time for scaling. The presence of such a node allows the cluster autoscaler not to wait for node initialization (which may take several minutes), but to immediately place a load on it.

  The value can be an absolute number (for example, 2) or a percentage of desired nodes (for example, 10%). If a percentage is specified, the absolute number is calculated based on the percentage of the maximum number of nodes (the maxPerZone parameter) rounded down, but not less than one.

  Pattern: `^[0-9]+%?$`

- **spec.cloudInstances.standbyHolder**
  object

  Amount of reserved resources.

  Used to determine whether to order overprovisioned nodes.

  - **spec.cloudInstances.standbyHolder.notHeldResources**
    Deprecated
    object

    Deprecated: the parameter is no longer used. Use the `overprovisioningRate` parameter.

    Describes the resources that will not be held (consumed) by the standby holder.

    - **spec.cloudInstances.standbyHolder.notHeldResources.cpu**
      integer or string

      Describes the amount of CPU that will not be held by standby holder on Nodes

from this NodeGroup.

The value can be an absolute number of cpus (for example, 2) as well as a milli representation (for example, 1500m).

Pattern: `^[0-9]+m?$`

- **spec.cloudInstances.standbyHolder.notHeldResources.memory**
  integer or string

  Describes the amount of memory that will not be held by standby holder on Nodes from this NodeGroup.

  The value can be an absolute number of bytes (for example, 128974848) as well as a fixed-point number using one of memory suffixes: G, Gi, M, Mi.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.cloudInstances.standbyHolder.overprovisioningRate**
  integer

  Percentage of reserved resources calculated from the capacity of a node of a `NodeGroup`.

  Default: `50`

  Allowed values: `1 <= X <= 80`

- **spec.cloudInstances.zones**
  array of strings

  List of availability zones to create instances in.

  The default value depends on the cloud provider selected and usually corresponds to all zones of the region being used.

  Example:

```
zones:
- Helsinki
- Espoo
- Tampere
```

- **spec.cri**
  object

  Container runtime parameters.

  - **spec.cri.containerd**
    object

    Containerd runtime parameters.

    If used, `cri.type` must be set to `Containerd`.

    - **spec.cri.containerd.maxConcurrentDownloads**
      integer

      Set the max concurrent downloads for each pull.

      Default: `3`

  - **spec.cri.containerdV2**
    object

    ContainerdV2 runtime parameters.

    If used, `cri.type` must be set to `ContainerdV2`.

    When using `ContainerdV2`, `CgroupsV2` will be used (providing improved security and resource management).

    To use `ContainerdV2` as a container runtime, the nodes in the group must meet the following requirements:

    - Support for `CgroupsV2`.
    - Linux kernel version `5.8` or newer.
    - Systemd version `244` or newer.
    - Support for `erofs` kernel module.
    - **spec.cri.containerdV2.maxConcurrentDownloads**
      integer

Set the max concurrent downloads for each pull.

Default: `3`

- **spec.cri.docker**
  Deprecated
  object

  Docker settings for nodes.

  - **spec.cri.docker.manage**
    boolean

    Enable Docker maintenance from bashible.

    Default: `true`

  - **spec.cri.docker.maxConcurrentDownloads**
    integer

    Set the max concurrent downloads for each pull.

    Default: `3`

- **spec.cri.notManaged**
  object

  Settings for not managed CRI for nodes.

  - **spec.cri.notManaged.criSocketPath**
    string

    Path to CRI socket.

- **spec.cri.type**
  string

  Container runtime type.

  If not specified, the `defaultCRI` parameter value of ClusterConfiguration is used.

  > **i** **Note.** Docker support is deprecated.

  Allowed values: `Docker`, `Containerd`, `ContainerdV2`, `NotManaged`

- **spec.disruptions**
  object

  Disruptions settings for nodes.

  Example:

```
disruptions:
  approvalMode: Automatic
  automatic:
    drainBeforeApproval: false
    windows:
    - from: '06:00'
      to: '08:00'
      days:
      - Tue
      - Sun
```

  - **spec.disruptions.approvalMode**
    string

    The approval mode for disruptive updates:

    - `Manual` — disable automatic disruption approval; the alert will be displayed if disruption is needed. Nodes are not drained automatically in `Manual` mode. If necessary, manually drain nodes before setting the `update.node.deckhouse.io/disruption-approved=` annotation. **Caution!** The `master` node group update mode must be `Manual` to avoid issues with draining.
    - `Automatic` — automatically approve disruption-involving updates. Nodes could be drained automatically before reboot, as configured by the drainBeforeApproval option.
    - `RollingUpdate` — in this mode, a **new** node with new settings will be created; then, the old node will be deleted. Available only for cloud nodes.

If the `RollingUpdate` mode is not used, when updating, the node is first drained and then updated (rebooted) and put back into operation (uncordoned). Note that in this case, the cluster must have sufficient resources to accommodate the load while the node being updated is unavailable. In the `RollingUpdate` mode, the node is **replaced** by the updated node, i.e., an extra node appears in the cluster for the duration of the update. In cloud infrastructures, the `RollingUpdate` mode is convenient, for example, if there are no resources in the cluster to temporarily host the load from the node being updated.

Default: `Automatic`

Allowed values: `Manual`, `Automatic`, `RollingUpdate`

- **spec.disruptions.automatic**
  object

  Additional parameters for the `Automatic` mode.

  - **spec.disruptions.automatic.drainBeforeApproval**
    boolean

    Drain Pods from the nodes before approving disruption.

    Caution! This setting ignores (nodes will be approved without draining Pods):

    - for the nodeGroup `master` with a single node;
    - for a single `ready` node in a nodeGroup picked out for Deckhouse placement.

    Default: `true`

  - **spec.disruptions.automatic.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.automatic.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

      ```
      days: Wed
      ```

      - **Element of the array**
        string

        Day of the week.

        Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

    - **spec.disruptions.automatic.windows.from**
      string

      Required value

      Start time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      from: '13:00'
      ```

    - **spec.disruptions.automatic.windows.to**
      string

      Required value

      End time of disruptive update window (UTC timezone).

      Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

      Example:

      ```
      to: '18:30'
      ```

- **spec.disruptions.rollingUpdate**

object

Additional parameters for the `RollingUpdate` mode.

- **spec.disruptions.rollingUpdate.windows**
  array of objects

  Time windows for node disruptive updates.

  - **spec.disruptions.rollingUpdate.windows.days**
    array of strings

    Days of the week when node could be updated.

    Examples:

    ```
    days: Mon
    ```

    ```
    days: Wed
    ```

    - **Element of the array**
      string

      Day of the week.

      Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

  - **spec.disruptions.rollingUpdate.windows.from**
    string

    Required value

    Start time of disruptive update window (UTC timezone).

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    from: '13:00'
    ```

  - **spec.disruptions.rollingUpdate.windows.to**
    string

    Required value

    End time of disruptive update window (UTC timezone).

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    to: '18:30'
    ```

- **spec.fencing**
  object

  Enable the fencing-controller for a node group.

  - **spec.fencing.mode**
    string

    Required value

    Specifies the operating mode of the fencing-controller.

    Supported modes:

    - `Watchdog`: Uses the watchdog kernel module to automatically reboot nodes that lose connectivity with the cluster. In this mode, the fencing-agent also monitors node availability in the cluster.

    When `fencing` is enabled, the NodeGroupConfiguration script loads the `softdog` kernel module with the `soft margin` parameter set to the value of `spec.fencing.watchdog.timeout` (60 seconds by default) and `soft_panic=1`.

    How the fencing-agent works:

    - The agent opens the `/dev/watchdog` device and sets the `node-manager.deckhouse.io/fencing-enabled` label on the node, as well as the `node-`

`manager.deckhouse.io/fencing-mode` label with the value `Watchdog`.
- The fencing-agent joins a gossip cluster (`memberlist`) with agents from the same node group.
- The agent regularly checks quorum (availability of the majority of nodes in the group):
- If quorum is lost (`quorum=false`), the agent performs an additional check of Kubernetes API availability.
- If quorum is present or the Kubernetes API is reachable, the agent resets the watchdog timer.
- If neither quorum nor access to the Kubernetes API is available, the watchdog is no longer reset, the timer expires, and a kernel panic occurs.
- The agent respects maintenance annotations `node-manager.deckhouse.io/fencing-disable`, `update.node.deckhouse.io/approved`, and `update.node.deckhouse.io/disruption-approved`, temporarily disabling the watchdog during planned operations.

When `fencing` is enabled, automatic node reboot after a kernel panic is disabled at the OS level. This prevents a node from returning in an undefined state before it is properly handled (manually for static nodes, or via the cloud-provider-controller for cloud nodes).

The fencing-controller takes the node type (`node.deckhouse.io/type`) into account when handling a failed node:

- For cloud nodes (`CloudEphemeral`, `CloudPermanent`), the controller deletes the Node object, after which the cloud-provider-controller recreates the corresponding virtual machine.
- For static nodes (`Static`, `CloudStatic`), the controller only evicts workloads while keeping the Node object in the cluster.

For details on how fencing handles different node types, see FAQ.

Allowed values: `Watchdog`

- **spec.fencing.watchdog**
  object
  - **spec.fencing.watchdog.timeout**
    string

    Required value

    Watchdog timeout duration. Should be specified in seconds, minutes or hours.

    Default: `60s`

    Pattern: `^[0-9]+[smh]{1}$`

- **spec.gpu**
  object

  Available in editions: EE

  GPU parameters.

  - **spec.gpu.exclusive**
    object

    Without GPU sharing.

  - **spec.gpu.mig**
    object

    `MIG` sharing strategy parameters.

    - **spec.gpu.mig.customConfigs**
      array of objects

      Custom MIG partitioning by GPU index.

      Used only when `partedConfig: custom` is set.

      Represents an array of devices (a map keyed by `index`), where each entry refers to a GPU by its index and describes the slices to be created.

      Examples:

      ```
      customConfigs:
        profile: 3g.40gb
        count: 2
      ```

```
customConfigs:
  profile: 1g.10gb.me
  count: 1
```

- **spec.gpu.mig.customConfigs.index**
  integer

  Required value

  GPU index on the node.

  Allowed values: `0 <= X`

- **spec.gpu.mig.customConfigs.slices**
  array of objects

  Required value

  List of MIG slices to create.

  - **spec.gpu.mig.customConfigs.slices.count**
    integer

    Required value

    Number of slices in the selected profile.

    Default: `1`

    Allowed values: `1 <= X <= 7`

  - **spec.gpu.mig.customConfigs.slices.profile**
    string

    Required value

    MIG profile name.

    Pattern: `^[0-9]+g\.[0-9]+gb(\.me)?$`

    Examples:

    ```
    profile: 3g.40gb
    ```

    ```
    profile: 1g.10gb
    ```

    ```
    profile: 1g.10gb.me
    ```

- **spec.gpu.mig.partedConfig**
  string

  MIG configuration name.

  Standard `all-*` profiles are supported (the same partitioning applied to all GPUs), as well as the `custom` value, which allows defining partitioning individually for each GPU.

  Default: `all-1g.5gb`

- **spec.gpu.sharing**
  string

  GPU sharing strategy:

  - `Exclusive` — no sharing (each GPU is fully allocated to a single Pod).
  - `TimeSlicing` — time-sliced sharing (multiple Pods can share one GPU concurrently by splitting GPU time).
  - `MIG` — use NVIDIA Multi-Instance GPU (MIG) to split each GPU into multiple instances (if supported by hardware).

  Allowed values: `TimeSlicing`, `MIG`, `Exclusive`

- **spec.gpu.timeSlicing**
  object

  `TimeSlicing` sharing strategy parameters.

  - **spec.gpu.timeSlicing.partitionCount**
    number

Count of partition per GPU.

Default: `4`

Allowed values: `1 <= X <= 100`

- **spec.kubelet**
  object

  Kubelet settings for nodes.

  - **spec.kubelet.containerLogMaxFiles**
    integer

    How many rotated log files to store before deleting them.

    Default: `4`

    Allowed values: `1 <= X <= 20`

  - **spec.kubelet.containerLogMaxSize**
    string

    Maximum log file size before it is rotated.

    Default: `50Mi`

    Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

  - **spec.kubelet.maxPods**
    integer

    Set the max count of pods per node for given `NodeGroup`. When left unspecified, the system automatically determines this limit according to the value of the podSubnetNodeCIDRPrefix ClusterConfiguration parameter:

    - `120` pods for `podSubnetNodeCIDRPrefix` ≥ `24`;
    - `250` pods for `podSubnetNodeCIDRPrefix` = `23`;
    - `500` pods for `podSubnetNodeCIDRPrefix` = `22`;
    - `1000` pods for `podSubnetNodeCIDRPrefix` ≤ `21`.

  - **spec.kubelet.memorySwap**
    object

    Configuration of swap memory usage for kubelet.

    - **spec.kubelet.memorySwap.limitedSwap**
      object

      Configuration for the limited swap mode. Required when `swapBehavior` is set to `LimitedSwap`.

      - **spec.kubelet.memorySwap.limitedSwap.size**
        string

        Required value

        Size of the swap file to create, specified in GB (for example, “2G”, “4G”).

        Pattern: `^\d+G$`

        Example:

        ```
        size: 1G
        ```

    - **spec.kubelet.memorySwap.swapBehavior**
      string

      Defines how swap memory is handled on the node:

      - `NoSwap`: Swap is disabled. This is the traditional Kubernetes behavior.
      - `LimitedSwap`: Kubelet can use swap memory up to the limit specified in `limitedSwap.size`.

      For details on swap memory usage on nodes, refer to Kubernetes documentation.

      Allowed values: `NoSwap`, `LimitedSwap`

    - **spec.kubelet.memorySwap.swappiness**
      integer

      Defines the kernel’s tendency to use the swap.

- `0`: Minimal swap usage (only to avoid OOM).
- `60`: Default balanced behavior.
- `100`: Aggressive swap usage.

This value is set via `vm.swappiness` sysctl parameter.

Default: `60`

Allowed values: `0 <= X <= 100`

- **spec.kubelet.resourceReservation**
  object

  Management of resource reservation for system daemons on a node.

  More info in the Kubernetes documentation.

  - **spec.kubelet.resourceReservation.mode**
    string

    Defines the system resource reservation mode:

    - `Off` — disables resource reservation.
    - `Auto` — reserves resources based on the Node capacity.
    - `Static` — reserves resources based on the values provided by the user via the `static` parameter.

    Note that currently we do not use a dedicated group `cgroup` for resource reservation (`-system-reserved-cgroup` is not used).

    Default: `Auto`

  - **spec.kubelet.resourceReservation.static**
    object

    Resource reservation parameters for the 'Static' mode.

    - **spec.kubelet.resourceReservation.static.cpu**
      integer or string

      Pattern: `\d+[m]`

    - **spec.kubelet.resourceReservation.static.ephemeralStorage**
      integer or string

      Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

    - **spec.kubelet.resourceReservation.static.memory**
      integer or string

      Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

- **spec.kubelet.rootDir**
  string

  Directory path for managing kubelet files (volume mounts,etc).

  Default: `/var/lib/kubelet`

- **spec.kubelet.topologyManager**
  object

  Controls a topology manager.

  The topology manager allows the Kubernetes scheduler to take resource topology data into account when scheduling pods.

  In a cluster with NUMA nodes, the topology manager can improve application performance by aligning workloads with NUMA nodes that are more resource-efficient.

  For more information, see the Kubernetes documentation.

  - **spec.kubelet.topologyManager.enabled**
    boolean

    Enables Topology Management on a node.

    If the topology manager is enabled, strict resource allocation modes are activated for containers in Guaranteed pods. The following parameter values are set in the kubelet configuration:

    - `cpuManagerPolicy: static`: The kubelet exclusively assigns whole physical cores to a container with an integer CPU request.

- `memoryManagerPolicy: Static`: The kubelet assigns the container's memory to a minimum number of NUMA nodes (preferably one).

Default: `false`

- **spec.kubelet.topologyManager.policy**
  string

  Resource/topology alignment policy to use when scheduling a pod.

  There are four supported policies:

  - `None` — no resource alignment (default).
  - `BestEffort` — a preferred NUMA node is defined for each container. If there are no preferred nodes for the pod available, it will be scheduled to a node without taking topology manager data into account, while the already running pod will keep running.
  - `Restricted` — a preferred NUMA node is defined for each pod container. If there are no preferred nodes available, a new pod will not be scheduled to a node while an already running pod will be stopped.
  - `SingleNumaNode` — a preferred NUMA node is defined for each pod container. If there is no NUMA node available that suits **all pod containers**, a new pod will not be scheduled while an already running pod will be stopped.

  More information can be found in the Kubernetes documentation.

  Default: `None`

  Allowed values: `None`, `BestEffort`, `Restricted`, `SingleNumaNode`

- **spec.kubelet.topologyManager.scope**
  string

  Defines granularity with which resources are aligned:

  - `Container`. The preferred resources are computed for a container. The computation does not take into account that multiple containers may belong to the same pod.
  - `Pod`. The preferred resources are computed for the pod. All containers in the pod are treated as a whole in the computation.

  Default: `Container`

  Allowed values: `Container`, `Pod`

- **spec.nodeDrainTimeoutSecond**
  integer

  Maximum duration (in seconds) for which the controller attempts to reschedule pods to a new machine during node draining.

- **spec.nodeTemplate**
  object

  Specification of some of the fields that will be maintained in all nodes of the group.

  Example:

```
nodeTemplate:
  labels:
    environment: production
    app: warp-drive-ai
  annotations:
    ai.fleet.com/discombobulate: 'true'
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
```

  - **spec.nodeTemplate.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

```
annotations:
  ai.fleet.com/discombobulate: 'true'
```

- **spec.nodeTemplate.labels**
  object

  Similar to the standard `metadata.labels` field.

  Example:

  ```
  labels:
    environment: production
    app: warp-drive-ai
  ```

- **spec.nodeTemplate.taints**
  array of objects

  Similar to the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **spec.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.nodeTemplate.taints.key**
    string
  - **spec.nodeTemplate.taints.value**
    string

- **spec.nodeType**
  string

  Required value

  The type of nodes this group provides:

  - `CloudEphemeral` — nodes for this group will be automatically created (and deleted) in the cloud of the specified cloud provider;
  - `CloudPermanent` — nodes from ProviderClusterConfiguration will be created via dhctl;
  - `CloudStatic` — a static node (created manually or using any external tools) hosted in the cloud integrated with one of the cloud providers. This node has the CSI running, and it is managed by the cloud-controller-manager: the `Node` object automatically gets the information about the zone and region based on the cloud data; if a node gets deleted from the cloud, its corresponding Node object will be deleted in Kubernetes;
  - `Static` — a static node hosted on a bare metal or virtual machine. The cloud-controller-manager does not manage the node even if one of the cloud providers is enabled.

  Allowed values: `CloudEphemeral`, `CloudPermanent`, `CloudStatic`, `Static`

- **spec.operatingSystem**
  object

  Operating System settings for nodes.

  - **spec.operatingSystem.manageKernel**
    Deprecated
    boolean

    This parameter has no effect. Earlier, it enabled kernel maintenance on behalf of bashible.

    Default: `true`

- **spec.staticInstances**
  object

  Parameter for provisioning static machines to the cluster.

- **spec.staticInstances.count**
  integer

  Target number of StaticInstance resources (matching the `labelSelector`) that DKP bootstraps and adds into the cluster.

  In a NodeGroup with Static or CloudStatic nodes, this parameter sets the expected number of nodes. DKP uses this value for state control and automation purposes.

  > **Warning.** Set this parameter explicitly. The default value is `0`, which means DKP won't bootstrap any StaticInstance resource or add any node to the group unless this value is modified. To add static nodes, specify the required number here (greater than `0`).

  Default: `0`

  Allowed values: `0 <= X`

- **spec.staticInstances.labelSelector**
  object

  A label selector is a label query over a set of `staticInstances` resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

  - **spec.staticInstances.labelSelector.matchExpressions**
    array of objects

    A list of label selector requirements. The requirements are ANDed.

    A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

    - **spec.staticInstances.labelSelector.matchExpressions.key**
      string

      key is the label key that the selector applies to.

    - **spec.staticInstances.labelSelector.matchExpressions.operator**
      string

      operator represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

    - **spec.staticInstances.labelSelector.matchExpressions.values**
      array of strings

      values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

      - **Element of the array**
        string

        Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

        Length: `1..63`

  - **spec.staticInstances.labelSelector.matchLabels**
    object

    matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is "key", the operator is "In", and the values array contains only "value". The requirements are ANDed.

- **spec.update**
  object
  - **spec.update.maxConcurrent**
    integer or string

    Maximum number of concurrently updating nodes.

    Can be set as absolute count or as a percent of total nodes.

    Default: `1`

    Pattern: `^[1-9][0-9]*%?$`

Describes the runtime parameters of the node group.

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `42`

- **status**
  object
  - **status.conditionSummary**
    object
    - **status.conditionSummary.ready**
      string

      Status of the condition summary.

      Allowed values: `True`, `False`

    - **status.conditionSummary.statusMessage**
      string

      Status message about group handling.

  - **status.desired**
    integer

    Number of desired machines in the group.

  - **status.error**
    string

    Error message about possible problems with the group handling.

  - **status.instances**
    integer

    Number of instances (in any state) in the group.

  - **status.kubernetesVersion**
    string

    The current version of kubernetes on the nodes, or the version to which the nodes will be upgraded.

  - **status.lastMachineFailures**
    array of objects
    - **status.lastMachineFailures.lastOperation**
      object
      - **status.lastMachineFailures.lastOperation.description**
        string

        Last operation’s description.

      - **status.lastMachineFailures.lastOperation.lastUpdateTime**
        string

        Timestamp of last status update for operation.

      - **status.lastMachineFailures.lastOperation.state**
        string

        Machine’s operation state.

      - **status.lastMachineFailures.lastOperation.type**
        string

        Type of operation.

    - **status.lastMachineFailures.name**
      string

      Machine’s name.

    - **status.lastMachineFailures.ownerRef**
      string

      Machine owner’s name.

    - **status.lastMachineFailures.providerID**
      string

Machine’s ProviderID.

- **status.max**
  integer

  Maximum amount of instances in the group.

- **status.min**
  integer

  Minimal amount of instances in the group.

- **status.nodes**
  integer

  Number of Kubernetes nodes (in any state) in the group.

- **status.ready**
  integer

  Number of ready Kubernetes nodes in the group.

- **status.standby**
  integer

  Number of overprovisioned instances in the group.

- **status.upToDate**
  integer

  Number of up-to-date nodes in the group.

- **spec**
  object

  Required value

  - **spec.chaos**
    object

    Chaos monkey settings.

    Example:

    ```
    chaos:
      mode: DrainAndDelete
      period: 24h
    ```

    - **spec.chaos.mode**
      string

      The chaos monkey mode:

      - `DrainAndDelete` — drains and deletes a node when triggered;
      - `Disabled` — leaves this NodeGroup intact.

      Default: `Disabled`

      Allowed values: `Disabled`, `DrainAndDelete`

    - **spec.chaos.period**
      string

      The time interval to use for the chaos monkey (can be specified in the Go format).

      Default: `6h`

      Pattern: `^[0-9]+[mh]{1}$`

  - **spec.cloudInstances**
    object

    Parameter for provisioning the cloud-based VMs.

    > **i** **Caution!** Can only be used together with `nodeType: CloudEphemeral`.

    - **spec.cloudInstances.classReference**
      object

      Required value

The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

- **spec.cloudInstances.classReference.kind**
  string

  The object type (e.g., `OpenStackInstanceClass`). The object type is specified in the documentation of the corresponding `cloud-provider-` module.

  Allowed values: `OpenStackInstanceClass`, `GCPInstanceClass`, `VsphereInstanceClass`, `AWSInstanceClass`, `YandexInstanceClass`, `AzureInstanceClass`, `VCDInstanceClass`, `ZvirtInstanceClass`, `DynamixInstanceClass`, `HuaweiCloudInstanceClass`, `DVPInstanceClass`

- **spec.cloudInstances.classReference.name**
  string

  The name of the required `InstanceClass` object (e.g., `finland-medium`).

- **spec.cloudInstances.maxPerZone**
  integer

  Required value

  The maximum number of instances for the group in each zone.

  This value is used as the upper bound in cluster-autoscaler.

  Allowed values: `0 <= X`

- **spec.cloudInstances.maxSurgePerZone**
  integer

  The maximum number of instances to rollout simultaneously in the group in each zone.

  Default: `1`

  Allowed values: `0 <= X`

- **spec.cloudInstances.maxUnavailablePerZone**
  integer

  The maximum number of unavailable instances (during rollout) in the group in each zone.

  Default: `0`

  Allowed values: `0 <= X`

- **spec.cloudInstances.minPerZone**
  integer

  Required value

  The minimum number of instances for the group in each zone.

  This value is used in the `MachineDeployment` object and as a lower bound in cluster-autoscaler.

  Allowed values: `0 <= X`

- **spec.cloudInstances.standby**
  integer or string

  The summary number of overprovisioned nodes for this `NodeGroup` in all zones.

  An overprovisioned node is a cluster node on which resources are reserved that are available at any time for scaling. The presence of such a node allows the cluster autoscaler not to wait for node initialization (which may take several minutes), but to immediately place a load on it.

  The value can be an absolute number (for example, 2) or a percentage of desired nodes (for example, 10%). If a percentage is specified, the absolute number is calculated based on the percentage of the maximum number of nodes (the maxPerZone parameter) rounded down, but not less than one.

  Pattern: `^[0-9]+%?$`

- **spec.cloudInstances.standbyHolder**
  object

  Amount of reserved resources.

  Used to determine whether to order overprovisioned nodes.

- **spec.cloudInstances.standbyHolder.notHeldResources**
  object

  Describes the resources that will not be held (consumed) by the standby holder.

  - **spec.cloudInstances.standbyHolder.notHeldResources.cpu**
    integer or string

    Describes the amount of CPU that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of cpus (for example, 2) as well as a milli representation (for example, 1500m).

    Pattern: `^[0-9]+m?$`

  - **spec.cloudInstances.standbyHolder.notHeldResources.memory**
    integer or string

    Describes the amount of memory that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of bytes (for example, 128974848) as well as a fixed-point number using one of memory suffixes: G, Gi, M, Mi.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.cloudInstances.zones**
  array of strings

  List of availability zones to create instances in.

  The default value depends on the cloud provider selected and usually corresponds to all zones of the region being used.

  Example:

  ```
  zones:
  - Helsinki
  - Espoo
  - Tampere
  ```

- **spec.cri**
  object

  Container runtime parameters.

  - **spec.cri.containerd**
    object

    Containerd runtime parameters.

    If used, `cri.type` must be set to `Containerd`.

    - **spec.cri.containerd.maxConcurrentDownloads**
      integer

      Set the max concurrent downloads for each pull.

      Default: `3`

  - **spec.cri.docker**
    object

    Docker settings for nodes.

    > **i** **Note!** the `Docker` is deprecated.

    - **spec.cri.docker.manage**
      boolean

      Enable Docker maintenance from bashible.

      Default: `true`

    - **spec.cri.docker.maxConcurrentDownloads**
      integer

      Set the max concurrent downloads for each pull.

Default: `3`

- **spec.cri.notManaged**
  object

  Settings for not managed CRI for nodes.

  - **spec.cri.notManaged.criSocketPath**
    string

    Path to CRI socket.

- **spec.cri.type**
  string

  Container runtime type.

  Value `defaultCRI` from the initial cluster configration (`cluster-configuration.yaml` parameter from the `d8-cluster-configuration` secret in the `kube-system` namespace) is used if not specified.

  > **i** **Note.** Docker support is deprecated.

  Allowed values: `Docker`, `Containerd`, `NotManaged`

- **spec.disruptions**
  object

  Disruptions settings for nodes.

  Example:

```
disruptions:
  approvalMode: Automatic
  automatic:
    drainBeforeApproval: false
    windows:
    - from: '06:00'
      to: '08:00'
      days:
      - Tue
      - Sun
```

  - **spec.disruptions.approvalMode**
    string

    The approval mode for disruptive updates:

    - `Manual` — disable automatic disruption approval; the alert will be displayed if disruption is needed. **Caution!** The `master` node group update mode must be `Manual` to avoid issues with draining.
    - `Automatic` — automatically approve disruption-involving updates.
    - `RollingUpdate` — in this mode, a **new** node with new settings will be created; then, the old node will be deleted. Available only for cloud nodes.

    If the `RollingUpdate` mode is not used, when updating, the node is first drained and then updated (rebooted) and put back into operation (uncordoned). Note that in this case, the cluster must have sufficient resources to accommodate the load while the node being updated is unavailable. In the `RollingUpdate` mode, the node is **replaced** by the updated node, i.e., an extra node appears in the cluster for the duration of the update. In cloud infrastructures, the `RollingUpdate` mode is convenient, for example, if there are no resources in the cluster to temporarily host the load from the node being updated.

    Default: `Automatic`

    Allowed values: `Manual`, `Automatic`, `RollingUpdate`

  - **spec.disruptions.automatic**
    object

    Additional parameters for the `Automatic` mode.

    - **spec.disruptions.automatic.drainBeforeApproval**
      boolean

      Drain Pods from the nodes before approving disruption.

Caution! This setting ignores (nodes will be approved without draining Pods):

- for the nodeGroup `master` with a single node;
- for a single `ready` node in a nodeGroup picked out for Deckhouse placement.

Default: `true`

- **spec.disruptions.automatic.windows**
  array of objects

  Time windows for node disruptive updates.

  - **spec.disruptions.automatic.windows.days**
    array of strings

    Days of the week when node could be updated.

    Examples:

    ```
    days: Mon
    ```

    ```
    days: Wed
    ```

    - **Element of the array**
      string

      Day of the week.

      Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

  - **spec.disruptions.automatic.windows.from**
    string

    Required value

    Start time of disruptive update window (UTC timezone).

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    from: '13:00'
    ```

  - **spec.disruptions.automatic.windows.to**
    string

    Required value

    End time of disruptive update window (UTC timezone).

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    to: '18:30'
    ```

- **spec.disruptions.rollingUpdate**
  object

  Additional parameters for the `RollingUpdate` mode.

  - **spec.disruptions.rollingUpdate.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.rollingUpdate.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

      ```
      days: Wed
      ```

        - **Element of the array**
          string

          Day of the week.

          Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

      - **spec.disruptions.rollingUpdate.windows.from**
        string

        Required value

        Start time of disruptive update window (UTC timezone).

        Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

        Example:

        ```
        from: '13:00'
        ```

      - **spec.disruptions.rollingUpdate.windows.to**
        string

        Required value

        End time of disruptive update window (UTC timezone).

        Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

        Example:

        ```
        to: '18:30'
        ```

- **spec.kubelet**
  object

  Kubelet settings for nodes.

  - **spec.kubelet.containerLogMaxFiles**
    integer

    How many rotated log files to store before deleting them.

    > **WARNING!** This parameter does nothing if CRI type is `Docker`.

    Default: `4`

    Allowed values: `1 <= X <= 20`

  - **spec.kubelet.containerLogMaxSize**
    string

    Maximum log file size before it is rotated.

    > **WARNING!** This parameter does nothing if CRI type is `Docker`.

    Default: `50Mi`

    Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

  - **spec.kubelet.maxPods**
    integer

    Set the max count of pods per node for given `NodeGroup`. When left unspecified, the system automatically determines this limit according to the value of the podSubnetNodeCIDRPrefix ClusterConfiguration parameter:

    - `120` pods for `podSubnetNodeCIDRPrefix` ≥ `24`;
    - `250` pods for `podSubnetNodeCIDRPrefix` = `23`;
    - `500` pods for `podSubnetNodeCIDRPrefix` = `22`;
    - `1000` pods for `podSubnetNodeCIDRPrefix` ≤ `21`.
  - **spec.kubelet.rootDir**
    string

    Directory path for managing kubelet files (volume mounts,etc).

Default: `/var/lib/kubelet`

- **spec.nodeTemplate**
  object

  Specification of some of the fields that will be maintained in all nodes of the group.

  Example:

  ```
  nodeTemplate:
    labels:
      environment: production
      app: warp-drive-ai
    annotations:
      ai.fleet.com/discombobulate: 'true'
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
  ```

  - **spec.nodeTemplate.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **spec.nodeTemplate.labels**
    object

    Similar to the standard `metadata.labels` field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

  - **spec.nodeTemplate.taints**
    array of objects

    Similar to the `.spec.taints` field of the Node object.

    > **i** Available fields: `effect`, `key`, and `values`.

    Example:

    ```
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
    ```

    - **spec.nodeTemplate.taints.effect**
      string

      Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

    - **spec.nodeTemplate.taints.key**
      string
    - **spec.nodeTemplate.taints.value**
      string

- **spec.nodeType**
  string

  Required value

  The type of nodes this group provides.

  - `Cloud` — nodes for this group will be automatically created (and deleted) in the cloud of the

specified cloud provider;
- `Static` — a static node hosted on a bare metal or virtual machine. The cloud-controller-manager does not manage the node even of one of the cloud providers is enabled;
- `Hybrid` — a static node (created manually or using any external tools) hosted in the cloud integrated with one of the cloud provider. This node has the CSI running, and it is managed by the cloud-controller-manager: the Node object automatically gets the information about the zone and region based on the cloud data; if a node gets deleted from the cloud, its corresponding Node object will be deleted in Kubernetes.

Allowed values: `Cloud`, `Static`, `Hybrid`

- **spec.operatingSystem**
  object

  Operating System settings for nodes.

  - **spec.operatingSystem.manageKernel**
    boolean

    Enable kernel maintenance from bashible.

    Default: `true`

Defines the runtime parameters of a node group.

- **metadata**
  object
  - **metadata.name**
    string

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?$`

    Maximum length: `42`
- **status**
  object
  - **status.conditionSummary**
    object
    - **status.conditionSummary.ready**
      string

      Status of the condition summary.

      Allowed values: `True`, `False`

    - **status.conditionSummary.statusMessage**
      string

      Status message about group handling.
  - **status.desired**
    integer

    Number of desired machines in the group.
  - **status.error**
    string

    Error message about possible problems with the group handling.
  - **status.instances**
    integer

    Number of instances (in any state) in the group.
  - **status.kubernetesVersion**
    string

    The current version of kubernetes on the nodes, or the version to which the nodes will be upgraded.
  - **status.lastMachineFailures**
    array of objects
    - **status.lastMachineFailures.lastOperation**
      object
      - **status.lastMachineFailures.lastOperation.description**
        string

        Last operation’s description.

      - **status.lastMachineFailures.lastOperation.lastUpdateTime**
        string

Timestamp of last status update for operation.

- **status.lastMachineFailures.lastOperation.state**
  string

  Machine’s operation state.

- **status.lastMachineFailures.lastOperation.type**
  string

  Type of operation.

- **status.lastMachineFailures.name**
  string

  Machine’s name.

- **status.lastMachineFailures.ownerRef**
  string

  Machine owner’s name.

- **status.lastMachineFailures.providerID**
  string

  Machine’s ProviderID.

- **status.max**
  integer

  Maximum amount of instances in the group.

- **status.min**
  integer

  Minimal amount of instances in the group.

- **status.nodes**
  integer

  Number of Kubernetes nodes (in any state) in the group.

- **status.ready**
  integer

  Number of ready Kubernetes nodes in the group.

- **status.standby**
  integer

  Number of overprovisioned instances in the group.

- **status.upToDate**
  integer

  Number of up-to-date nodes in the group.

- **spec**
  object

  Required value

  - **spec.chaos**
    object

    Chaos monkey settings.

    Example:

    ```
    chaos:
      mode: DrainAndDelete
      period: 24h
    ```

    - **spec.chaos.mode**
      string

      The chaos monkey mode:

      - `DrainAndDelete` — drains and deletes a node when triggered;
      - `Disabled` — leaves this NodeGroup intact.

      Default: `Disabled`

Allowed values: `Disabled`, `DrainAndDelete`

- **spec.chaos.period**
  string

  The time interval to use for the chaos monkey (can be specified in the Go format).

  Default: `6h`

  Pattern: `^[0-9]+[mh]{1}$`

- **spec.cloudInstances**
  object

  Parameter for provisioning the cloud-based VMs.

  > **Caution!** Can only be used together with `nodeType: CloudEphemeral`.

  - **spec.cloudInstances.classReference**
    object

    Required value

    The reference to the `InstanceClass` object. It is unique for each `cloud-provider-*` module.

    - **spec.cloudInstances.classReference.kind**
      string

      The object type (e.g., `OpenStackInstanceClass`). The object type is specified in the documentation of the corresponding `cloud-provider-` module.

      Allowed values: `OpenStackInstanceClass`, `GCPInstanceClass`, `VsphereInstanceClass`, `AWSInstanceClass`, `YandexInstanceClass`, `AzureInstanceClass`, `VCDInstanceClass`, `ZvirtInstanceClass`, `DynamixInstanceClass`, `HuaweiCloudInstanceClass`, `DVPInstanceClass`

    - **spec.cloudInstances.classReference.name**
      string

      The name of the required `InstanceClass` object (e.g., `finland-medium`).

  - **spec.cloudInstances.maxPerZone**
    integer

    Required value

    The maximum number of instances for the group in each zone.

    This value is used as the upper bound in cluster-autoscaler.

    With a value of 0, you need to set capacity for some `InstanceClass`. Get more details in the description of the necessary `InstanceClass`.

    Allowed values: `0 <= X`

  - **spec.cloudInstances.maxSurgePerZone**
    integer

    The maximum number of instances to rollout simultaneously in the group in each zone.

    Default: `1`

    Allowed values: `0 <= X`

  - **spec.cloudInstances.maxUnavailablePerZone**
    integer

    The maximum number of unavailable instances (during rollout) in the group in each zone.

    Default: `0`

    Allowed values: `0 <= X`

  - **spec.cloudInstances.minPerZone**
    integer

    Required value

    The minimum number of instances for the group in each zone.

This value is used in the `MachineDeployment` object and as a lower bound in cluster-autoscaler.

Allowed values: `0 <= X`

- **spec.cloudInstances.standby**
integer or string

The summary number of overprovisioned nodes for this `NodeGroup` all zones.

An overprovisioned node is a cluster node on which resources are reserved that are available at any time for scaling. The presence of such a node allows the cluster autoscaler not to wait for node initialization (which may take several minutes), but to immediately place a load on it.

The value can be an absolute number (for example, 2) or a percentage of desired nodes (for example, 10%). If a percentage is specified, the absolute number is calculated based on the percentage of the maximum number of nodes (the maxPerZone parameter) rounded down, but not less than one.

Pattern: `^[0-9]+%?$`

- **spec.cloudInstances.standbyHolder**
object

Amount of reserved resources.

Used to determine whether to order overprovisioned nodes.

  - **spec.cloudInstances.standbyHolder.notHeldResources**
  object

  Describes the resources that will not be held (consumed) by the standby holder.

    - **spec.cloudInstances.standbyHolder.notHeldResources.cpu**
    integer or string

    Describes the amount of CPU that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of cpus (for example, 2) as well as a milli representation (for example, 1500m).

    Pattern: `^[0-9]+m?$`

    - **spec.cloudInstances.standbyHolder.notHeldResources.memory**
    integer or string

    Describes the amount of memory that will not be held by standby holder on Nodes from this NodeGroup.

    The value can be an absolute number of bytes (for example, 128974848) as well as a fixed-point number using one of memory suffixes: G, Gi, M, Mi.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|K|Ei|Pi|Ti|Gi|Mi|Ki)?$`

- **spec.cloudInstances.zones**
array of strings

List of availability zones to create instances in.

The default value depends on the cloud provider selected and usually corresponds to all zones of the region being used.

Example:

```
zones:
- Helsinki
- Espoo
- Tampere
```

- **spec.cri**
object

Container runtime parameters.

  - **spec.cri.containerd**
  object

  Containerd runtime parameters.

If used, `cri.type` must be set to `Containerd`.

- **spec.cri.containerd.maxConcurrentDownloads**
  integer

  Set the max concurrent downloads for each pull.

  Default: `3`

- **spec.cri.type**
  string

  Container runtime type.

  If not specified, the `defaultCRI` parameter value of ClusterConfiguration is used.

  > **Note.** Docker support is deprecated.

  Allowed values: `Docker`, `Containerd`, `NotManaged`

- **spec.disruptions**
  object

  Disruptions settings for nodes.

  Example:

```
disruptions:
  approvalMode: Automatic
  automatic:
    drainBeforeApproval: false
    windows:
    - from: '06:00'
      to: '08:00'
      days:
      - Tue
      - Sun
```

  - **spec.disruptions.approvalMode**
    string

    The approval mode for disruptive updates:

    - `Manual` — disable automatic disruption approval; the alert will be displayed if disruption is needed. **Caution!** The `master` node group update mode must be `Manual` to avoid issues with draining.
    - `Automatic` — automatically approve disruption-involving updates.
    - `RollingUpdate` — in this mode, a **new** node with new settings will be created; then, the old node will be deleted. Available only for cloud nodes.

    If the `RollingUpdate` mode is not used, when updating, the node is first drained and then updated (rebooted) and put back into operation (uncordoned). Note that in this case, the cluster must have sufficient resources to accommodate the load while the node being updated is unavailable. In the `RollingUpdate` mode, the node is **replaced** by the updated node, i.e., an extra node appears in the cluster for the duration of the update. In cloud infrastructures, the `RollingUpdate` mode is convenient, for example, if there are no resources in the cluster to temporarily host the load from the node being updated.

    Default: `Automatic`

    Allowed values: `Manual`, `Automatic`, `RollingUpdate`

  - **spec.disruptions.automatic**
    object

    Additional parameters for the `Automatic` mode.

    - **spec.disruptions.automatic.drainBeforeApproval**
      boolean

      Drain Pods from the nodes before approving disruption.

      Caution! This setting ignores (nodes will be approved without draining Pods):

      - for the nodeGroup `master` with a single node;
      - for a single `ready` node in a nodeGroup picked out for Deckhouse placement.

Default: `true`

- **spec.disruptions.automatic.windows**
  array of objects

  Time windows for node disruptive updates.

  - **spec.disruptions.automatic.windows.days**
    array of strings

    Days of the week when node could be updated.

    Examples:

    ```
    days: Mon
    ```

    ```
    days: Wed
    ```

    - **Element of the array**
      string

      Day of the week.

      Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

  - **spec.disruptions.automatic.windows.from**
    string

    Required value

    Start time of disruptive update window (UTC timezone).

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    from: '13:00'
    ```

  - **spec.disruptions.automatic.windows.to**
    string

    Required value

    End time of disruptive update window (UTC timezone).

    Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

    Example:

    ```
    to: '18:30'
    ```

- **spec.disruptions.rollingUpdate**
  object

  Additional parameters for the `RollingUpdate` mode.

  - **spec.disruptions.rollingUpdate.windows**
    array of objects

    Time windows for node disruptive updates.

    - **spec.disruptions.rollingUpdate.windows.days**
      array of strings

      Days of the week when node could be updated.

      Examples:

      ```
      days: Mon
      ```

      ```
      days: Wed
      ```

      - **Element of the array**
        string

        Day of the week.

Allowed values: `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, `Sat`, `Sun`

- **spec.disruptions.rollingUpdate.windows.from**
  string

  Required value

  Start time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

  ```
  from: '13:00'
  ```

- **spec.disruptions.rollingUpdate.windows.to**
  string

  Required value

  End time of disruptive update window (UTC timezone).

  Pattern: `^(?:\d|[01]\d|2[0-3]):[0-5]\d$`

  Example:

  ```
  to: '18:30'
  ```

- **spec.docker**
  object

  Docker settings for nodes.

  If used, `cri.type` must be set to `Docker`.

  > **Note!** the `Docker` is deprecated.

  - **spec.docker.manage**
    boolean

    Enable Docker maintenance from bashible.

    Default: `true`

  - **spec.docker.maxConcurrentDownloads**
    integer

    Set the max concurrent downloads for each pull.

    Default: `3`

- **spec.kubelet**
  object

  Kubelet settings for nodes.

  - **spec.kubelet.containerLogMaxFiles**
    integer

    How many rotated log files to store before deleting them.

    > **WARNING!** This parameter does nothing if CRI type is `Docker`.

    Default: `4`

    Allowed values: `1 <= X <= 20`

  - **spec.kubelet.containerLogMaxSize**
    string

    Maximum log file size before it is rotated.

    > **WARNING!** This parameter does nothing if CRI type is `Docker`.

Default: `50Mi`

Pattern: `\d+[Ei|Pi|Ti|Gi|Mi|Ki|E|P|T|G|M|k|m]`

- **spec.kubelet.maxPods**
  integer

  Set the max count of pods per node for given `NodeGroup`. When left unspecified, the system automatically determines this limit according to the value of the podSubnetNodeCIDRPrefix ClusterConfiguration parameter:

  - `120` pods for `podSubnetNodeCIDRPrefix` ≥ `24`;
  - `250` pods for `podSubnetNodeCIDRPrefix` = `23`;
  - `500` pods for `podSubnetNodeCIDRPrefix` = `22`;
  - `1000` pods for `podSubnetNodeCIDRPrefix` ≤ `21`.
- **spec.kubelet.rootDir**
  string

  Directory path for managing kubelet files (volume mounts,etc).

  Default: `/var/lib/kubelet`

- **spec.kubernetesVersion**
  string

  The desired minor version of Kubernetes.

  By default, it corresponds to the version selected for the cluster globally (see installation documentation) or to the current version of the control plane (if the global version is not defined).

  Allowed values: `1.31`, `1.32`, `1.33`, `1.34`, `1.35`

  Example:

  ```
  kubernetesVersion: '1.32'
  ```

- **spec.nodeTemplate**
  object

  Specification of some of the fields that will be maintained in all nodes of the group.

  Example:

  ```
  nodeTemplate:
    labels:
      environment: production
      app: warp-drive-ai
    annotations:
      ai.fleet.com/discombobulate: 'true'
    taints:
    - effect: NoExecute
      key: ship-class
      value: frigate
  ```

  - **spec.nodeTemplate.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

    ```
    annotations:
      ai.fleet.com/discombobulate: 'true'
    ```

  - **spec.nodeTemplate.labels**
    object

    Similar to the standard `metadata.labels` field.

    Example:

    ```
    labels:
      environment: production
      app: warp-drive-ai
    ```

- **spec.nodeTemplate.taints**
  array of objects

  Similar to the `.spec.taints` field of the Node object.

  > **i** Available fields: `effect`, `key`, and `values`.

  Example:

  ```
  taints:
  - effect: NoExecute
    key: ship-class
    value: frigate
  ```

  - **spec.nodeTemplate.taints.effect**
    string

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.nodeTemplate.taints.key**
    string
  - **spec.nodeTemplate.taints.value**
    string

- **spec.nodeType**
  string

  Required value

  The type of nodes this group provides.

  - `Cloud` — nodes for this group will be automatically created (and deleted) in the cloud of the specified cloud provider;
  - `Static` — a static node hosted on a bare metal or virtual machine. The cloud-controller-manager does not manage the node even of one of the cloud providers is enabled;
  - `Hybrid` — a static node (created manually or using any external tools) hosted in the cloud integrated with one of the cloud provider. This node has the CSI running, and it is managed by the cloud-controller-manager: the Node object automatically gets the information about the zone and region based on the cloud data; if a node gets deleted from the cloud, its corresponding Node object will be deleted in Kubernetes.

  Allowed values: `Cloud`, `Static`, `Hybrid`

- **spec.operatingSystem**
  Deprecated
  object

  Operating System settings for nodes.

  - **spec.operatingSystem.manageKernel**
    Deprecated
    boolean

    Enable kernel maintenance from bashible.

    Default: `true`

- **spec.static**
  object

  Static node parameters

  - **spec.static.internalNetworkCIDRs**
    array of strings

    Subnet CIDR

NodeGroupConfiguration

Short names: ngc

Scope: Cluster
Version: v1alpha1

Executes bash scripts on nodes.

Read more in the module documentation.

- **spec**
  object

  Required value

  - **spec.bundles**
    array of strings

    Required value

    Bundles for step execution. You can set `'*'` for selecting all bundles.

    Examples:

    ```
    bundles:
    - ubuntu-lts
    - centos-7
    ```

    ```
    bundles:
    - ubuntu-lts
    ```

    ```
    bundles:
    - "*"
    ```

    - **Element of the array**
      string

      Allowed values: `ubuntu-lts`, `centos`, `debian`, `redos`, `rosa`, `astra`, `altlinux`, `opensuse`, `*`

  - **spec.content**
    string

    Required value

    A bash script that does the same things you would do in a configuration step.

    You can use Go Template to generate a script.

    The list of parameters available for use in templates can be retrieved from the `bashible-apiserver-context` Secret as follows:

    ```
    d8 k -n d8-cloud-instance-manager get secrets bashible-apiserver-context -o
    jsonpath='{.data.input\.yaml}'| base64 -d
    ```

    For example:

    ```
    {{- range .nodeUsers }}
    echo 'Tuning environment for user {{ .name }}'
    # Some code for tuning user environment
    {{- end }}
    ```

    You can also use the pre-defined bashbooster commands in the script. For example:

    ```
    bb-event-on 'bb-package-installed' 'post-install'
    post-install() {
      bb-log-info "Setting reboot flag due to kernel was updated"
      bb-flag-set reboot
    }
    ```

    Example of using the proxy parameters of ClusterConfiguration resource:

    ```
    bb-set-proxy
    curl -I https://google.com
    bb-unset-proxy
    ```

```
test-function-with-proxy() {
  bb-set-proxy
  trap bb-unset-proxy RETURN
  curl -I https://google.com
}
test-function-with-proxy
```

- **spec.nodeGroups**
  array of strings

  Required value

  List of NodeGroups to apply the step for. You can set `'*'` for selecting all NodeGroups.

  Examples:

  ```
  nodeGroups:
  - master
  - worker
  ```

  ```
  nodeGroups:
  - worker
  ```

  ```
  nodeGroups:
  - "*"
  ```

- **spec.weight**
  integer

  Order of the step execution.

  Default: `100`

NodeUser

Scope: Cluster

- v1
- v1alpha1

Defines the linux users to create on all nodes.

The user's home directory is created in the `/home/deckhouse/` directory.

- **spec**
  object

  Required value

  - **spec.extraGroups**
    array of strings

    Node user additional system groups.

    Examples:

    ```
    extraGroups:
    - docker
    ```

    ```
    extraGroups:
    - docker
    - ftp
    ```

  - **spec.isSudoer**
    boolean

    Persistence of node user in sudo group.

    Default: `false`

    Example:

```
isSudoer: true
```

- **spec.nodeGroups**
  array of strings

  List of NodeGroups to apply the user for.

  Default: `["*"]`

  Examples:

  ```
  nodeGroups:
  - master
  - worker
  ```

  ```
  nodeGroups:
  - worker
  ```

  ```
  nodeGroups:
  - "*"
  ```

- **spec.passwordHash**
  string

  Hashed user password.

  The format corresponds to the password hashes in `/etc/shadow`. You can get it using the following command: `openssl passwd -6`.

  Example:

  ```
  passwordHash: "$2a$10$F9ey7zW.sVliT224RFxpWeMsgzO.D9YRG54a8T36/K2MCiT41nzmC"
  ```

- **spec.sshPublicKey**
  Deprecated
  string

  Node user SSH public key.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKey: ssh-rsa AAABBB
  ```

- **spec.sshPublicKeys**
  array of strings

  Node user SSH public keys.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKeys:
  - ssh-rsa AAABBB
  - cert-authority,principals="name" ssh-rsa BBBCCC
  ```

- **spec.uid**
  number

  Required value

  Node user ID.

  We recommend using the values `>= 1100` to avoid conflicts with manually created users.

  This parameter does not change during the entire resource life.

  Allowed values: `1001 <= X`

  Example:

```
uid: 1100
```

- **status**
  object

  User creation status information

  - **status.errors**
    object

    List of user creation errors on each node

Deprecated resource. Support for the resource might be removed in a later release.

Defines the linux users to create on all nodes.

The user’s home directory is created in the `/home/deckhouse/` directory.

- **spec**
  object

  Required value

  - **spec.extraGroups**
    array of strings

    Node user additional system groups.

    Examples:

    ```
    extraGroups:
    - docker
    ```

    ```
    extraGroups:
    - docker
    - ftp
    ```

  - **spec.isSudoer**
    boolean

    Persistence of node user in sudo group.

    Default: `false`

    Example:

    ```
    isSudoer: true
    ```

  - **spec.nodeGroups**
    array of strings

    List of NodeGroups to apply the user for.

    Default: `["*"]`

    Examples:

    ```
    nodeGroups:
    - master
    - worker
    ```

    ```
    nodeGroups:
    - worker
    ```

    ```
    nodeGroups:
    - "*"
    ```

  - **spec.passwordHash**
    string

    Hashed user password.

    The format corresponds to the password hashes in `/etc/shadow`. You can get it using the following command: `openssl passwd -6`.

Example:

```
passwordHash: "$2a$10$F9ey7zW.sVliT224RFxpWeMsgzO.D9YRG54a8T36/K2MCiT41nzmC"
```

- **spec.sshPublicKey**
  Deprecated
  string

  Node user SSH public key.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKey: ssh-rsa AAABBB
  ```

- **spec.sshPublicKeys**
  array of strings

  Node user SSH public keys.

  Either `sshPublicKey` or `sshPublicKeys` **must** be specified.

  Example:

  ```
  sshPublicKeys:
  - ssh-rsa AAABBB
  - cert-authority,principals="name" ssh-rsa BBBCCC
  ```

- **spec.uid**
  number

  Required value

  Node user ID.

  We recommend using the values `>= 1100` to avoid conflicts with manually created users.

  This parameter does not change during the entire resource life.

  Allowed values: `1001 <= X`

  Example:

  ```
  uid: 1100
  ```

SSHCredentials

Scope: Cluster

- v1alpha2
- v1alpha1

Contains credentials required by Cluster API Provider Static (CAPS) to connect over SSH. CAPS connects to the server (virtual machine) defined in the StaticInstance custom resource to manage its state.

A reference to this resource is specified in the credentialsRef parameter of the `StaticInstance` resource.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

SSHCredentialsSpec defines the desired state of SSHCredentials.

- **spec.privateSSHKey**
  string

  Private SSH key in PEM format encoded as base64 string.

- **spec.sshExtraArgs**
  string

  A list of additional arguments to pass to the openssh command.

  Examples:

  ```
  sshExtraArgs: "-vvv"
  ```

  ```
  sshExtraArgs: "-c chacha20-poly1305@openssh.com"
  ```

  ```
  sshExtraArgs: "-c aes256-gcm@openssh.com"
  ```

  ```
  sshExtraArgs: "-m umac-64-etm@openssh.com"
  ```

  ```
  sshExtraArgs: "-m hmac-sha2-512-etm@openssh.com"
  ```

- **spec.sshPort**
  integer

  A port to connect to the host via SSH.

  Default: `22`

  Allowed values: `1 <= X <= 65535`

- **spec.sudoPasswordEncoded**
  string

  Base64 encoded sudo password for the user.

- **spec.user**
  string

  Required value

  A username to connect to the host via SSH.

Contains credentials required by Cluster API Provider Static (CAPS) to connect over SSH. CAPS connects to the server (virtual machine) defined in the StaticInstance custom resource to manage its state.

A reference to this resource is specified in the credentialsRef parameter of the `StaticInstance` resource.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  SSHCredentialsSpec defines the desired state of SSHCredentials.

  - **spec.privateSSHKey**
    string

    Private SSH key in PEM format encoded as base64 string.

  - **spec.sshExtraArgs**

string

A list of additional arguments to pass to the openssh command.

Examples:

```
sshExtraArgs: "-vvv"
```

```
sshExtraArgs: "-c chacha20-poly1305@openssh.com"
```

```
sshExtraArgs: "-c aes256-gcm@openssh.com"
```

```
sshExtraArgs: "-m umac-64-etm@openssh.com"
```

```
sshExtraArgs: "-m hmac-sha2-512-etm@openssh.com"
```

- **spec.sshPort**
  integer

  A port to connect to the host via SSH.

  Default: `22`

  Allowed values: `1 <= X <= 65535`

- **spec.sudoPassword**
  string

  A sudo password for the user.

- **spec.user**
  string

  Required value

  A username to connect to the host via SSH.

StaticInstance

Scope: Cluster

- v1alpha2
- v1alpha1

StaticInstance describes a machine for the Cluster API Provider Static.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  StaticInstanceSpec defines the desired state of StaticInstance.

  - **spec.address**
    string

    Required value

    The IP address of the host.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **spec.credentialsRef**

object

Required value

The reference to the `SSHCredentials` object.

- **spec.credentialsRef.apiVersion**
  string

  API version of the referent.

- **spec.credentialsRef.fieldPath**
  string

  If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

- **spec.credentialsRef.kind**
  string

  Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **spec.credentialsRef.name**
  string

  Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.credentialsRef.namespace**
  string

  Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

- **spec.credentialsRef.resourceVersion**
  string

  Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

- **spec.credentialsRef.uid**
  string

  UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status**
  object

  StaticInstanceStatus defines the observed state of StaticInstance.

  - **status.conditions**
    array of objects

    Conditions defines current service state of the StaticInstance.

    Condition contains details for one aspect of the current state of this API Resource.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

    - **status.conditions.message**
      string

      Required value

      message is a human readable message indicating details about the transition. This may be an empty string.

Maximum length: `32768`

- **status.conditions.observedGeneration**
  integer

  observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

  Allowed values: `0 <= X`

- **status.conditions.reason**
  string

  Required value

  reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

  Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

  Length: `1..1024`

- **status.conditions.status**
  string

  Required value

  status of the condition, one of True, False, Unknown.

  Allowed values: `True`, `False`, `Unknown`

- **status.conditions.type**
  string

  Required value

  type of condition in CamelCase or in foo.example.com/CamelCase.

  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

  Maximum length: `316`

- **status.currentStatus**
  object
  - **status.currentStatus.lastUpdateTime**
    string
  - **status.currentStatus.phase**
    string

    Allowed values: `Error`, `Pending`, `Bootstrapping`, `Running`, `Cleaning`

- **status.machineRef**
  object

  The reference to the `StaticMachine` object.

  - **status.machineRef.apiVersion**
    string

    API version of the referent.

  - **status.machineRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: "spec.containers{name}" (where "name" refers to the name of the container that triggered the event) or if no container name is specified "spec.containers[2]" (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **status.machineRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

        - **status.machineRef.name**
          string

          Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **status.machineRef.namespace**
          string

          Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

        - **status.machineRef.resourceVersion**
          string

          Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

        - **status.machineRef.uid**
          string

          UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

    - **status.nodeRef**
      object

      The reference to the `Node` object.

        - **status.nodeRef.apiVersion**
          string

          API version of the referent.

        - **status.nodeRef.fieldPath**
          string

          If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

        - **status.nodeRef.kind**
          string

          Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

        - **status.nodeRef.name**
          string

          Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **status.nodeRef.namespace**
          string

          Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

        - **status.nodeRef.resourceVersion**
          string

          Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

        - **status.nodeRef.uid**
          string

          UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

StaticInstance describes a machine for the Cluster API Provider Static.

- **apiVersion**
  string

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  StaticInstanceSpec defines the desired state of StaticInstance.

  - **spec.address**
    string

    Required value

    The IP address of the host.

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

  - **spec.credentialsRef**
    object

    Required value

    The reference to the `SSHCredentials` object.

    - **spec.credentialsRef.apiVersion**
      string

      API version of the referent.

    - **spec.credentialsRef.fieldPath**
      string

      If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

    - **spec.credentialsRef.kind**
      string

      Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

    - **spec.credentialsRef.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.credentialsRef.namespace**
      string

      Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

    - **spec.credentialsRef.resourceVersion**
      string

      Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

    - **spec.credentialsRef.uid**
      string

      UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status**

object

StaticInstanceStatus defines the observed state of StaticInstance.

- **status.conditions**
  array of objects

  Conditions defines current service state of the StaticInstance.

  Condition contains details for one aspect of the current state of this API Resource.

  - **status.conditions.lastTransitionTime**
    string

    Required value

    lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

  - **status.conditions.message**
    string

    Required value

    message is a human readable message indicating details about the transition. This may be an empty string.

    Maximum length: `32768`

  - **status.conditions.observedGeneration**
    integer

    observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

    Allowed values: `0 <= X`

  - **status.conditions.reason**
    string

    Required value

    reason contains a programmatic identifier indicating the reason for the condition’s last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

    Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

    Length: `1..1024`

  - **status.conditions.status**
    string

    Required value

    status of the condition, one of True, False, Unknown.

    Allowed values: `True`, `False`, `Unknown`

  - **status.conditions.type**
    string

    Required value

    type of condition in CamelCase or in foo.example.com/CamelCase.

    Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

    Maximum length: `316`

- **status.currentStatus**
  object
  - **status.currentStatus.lastUpdateTime**
    string
  - **status.currentStatus.phase**
    string

    Allowed values: `Error`, `Pending`, `Bootstrapping`, `Running`, `Cleaning`

- **status.machineRef**
  object

  The reference to the `StaticMachine` object.

  - **status.machineRef.apiVersion**
    string

    API version of the referent.

  - **status.machineRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **status.machineRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

  - **status.machineRef.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **status.machineRef.namespace**
    string

    Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

  - **status.machineRef.resourceVersion**
    string

    Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

  - **status.machineRef.uid**
    string

    UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

- **status.nodeRef**
  object

  The reference to the `Node` object.

  - **status.nodeRef.apiVersion**
    string

    API version of the referent.

  - **status.nodeRef.fieldPath**
    string

    If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as desiredState.manifest.containers[2]. For example, if the object reference is to a container within a pod, this would take on a value like: “spec.containers{name}” (where “name” refers to the name of the container that triggered the event) or if no container name is specified “spec.containers[2]” (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

  - **status.nodeRef.kind**
    string

    Kind of the referent. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

  - **status.nodeRef.name**
    string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **status.nodeRef.namespace**
  string

  Namespace of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/

- **status.nodeRef.resourceVersion**
  string

  Specific resourceVersion to which this reference is made, if any. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency

- **status.nodeRef.uid**
  string

  UID of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids

FAQ

> **i** The module lifecycle stage: General Availability

How do I add master nodes to a cloud cluster?

For the procedure of converting a cluster with a single master node to a multi-master cluster, refer to the FAQ of the `control-plane-manager` module.

How do I reduce the number of master nodes in a cloud cluster?

For the procedure of converting a multi-master cluster to a cluster with a single master node, refer to the FAQ of the `control-plane-manager` module.

Static nodes

You can add a static node to the cluster manually (an example) or by using Cluster API Provider Static.

How do I add a static node to a cluster (Cluster API Provider Static)?

To add a static node to a cluster (bare metal server or virtual machine), follow these steps:

1. Prepare the required resources:
   - Allocate a server or virtual machine and ensure that the node has the necessary network connectivity with the cluster.
   - If necessary, install additional operating system packages and configure the mount points that will be used on the node.
2. Create a user with `sudo` privileges:
   - Add a new user (in this example, `caps`) with `sudo` privileges:

     ```
     useradd -m -s /bin/bash caps
     usermod -aG sudo caps
     ```

   - Allow the user to run `sudo` commands without having to enter a password. For this, add the following line to the `sudo` configuration on the server (you can either edit the `/etc/sudoers` file, or run the `sudo visudo` command, or use some other method):

     ```
     caps ALL=(ALL) NOPASSWD: ALL
     ```

3. Set `UsePAM` to `yes` in `/etc/ssh/sshd_config` on server and restart sshd service:

   ```
   sudo systemctl restart sshd
   ```

4. Generate a pair of SSH keys with an empty passphrase on the server:

```
ssh-keygen -t ed25519 -f caps-id -C "" -N ""
```

The public and private keys of the caps user will be stored in the `caps-id.pub` and `caps-id` files in the current directory on the server.

5. Add the generated public key to the `/home/caps/.ssh/authorized_keys` file of the `caps` user by executing the following commands in the keys directory on the server:

```
mkdir -p /home/caps/.ssh
cat caps-id.pub >> /home/caps/.ssh/authorized_keys
chmod 700 /home/caps/.ssh
chmod 600 /home/caps/.ssh/authorized_keys
chown -R caps:caps /home/caps/
```

6. Create the SSHCredentials resource.
7. Create the StaticInstance resource.
8. Create the NodeGroup resource with the `Static` nodeType, specify the desired number of nodes in the group and, if necessary, the filter for `StaticInstance`.

An example of adding a static node.

How do I add a batch of static nodes to a cluster manually?

Use an existing one or create a new NodeGroup custom resource (example of the `NodeGroup` called `worker`). The nodeType parameter for static nodes in the NodeGroup must be `Static` or `CloudStatic`.

You can automate the bootstrap process with any automation platform you prefer. The following is an example for Ansible.

1. Pick up one of Kubernetes API Server endpoints. Note that this IP must be accessible from nodes that are being added to the cluster:

```
d8 k -n default get ep kubernetes -o json | jq '.subsets[0].addresses[0].ip + ":" +
(.subsets[0].ports[0].port | tostring)' -r
```

Check the K8s version. If the version >= 1.25, create `node-group` token:

```
d8 k create token node-group --namespace d8-cloud-instance-manager --duration 1h
```

Save the token you got and add it to the `token:` field of the Ansible playbook in the next steps.

2. If the Kubernetes version is smaller than 1.25, get a Kubernetes API token for a special ServiceAccount that Deckhouse manages:

```
d8 k -n d8-cloud-instance-manager get $(d8 k -n d8-cloud-instance-manager get secret -o name | grep
node-group-token) \
  -o json | jq '.data.token' -r | base64 -d && echo ""
```

3. Create Ansible playbook with `vars` replaced with values from previous steps:

```
- hosts: all
  become: yes
  gather_facts: no
  vars:
    kube_apiserver: <KUBE_APISERVER>
    token: <TOKEN>
  tasks:
    - name: Check if node is already bootsrapped
      stat:
        path: /var/lib/bashible
      register: bootstrapped
    - name: Get bootstrap secret
      uri:
        url: "https://{{ kube_apiserver }}/api/v1/namespaces/d8-cloud-instance-
manager/secrets/manual-bootstrap-for-{{ node_group }}"
        return_content: yes
        method: GET
        status_code: 200
        body_format: json
        headers:
          Authorization: "Bearer {{ token }}"
        validate_certs: no
      register: bootstrap_secret
      when: bootstrapped.stat.exists == False
    - name: Run bootstrap.sh
      shell: "{{ bootstrap_secret.json.data['bootstrap.sh'] | b64decode }}"
      args:
        executable: /bin/bash
      ignore_errors: yes
      when: bootstrapped.stat.exists == False
    - name: wait
      wait_for_connection:
        delay: 30
      when: bootstrapped.stat.exists == False
```

4. Specify one more `node_group` variable. This variable must be the same as the name of `NodeGroup` to which node will belong. Variable can be passed in different ways, for example, by using an inventory file.:

```
[system]
system-0
system-1

[system:vars]
node_group=system

[worker]
worker-0
worker-1

[worker:vars]
node_group=worker
```

5. Run the playbook with the inventory file.

How do I clean up a static node manually?

> **i** This method is valid for both manually configured nodes (using the bootstrap script) and nodes configured using CAPS.

To decommission a node from the cluster and clean up the server (VM), run the following command on the node:

For all nodes except the control-plane

1. Delete a node from the Kubernetes cluster:

```
d8 k drain <node>
d8 k drain <node> --ignore-daemonsets --delete-emptydir-data
d8 k delete pods --all-namespaces --field-selector spec.nodeName=<node> --force
d8 k delete node <node>
```

2. Run the cleanup script on the node:

```
bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
```

3. After restarting the node run the script `bootstrap.sh`.

For control-plane nodes

1. Remove the labels `node-role.kubernetes.io/control-plane`, `node-role.kubernetes.io/master`, and `node.deckhouse.io/group` from the node:

```
d8 k label node <node> node-role.kubernetes.io/control-plane- node-role.kubernetes.io/master- node.deckhouse.io/group-
```

2. Make sure the removed node with control-plane has disappeared from the list of etcd cluster members:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name | head -n1) -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key --endpoints https://127.0.0.1:2379/ member list -w table
```

3. Delete a node from the Kubernetes cluster:

```
d8 k drain <node>
d8 k drain <node> --ignore-daemonsets --delete-emptydir-data
d8 k delete pods --all-namespaces --field-selector spec.nodeName=<node> --force
d8 k delete node <node>
```

4. Run the cleanup script on the node:

```
bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
```

5. After restarting the node run the script `bootstrap.sh`.
6. Wait for the Deckhouse queues to be processed and ensure that the etcd cluster member has reappeared in the list:

```
d8 k -n kube-system exec -ti $(d8 k -n kube-system get pod -l component=etcd,tier=control-plane -o name | head -n1) -- etcdctl --cacert /etc/kubernetes/pki/etcd/ca.crt --cert /etc/kubernetes/pki/etcd/ca.crt --key /etc/kubernetes/pki/etcd/ca.key --endpoints https://127.0.0.1:2379/ member list -w table
```

Can I delete a StaticInstance?

A StaticInstance that is in the `Pending` state can be deleted with no adverse effects.

To delete a StaticInstance in any state other than `Pending` (`Running`, `Cleaning`, `Bootstrapping`), you need to:

1. Add the label `"node.deckhouse.io/allow-bootstrap": "false"` to the StaticInstance.

   Example command for adding a label:

```
d8 k label staticinstance d8cluster-worker node.deckhouse.io/allow-bootstrap=false
```

2. Wait until the StaticInstance status becomes `Pending`.

   To check the status of StaticInstance, use the command:

```
d8 k get staticinstances
```

3. Delete the StaticInstance.

   Example command for deleting StaticInstance:

   ```
   d8 k delete staticinstance d8cluster-worker
   ```

4. Decrease the `NodeGroup.spec.staticInstances.count` field by 1.

How do I change the IP address of a StaticInstance?

You cannot change the IP address in the `StaticInstance` resource. If an incorrect address is specified in `StaticInstance`, you have to delete the StaticInstance and create a new one.

How do I migrate a manually configured static node under CAPS control?

You need to clean up the node, then hand over the node under CAPS control.

How do I change the NodeGroup of a static node?

Note that if a node is under CAPS control, you **cannot** change the `NodeGroup` membership of such a node. The only alternative is to delete StaticInstance and create a new one.

To switch an existing manually created static node to another `NodeGroup`, you need to change its group label:

```
d8 k label node --overwrite <node_name> node.deckhouse.io/group=<new_node_group_name>
d8 k label node <node_name> node-role.kubernetes.io/<old_node_group_name>-
```

Applying the changes will take some time.

How to clean up a node for adding to the cluster?

This is only needed if you have to move a static node from one cluster to another. Be aware these operations remove local storage data. If you just need to change a NodeGroup, follow this instruction.

> ⚠ Evict resources from the node and remove the node from LINSTOR/DRBD using the instruction if the node you are cleaning up has LINSTOR/DRBD storage pools.

1. Delete the node from the Kubernetes cluster:

   ```
   d8 k drain <node> --ignore-daemonsets --delete-emptydir-data
   d8 k delete node <node>
   ```

2. Run cleanup script on the node:

   ```
   bash /var/lib/bashible/cleanup_static_node.sh --yes-i-am-sane-and-i-understand-what-i-am-doing
   ```

3. Run the `bootstrap.sh` script after reboot of the node.

How do I know if something went wrong?

If a node in a nodeGroup is not updated (the value of `UPTODATE` when executing the `d8 k get nodegroup` command is less than the value of `NODES`) or you assume some other problems that may be related to the `node-manager` module, then you need to look at the logs of the `bashible` service. The `bashible` service runs on each node managed by the `node-manager` module.

To view the logs of the `bashible` service on a specific node, run the following command:

```
journalctl -fu bashible
```

Example of output when the `bashible` service has performed all necessary actions:

```
May 25 04:39:16 kube-master-0 systemd[1]: Started Bashible service.
May 25 04:39:16 kube-master-0 bashible.sh[1976339]: Configuration is in sync, nothing to
do.
May 25 04:39:16 kube-master-0 systemd[1]: bashible.service: Succeeded.
```

How do I know what is running on a node while it is being created?

You can analyze `cloud-init` to find out what's happening on a node during the bootstrapping process:

1. Find the node that is currently bootstrapping:

   ```
   d8 k get instances | grep Pending
   ```

   An example:

   ```
   d8 k get instances | grep Pending
   dev-worker-2a6158ff-6764d-nrtbj   Pending   46s
   ```

2. Get information about connection parameters for viewing logs:

   ```
   d8 k get instances dev-worker-2a6158ff-6764d-nrtbj -o yaml | grep 'bootstrapStatus' -B0 -A2
   ```

   An example:

   ```
   d8 k get instances dev-worker-2a6158ff-6764d-nrtbj -o yaml | grep 'bootstrapStatus' -B0 -A2
   bootstrapStatus:
     description: Use 'curl -N http://192.168.199.158:8000' to get bootstrap logs.
     logsEndpoint: http://192.168.199.158:8000
   ```

3. Run the command you got (`curl -N http://192.168.199.158:8000` according to the example above) to see `cloud-init` logs and determine the cause of the problem on the node.

The logs of the initial node configuration are located at `/var/log/cloud-init-output.log`.

How do I update kernel on nodes?

Debian-based distros

Create a `Node Group Configuration` resource by specifying the desired kernel version in the `desired_version` variable of the shell script (the resource's spec.content parameter):

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: install-kernel.sh
spec:
  bundles:
    - '*'
  nodeGroups:
    - '*'
  weight: 32
  content: |
    # Copyright 2022 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");

    desired_version="5.15.0-53-generic"

    bb-event-on 'bb-package-installed' 'post-install'
    post-install() {
      bb-log-info "Setting reboot flag due to kernel was updated"
      bb-flag-set reboot
    }

    version_in_use="$(uname -r)"

    if [[ "$version_in_use" == "$desired_version" ]]; then
      exit 0
    fi

    bb-deckhouse-get-disruptive-update-approval
    bb-apt-install "linux-image-${desired_version}"
```

CentOS-based distros

Create a `Node Group Configuration` resource by specifying the desired kernel version in the `desired_version` variable of the shell script (the resource’s spec.content parameter):

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: install-kernel.sh
spec:
  bundles:
    - '*'
  nodeGroups:
    - '*'
  weight: 32
  content: |
    # Copyright 2022 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    desired_version="3.10.0-1160.42.2.el7.x86_64"

    bb-event-on 'bb-package-installed' 'post-install'
    post-install() {
      bb-log-info "Setting reboot flag due to kernel was updated"
      bb-flag-set reboot
    }

    version_in_use="$(uname -r)"

    if [[ "$version_in_use" == "$desired_version" ]]; then
      exit 0
    fi

    bb-deckhouse-get-disruptive-update-approval
    bb-dnf-install "kernel-${desired_version}"
```

NodeGroup parameters and their result

The NodeGroup parameter	Disruption update	Node provisioning	Kubelet restart
chaos	-	-	-
cloudInstances.classReference	-	+	-
cloudInstances.maxSurgePerZone	-	-	-
cri.containerd.maxConcurrentDownloads	-	-	+
cri.type	- (NotManaged) / + (other)	-	-
disruptions	-	-	-
kubelet.maxPods	-	-	+
kubelet.rootDir	-	-	+
kubernetesVersion	-	-	+
nodeTemplate	-	-	-

The NodeGroup parameter	Disruption update	Node provisioning	Kubelet restart
static	-	-	+
update.maxConcurrent	-	-	-

Refer to the description of the NodeGroup custom resource for more information about the parameters.

When the `InstanceClass` or `instancePrefix` parameters are modified, the process is similar to updating a Deployment in Kubernetes (changing `InstanceClass` results in creating a new MachineSet, and changing `instancePrefix` results in creating a new MachineDeployment). New instances will be created according to the value of the `cloudInstances.maxSurgePerZone` parameter. As the new instances are created, the old ones will be gradually removed, with a drain operation performed beforehand.

During the disruption update, an evict of the pods from the node is performed. If any pod fails to evict, the evict is repeated every 20 seconds until a global timeout of 5 minutes is reached. After that, the pods that failed to evict are removed.

How do I redeploy ephemeral machines in the cloud with a new configuration?

If the Deckhouse configuration is changed (both in the node-manager module and in any of the cloud providers), the VMs will not be redeployed. The redeployment is performed only in response to changing `InstanceClass` or `NodeGroup` objects.

To force the redeployment of all Machines, you need to add/modify the `manual-rollout-id` annotation to the `NodeGroup`: `d8 k annotate NodeGroup name_ng "manual-rollout-id=$(uuidgen)" --overwrite`.

How do I allocate nodes to specific loads?

⚠ You cannot use the `deckhouse.io` domain in `labels` and `taints` keys of the `NodeGroup`. It is reserved for Deckhouse components. Please, use the `dedicated` or `dedicated.client.com` keys.

There are two ways to solve this problem:

1. You can set labels to `NodeGroup`'s `spec.nodeTemplate.labels`, to use them in the `Pod`'s spec.nodeSelector or spec.affinity.nodeAffinity parameters. In this case, you select nodes that the scheduler will use for running the target application.
2. You cat set taints to `NodeGroup`'s `spec.nodeTemplate.taints` and then remove them via the `Pod`'s spec.tolerations parameter. In this case, you disallow running applications on these nodes unless those applications are explicitly allowed.

i Deckhouse tolerates the `dedicated` by default, so we recommend using the `dedicated` key with any `value` for taints on your dedicated nodes.

To use custom keys for `taints` (e.g., `dedicated.client.com`), you must add the key's value to the array `.spec.settings.modules.placement.customTolerationKeys` parameters. This way, deckhouse can deploy system components (e.g., `cni-flannel`) to these dedicated nodes.

How to allocate nodes to system components?

Frontend

For Ingress controllers, use the `NodeGroup` with the following configuration:

```
nodeTemplate:
  labels:
    node-role.deckhouse.io/frontend: ""
  taints:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      value: frontend
```

System components

`NodeGroup` for components of Deckhouse subsystems will look as follows:

```
nodeTemplate:
  labels:
    node-role.deckhouse.io/system: ""
  taints:
    - effect: NoExecute
      key: dedicated.deckhouse.io
      value: system
```

How do I speed up node provisioning on the cloud when scaling applications horizontally?

The most efficient way is to have some extra nodes “ready”. In this case, you can run new application replicas on them almost instantaneously. The obvious disadvantage of this approach is the additional maintenance costs related to these nodes.

Here is how you should configure the target `NodeGroup`:

1. Specify the number of “ready” nodes (or a percentage of the maximum number of nodes in the group) using the `cloudInstances.standby` parameter.
2. If there are additional service components on nodes that are not handled by Deckhouse (e.g., the `filebeat` DaemonSet), you can specify the percentage of node resources they can consume via the `standbyHolder.overprovisioningRate` parameter.
3. This feature requires that at least one group node is already running in the cluster. In other words, there must be either a single replica of the application, or the `cloudInstances.minPerZone` parameter must be set to `1`.

An example:

```
cloudInstances:
  maxPerZone: 10
  minPerZone: 1
  standby: 10%
  standbyHolder:
    overprovisioningRate: 30%
```

How do I disable machine-controller-manager/CAPI in the case of potentially cluster-damaging changes?

✖ Use this switch only if you know what you are doing and clearly understand the consequences.

Set the `mcmEmergencyBrake` parameter to true:

```
mcmEmergencyBrake: true
```

For disabling CAPI, set the `capiEmergencyBrake` parameter to true:

```
capiEmergencyBrake: true
```

How do I restore the master node if kubelet cannot load the control plane components?

Such a situation may occur if images of the control plane components on the master were deleted in a cluster that has a single master node (e.g., the directory `/var/lib/containerd` was deleted). In this case, kubelet cannot pull images of the control plane components when restarted since the master node lacks authorization parameters required for accessing `registry.deckhouse.io`.

Below is an instruction on how you can restore the master node.

containerd

Execute the following command to restore the master node in any cluster running under Deckhouse:

```
d8 k -n d8-system get secrets deckhouse-registry -o json |
jq -r '.data.".dockerconfigjson"' | base64 -d |
jq -r '.auths."registry.deckhouse.io".auth'
```

Copy the command’s output and use it for setting the `AUTH` variable on the corrupted master.

Next, you need to pull images of `control plane` components to the corrupted master:

```
for image in $(grep "image:" /etc/kubernetes/manifests/* | awk '{print $3}'); do
  crictl pull --auth $AUTH $image
done
```

You need to restart `kubelet` after pulling the images.

How to change CRI for NodeGroup?

⚠ CRI can only be switched from `Containerd` to `NotManaged` and back (the cri.type parameter).

Set NodeGroup `cri.type` to `Containerd` or `NotManaged`.

NodeGroup YAML example:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  cri:
    type: Containerd
```

Also, this operation can be done with patch:

- For `Containerd`:

  ```
  d8 k patch nodegroup <NodeGroup name> --type merge -p '{"spec":{"cri":{"type":"Containerd"}}}'
  ```

- For `NotManaged`:

  ```
  d8 k patch nodegroup <NodeGroup name> --type merge -p '{"spec":{"cri":{"type":"NotManaged"}}}'
  ```

⚠ While changing `cri.type` for NodeGroups, created using `dhctl`, you must change it in `dhctl config edit provider-cluster-configuration` and in `NodeGroup` object.

After setting up a new CRI for NodeGroup, the node-manager module drains nodes one by one and installs a new CRI on them. Node update is accompanied by downtime (disruption). Depending on the `disruption` setting for NodeGroup, the node-manager module either automatically allows node updates or requires manual confirmation.

Why might the CRI change not apply?

When attempting to switch the CRI, the changes may not take effect. The most common reason is the presence of special node labels: `node.deckhouse.io/containerd-v2-unsupported` and `node.deckhouse.io/containerd-config=custom`.

The `node.deckhouse.io/containerd-v2-unsupported` label is set to a node if at least one of the following conditions is true:

- Kernel version lower than 5.8
- Linux kernel version is in the range 6.12.0–6.12.28 or 6.14.0–6.14.6 (these versions are affected by CVE-2025-37999 in EROFS)
- systemd version lower than 244
- cgroup v2 is disabled
- EROFS file system is unavailable.

The `node.deckhouse.io/containerd-config=custom` label is set if the node contains `.toml` files in the `/etc/containerd/conf.d/` (if CRI containerd v1 is used on the cluster nodes) or `/etc/containerd/conf2.d/` (if CRI containerd v2 is used on the cluster nodes) directories. In this case, you should remove such files (provided this will not have critical impact on running containers) and delete the corresponding NodeGroupConfiguration (NGC) resources through which they may have been added.

If the Deckhouse Virtualization Platform is used, an additional reason why the CRI may fail to switch can be the `containerd-dvcr-config.sh` NGC. If the virtualization platform is already installed and running, this

NGC can be removed.

If you cannot remove the NodeGroupConfiguration resource that modifies the containerd configuration and is incompatible with containerd v2, use the universal template:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
spec:
  bundles:
  - '*'
  content: |
    {{- if eq .cri "ContainerdV2" }}
  # <Script to modify the configuration for ContainerdV2>.
    {{- else }}
  # <Script to modify the configuration for ContainerdV1>.
    {{- end }}
  nodeGroups:
  - '*'
  weight: 31
```

Additionally, to switch the CRI you may need to remove the custom label `node.deckhouse.io/containerd-config=custom`. You can do this with the following command:

```
for node in $(d8 k get nodes -l node-role.kubernetes.io/<Name of NodeGroup where CRI is changed>=); do kubectl label $node node.deckhouse.io/containerd-config-; done
```

How to change CRI for the whole cluster?

⚠ CRI can only be switched from `Containerd` to `NotManaged` and back (the cri.type parameter).

It is necessary to use the `dhctl` utility to edit the `defaultCRI` parameter in the `cluster-configuration` config.

Also, this operation can be done with the following patch:

- For `Containerd`:

  ```
  data="$(d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r '.data."cluster-configuration.yaml"' | base64 -d | sed "s/NotManaged/Containerd/" | base64 -w0)"
  d8 k -n kube-system patch secret d8-cluster-configuration -p "{\"data\":{\"cluster-configuration.yaml\":\"$data\"}}"
  ```

- For `NotManaged`:

  ```
  data="$(d8 k -n kube-system get secret d8-cluster-configuration -o json | jq -r '.data."cluster-configuration.yaml"' | base64 -d | sed "s/Containerd/NotManaged/" | base64 -w0)"
  d8 k -n kube-system patch secret d8-cluster-configuration -p "{\"data\":{\"cluster-configuration.yaml\":\"$data\"}}"
  ```

If it is necessary to leave some NodeGroup on another CRI, then before changing the `defaultCRI` it is necessary to set CRI for this NodeGroup, as described here.

✖ Changing `defaultCRI` entails changing CRI on all nodes, including master nodes. If there is only one master node, this operation is dangerous and can lead to a complete failure of the cluster! The preferred option is to make a multi-master and change the CRI type.

When changing the CRI in the cluster, additional steps are required for the master nodes:

1. Deckhouse updates nodes in master NodeGroup one by one, so you need to discover which node is updating right now:

```
d8 k get nodes -l node-role.kubernetes.io/control-plane="" -o json | jq '.items[] |
select(.metadata.annotations."update.node.deckhouse.io/approved"=="") |
.metadata.name' -r
```

2. Confirm the disruption of the master node that was discovered in the previous step:

   ```
   d8 k annotate node <master node name> update.node.deckhouse.io/disruption-approved=
   ```

3. Wait for the updated master node to switch to `Ready` state. Repeat steps for the next master node.

How to add node configuration step?

Additional node configuration steps are set via the NodeGroupConfiguration custom resource.

How to automatically put custom labels on the node?

1. On the node, create the directory `/var/lib/node_labels`.
2. Create a file or files containing the necessary labels in it. The number of files can be any, as well as the number of subdirectories containing them.
3. Add the necessary labels to the files in the `key=value` format. For example:

   ```
   example-label=test
   ```

4. Save the files.

When adding a node to the cluster, the labels specified in the files will be automatically affixed to the node.

⚠ Please note that it is not possible to add labels used in DKP in this way. This method will only work with custom labels that do not overlap with those reserved for Deckhouse.

How to deploy custom containerd configuration?

i The example of `NodeGroupConfiguration` uses functions of the script 032_configure_containerd.sh.

✖ Adding custom settings causes a restart of the containerd service.

Bashible on nodes merges main DKP containerd configuration with the following configuration files:

- `/etc/containerd/conf.d/*.toml`: If containerd v1 is used as the CRI on the cluster nodes.
- `/etc/containerd/conf2.d/*.toml`: If containerd v2 is used as the CRI on the cluster nodes.

⚠ You can override the values of the parameters that are specified in the file `/etc/containerd/deckhouse.toml`, but you will have to ensure their functionality on your own. Also, it is better not to change the configuration for the master nodes (nodeGroup `master`).

The following are configuration examples of the NodeGroupConfiguration resources adding a custom configuration file for a corresponding containerd version.

- For containerd v1
- For containerd v2

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-option-config.sh
spec:
  bundles:
    - '*'
  content: |

    mkdir -p /etc/containerd/conf2.d
    bb-sync-file /etc/containerd/conf2.d/runtimeclass.toml - << "EOF"
    [plugins."io.containerd.cri.v1.runtime".containerd.runtimes.gpu-large-shm]
      runtime_type = "io.containerd.runc.v2"
      [plugins."io.containerd.cri.v1.runtime".containerd.runtimes.gpu-large-shm.options]
        BinaryName = ""
        SystemdCgroup = true
        ShmSize = 17179869184
    EOF
  nodeGroups:
    - "worker"
  weight: 31
```

How to add configuration for an additional registry?

Containerd supports two methods for registry configuration: the **deprecated** method and the **actual** method.

To check for the presence of the **deprecated** configuration method, run the following commands on the cluster nodes:

```
cat /etc/containerd/config.toml | grep 'plugins."io.containerd.grpc.v1.cri".registry.mirrors'
cat /etc/containerd/config.toml | grep 'plugins."io.containerd.grpc.v1.cri".registry.configs'

# Example output:
# [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
#   [plugins."io.containerd.grpc.v1.cri".registry.mirrors."<REGISTRY_URL>"]
# [plugins."io.containerd.grpc.v1.cri".registry.configs]
#   [plugins."io.containerd.grpc.v1.cri".registry.configs."<REGISTRY_URL>".auth]
```

To check for the presence of the **actual** configuration method, run the following command on the cluster nodes:

```
cat /etc/containerd/config.toml | grep '/etc/containerd/registry.d'

# Example output:
# config_path = "/etc/containerd/registry.d"
```

Old Method

⚠ This containerd configuration format is deprecated.

i Used in containerd v1 when Deckhouse is not managed by the Registry module.

The configuration is described in the main containerd configuration file `/etc/containerd/config.toml`.

Adding custom configuration is carried out through the `toml merge` mechanism. Configuration files from the `/etc/containerd/conf.d` directory are merged with the main file `/etc/containerd/config.toml`. The merge takes place during the execution of the `032_configure_containerd.sh` script, so the corresponding files must be added in advance.

Example configuration file for the `/etc/containerd/conf.d/` directory:

```
[plugins]
  [plugins."io.containerd.grpc.v1.cri"]
    [plugins."io.containerd.grpc.v1.cri".registry]
      [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
        [plugins."io.containerd.grpc.v1.cri".registry.mirrors."${REGISTRY_URL}"]
          endpoint = ["https://${REGISTRY_URL}"]
      [plugins."io.containerd.grpc.v1.cri".registry.configs]
        [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".auth]
          auth = "${BASE_64_AUTH}"
          username = "${USERNAME}"
          password = "${PASSWORD}"
        [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".tls]
          ca_file = "${CERT_DIR}/${CERT_NAME}.crt"
          insecure_skip_verify = true
```

✖ Adding custom settings through the `toml merge` mechanism causes the containerd service to restart.

How to add additional registry auth (deprecated method)?

Example of adding authorization to a additional registry when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step.
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."${REGISTRY_URL}"]
              endpoint = ["https://${REGISTRY_URL}"]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]
            [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".auth]
              username = "username"
              password = "password"
              # OR
              auth = "dXNlcm5hbWU6cGFzc3dvcmQ="
    EOF
```

How to configure a certificate for an additional registry (deprecated method)?

Example of configuring a certificate for an additional registry when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-tls.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step.
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example
    CERT_FILE_NAME=${REGISTRY_URL}
    CERTS_FOLDER="/var/lib/containerd/certs/"

    mkdir -p ${CERTS_FOLDER}
    bb-sync-file "${CERTS_FOLDER}/${CERT_FILE_NAME}.crt" - << EOF
    -----BEGIN CERTIFICATE-----
    ...
    -----END CERTIFICATE-----
    EOF

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]
            [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".tls]
              ca_file = "${CERTS_FOLDER}/${CERT_FILE_NAME}.crt"
    EOF
```

i In addition to containerd, the certificate can be added into the OS.

How to add TLS skip verify (deprecated method)?

Example of adding TLS skip verify when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-skip-tls.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step.
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]
            [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".tls]
              insecure_skip_verify = true
    EOF
```

After applying the configuration file, verify access to the registry from the nodes using the command:

```
# Via the CRI interface
crictl pull private.registry.example/image/repo:tag
```

How to set up a mirror for public image registries (deprecated method)?

Example of configuring a mirror for public image registries when using the **deprecated** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: mirror-to-harbor.sh
spec:
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    sed -i '/endpoint = \["https:\/\/registry-1.docker.io"\]/d'
/var/lib/bashible/bundle_steps/032_configure_containerd.sh
    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/mirror-to-harbor.toml - << "EOF"
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."docker.io"]
              endpoint = ["https://registry.private.network/v2/dockerhub-proxy/"]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."gcr.io"]
              endpoint = ["https://registry.private.network/v2/YOUR_GCR_PROXY_REPO/"]
    EOF
```

New Method

> **i** Used in containerd v2.
>
> Used in containerd v1 when managed through the `registry` module (for example, in `Direct` mode).

The configuration is defined in the `/etc/containerd/registry.d` directory.
Configuration is specified by creating subdirectories named after the registry address:

```
/etc/containerd/registry.d
├── private.registry.example:5001
│   ├── ca.crt
│   └── hosts.toml
└── registry.deckhouse.io
    ├── ca.crt
    └── hosts.toml
```

Example contents of the `hosts.toml` file:

```
[host]
  # Mirror 1.
  [host."https://${REGISTRY_URL_1}"]
    capabilities = ["pull", "resolve"]
    ca = ["${CERT_DIR}/${CERT_NAME}.crt"]

    [host."https://${REGISTRY_URL_1}".auth]
      username = "${USERNAME}"
      password = "${PASSWORD}"

  # Mirror 2.
  [host."http://${REGISTRY_URL_2}"]
    capabilities = ["pull", "resolve"]
    skip_verify = true
```

i Configuration changes do not cause the containerd service to restart.

How to add additional registry auth (actual method)?

Example of adding authorization to a additional registry when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required.
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        [host."https://${REGISTRY_URL}".auth]
          username = "username"
          password = "password"
    EOF
```

How to configure a certificate for an additional registry (actual method)?

Example of configuring a certificate for an additional registry when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-tls.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required.
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"

    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/ca.crt" - << EOF
    -----BEGIN CERTIFICATE-----
    ...
    -----END CERTIFICATE-----
    EOF

    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        ca = ["/etc/containerd/registry.d/${REGISTRY_URL}/ca.crt"]
    EOF
```

i In addition to containerd, the certificate can be added into the OS.

How to add TLS skip verify (actual method)?

Example of adding TLS skip verify when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-skip-tls.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required.
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        skip_verify = true
    EOF
```

After applying the configuration file, check access to the registry from the nodes using the following commands:

```
# Via the CRI interface.
crictl pull private.registry.example/image/repo:tag

# Via ctr with the configuration directory specified.
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/ private.registry.example/image/repo:tag

# Via ctr for an HTTP registry.
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/ --plain-http
private.registry.example/image/repo:tag
```

How to set up a mirror for public image registries (actual method)?

Example of configuring a mirror for public image registries when using the **actual** configuration method:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: mirror-to-harbor.sh
spec:
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY1_URL=docker.io
    mkdir -p "/etc/containerd/registry.d/${REGISTRY1_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY1_URL}/hosts.toml" - << EOF
    [host."https://registry.private.network/v2/dockerhub-proxy/"]
      capabilities = ["pull", "resolve"]
      override_path = true
    EOF
    REGISTRY2_URL=gcr.io
    mkdir -p "/etc/containerd/registry.d/${REGISTRY2_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY2_URL}/hosts.toml" - << EOF
    [host."https://registry.private.network/v2/dockerhub-proxy/"]
      capabilities = ["pull", "resolve"]
      override_path = true
    EOF
```

How to use NodeGroup’s priority feature

The priority field of the `NodeGroup` CustomResource allows you to define the order in which nodes will be provisioned in the cluster. For example, `cluster-autoscaler` can first provision *spot-nodes* and switch to regular ones when they run out. Or it can provision larger nodes when there are plenty of resources in the cluster and then switch to smaller nodes once cluster resources run out.

Here is an example of creating two `NodeGroups` using spot-node nodes:

```
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker-spot
spec:
  cloudInstances:
    classReference:
      kind: AWSInstanceClass
      name: worker-spot
    maxPerZone: 5
    minPerZone: 0
    priority: 50
  nodeType: CloudEphemeral
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  cloudInstances:
    classReference:
      kind: AWSInstanceClass
      name: worker
    maxPerZone: 5
    minPerZone: 0
    priority: 30
  nodeType: CloudEphemeral
```

In the above example, `cluster-autoscaler` will first try to provision a spot-node. If it fails to add such a node to the cluster within 15 minutes, the `worker-spot` NodeGroup will be paused (for 20 minutes), and `cluster-autoscaler` will start provisioning nodes from the `worker` NodeGroup. If, after 30 minutes, another node needs to be deployed in the cluster, `cluster-autoscaler` will first attempt to provision a node from the `worker-spot` NodeGroup before provisioning one from the `worker` NodeGroup.

Once the `worker-spot` NodeGroup reaches its maximum (5 nodes in the example above), the nodes will be provisioned from the `worker` NodeGroup.

Note that node templates (labels/taints) for `worker` and `worker-spot` NodeGroups must be the same (or at least suitable for the load that triggers the cluster scaling process).

How to interpret Node Group states?

Ready — the node group contains the minimum required number of scheduled nodes with the status `Ready` for all zones.

Example 1. A group of nodes in the `Ready` state:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: ng1
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    maxPerZone: 5
    minPerZone: 1
status:
  conditions:
  - status: "True"
    type: Ready
---
apiVersion: v1
kind: Node
metadata:
  name: node1
  labels:
    node.deckhouse.io/group: ng1
status:
  conditions:
  - status: "True"
    type: Ready
```

Example 2. A group of nodes in the `Not Ready` state:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: ng1
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    maxPerZone: 5
    minPerZone: 2
status:
  conditions:
  - status: "False"
    type: Ready
---
apiVersion: v1
kind: Node
metadata:
  name: node1
  labels:
    node.deckhouse.io/group: ng1
status:
  conditions:
  - status: "True"
    type: Ready
```

Updating — a node group contains at least one node in which there is an annotation with the prefix `update.node.deckhouse.io` (for example, `update.node.deckhouse.io/waiting-for-approval`).

WaitingForDisruptiveApproval - a node group contains at least one node that has an annotation `update.node.deckhouse.io/disruption-required` and there is no annotation `update.node.deckhouse.io/disruption-approved`.

Scaling — calculated only for node groups with the type `CloudEphemeral`. The state `True` can be in two cases:

1. When the number of nodes is less than the *desired number of nodes* in the group, i.e. when it is necessary to increase the number of nodes in the group.
2. When a node is marked for deletion or the number of nodes is greater than the *desired number of nodes*, i.e. when it is necessary to reduce the number of nodes in the group.

The *desired number of nodes* is the sum of all replicas in the node group.

Example. The desired number of nodes is 2:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: ng1
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    maxPerZone: 5
    minPerZone: 2
status:
...
  desired: 2
...
```

Error — contains the last error that occurred when creating a node in a node group.

How do I make werf ignore the Ready conditions in a node group?

werf checks the `Ready` status of resources and, if available, waits for the value to become `True`.

Creating (updating) a nodeGroup resource in a cluster can take a significant amount of time to create the required number of nodes. When deploying such a resource in a cluster using werf (e.g., as part of a CI/CD process), deployment may terminate when resource readiness timeout is exceeded. To make werf ignore the nodeGroup status, the following `nodeGroup` annotations must be added:

```
metadata:
  annotations:
    werf.io/fail-mode: IgnoreAndContinueDeployProcess
    werf.io/track-termination-mode: NonBlocking
```

What is an Instance resource?

An Instance resource contains a description of an implementation-independent ephemeral machine resource. For example, machines created by MachineControllerManager or Cluster API Provider Static will have a corresponding Instance resource.

The object does not contain a specification. The status contains:

1. A link to the InstanceClass if it exists for this implementation;
2. A link to the Kubernetes Node object;
3. Current machine status;
4. Information on how to view machine creation logs (at the machine creation stage).

When a machine is created/deleted, the Instance object is created/deleted accordingly. You cannot create an Instance resource yourself, but you can delete it. In this case, the machine will be removed from the cluster (the removal process depends on implementation details).

When is a node reboot required?

Node reboots may be required after configuration changes. For example, after changing certain sysctl settings, specifically when modifying the `kernel.yama.ptrace_scope` parameter (e.g., using `astra-ptrace-lock enable/disable` in the Astra Linux distribution).

How to enable a delay before a node shutdown or restart while critical pods are running on it?

> ⚠ To decide whether to block a node shutdown, DKP additionally queries the NodeGroup. If the current node belongs to the `master` group and it is the only master node in the cluster, the shutdown block will not be applied to it.

To enable the mechanism that delays a pod's restart or shutdown, add the label `pod.deckhouse.io/inhibit-node-shutdown` to the Pod (for a Deployment, specify the label in the pod template).

Example of a Pod manifest with the `pod.deckhouse.io/inhibit-node-shutdown` label:

```
apiVersion: v1
kind: Pod
metadata:
  name: my-stateful-app
  labels:
    app: my-stateful-app
    pod.deckhouse.io/inhibit-node-shutdown: "true"
spec:
  containers:
    - name: app
      image: my-registry/my-app:1.0.0
```

⚠ The block only applies to pods labeled with `pod.deckhouse.io/inhibit-node-shutdown` that are in the `Running` phase on the node. Kubelet shuts down the pods without this label according to the standard graceful shutdown process.

Searching pods that prevent shutdown and performing the node troubleshooting

To search the pods that are preventing a node shutdown, use the following command:

```
d8 k get po -A -l pod.deckhouse.io/inhibit-node-shutdown -o wide
```

To view the `GracefulShutdownPostpone` condition on a node, use the following command:

```
d8 k get node <NODE_NAME> -o jsonpath='{range .status.conditions[?
(@.type=="GracefulShutdownPostpone")]}{.type}{"\t"}{.status}{"\t"}{.reason}{"\t"}
{.message}{"\n"}{end}'
```

Possible values of the `reason` field:

- `WaitingForShutdownSignal`: The shutdown blocking mechanism is running on the node, but the blocking has not yet begun.
- `PodsWithLabelAreRunningOnNode`: The shutdown has been blocked because there are pods with the label `pod.deckhouse.io/inhibit-node-shutdown` still running on the node.
- `NoRunningPodsWithLabel`: The blocking has been released and the shutdown can continue.

How the fencing mechanism handles different node types?

The fencing mechanism is triggered when a node loses connectivity with the cluster and protects it from “zombie” nodes in an undefined state. To prevent short-time failures from causing cascading actions, the mechanism operates in two stages: first, it marks the node as suspicious (at the `memberlist/Lifeguard` gossip protocol level), and then isolates it — shuts the node down and, if necessary, deletes the associated Node object.

For more details on how the fencing-agent and fencing-controller work, refer to the description of the `spec.fencing.mode` parameter of the NodeGroup resource.

The behavior depends on the node type (the `node.deckhouse.io/type` label).

Cloud nodes (CloudEphemeral, CloudPermanent)

When fencing is triggered in `Watchdog` mode:

1. The fencing-agent stops resetting the watchdog timer (the `softdog` kernel module). When the timeout expires, a kernel panic occurs — this guarantees that no workloads remain running on the node.
2. The fencing-controller deletes the Node object from the cluster.
3. The cloud-provider-controller (MCM/CAPI) picks up the Node deletion, removes the corresponding virtual machine, and provisions a new one if needed. As a result, the failed node is recreated automatically.

Theoretically, a scenario is possible where kubelet on a “stuck” VM recovers before the cloud-provider deletes the machine and attempts to re-register the node in the cluster. The probability of this is minimal due to the following protecting mechanisms:

- A kernel panic leaves the node in a non-operational state. Manual VM restart is required for recovery.
- Automatic node reboot after a kernel panic is disabled at the OS level for all nodes with `fencing` enabled.
- There are safety delays between the kernel panic and the moment the cloud-provider processes the machine.

Static nodes (Static, CloudStatic)

For static nodes, the Node object is **not deleted**, since the underlying machine cannot be automatically recreated. In this case:

1. The fencing-agent shuts the node down via a kernel panic to prevent undefined behavior.
2. The fencing-controller only deletes pods from node.
3. The Node object remains in the cluster, and the node waits until it is manually restored by an operator.

Disabling automatic reboot after kernel panic

In all cases, when `fencing` is enabled, automatic node reboot after a kernel panic is disabled at the OS level (via kernel settings). This prevents a node from rejoining the cluster in an undefined state:

- **For cloud nodes**: Until the cloud-provider deletes or recreates the virtual machine.
- **For static nodes**: Until the operator restores the node manually.

If you observe a scenario where a node with `fencing` enabled returns to the cluster in a way that differs from the behavior described above, contact the support. This will help clarify the sequence of checks and protecting mechanisms.

How do I work with GPU nodes?

Step-by-step procedure for adding a GPU node to the cluster

Starting with Deckhouse 1.71, if a NodeGroup resource contains the `spec.gpu` section, the `node-manager` module **automatically**:

- Configures containerd with `default_runtime = "nvidia"`.
- Applies the required system settings (including fixes for the NVIDIA Container Toolkit).
- Deploys the following system components:
  - NFD
  - GFD
  - NVIDIA Device Plugin
  - DCGM Exporter
  - MIG Manager (if needed)

For the list of platforms supported by NVIDIA Container Toolkit, see the official documentation.

> **i** To ensure correct operation, clearly specify the GPU sharing strategy in the `spec.gpu.sharing` parameter (`Exclusive`, `TimeSlicing`, or `MIG`).
>
> Containerd on GPU nodes is configured automatically. Do not change its configuration manually (for example, via the NodeGroupConfiguration resource or a configuration on the node).

> **i** If a GPU is used in a single-node cluster and the `MIG` strategy is selected, an additional manual procedure is required after each node reboot to reapply the MIG configuration. For details, see MIG in a single-node cluster section.

To add a GPU node to the cluster, perform the following steps:

1. Create a NodeGroup resource for GPU nodes.

   An example with **TimeSlicing** enabled (`partitionCount: 4`) and typical `taints` and `labels`:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: gpu
spec:
  nodeType: CloudStatic  # Can also be Static or CloudEphemeral — depending on your
infrastructure.
  gpu:
    sharing: TimeSlicing
    timeSlicing:
      partitionCount: 4
  nodeTemplate:
    labels:
      node-role/gpu: ""
    taints:
    - key: node-role
      value: gpu
      effect: NoSchedule
```

> **i** If you use custom taint keys, ensure they are allowed in the ModuleConfig `global` in the array `.spec.settings.modules.placement.customTolerationKeys`, so that workloads can add the corresponding `tolerations`.

A full field schema is available in the NodeGroup custom resource reference.

2. Install the NVIDIA driver and NVIDIA Container Toolkit.

   Install the NVIDIA driver and NVIDIA Container Toolkit directly on the nodes, either manually or via the NodeGroupConfiguration resource. Current NodeGroupConfiguration examples for the `gpu` NodeGroup (Ubuntu, Debian, CentOS) are available in the `gpu` module FAQ.

3. After the configuration is applied, perform a bootstrap and reboot the nodes so that settings are applied and the drivers get installed.

4. Verify installation on the node using the command:

   ```
   nvidia-smi
   ```

   > **⚠** If the GPU node was prepared in advance, shipped with preinstalled NVIDIA drivers, or runs an OS with a graphical environment, make sure that the GPU is not being used by third-party processes.
   >
   > In the `nvidia-smi` output, the `Processes` section must not contain third-party processes using the GPU. On nodes with a graphical environment, these may include, for example, graphical session or display manager processes: `Xorg`, `gnome-shell`, `gdm`, `sddm`, `lightdm`, and others. Such processes can consume GPU memory and interfere with correct workload operation as well as MIG configuration.

   Expected proper output (example):

```
root@k8s-dvp-w1-gpu:~# nvidia-smi
Tue Aug  5 07:08:48 2025
+-----------------------------------------------------------------------------------------
----+
| NVIDIA-SMI 535.247.01             Driver Version: 535.247.01   CUDA Version: 12.2
|

```

5. Verify infrastructure components in the cluster.

   NVIDIA Pods in the `d8-nvidia-gpu` namespace:

   ```
   d8 k -n d8-nvidia-gpu get pod
   ```

   Expected proper output (example):

   ```
   NAME                                   READY   STATUS    RESTARTS   AGE
   gpu-feature-discovery-80ceb7d-r842q   2/2     Running   0          2m53s
   nvidia-dcgm-exporter-w9v9h            1/1     Running   0          2m53s
   nvidia-dcgm-njqqb                     1/1     Running   0          2m53s
   nvidia-device-plugin-80ceb7d-8xt8g    2/2     Running   0          2m53s
   ```

   NFD Pods in the `d8-cloud-instance-manager` namespace:

   ```
   d8 k -n d8-cloud-instance-manager get pods | egrep '^(NAME|node-feature-discovery)'
   ```

   Expected proper output (example):

   ```
   NAME                                          READY   STATUS      RESTARTS
   AGE
   node-feature-discovery-gc-6d845765df-45vpj       1/1     Running     0
   3m6s
   node-feature-discovery-master-74696fd9d5-wkjk4   1/1     Running     0
   3m6s
   node-feature-discovery-worker-5f4kv              1/1     Running     0
   3m8s
   ```

   Resource exposure on the node:

```
d8 k describe node <node-name>
```

Output snippet (example):

```
Capacity:
  cpu:                40
  memory:             263566308Ki
  nvidia.com/gpu:     4
Allocatable:
  cpu:                39930m
  memory:             262648294441
  nvidia.com/gpu:     4
```

6. Run functional tests.

   Option A. Invoke `nvidia-smi` from inside a container.

   1. Create a Job:

      ```
      apiVersion: batch/v1
      kind: Job
      metadata:
        name: nvidia-cuda-test
        namespace: default
      spec:
        completions: 1
        template:
          spec:
            restartPolicy: Never
            nodeSelector:
              node.deckhouse.io/group: gpu
              node-role/gpu: ""
            tolerations:
              - key: "node-role"
                operator: "Equal"
                value: "gpu"
                effect: "NoSchedule"
            containers:
              - name: nvidia-cuda-test
                image: nvidia/cuda:11.6.2-base-ubuntu20.04
                imagePullPolicy: "IfNotPresent"
                command:
                  - nvidia-smi
      ```

   2. Check the logs using the command:

      ```
      d8 k logs job/nvidia-cuda-test
      ```

      Output example:

```
Tue Aug  5 07:48:02 2025
+---------------------------------------------------------------------------
--------+
| NVIDIA-SMI 535.247.01             Driver Version: 535.247.01   CUDA Version:

```

Option B. CUDA sample (vectoradd).

1. Create a Job:

```
apiVersion: batch/v1
kind: Job
metadata:
  name: gpu-operator-test
  namespace: default
spec:
  completions: 1
  template:
    spec:
      restartPolicy: Never
      nodeSelector:
        node.deckhouse.io/group: gpu
      tolerations:
        - key: "node-role"
          operator: "Equal"
          value: "gpu"
          effect: "NoSchedule"
      containers:
        - name: gpu-operator-test
          image: nvidia/samples:vectoradd-cuda10.2
          imagePullPolicy: "IfNotPresent"
```

2. Check the logs using the command:

   ```
   d8 k logs job/gpu-operator-test
   ```

   Output example:

   ```
   [Vector addition of 50000 elements]
   Copy input data from the host memory to the CUDA device
   CUDA kernel launch with 196 blocks of 256 threads
   Copy output data from the CUDA device to the host memory
   Test PASSED
   Done
   ```

How to monitor GPUs?

Deckhouse Kubernetes Platform automatically deploys **DCGM Exporter**; GPU metrics are scraped by Prometheus and available in Grafana.

Which GPU modes are supported?

- **Exclusive** — the node exposes the `nvidia.com/gpu` resource; each Pod receives an entire GPU.
- **TimeSlicing** — time-sharing a single GPU among multiple Pods (default `partitionCount: 4`); Pods still request `nvidia.com/gpu`.
- **MIG (Multi-Instance GPU)** — hardware partitioning of supported GPUs into independent instances; with the `all-1g.5gb` profile the cluster exposes resources like `nvidia.com/mig-1g.5gb`.

See examples in Managing nodes: examples section.

How to view available MIG profiles in the cluster?

Pre-defined profiles are stored in the **`mig-parted-config`** ConfigMap inside the **`d8-nvidia-gpu`** namespace and can be viewed with the command:

```
d8 k -n d8-nvidia-gpu get cm mig-parted-config -o json | jq -r '.data["config.yaml"]'
```

The `mig-configs:` section lists the **GPU models (by PCI ID) and the MIG profiles each card supports**—for example `all-1g.5gb`, `all-2g.10gb`, `all-balanced`. Select the profile that matches your accelerator and set its name in `spec.gpu.mig.partedConfig` of the NodeGroup.

How to set a custom per-GPU MIG layout on a node?

Set the `partedConfig` parameter in NodeGroup to `custom` and define MIG partitioning per GPU index:

```
spec:
  gpu:
    sharing: MIG
    mig:
      partedConfig: custom
      customConfigs:
        - index: 0
          slices:
            - profile: 7g.80gb
              count: 1   # Can be in the range from 1 to 7.
        - index: 1
          slices:
            - profile: 3g.40gb
              count: 2
            - profile: 1g.10gb
              count: 1
        # Add more indexes as needed.
```

As a result, the `node-manager` module automatically:

- Adds a configuration named `custom-<node-group-name>-<hash>` into the `mig-parted-config` ConfigMap, where `<hash>` is calculated based on the partitioning scheme (long NodeGroup names are truncated with a hash suffix to fit into a label).
- Sets the label `nvidia.com/mig.config=custom-<node-group-name>-<hash>` to the nodes in the corresponding group.

A separate `custom-<ng>-<hash>` configuration is created for each group of nodes, and configuration names do not overlap.

MIG profile does not activate — what to check?

1. Check the GPU model. MIG is supported in the H100/A100/A30 models and **not** supported in V100/T4. To verify the support in a model, refer to profile tables in the NVIDIA MIG guide.
2. Ensure the GPU is not being used by OS processes or user applications. If a graphical environment, display manager, or other GPU-consuming processes are running on the node, applying the MIG configuration may fail or may not take effect until the GPU is released. Check this with the following command:

   ```
   nvidia-smi
   ```

3. Check the NodeGroup configuration:

   ```
   gpu:
     sharing: MIG
     mig:
       partedConfig: all-1g.5gb
   ```

4. Wait until `nvidia-mig-manager` completes the **drain** of the node and reconfigures the GPU.

   This process can take several minutes.

   While it is running, the node is tainted with `mig-reconfigure`. When the operation succeeds, that taint is removed.

5. Track the progress via the `nvidia.com/mig.config.state` label on the node:

   `pending`, `rebooting`, `success` (or `error` if something goes wrong).

6. If `nvidia.com/mig-*` resources are still missing, check:

   ```
   d8 k -n d8-nvidia-gpu logs daemonset/nvidia-mig-manager
   nvidia-smi -L
   ```

Are AMD or Intel GPUs supported?

At this time, Deckhouse Kubernetes Platform automatically configures **NVIDIA GPUs only**. Support for **AMD (ROCm)** and **Intel GPUs** is being worked on and is planned for future releases.

Examples

> **i** The module lifecycle stage: General Availability

Below are some examples of NodeGroup description, as well as installing the cert-manager plugin for `kubectl` and setting the `sysctl` parameter.

Examples of the `NodeGroup` configuration

Cloud nodes

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: test
spec:
  nodeType: CloudEphemeral
  cloudInstances:
    zones:
      - eu-west-1a
      - eu-west-1b
    minPerZone: 1
    maxPerZone: 2
    classReference:
      kind: AWSInstanceClass
      name: test
  nodeTemplate:
    labels:
      tier: test
```

Static nodes

Use `nodeType: Static` for physical servers and VMs on Hypervisors.

An example:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
```

Adding nodes to such a group is done manually using the pre-made scripts.

You can also use a method that adds static nodes using the Cluster API Provider Static.

System nodes

Below is an example of a system node group manifest.

When describing a NodeGroup with Static nodes, specify the value `Static` in the `nodeType` field and use the `staticInstances` field to describe the parameters for provisioning static machines to the cluster.

When describing a NodeGroup with CloudEphemeral type cloud nodes, specify the value `CloudEphemeral` in the `nodeType` field and use the `cloudInstances` field to describe the parameters for provisioning the cloud-based VMs.

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: system
spec:
  nodeTemplate:
    labels:
      node-role.deckhouse.io/system: ""
    taints:
      - effect: NoExecute
        key: dedicated.deckhouse.io
        value: system
  # Example for Static nodes.
  nodeType: Static
  staticInstances:
    count: 2
    labelSelector:
      matchLabels:
        role: system
  # Example for CloudEphemeral nodes.
  # nodeType: CloudEphemeral
  # cloudInstances:
  #   classReference:
  #     kind: YandexInstanceClass
  #     name: large
  #   maxPerZone: 2
  #   minPerZone: 1
  #   zones:
  #   - ru-central1-d
```

Nodes with GPU

GPU nodes require the **NVIDIA driver** and the **NVIDIA Container Toolkit**. There are two ways to install the driver:

1. **Manual installation** — the administrator installs the driver before the node joins the cluster.
2. **Automation via `NodeGroupConfiguration`** (more details in the Step-by-step procedure for adding a GPU node to the cluster section).

After the driver is detected and the NodeGroup includes the `spec.gpu` section, `node-manager` enables full GPU support by deploying **NFD**, **GFD**, **NVIDIA Device Plugin**, **DCGM Exporter**, and, if required, **MIG Manager**.

> **i** GPU nodes are usually tainted (e.g. `node-role=gpu:NoSchedule`) so that regular workloads don’t land there by accident. A workload that needs a GPU just adds the matching `tolerations` and `nodeSelector`.

See the full field reference in the NodeGroup custom resource documentation.

Below are examples of NodeGroup manifests for typical GPU operating modes (Exclusive, TimeSlicing, MIG).

Exclusive mode (one Pod — one GPU)

Each Pod gets an entire physical GPU; the cluster exposes the `nvidia.com/gpu` resource.

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: gpu-exclusive
spec:
  nodeType: Static
  gpu:
    sharing: Exclusive
  nodeTemplate:
    labels:
      node-role/gpu: ""
    taints:
    - key: node-role
      value: gpu
      effect: NoSchedule
```

Time-slicing (4 partitions)

The GPU is time-sliced: up to four Pods can share one card sequentially. Suitable for experiments, CI, and light inference workloads.

Pods still request the `nvidia.com/gpu` resource.

```
spec:
  gpu:
    sharing: TimeSlicing
    timeSlicing:
      partitionCount: 4
```

MIG (`all-1g.5gb` profile)

A hardware-partitioned GPU (A100, A30, etc.) is split into independent instances. The scheduler exposes resources like `nvidia.com/mig-1g.5gb`.

For a complete list of supported GPUs and their profiles you can see it by using instruction.

```
spec:
  gpu:
    sharing: MIG
    mig:
      partedConfig: all-1g.5gb
```

Smoke-test Job (CUDA vectoradd)

```
apiVersion: batch/v1
kind: Job
metadata:
  name: cuda-vectoradd
spec:
  template:
    spec:
      restartPolicy: OnFailure
      nodeSelector:
        node-role/gpu: ""
      tolerations:
      - key: node-role
        value: gpu
        effect: NoSchedule
      containers:
      - name: cuda-vectoradd
        image: nvcr.io/nvidia/k8s/cuda-sample:vectoradd-cuda11.7.1-ubuntu20.04
        resources:
          limits:
            nvidia.com/gpu: 1
```

This Job runs NVIDIA's **vectoradd** CUDA sample. If the Pod finishes with `Succeeded`, the GPU is present and configured correctly.

Adding a static node to a cluster

Adding a static node can be done manually or using the Cluster API Provider Static.

Manually

Follow the steps below to add a new static node (e.g., VM or bare metal server) to the cluster:

1. For CloudStatic nodes in the following cloud providers, refer to the steps outlined in the documentation:
   - For AWS
   - For GCP
   - For YC
2. Use the existing one or create a new NodeGroup custom resource (see the example for the `NodeGroup` called `worker`). The nodeType parameter for static nodes in the NodeGroup must be `Static` or `CloudStatic`.
3. Get the Base64-encoded script code to add and configure the node.

   Here is how you can get Base64-encoded script code to add a node to the `worker` NodeGroup:

   ```
   NODE_GROUP=worker
   d8 k -n d8-cloud-instance-manager get secret manual-bootstrap-for-${NODE_GROUP} -o json | jq
   '.data."bootstrap.sh"' -r
   ```
4. Pre-configure the new node according to the specifics of your environment. For example:
   - Add all the necessary mount points to the `/etc/fstab` file (NFS, Ceph, etc.).
   - Install the necessary packages.
   - Configure network connectivity between the new node and the other nodes of the cluster.
5. Connect to the new node over SSH and run the following command, inserting the Base64 string you got in step 3:

   ```
   echo <Base64-CODE> | base64 -d | bash
   ```

Using the Cluster API Provider Static

> ⚠ If you have previously increased the number of master nodes in the cluster in the NodeGroup `master` (parameter `spec.staticInstances.count`), before adding regular nodes using CAPS, make sure that they will not be "captured".

A brief example of adding a static node to a cluster using Cluster API Provider Static (CAPS):

1. Prepare the necessary resources.

- Allocate a server (or a virtual machine), configure networking, etc. If required, install specific OS packages and add the mount points on the node.
- Create a user (`caps` in the example below) and add it to sudoers by running the following command **on the server**:

  ```
  useradd -m -s /bin/bash caps
  usermod -aG sudo caps
  ```

- Allow the user to run sudo commands without having to enter a password. For this, add the following line to the sudo configuration **on the server** (you can either edit the `/etc/sudoers` file, or run the `sudo visudo` command, or use some other method):

  ```
  caps ALL=(ALL) NOPASSWD: ALL
  ```

- Generate a pair of SSH keys with an empty passphrase **on the server**:

  ```
  ssh-keygen -t  -f caps-id -C "" -N ""
  ```

  The public and private keys of the `caps` user will be stored in the `caps-id.pub` and `caps-id` files in the current directory on the server.

- Add the generated public key to the `/home/caps/.ssh/authorized_keys` file of the `caps` user by executing the following commands in the keys directory **on the server**:

  ```
  mkdir -p /home/caps/.ssh
  cat caps-id.pub >> /home/caps/.ssh/authorized_keys
  chmod 700 /home/caps/.ssh
  chmod 600 /home/caps/.ssh/authorized_keys
  chown -R caps:caps /home/caps/
  ```

2. Create a SSHCredentials resource in the cluster:

   Run the following command in the user key directory **on the server** to encode the private key to Base64:

   ```
   base64 -w0 caps-id
   ```

   On any computer with `kubectl` configured to manage the cluster, create an environment variable with the value of the Base64-encoded private key you generated in the previous step:

   ```
   CAPS_PRIVATE_KEY_BASE64=<BASE64-ENCODED PRIVATE KEY>
   ```

   Create a `SSHCredentials` resource in the cluster (note that from this point on, you have to use `kubectl` configured to manage the cluster):

   ```
   d8 k create -f - <<EOF
   apiVersion: deckhouse.io/v1alpha1
   kind: SSHCredentials
   metadata:
     name: credentials
   spec:
     user: caps
     privateSSHKey: "${CAPS_PRIVATE_KEY_BASE64}"
   EOF
   ```

3. Create a StaticInstance resource in the cluster; specify the IP address of the static node server:

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-worker-1
  labels:
    role: worker
spec:
  # Specify the IP address of the static node server.
  address: "<SERVER-IP>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
EOF
```

4. Create a NodeGroup resource in the cluster. Value of `count` defines number of `staticInstances` which fall under the `labelSelector` that will be bootstrapped and joined into the `nodeGroup`, in this example this is `1`:

> **i** The `labelSelector` field in the `NodeGroup` resource is immutable. To update the `labelSelector`, you need to create a new `NodeGroup` and move the static nodes into it by changing their labels.

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: worker
EOF
```

> **i** If it is necessary to add nodes to an existing node group, specify the desired number in the `.spec.count` field of the NodeGroup.

Using Cluster API Provider Static for multiple node groups

This example shows how you can use filters in the StaticInstance label selector to group static nodes and use them in different NodeGroups. Here, two node groups (`front` and `worker`) are used for different tasks. Each group includes nodes with different characteristics — the `front` group has two servers and the `worker` group has one.

1. Prepare the required resources (3 servers or virtual machines) and create the `SSHCredentials` resource in the same way as step 1 and step 2 of the example.
2. Create two NodeGroup in the cluster (from this point on, use `kubectl` configured to manage the cluster):

> **i** The `labelSelector` field in the `NodeGroup` resource is immutable. To update the `labelSelector`, you need to create a new `NodeGroup` and move the static nodes into it by changing their labels.

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: front
spec:
  nodeType: Static
  staticInstances:
    count: 2
    labelSelector:
      matchLabels:
        role: front
---
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: worker
EOF
```

3. Create StaticInstance resources in the cluster and specify the valid IP addresses of the servers:

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-front-1
  labels:
    role: front
spec:
  address: "<SERVER-FRONT-IP1>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
---
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-front-2
  labels:
    role: front
spec:
  address: "<SERVER-FRONT-IP2>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
---
apiVersion: deckhouse.io/v1alpha1
kind: StaticInstance
metadata:
  name: static-worker-1
  labels:
    role: worker
spec:
  address: "<SERVER-WORKER-IP>"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
EOF
```

Cluster API Provider Static: Moving Instances Between Node Groups

⚠ During the process of transferring instances between node groups, the instance will be cleaned and re-bootstrapped, and the `Node` object will be recreated.

This section describes the process of moving static instances between different node groups (NodeGroup) using the Cluster API Provider Static (CAPS). The process involves modifying the NodeGroup configuration and updating the labels of the corresponding StaticInstance.

Initial Configuration

Assume that there is already a NodeGroup named `worker` in the cluster, configured to manage one static instance with the label `role: worker`.

`NodeGroup` worker:

```
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: worker
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: worker
```

`StaticInstance` static-worker-1:

```
apiVersion: deckhouse.io/v1alpha2
kind: StaticInstance
metadata:
  name: static-worker-1
  labels:
    role: worker
spec:
  address: "192.168.1.100"
  credentialsRef:
    kind: SSHCredentials
    name: credentials
```

Steps to Move an Instance Between Node Groups

1. Create a New `NodeGroup` for the Target Node Group

Create a new NodeGroup resource, for example, named `front`, which will manage a static instance with the label `role: front`.

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: NodeGroup
metadata:
  name: front
spec:
  nodeType: Static
  staticInstances:
    count: 1
    labelSelector:
      matchLabels:
        role: front
EOF
```

2. Update the Label on the `StaticInstance`

Change the `role` label of the existing StaticInstance from `worker` to `front`. This will allow the new NodeGroup `front` to manage this instance.

```
d8 k label staticinstance static-worker-1 role=front --overwrite
```

3. Decrease the Number of Static Instances in the Original `NodeGroup`

Update the NodeGroup resource `worker` by reducing the `count` parameter from `1` to `0`.

```
d8 k patch nodegroup worker -p '{"spec": {"staticInstances": {"count": 0}}}' --type=merge
```

An example of the `NodeUser` configuration

```
apiVersion: deckhouse.io/v1
kind: NodeUser
metadata:
  name: testuser
spec:
  uid: 1100
  sshPublicKeys:
    - "<SSH_PUBLIC_KEY>"
  passwordHash: <PASSWORD_HASH>
  isSudoer: true
```

An example of the `NodeGroupConfiguration` configuration

Installing the cert-manager plugin for kubectl on master nodes

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: add-cert-manager-plugin.sh
spec:
  weight: 100
  bundles:
  - "*"
  nodeGroups:
  - "master"
  content: |
    if [ -x /usr/local/bin/kubectl-cert_manager ]; then
      exit 0
    fi
    curl -L https://github.com/cert-manager/cert-
manager/releases/download/v1.7.1/kubectl-cert_manager-linux-amd64.tar.gz -o - | tar -zxvf
- kubectl-cert_manager
    mv kubectl-cert_manager /usr/local/bin
```

Tuning sysctl parameters

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: sysctl-tune.sh
spec:
  weight: 100
  bundles:
  - "*"
  nodeGroups:
  - "*"
  content: |
    sysctl -w vm.max_map_count=262144
```

Adding a root certificate to the host

⚠ Example is given for Ubuntu OS.
The method of adding certificates to the store may differ depending on the OS.

Change the bundles and content parameters to adapt the script to a different OS.

⚠ To use the certificate in `containerd` (including pulling containers from a private repository), a restart of the service is required after adding the certificate.

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: add-custom-ca.sh
spec:
  weight: 31
  nodeGroups:
  - '*'
  bundles:
  - 'ubuntu-lts'
  content: |-
    CERT_FILE_NAME=example_ca
    CERTS_FOLDER="/usr/local/share/ca-certificates"
    CERT_CONTENT=$(cat <<EOF

Adding the ability to download images from insecure container registry to containerd

The ability to download images from an insecure container registry is enabled using the `insecure_skip_verify` parameter in the containerd configuration file. For more information, see the How to add configuration for an additional registry.

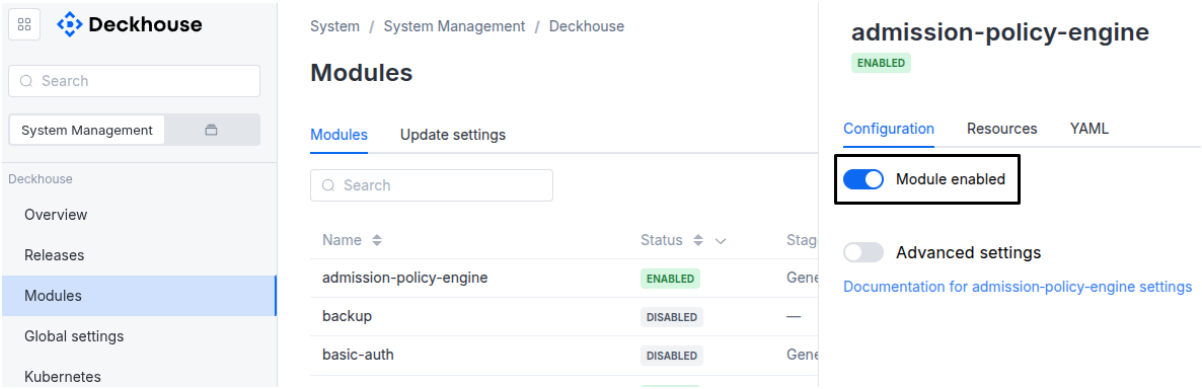
The okmeter module

> **i** The module lifecycle stage: General Availability

The `okmeter` module installs the Okmeter agent as a `daemonset` in the `d8-okmeter` namespace, and deletes `okmeter` installed manually.

Configuration

> **i** The module lifecycle stage: General Availability



The module has 1 alert.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `okmeter` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

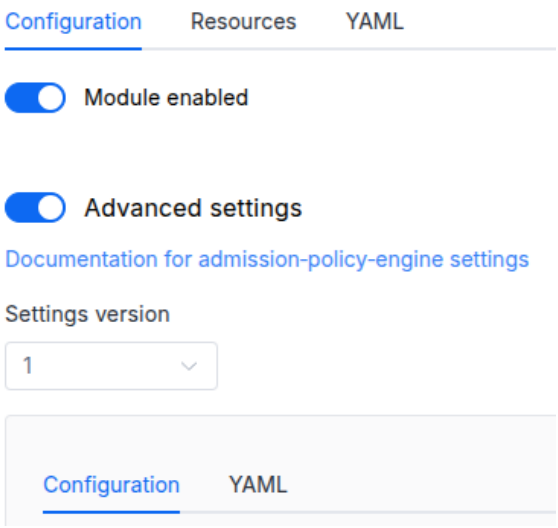
```
d8 system module enable okmeter
```

- **Using ModuleConfig `okmeter`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `okmeter` (create it if necessary);

  Example of a manifest to enable module `okmeter`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: okmeter
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `okmeter` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

Example:

You can also edit the ModuleConfig object `okmeter` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `okmeter`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `okmeter` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc okmeter
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `okmeter` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `okmeter`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: okmeter
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.apiKey**
    string

    Required value

    Key to access Okmeter API.

You can get the key from your personal Okmeter account (`OKMETER_API_TOKEN`).

Example:

```
apiKey: 5ff9z2a3-9127-1sh4-2192-06a3fc6e13e3
```

- **settings.disableAutoDiscovery**

  Disables okagent autodiscovery. Setting this option to `true` will leave only basic host monitoring, all other plugins (postgresql/mysql/redis/etc.) will be disabled. Default value is `false`

- **settings.image**
  object
  - **settings.image.repository**
    string

    Required value

    Docker repository for okmeter agent image.

    Default: `registry.okmeter.io/agent/okagent`

  - **settings.image.tag**
    string

    Required value

    Okmeter agent image tag.

    Default: `latest`

- **settings.nodeSelector**
  object

  The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    test: test
  ```

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

Examples

> **i** The module lifecycle stage: General Availability

Example

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: okmeter
spec:
  version: 1
  enabled: true
  settings:
    apiKey: 5ff9z2a3-9127-1sh4-2192-06a3fc6e13e3
```

The openvpn module

> **i** The module lifecycle stage: General Availability

> **i** Web interfaces associated with the module: openvpn-admin

The openvpn module allows peers to authenticate each other using certificates and provides a simple web interface.

Using the web interface, you can:

- Issue certificates.
- Revoke certificates.
- Cancel certificate revocation.
- Get a ready-to-use custom configuration file.

Integrating with the user-authn module lets you manage user access to the web interface.

Exposing the VPN service

1. Select one or more external IP addresses for connection.
2. Use one of the connection methods:
   - By external IP address (`ExternalIP`) - if there are nodes with public IP addresses.
   - Using `LoadBalancer` - for all cloud providers and their placement schemes that support LoadBalancer ordering.
   - `Direct` - configure the traffic path manually: from the entry point to the cluster to the pod with OpenVPN.

Available cluster resources after connecting to the VPN

The following parameters are pushed to the user's computer after connecting to the VPN:

- The `kube-dns` address is added to the client's DNS servers to allow direct access to Kubernetes services via FQDN.
- A route to the local network.
- A route to the cluster service network.
- A route to the Pod network.

User's traffic audit

The module can log user's activity via VPN in JSON format. Traffic is grouped by `src_ip`, `dst_ip`, `src_port`, `dst_port`, `ip_proto` fields. Using the log-shipper module, container logs can be collected and stored for later auditing.

Third-party components

List of third-party software used in the `openvpn` module:

- OpenVPN 2.6.12

  License: Mixed

  A secure tunneling daemon.

- OpenSSL 3.3.2

  License: Apache License 2.0

  TLS/SSL and crypto library.

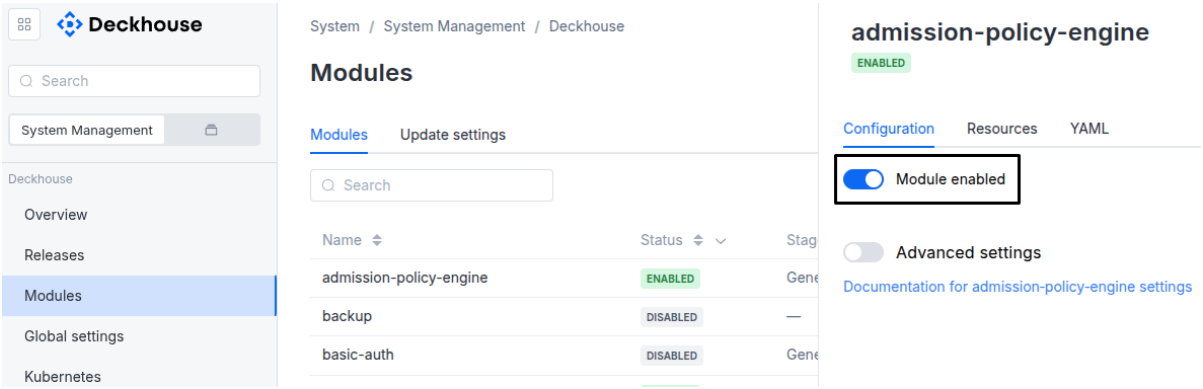
- Libcap-ng 0.8.5

  License: GNU General Public License v2.0

  Libcap-ng is a library for Linux that makes using posix capabilities easy..

Configuration

> **i** The module lifecycle stage: General Availability



The module has 9 alerts.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `openvpn` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

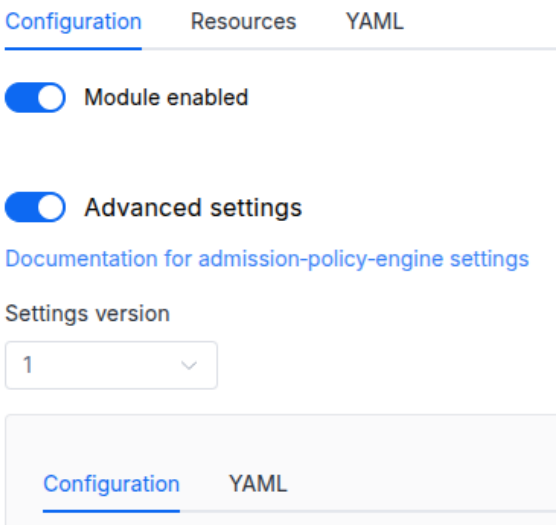
```
d8 system module enable openvpn
```

- **Using ModuleConfig `openvpn`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `openvpn` (create it if necessary);

  Example of a manifest to enable module `openvpn`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: openvpn
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `openvpn` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `openvpn` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `openvpn`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `openvpn` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc openvpn
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `openvpn` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `openvpn`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: openvpn
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Conversion description is missing.

  Actions performed by the conversion (jq syntax)...

  - `del(.auth.password) | if .auth == {} then del(.auth) end`
  - `del(.storageClass)`

Parameters

Schema version: 2

- **settings**
  object
  - **settings.auth**
    object

    Options related to authentication or authorization in the application.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module's public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    - **settings.auth.allowedUserGroups**
      array of strings

      An array of user groups that can access the OpenVPN admin panel.

      This parameter is used if the user-authn module is enabled or the externalAuthentication parameter is set.

      > **Caution!** Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

    - **settings.auth.externalAuthentication**
      object

      Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the Nginx auth_request module.

      > **Note!** External authentication is enabled automatically if the user-authn module is enabled.

      - **settings.auth.externalAuthentication.authSignInURL**
        string

        The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

      - **settings.auth.externalAuthentication.authURL**
        string

        The URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

    - **settings.auth.whitelistSourceRanges**
      array of strings

      The CIDR range for which authentication to access the OpenVPN is allowed.

  - **settings.clientCertExpirationDays**
    integer

    Certificate client expired period for OpenVPN in days. Specifies the number of days for which a client certificate generated using EasyRSA will be issued.

    Client certificate lifetime must be at least 1 day and no more than 10 years.

    Default: `3650`

    Allowed values: `1 <= X <= 3650`

  - **settings.externalHost**
    string

    An IP address or a domain clients use to connect to the OpenVPN server.

    By default, data from an `openvpn-external` service are used.

  - **settings.externalIP**
    string

    The IP address of a cluster node to connect OpenVPN clients.

It is only required if the `ExternalIP` inlet is used.

- **settings.externalPort**
  integer

  The port to expose on the `externalIP` or load balancer.

  Default: `5416`

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

  By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

- **settings.hostPort**
  integer

  Port to connect to the OpenVPN server, which will be available on the node where it is scheduled.

  The parameter is available when selecting inlet `HostPort`.

  Default: `5416`

- **settings.https**
  object

  What certificate type to use with the OpenVPN admin panel.

  This parameter completely overrides the `global.modules.https` settings.

  - **settings.https.certManager**
    object
    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for the OpenVPN admin panel (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.https.customCertificate**
    object
    - **settings.https.customCertificate.secretName**
      string

      The name of the Secret in the `d8-system` namespace to use with the OpenVPN admin panel (this Secret must have the kubernetes.io/tls format).

      Default: `false`

  - **settings.https.mode**
    string

    The HTTPS usage mode:

    - `CertManager` — the OpenVPN admin panel will use HTTPS and get a certificate from the ClusterIssuer defined in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate` — the OpenVPN admin panel will use the certificate from the `d8-system` namespace for HTTPS.
    - `Disabled` — in this mode, the OpenVPN admin panel works over HTTP only.
    - `OnlyInURI` — the OpenVPN admin panel will work over HTTP (thinking that there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). All the links in the user-authn will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

    Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for the OpenVPN admin panel.

  By default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.inlet**
  string

  The way the connection is implemented.

  The following inlet types are supported:

  - `ExternalIP` — when there are nodes with public IPs. It is used together with the `externalIP` parameter.
  - `LoadBalancer` — for all cloud providers and cloud-based placement strategies that support the provision of LoadBalancers.
  - `HostPort` — the port of the OpenVPN server will be available on the node where it is scheduled. The port can be configured in the `hostPort` parameter.
  - `Direct` — for non-standard cases. You need to create a service called `openvpn-external` in the `d8-openvpn` namespace. It will route traffic to the Pod with the `app: openvpn` label to the port called `ovpn-tcp` (or just 1194). This service provides the externalIP, the IP address of the balancer or its host. If none of these are present, you need to specify the `externalHost` parameter.

  Allowed values: `ExternalIP`, `LoadBalancer`, `HostPort`, `Direct`

- **settings.loadBalancer**
  object

  A section of optional parameters of the `LoadBalancer` inlet.

  - **settings.loadBalancer.annotations**
    object

    Annotations to assign to the service for flexible configuration of the load balancer.

    > **i** **Note** that module does not take into account the specifics of setting annotations in different clouds. If annotations for the provision of the load balancer are only used when the service is being created, then you need to restart the module (disable/enable it) to update them.

  - **settings.loadBalancer.sourceRanges**
    array of strings

    A list of CIDRs that are allowed to connect to the Load Balancer.

    The cloud provider may not support this option or ignore it.

- **settings.nodeSelector**
  object

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.pmacctEnabled**
  boolean

  Enable logging of user's activity via VPN in JSON format.

  All connections within `tun` interfaces will be collected via `libpcap` and logged as `{"event type": "purge", "ip src": "172.25.175.10", "ip dst": "10.222.0.10", "port_src": 32172, "port_dst": 53, "ip_proto": "udp", "packets": 1, "bytes": 53}`

  Default: `false`

- **settings.pushDefaultGatewayToClient**
  boolean

  Routing all client traffic through the VPN. A default route will be added to clients.

  Default: `false`

- **settings.pushToClientDNS**
  string

  The IP address of the DNS server to send to clients upon connection.

  By default, the IP address of the `kube-system/kube-dns` service is used.

- **settings.pushToClientRoutes**
  array of strings

  A list of routes to send to clients upon their connection.

By default, this list is generated automatically using the local cluster network, service subnet, and Pod subnet.

Example:

```
pushToClientRoutes:
- 172.25.176.0/24
- 172.25.178.0/255.255.255.0
```

- **settings.pushToClientSearchDomains**
  array of strings

  A list of search domains to send to clients upon connection.

  The default value is a value from the `global.discovery.clusterDomain` variable.

- **settings.tcpEnabled**
  boolean

  Default: `true`

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

- **settings.tunnelNetwork**
  string

  Tunnel network for OpenVPN server.

  Default: `172.25.175.0/24`

  Examples:

  ```
  tunnelNetwork: 172.25.175.0/24
  ```

  ```
  tunnelNetwork: 172.25.178.0/255.255.255.0
  ```

- **settings.udpEnabled**
  boolean

  Default: `false`

Authentication

user-authn module provides authentication by default. You can also configure authentication using the externalAuthentication parameter. If these options are disabled, the module will use basic auth with the auto-generated password.

To view the generated password, run the command:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values openvpn -o json | jq '.openvpn.internal.auth.password'
```

To generate a new password, delete the Secret:

```
d8 k -n d8-openvpn delete secret/basic-auth
```

> **i** The `auth.password` parameter is deprecated.

FAQ

> The module lifecycle stage: General Availability

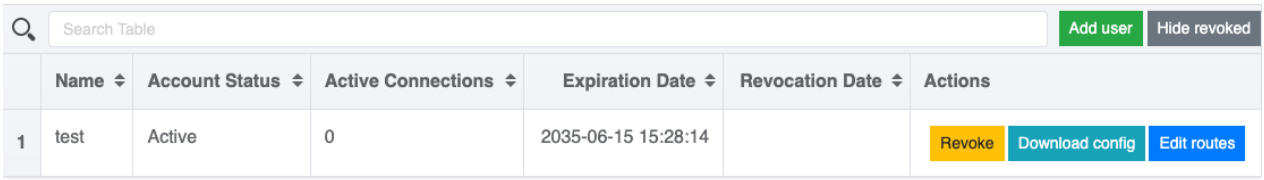
Why doesn’t automatic DNS server configuration work when connecting to macOS and Linux using the OpenVPN client

Due to the architectural features of the Linux and macOS operating systems, automatic DNS server configuration when using the official OpenVPN client is not possible.

To configure the DNS server on such operating systems, the service provides the ability to use third-party scripts that run when the client connects or disconnects.

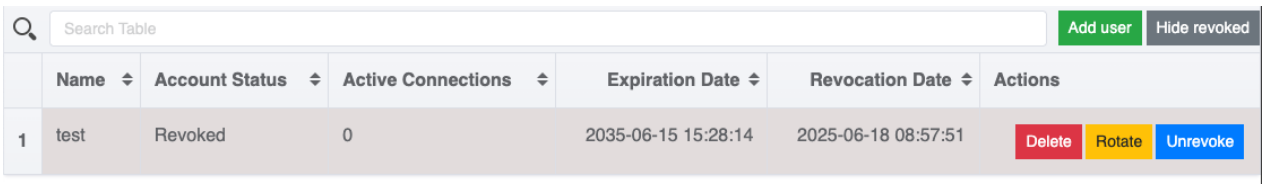
In the client configurations generated by the module, the blocks responsible for these settings are predefined and commented out:

```
# Uncomment the lines below for use with Linux
#script-security 2
# If you use resolved
#up /etc/openvpn/update-resolv-conf
#down /etc/openvpn/update-resolv-conf
# If you use systemd-resolved, first install the openvpn-systemd-resolved package
#up /etc/openvpn/update-systemd-resolved
#down /etc/openvpn/update-systemd-resolved
```



To use these code blocks, uncomment them (remove the initial `#` symbol), and specify the correct paths to the scripts.

You can either prepare the scripts yourself or use ready-made scripts from the official OpenVPN Community (for Linux). For macOS, you can use a third-party script.



> Scripts must have execution permissions.

How to revoke, rotate or delete a user certificate

All operations with client certificates are performed via the openvpn-admin web interface. Buttons for managing certificates are available to the right of each user’s name:

To rotate (issue a new certificate) or delete a client, you must first revoke their current certificate:

Once revoked, the Renew (rotation) and Delete (removal) actions become available.

How to rotate a server certificate

The server certificate is rotated automatically several days before it expires.

If you need to rotate the certificate manually (e.g., due to certificate corruption or an unscheduled replacement), follow these steps:

1. Delete the secret `openvpn-pki-server` in the namespace `d8-openvpn`:

   ```
   d8 k -n d8-openvpn delete secrets openvpn-pki-server
   ```

2. Restart the OpenVPN pods to trigger the generation of a new certificate:

   ```
   d8 k -n d8-openvpn rollout restart sts openvpn
   ```

A new certificate will be generated automatically when the pods start.

How to rotate a root certificate (CA)

The root certificate (CA) and server certificate are rotated automatically 1 day before expiration. Automatic rotation of clients certificates is not provided. The root certificate (CA) is used to sign all certificates in OpenVPN — both server and client. Therefore, when replacing the CA, you must reissue all dependent certificates.

Steps to rotate the root certificate:

1. Revoke or delete all active client certificates using the openvpn-admin web interface. If you choose to revoke certificates, you can rotate them later (Renew) after the CA is replaced, without recreating the clients.
2. Delete secrets `openvpn-pki-ca` and `openvpn-pki-server` in the namespace `d8-openvpn`:

   ```
   d8 k -n d8-openvpn delete secrets openvpn-pki-ca openvpn-pki-server
   ```

3. Restart OpenVPN pods:

   ```
   d8 k -n d8-openvpn rollout restart sts openvpn
   ```

4. Rotate certificates of revoked users, or create new ones.
5. Delete all revoked certificate secrets:

   ```
   d8 k -n d8-openvpn delete secrets -l revokedForever=true
   ```

Examples

> **i** The module lifecycle stage: General Availability

An example for bare metal clusters

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: openvpn
spec:
  version: 2
  enabled: true
  settings:
   inlet: ExternalIP
   externalIP: 5.4.54.4
```

An example for AWS & Google Cloud

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: openvpn
spec:
  version: 2
  enabled: true
  settings:
    inlet: LoadBalancer
```

An example for an external load balancer with a public IP address

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: openvpn
spec:
  version: 2
  enabled: true
  settings:
    externalHost: 5.4.54.4
    externalIP: 192.168.0.30 # The internal IP address to forward the external LB's
traffic to.
    inlet: ExternalIP
    nodeSelector:
      kubernetes.io/hostname: node
```

The operator-prometheus module

> **i** The module lifecycle stage: General Availability

The module installs the Prometheus Operator, which automates the deployment and management of Prometheus installations.

Operator:

- Creates the following custom resources:
  - Prometheus — describes a Prometheus installation (cluster);
  - ServiceMonitor — defines how to collect metrics from services;
  - Alertmanager — describes an Alertmanager cluster;
  - PrometheusRule — contains a set of Prometheus rules.
- Watches these resources and:
  - Generates a StatefulSet with Prometheus and the required configuration files, storing them in a Secret.
  - When ServiceMonitor or PrometheusRule change, updates the Prometheus configuration by modifying the corresponding Secret.

Prometheus

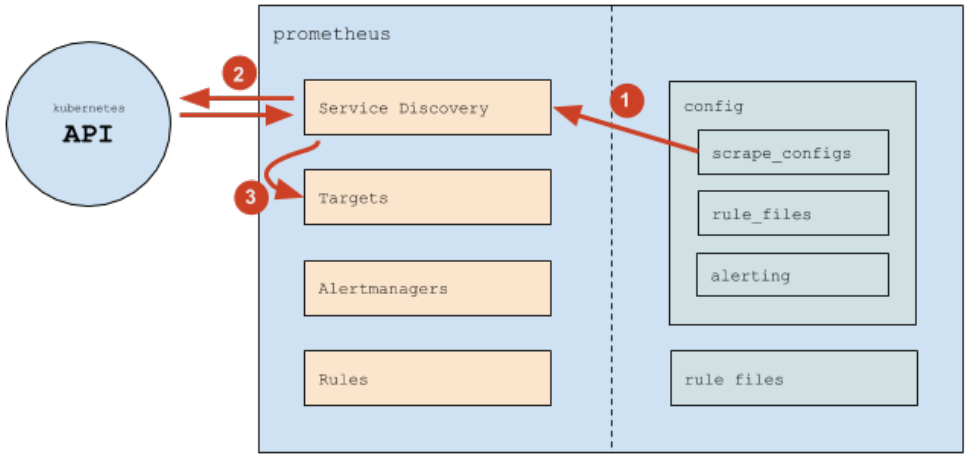
Prometheus functions

The Prometheus server performs two primary tasks — it collects metrics and processes rules.

- For each monitoring target, at every `scrape_interval` an HTTP request is sent to that target. The metrics in its own text format are stored in the Prometheus database.
- At every `evaluation_interval`, rules are processed, resulting in:
  - alerts being sent;
  - new metrics (rule evaluation results) being written to the database.

Prometheus configuration

Prometheus configuration consists of the main `config` file and rule files (`rule files`).



The key sections used in `config` are:

- `scrape_configs`: Defines where and how to discover monitoring targets.
- `rule_files`: Lists the paths to rule files that Prometheus should load. Example:

  ```yaml rule_files:
  - /etc/prometheus/rules/rules-0/*
  - /etc/prometheus/rules/rules-1/*
  ```
- `alerting`: Defines how to discover and where to send alerts to Alertmanager clusters. Structurally, this section is similar to `scrape_configs`, but its result is a list of endpoints to which Prometheus sends notifications.

Sources of monitoring targets

General Prometheus workflow:

- Prometheus reads the `scrape_configs` section and configures its internal Service Discovery.
- Service Discovery interacts with the Kubernetes API (retrieving endpoints and related metadata).
- Based on cluster events, Service Discovery updates the list of monitoring targets.

In `scrape_configs`, a set of `scrape job`s is defined — logical descriptions of where and how to collect metrics. Example:

```
scrape_configs:
  # General settings.
  - job_name: d8-monitoring/custom/0   # Name of the scrape job, shown in the Service
Discovery section.
    scrape_interval: 30s              # How often to scrape data.
    scrape_timeout: 10s               # Request timeout.
    metrics_path: /metrics             # HTTP path.
    scheme: http                      # HTTP or HTTPS.
    # Service Discovery settings.
    kubernetes_sd_configs:             # Get targets from Kubernetes.
    - api_server: null                # API server address is taken from environment
variables (present in every Pod).
      role: endpoints                 # Use endpoints as targets.
      namespaces:
        names:                        # Restrict the list of namespaces.
        - foo
        - baz
    # Filtering settings (which endpoints to include/exclude) and relabeling (which labels
to add or remove; applies to all scraped metrics).
    relabel_configs:
    # Filter by the value of the prometheus_custom_target label (taken from the Service
associated with the endpoint).
    - source_labels: [__meta_kubernetes_service_label_prometheus_custom_target]
      regex: .+                       # Any non-empty label.
      action: keep
    # Filter by port name.
    - source_labels: [__meta_kubernetes_endpointslice_port_name]
      regex: http-metrics              # Only the port named http-metrics.
      action: keep
    # Add the job label. Use the value of the prometheus_custom_target label on the
Service, prefixed with "custom-".
    #
    # The job label:
    #    * defines the group name under which the target will appear;
    #    * is added to metrics for convenient filtering in rules and dashboards.
    - source_labels: [__meta_kubernetes_service_label_prometheus_custom_target]
      regex: (.*)
      target_label: job
      replacement: custom-$1
      action: replace
    # Add the namespace label.
    - source_labels: [__meta_kubernetes_namespace]
      regex: (.*)
      target_label: namespace
      replacement: $1
      action: replace
    # Add the service label.
    - source_labels: [__meta_kubernetes_service_name]
      regex: (.*)
      target_label: service
      replacement: $1
      action: replace
    # Add the instance label (will contain the Pod name).
    - source_labels: [__meta_kubernetes_pod_name]
      regex: (.*)
      target_label: instance
      replacement: $1
      action: replace
```

Thus, Prometheus automatically tracks the addition and removal of:

- Pods (changes to endpoints lead to the addition or removal of monitoring targets)
- Services (and corresponding endpoints) in the specified namespaces

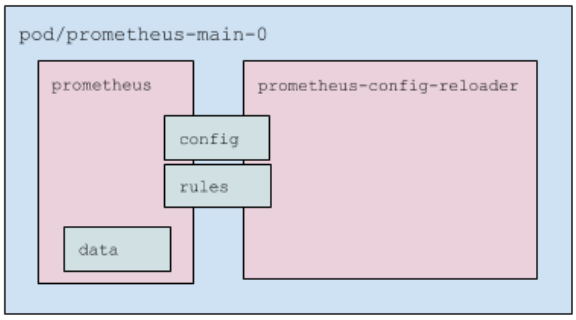
Configuration changes are required when you need to:

- Add a new `scrape_config` (usually a new class of services to monitor).
- Change the list of namespaces.

Prometheus Operator

Prometheus Operator functions

Using CRDs (Custom Resource Definitions), Prometheus Operator defines four custom resources:

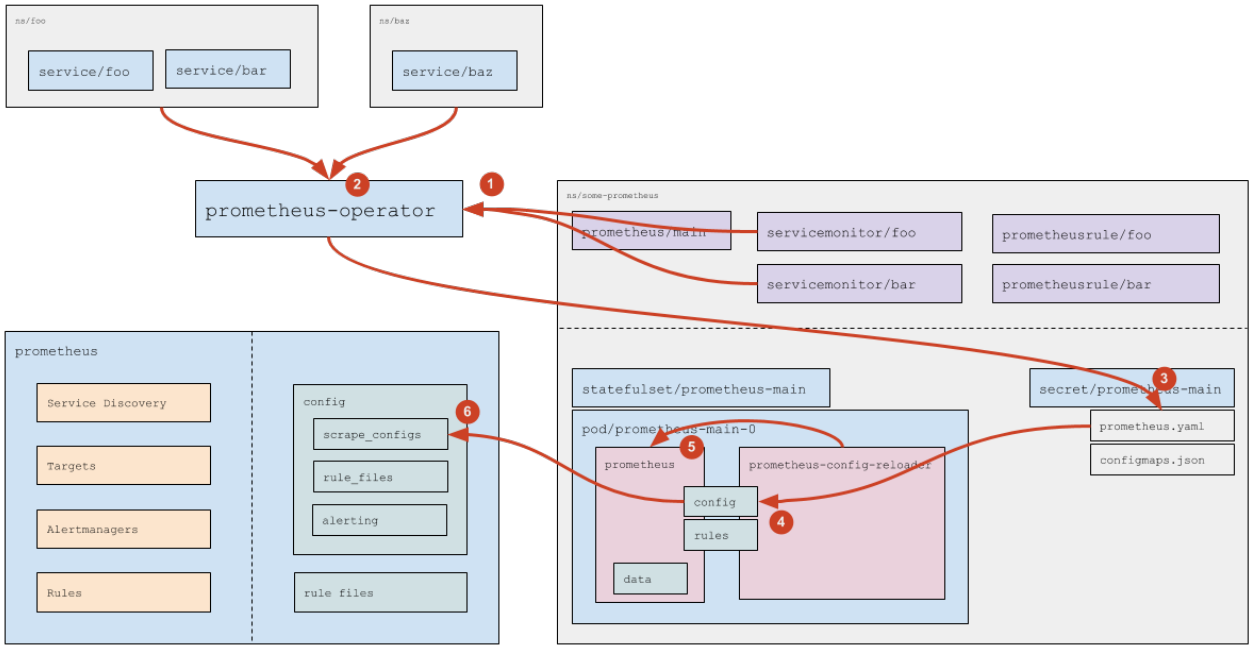


- Prometheus: Describes a Prometheus installation (cluster);
- ServiceMonitor: Specifies how to collect metrics from a set of services;
- Alertmanager: Describes an Alertmanager cluster;
- PrometheusRule: Contains a set of Prometheus rules.

Prometheus Operator also watches Prometheus resources and, for each one, generates:

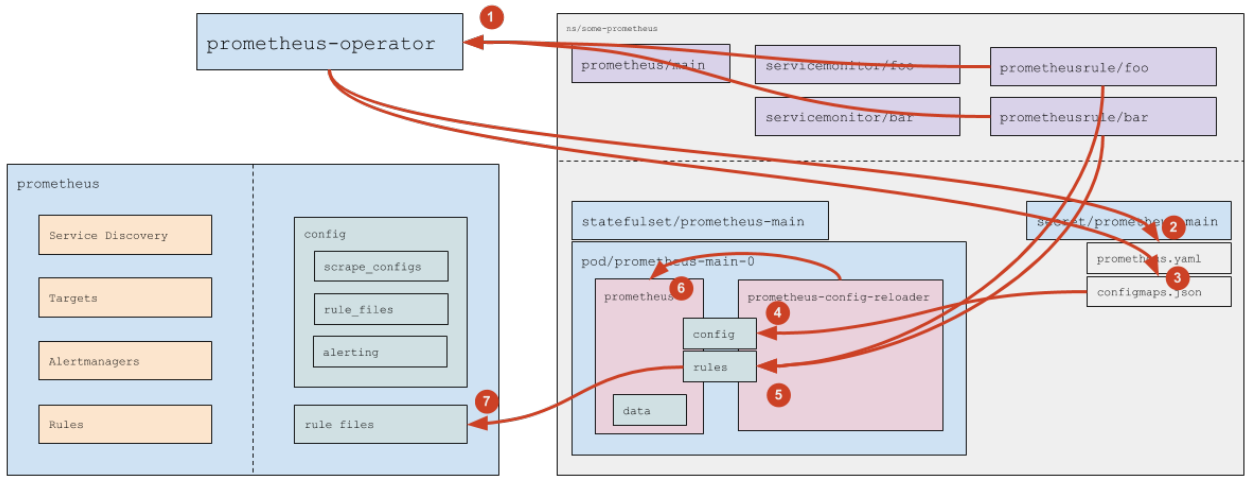
- StatefulSet with Prometheus itself
- Secret containing `prometheus.yaml` (the main configuration file) and `configmaps.json` (the configuration file for `prometheus-config-reloader`)

It watches ServiceMonitor and PrometheusRule resources and, based on them, updates the configuration (`prometheus.yaml` and `configmaps.json`) in the corresponding Secret.



Contents of the Prometheus Pod

Prometheus pods include:



- Three containers:
  - `prometheus`: Prometheus server itself.
  - `prometheus-config-reloader`: Utility that watches:
    - Changes made to `prometheus.yaml` and, if needed, triggers a Prometheus configuration reload (via a special HTTP request; see details below).
    - PrometheusRules (see details below), downloads them if necessary, and restarts Prometheus.
  - `kube-rbac-proxy`: Proxy that handles RBAC-based authentication and authorization for accessing Prometheus metrics.
- Key volumes:
  - `config`: Mounted Secret with the files `prometheus.yaml` and `configmaps.json`. Used by the `prometheus` and `prometheus-config-reloader` containers.
  - `rules`: An `emptyDir` populated by `prometheus-config-reloader` and read by `prometheus`. Mounted into both containers; in `prometheus`, it is read-only.
  - `data`: Prometheus data. Mounted only into the `prometheus` container.

ServiceMonitor processing

1. Prometheus Operator watches ServiceMonitor resources (which ones exactly is defined in the Prometheus resource spec; see details in the official documentation).
2. For each ServiceMonitor that does not specify an explicit list of namespaces (`any: true` is used), the operator queries the Kubernetes API to compute the list of namespaces with Service`s that match the labels from the ServiceMonitor.
3. Based on the discovered ServiceMonitor resources and the computed namespaces, the operator generates the Prometheus configuration fragment (the `scrape_configs` section) and stores it in the corresponding Secret.
4. Kubernetes mounting mechanism updates the files in the Prometheus pod — `prometheus.yaml` from the Secret is refreshed.
5. The `prometheus-config-reloader` container detects the change to `prometheus.yaml` and sends Prometheus an HTTP request to reload the configuration.
6. Prometheus rereads the configuration and applies the changes in `scrape_configs` according to its workflow.

Processing custom resources with rules

1. Prometheus Operator watches PrometheusRule objects that match the `ruleSelector` specified in the Prometheus resource.
2. When a new PrometheusRule appears or an existing one is deleted, the operator updates `prometheus.yaml` — after that, the same chain as for `ServiceMonitor` processing applies.
3. When a PrometheusRule is added, deleted, or its contents change, the operator updates the ConfigMap `prometheus-main-rulefiles-0`.
4. Kubernetes' mounting mechanism delivers the updated ConfigMap to the pod.
5. The `prometheus-config-reloader` container detects the changes and then:
   - writes the updated ConfigMaps to the `rules` directory (`emptyDir`);
   - sends Prometheus an HTTP request to reload the configuration.
6. Prometheus rereads the configuration and applies the updated rules.

Third-party components

List of third-party software used in the `operator-prometheus` module:

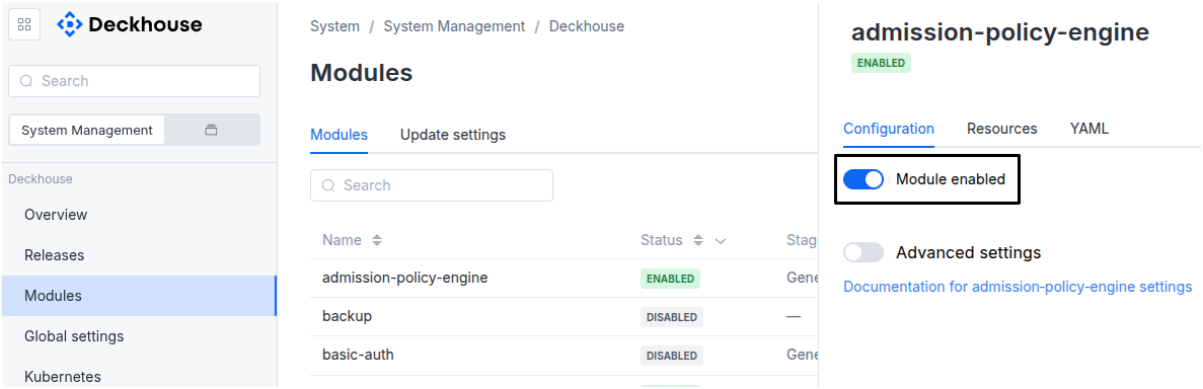
- Prometheus Operator

  License: Apache License 2.0

  Kubernetes native deployment and management of Prometheus and related monitoring components.

Configuration

> **i** The module lifecycle stage: General Availability



The module has 4 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `operator-prometheus` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

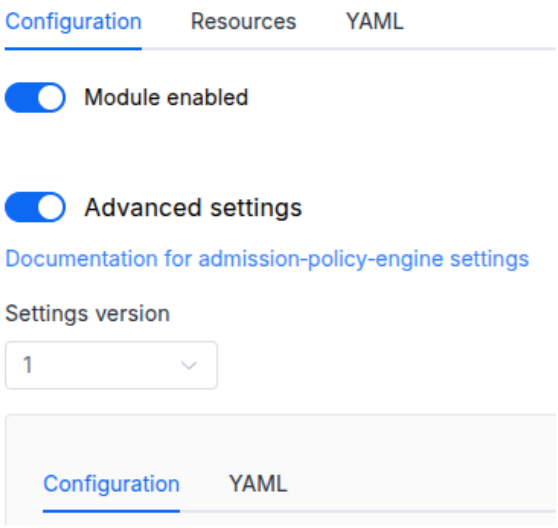
```
d8 system module enable operator-prometheus
```

- **Using ModuleConfig `operator-prometheus`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `operator-prometheus` (create it if necessary);

  Example of a manifest to enable module `operator-prometheus`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: operator-prometheus
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `operator-prometheus` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `operator-prometheus` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `operator-prometheus`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `operator-prometheus` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc operator-prometheus
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `operator-prometheus` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `operator-prometheus`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: operator-prometheus
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.nodeSelector**
    object

    The same as in the pods’ `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations**
    array of objects

    The same as in the pods’ `spec.tolerations` parameter in Kubernetes;

    If the parameter is omitted or `false`, it will be determined automatically.

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

Custom resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

PodMonitor

Short names: pmon

Scope: Namespaced
Version: v1

PodMonitor defines monitoring for a set of pods.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  Required value

  Specification of desired Pod selection for target discovery by Prometheus.

  - **spec.attachMetadata**
    object

    Attaches node metadata to discovered targets. Requires Prometheus v2.35.0 and above.

    - **spec.attachMetadata.node**
      boolean

      When set to true, Prometheus must have permissions to get Nodes.

  - **spec.jobLabel**
    string

    The label to use to retrieve the job name from.

  - **spec.keepDroppedTargets**
    integer

    Per-scrape limit on the number of targets dropped by relabeling that will be kept in memory. 0 means no limit. It requires Prometheus >= v2.47.0.

  - **spec.labelLimit**
    integer

    Per-scrape limit on number of labels that will be accepted for a sample. Only valid in Prometheus

versions 2.27.0 and newer.

- **spec.labelNameLengthLimit**
  integer

  Per-scrape limit on length of labels name that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelValueLengthLimit**
  integer

  Per-scrape limit on length of labels value that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.namespaceSelector**
  object

  Selector to select which namespaces the Endpoints objects are discovered from.

  - **spec.namespaceSelector.any**
    boolean

    Boolean describing whether all namespaces are selected in contrast to a list restricting them.

  - **spec.namespaceSelector.matchNames**
    array of strings

    List of namespace names to select from.

- **spec.podMetricsEndpoints**
  array of objects

  Required value

  A list of endpoints allowed as part of this PodMonitor.

  PodMetricsEndpoint defines a scrapeable endpoint of a Kubernetes Pod serving Prometheus metrics.

  - **spec.podMetricsEndpoints.authorization**
    object

    Authorization section for this endpoint

    - **spec.podMetricsEndpoints.authorization.credentials**
      object

      Selects a key of a Secret in the namespace that contains the credentials for authentication.

      - **spec.podMetricsEndpoints.authorization.credentials.key**
        string

        Required value

        The key of the secret to select from. Must be a valid secret key.

      - **spec.podMetricsEndpoints.authorization.credentials.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.podMetricsEndpoints.authorization.credentials.optional**
        boolean

        Specify whether the Secret or its key must be defined

    - **spec.podMetricsEndpoints.authorization.type**
      string

      Defines the authentication type. The value is case-insensitive. “Basic” is not a supported value. Default: “Bearer”

  - **spec.podMetricsEndpoints.basicAuth**
    object

    BasicAuth allow an endpoint to authenticate over basic authentication. More info: https://prometheus.io/docs/operating/configuration/#endpoint

    - **spec.podMetricsEndpoints.basicAuth.password**
      object

The secret in the service monitor namespace that contains the password for authentication.

- **spec.podMetricsEndpoints.basicAuth.password.key**
  string

  Required value

  The key of the secret to select from. Must be a valid secret key.

- **spec.podMetricsEndpoints.basicAuth.password.name**
  string

  Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.podMetricsEndpoints.basicAuth.password.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.podMetricsEndpoints.basicAuth.username**
  object

  The secret in the service monitor namespace that contains the username for authentication.

  - **spec.podMetricsEndpoints.basicAuth.username.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.podMetricsEndpoints.basicAuth.username.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.podMetricsEndpoints.basicAuth.username.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.podMetricsEndpoints.bearerTokenSecret**
  object

  Secret to mount to read bearer token for scraping targets. The secret needs to be in the same namespace as the pod monitor and accessible by the Prometheus Operator.

  - **spec.podMetricsEndpoints.bearerTokenSecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.podMetricsEndpoints.bearerTokenSecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.podMetricsEndpoints.bearerTokenSecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.podMetricsEndpoints.enableHttp2**
  boolean

  Whether to enable HTTP2.

- **spec.podMetricsEndpoints.filterRunning**
  boolean

  Drop pods that are not running. (Failed, Succeeded). Enabled by default. More info: https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle/#pod-phase

- **spec.podMetricsEndpoints.followRedirects**
  boolean

FollowRedirects configures whether scrape requests follow HTTP 3xx redirects.

- **spec.podMetricsEndpoints.honorLabels**
  boolean

  HonorLabels chooses the metric’s labels on collisions with target labels.

- **spec.podMetricsEndpoints.honorTimestamps**
  boolean

  HonorTimestamps controls whether Prometheus respects the timestamps present in scraped data.

- **spec.podMetricsEndpoints.interval**
  string

  Interval at which metrics should be scraped If not specified Prometheus’ global scrape interval is used.

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.podMetricsEndpoints.metricRelabelings**
  array of objects

  MetricRelabelConfigs to apply to samples before ingestion.

  RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  - **spec.podMetricsEndpoints.metricRelabelings.action**
    string

    Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: “Replace”

    Default: `replace`

    Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

  - **spec.podMetricsEndpoints.metricRelabelings.modulus**
    integer

    Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

  - **spec.podMetricsEndpoints.metricRelabelings.regex**
    string

    Regular expression against which the extracted value is matched.

  - **spec.podMetricsEndpoints.metricRelabelings.replacement**
    string

    Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

  - **spec.podMetricsEndpoints.metricRelabelings.separator**
    string

    Separator is the string between concatenated SourceLabels.

  - **spec.podMetricsEndpoints.metricRelabelings.sourceLabels**
    array of strings

    The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

    - **Element of the array**
      string

      LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

      Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

  - **spec.podMetricsEndpoints.metricRelabelings.targetLabel**

string

Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.podMetricsEndpoints.oauth2**
  object

  OAuth2 for the URL. Only valid in Prometheus versions 2.27.0 and newer.

  - **spec.podMetricsEndpoints.oauth2.clientId**
    object

    Required value

    The secret or configmap containing the OAuth2 client id

    - **spec.podMetricsEndpoints.oauth2.clientId.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.podMetricsEndpoints.oauth2.clientId.configMap.key**
        string

        Required value

        The key to select.

      - **spec.podMetricsEndpoints.oauth2.clientId.configMap.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.podMetricsEndpoints.oauth2.clientId.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must be defined

    - **spec.podMetricsEndpoints.oauth2.clientId.secret**
      object

      Secret containing data to use for the targets.

      - **spec.podMetricsEndpoints.oauth2.clientId.secret.key**
        string

        Required value

        The key of the secret to select from. Must be a valid secret key.

      - **spec.podMetricsEndpoints.oauth2.clientId.secret.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.podMetricsEndpoints.oauth2.clientId.secret.optional**
        boolean

        Specify whether the Secret or its key must be defined

  - **spec.podMetricsEndpoints.oauth2.clientSecret**
    object

    Required value

    The secret containing the OAuth2 client secret

    - **spec.podMetricsEndpoints.oauth2.clientSecret.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.podMetricsEndpoints.oauth2.clientSecret.name**
      string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.podMetricsEndpoints.oauth2.clientSecret.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.podMetricsEndpoints.oauth2.endpointParams**
  object

  Parameters to append to the token URL

- **spec.podMetricsEndpoints.oauth2.scopes**
  array of strings

  OAuth2 scopes used for the token request

- **spec.podMetricsEndpoints.oauth2.tokenUrl**
  string

  Required value

  The URL to fetch the token from

- **spec.podMetricsEndpoints.params**
  object

  Optional HTTP URL parameters

- **spec.podMetricsEndpoints.path**
  string

  HTTP path to scrape for metrics. If empty, Prometheus uses the default value (e.g. `/metrics`).

- **spec.podMetricsEndpoints.port**
  string

  Name of the pod port this endpoint refers to. Mutually exclusive with targetPort.

- **spec.podMetricsEndpoints.proxyUrl**
  string

  ProxyURL eg http://proxyserver:2195 Directs scrapes to proxy through this endpoint.

- **spec.podMetricsEndpoints.relabelings**
  array of objects

  RelabelConfigs to apply to samples before scraping. Prometheus Operator automatically adds relabelings for a few standard Kubernetes fields. The original scrape job's name is available via the `__tmp_prometheus_job_name` label. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  - **spec.podMetricsEndpoints.relabelings.action**
    string

    Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: "Replace"

    Default: `replace`

    Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

  - **spec.podMetricsEndpoints.relabelings.modulus**
    integer

    Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

  - **spec.podMetricsEndpoints.relabelings.regex**
    string

    Regular expression against which the extracted value is matched.

- **spec.podMetricsEndpoints.relabelings.replacement**
  string

  Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

- **spec.podMetricsEndpoints.relabelings.separator**
  string

  Separator is the string between concatenated SourceLabels.

- **spec.podMetricsEndpoints.relabelings.sourceLabels**
  array of strings

  The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

  - **Element of the array**
    string

    LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

    Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

- **spec.podMetricsEndpoints.relabelings.targetLabel**
  string

  Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.podMetricsEndpoints.scheme**
  string

  HTTP scheme to use for scraping. `http` and `https` are the expected values unless you rewrite the `__scheme__` label via relabeling. If empty, Prometheus uses the default value `http`.

  Allowed values: `http`, `https`

- **spec.podMetricsEndpoints.scrapeTimeout**
  string

  Timeout after which the scrape is ended If not specified, the Prometheus global scrape interval is used.

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.podMetricsEndpoints.targetPort**
  integer or string

  Deprecated: Use ‘port’ instead.

- **spec.podMetricsEndpoints.tlsConfig**
  object

  TLS configuration to use when scraping the endpoint.

  - **spec.podMetricsEndpoints.tlsConfig.ca**
    object

    Certificate authority used when verifying server certificates.

    - **spec.podMetricsEndpoints.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.podMetricsEndpoints.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.podMetricsEndpoints.tlsConfig.ca.configMap.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.podMetricsEndpoints.tlsConfig.ca.configMap.optional**
          boolean

          Specify whether the ConfigMap or its key must be defined

      - **spec.podMetricsEndpoints.tlsConfig.ca.secret**
        object

        Secret containing data to use for the targets.

        - **spec.podMetricsEndpoints.tlsConfig.ca.secret.key**
          string

          Required value

          The key of the secret to select from. Must be a valid secret key.

        - **spec.podMetricsEndpoints.tlsConfig.ca.secret.name**
          string

          Name of the referent. More info:
          https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.podMetricsEndpoints.tlsConfig.ca.secret.optional**
          boolean

          Specify whether the Secret or its key must be defined

    - **spec.podMetricsEndpoints.tlsConfig.cert**
      object

      Client certificate to present when doing client-authentication.

      - **spec.podMetricsEndpoints.tlsConfig.cert.configMap**
        object

        ConfigMap containing data to use for the targets.

        - **spec.podMetricsEndpoints.tlsConfig.cert.configMap.key**
          string

          Required value

          The key to select.

        - **spec.podMetricsEndpoints.tlsConfig.cert.configMap.name**
          string

          Name of the referent. More info:
          https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.podMetricsEndpoints.tlsConfig.cert.configMap.optional**
          boolean

          Specify whether the ConfigMap or its key must be defined

      - **spec.podMetricsEndpoints.tlsConfig.cert.secret**
        object

        Secret containing data to use for the targets.

        - **spec.podMetricsEndpoints.tlsConfig.cert.secret.key**
          string

          Required value

          The key of the secret to select from. Must be a valid secret key.

        - **spec.podMetricsEndpoints.tlsConfig.cert.secret.name**
          string

          Name of the referent. More info:
          https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.podMetricsEndpoints.tlsConfig.cert.secret.optional**
          boolean

          Specify whether the Secret or its key must be defined

    - **spec.podMetricsEndpoints.tlsConfig.insecureSkipVerify**

boolean

Disable target certificate validation.

- **spec.podMetricsEndpoints.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.podMetricsEndpoints.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.podMetricsEndpoints.tlsConfig.keySecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.podMetricsEndpoints.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.podMetricsEndpoints.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.podTargetLabels**
  array of strings

  PodTargetLabels transfers labels on the Kubernetes Pod onto the target.

- **spec.sampleLimit**
  integer

  SampleLimit defines per-scrape limit on number of scraped samples that will be accepted.

- **spec.selector**
  object

  Required value

  Selector to select Pod objects.

  - **spec.selector.matchExpressions**
    array of objects

    matchExpressions is a list of label selector requirements. The requirements are ANDed.

    A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

    - **spec.selector.matchExpressions.key**
      string

      Required value

      key is the label key that the selector applies to.

    - **spec.selector.matchExpressions.operator**
      string

      Required value

      operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

    - **spec.selector.matchExpressions.values**
      array of strings

      values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

  - **spec.selector.matchLabels**
    object

    matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is

equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **spec.targetLimit**
  integer

  TargetLimit defines a limit on the number of scraped targets that will be accepted.

Probe

Short names: prb

Scope: Namespaced
Version: v1

Probe defines monitoring for a set of static targets or ingresses.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  Required value

  Specification of desired Ingress selection for target discovery by Prometheus.

  - **spec.authorization**
    object

    Authorization section for this endpoint

    - **spec.authorization.credentials**
      object

      Selects a key of a Secret in the namespace that contains the credentials for authentication.

      - **spec.authorization.credentials.key**
        string

        Required value

        The key of the secret to select from. Must be a valid secret key.

      - **spec.authorization.credentials.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.authorization.credentials.optional**
        boolean

        Specify whether the Secret or its key must be defined

    - **spec.authorization.type**
      string

      Defines the authentication type. The value is case-insensitive. “Basic” is not a supported value. Default: “Bearer”

  - **spec.basicAuth**
    object

    BasicAuth allow an endpoint to authenticate over basic authentication. More info: https://prometheus.io/docs/operating/configuration/#endpoint

    - **spec.basicAuth.password**
      object

The secret in the service monitor namespace that contains the password for authentication.

- **spec.basicAuth.password.key**
  string

  Required value

  The key of the secret to select from. Must be a valid secret key.

- **spec.basicAuth.password.name**
  string

  Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.basicAuth.password.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.basicAuth.username**
  object

  The secret in the service monitor namespace that contains the username for authentication.

  - **spec.basicAuth.username.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.basicAuth.username.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.basicAuth.username.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.bearerTokenSecret**
  object

  Secret to mount to read bearer token for scraping targets. The secret needs to be in the same namespace as the probe and accessible by the Prometheus Operator.

  - **spec.bearerTokenSecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.bearerTokenSecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.bearerTokenSecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.interval**
  string

  Interval at which targets are probed using the configured prober. If not specified Prometheus' global scrape interval is used.

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.jobName**
  string

  The job name assigned to scraped metrics by default.

- **spec.keepDroppedTargets**
  integer

Per-scrape limit on the number of targets dropped by relabeling that will be kept in memory. 0 means no limit. It requires Prometheus >= v2.47.0.

- **spec.labelLimit**
  integer

  Per-scrape limit on number of labels that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelNameLengthLimit**
  integer

  Per-scrape limit on length of labels name that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelValueLengthLimit**
  integer

  Per-scrape limit on length of labels value that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.metricRelabelings**
  array of objects

  MetricRelabelConfigs to apply to samples before ingestion.

  RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  - **spec.metricRelabelings.action**
    string

    Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: “Replace”

    Default: `replace`

    Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

  - **spec.metricRelabelings.modulus**
    integer

    Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

  - **spec.metricRelabelings.regex**
    string

    Regular expression against which the extracted value is matched.

  - **spec.metricRelabelings.replacement**
    string

    Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

  - **spec.metricRelabelings.separator**
    string

    Separator is the string between concatenated SourceLabels.

  - **spec.metricRelabelings.sourceLabels**
    array of strings

    The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

    - **Element of the array**
      string

      LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

      Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

  - **spec.metricRelabelings.targetLabel**
    string

Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.module**
  string

  The module to use for probing specifying how to probe the target. Example module configuring in the blackbox exporter:
  https://github.com/prometheus/blackbox_exporter/blob/master/example.yml

- **spec.oauth2**
  object

  OAuth2 for the URL. Only valid in Prometheus versions 2.27.0 and newer.

  - **spec.oauth2.clientId**
    object

    Required value

    The secret or configmap containing the OAuth2 client id

    - **spec.oauth2.clientId.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.oauth2.clientId.configMap.key**
        string

        Required value

        The key to select.

      - **spec.oauth2.clientId.configMap.name**
        string

        Name of the referent. More info:
        https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.oauth2.clientId.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must be defined

    - **spec.oauth2.clientId.secret**
      object

      Secret containing data to use for the targets.

      - **spec.oauth2.clientId.secret.key**
        string

        Required value

        The key of the secret to select from. Must be a valid secret key.

      - **spec.oauth2.clientId.secret.name**
        string

        Name of the referent. More info:
        https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.oauth2.clientId.secret.optional**
        boolean

        Specify whether the Secret or its key must be defined

  - **spec.oauth2.clientSecret**
    object

    Required value

    The secret containing the OAuth2 client secret

    - **spec.oauth2.clientSecret.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

        - **spec.oauth2.clientSecret.name**
          string

          Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.oauth2.clientSecret.optional**
          boolean

          Specify whether the Secret or its key must be defined

      - **spec.oauth2.endpointParams**
        object

        Parameters to append to the token URL

      - **spec.oauth2.scopes**
        array of strings

        OAuth2 scopes used for the token request

      - **spec.oauth2.tokenUrl**
        string

        Required value

        The URL to fetch the token from

  - **spec.prober**
    object

    Specification for the prober to use for probing targets. The prober.URL parameter is required. Targets cannot be probed if left empty.

      - **spec.prober.path**
        string

        Path to collect metrics from. Defaults to `/probe`.

        Default: `/probe`

      - **spec.prober.proxyUrl**
        string

        Optional ProxyURL.

      - **spec.prober.scheme**
        string

        HTTP scheme to use for scraping. `http` and `https` are the expected values unless you rewrite the `__scheme__` label via relabeling. If empty, Prometheus uses the default value `http`.

        Allowed values: `http`, `https`

      - **spec.prober.url**
        string

        Required value

        Mandatory URL of the prober.

  - **spec.sampleLimit**
    integer

    SampleLimit defines per-scrape limit on number of scraped samples that will be accepted.

  - **spec.scrapeTimeout**
    string

    Timeout for scraping metrics from the Prometheus exporter. If not specified, the Prometheus global scrape timeout is used.

    Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

  - **spec.targetLimit**
    integer

    TargetLimit defines a limit on the number of scraped targets that will be accepted.

  - **spec.targets**
    object

Targets defines a set of static or dynamically discovered targets to probe.

- **spec.targets.ingress**
  object

  ingress defines the Ingress objects to probe and the relabeling configuration. If `staticConfig` is also defined, `staticConfig` takes precedence.

  - **spec.targets.ingress.namespaceSelector**
    object

    From which namespaces to select Ingress objects.

    - **spec.targets.ingress.namespaceSelector.any**
      boolean

      Boolean describing whether all namespaces are selected in contrast to a list restricting them.

    - **spec.targets.ingress.namespaceSelector.matchNames**
      array of strings

      List of namespace names to select from.

  - **spec.targets.ingress.relabelingConfigs**
    array of objects

    RelabelConfigs to apply to the label set of the target before it gets scraped. The original ingress address is available via the `__tmp_prometheus_ingress_address` label. It can be used to customize the probed URL. The original scrape job's name is available via the `__tmp_prometheus_job_name` label. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

    RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

    - **spec.targets.ingress.relabelingConfigs.action**
      string

      Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: "Replace"

      Default: `replace`

      Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

    - **spec.targets.ingress.relabelingConfigs.modulus**
      integer

      Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

    - **spec.targets.ingress.relabelingConfigs.regex**
      string

      Regular expression against which the extracted value is matched.

    - **spec.targets.ingress.relabelingConfigs.replacement**
      string

      Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

    - **spec.targets.ingress.relabelingConfigs.separator**
      string

      Separator is the string between concatenated SourceLabels.

    - **spec.targets.ingress.relabelingConfigs.sourceLabels**
      array of strings

      The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

      - **Element of the array**
        string

LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

- **spec.targets.ingress.relabelingConfigs.targetLabel**
  string

  Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.targets.ingress.selector**
  object

  Selector to select the Ingress objects.

  - **spec.targets.ingress.selector.matchExpressions**
    array of objects

    matchExpressions is a list of label selector requirements. The requirements are ANDed.

    A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

    - **spec.targets.ingress.selector.matchExpressions.key**
      string

      Required value

      key is the label key that the selector applies to.

    - **spec.targets.ingress.selector.matchExpressions.operator**
      string

      Required value

      operator represents a key’s relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

    - **spec.targets.ingress.selector.matchExpressions.values**
      array of strings

      values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

  - **spec.targets.ingress.selector.matchLabels**
    object

    matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is “key”, the operator is “In”, and the values array contains only “value”. The requirements are ANDed.

- **spec.targets.staticConfig**
  object

  staticConfig defines the static list of targets to probe and the relabeling configuration. If `ingress` is also defined, `staticConfig` takes precedence. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#static_config.

  - **spec.targets.staticConfig.labels**
    object

    Labels assigned to all metrics scraped from the targets.

  - **spec.targets.staticConfig.relabelingConfigs**
    array of objects

    RelabelConfigs to apply to the label set of the targets before it gets scraped. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

    RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

    - **spec.targets.staticConfig.relabelingConfigs.action**
      string

Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: “Replace”

Default: `replace`

Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

- **spec.targets.staticConfig.relabelingConfigs.modulus**
  integer

  Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

- **spec.targets.staticConfig.relabelingConfigs.regex**
  string

  Regular expression against which the extracted value is matched.

- **spec.targets.staticConfig.relabelingConfigs.replacement**
  string

  Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

- **spec.targets.staticConfig.relabelingConfigs.separator**
  string

  Separator is the string between concatenated SourceLabels.

- **spec.targets.staticConfig.relabelingConfigs.sourceLabels**
  array of strings

  The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

  - **Element of the array**
    string

    LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

    Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

- **spec.targets.staticConfig.relabelingConfigs.targetLabel**
  string

  Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.targets.staticConfig.static**
  array of strings

  The list of hosts to probe.

- **spec.tlsConfig**
  object

  TLS configuration to use when scraping the endpoint.

  - **spec.tlsConfig.ca**
    object

    Certificate authority used when verifying server certificates.

    - **spec.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

- **spec.tlsConfig.ca.configMap.name**
  string

  Name of the referent. More info:
  https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.tlsConfig.ca.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must be defined

- **spec.tlsConfig.ca.secret**
  object

  Secret containing data to use for the targets.

  - **spec.tlsConfig.ca.secret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.tlsConfig.ca.secret.name**
    string

    Name of the referent. More info:
    https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.tlsConfig.ca.secret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.tlsConfig.cert**
  object

  Client certificate to present when doing client-authentication.

  - **spec.tlsConfig.cert.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.tlsConfig.cert.configMap.key**
      string

      Required value

      The key to select.

    - **spec.tlsConfig.cert.configMap.name**
      string

      Name of the referent. More info:
      https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.tlsConfig.cert.configMap.optional**
      boolean

      Specify whether the ConfigMap or its key must be defined

  - **spec.tlsConfig.cert.secret**
    object

    Secret containing data to use for the targets.

    - **spec.tlsConfig.cert.secret.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.tlsConfig.cert.secret.name**
      string

      Name of the referent. More info:
      https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.tlsConfig.cert.secret.optional**
      boolean

Specify whether the Secret or its key must be defined

- **spec.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.tlsConfig.keySecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

ScrapeConfig

Short names: scfg

Scope: Namespaced
Version: v1alpha1

ScrapeConfig defines a namespaced Prometheus scrape_config to be aggregated across multiple namespaces into the Prometheus configuration.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  Required value

  ScrapeConfigSpec is a specification of the desired configuration for a scrape configuration.

  - **spec.authorization**
    object

    Authorization header to use on every scrape request.

    - **spec.authorization.credentials**
      object

      Selects a key of a Secret in the namespace that contains the credentials for authentication.

      - **spec.authorization.credentials.key**
        string

        Required value

The key of the secret to select from. Must be a valid secret key.

- **spec.authorization.credentials.name**
  string

  Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.authorization.credentials.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.authorization.type**
  string

  Defines the authentication type. The value is case-insensitive. “Basic” is not a supported value. Default: “Bearer”

- **spec.basicAuth**
  object

  BasicAuth information to use on every scrape request.

  - **spec.basicAuth.password**
    object

    The secret in the service monitor namespace that contains the password for authentication.

    - **spec.basicAuth.password.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.basicAuth.password.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.basicAuth.password.optional**
      boolean

      Specify whether the Secret or its key must be defined

  - **spec.basicAuth.username**
    object

    The secret in the service monitor namespace that contains the username for authentication.

    - **spec.basicAuth.username.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.basicAuth.username.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.basicAuth.username.optional**
      boolean

      Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs**
  array of objects

  ConsulSDConfigs defines a list of Consul service discovery configurations.

  ConsulSDConfig defines a Consul service discovery configuration See https://prometheus.io/docs/prometheus/latest/configuration/configuration/#consul_sd_config

  - **spec.consulSDConfigs.allow_stale**
    boolean

    Allow stale Consul results (see https://www.consul.io/api/features/consistency.html). Will reduce load on Consul. If unset, Prometheus uses its default value.

- **spec.consulSDConfigs.authorization**
  object

  Authorization header configuration to authenticate against the Consul Server.

  - **spec.consulSDConfigs.authorization.credentials**
    object

    Selects a key of a Secret in the namespace that contains the credentials for authentication.

    - **spec.consulSDConfigs.authorization.credentials.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.consulSDConfigs.authorization.credentials.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.consulSDConfigs.authorization.credentials.optional**
      boolean

      Specify whether the Secret or its key must be defined

  - **spec.consulSDConfigs.authorization.type**
    string

    Defines the authentication type. The value is case-insensitive. “Basic” is not a supported value. Default: “Bearer”

- **spec.consulSDConfigs.basicAuth**
  object

  BasicAuth information to authenticate against the Consul Server. More info: https://prometheus.io/docs/operating/configuration/#endpoints

  - **spec.consulSDConfigs.basicAuth.password**
    object

    The secret in the service monitor namespace that contains the password for authentication.

    - **spec.consulSDConfigs.basicAuth.password.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.consulSDConfigs.basicAuth.password.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.consulSDConfigs.basicAuth.password.optional**
      boolean

      Specify whether the Secret or its key must be defined

  - **spec.consulSDConfigs.basicAuth.username**
    object

    The secret in the service monitor namespace that contains the username for authentication.

    - **spec.consulSDConfigs.basicAuth.username.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.consulSDConfigs.basicAuth.username.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.consulSDConfigs.basicAuth.username.optional**
          boolean

          Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.datacenter**
  string

  Consul Datacenter name, if not provided it will use the local Consul Agent Datacenter.

- **spec.consulSDConfigs.enable_http2**
  boolean

  Whether to enable HTTP2. If unset, Prometheus uses its default value.

- **spec.consulSDConfigs.follow_redirects**
  boolean

  Configure whether HTTP requests follow HTTP 3xx redirects. If unset, Prometheus uses its default value.

- **spec.consulSDConfigs.namespace**
  string

  Namespaces are only supported in Consul Enterprise.

- **spec.consulSDConfigs.no_proxy**
  string

  Comma-separated string that can contain IPs, CIDR notation, domain names that should be excluded from proxying. IP and domain names can contain port numbers.

- **spec.consulSDConfigs.node_meta**
  object

  Node metadata key/value pairs to filter nodes for a given service.

- **spec.consulSDConfigs.oauth2**
  object

  Optional OAuth 2.0 configuration.

    - **spec.consulSDConfigs.oauth2.clientId**
      object

      Required value

      The secret or configmap containing the OAuth2 client id

        - **spec.consulSDConfigs.oauth2.clientId.configMap**
          object

          ConfigMap containing data to use for the targets.

            - **spec.consulSDConfigs.oauth2.clientId.configMap.key**
              string

              Required value

              The key to select.

            - **spec.consulSDConfigs.oauth2.clientId.configMap.name**
              string

              Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

            - **spec.consulSDConfigs.oauth2.clientId.configMap.optional**
              boolean

              Specify whether the ConfigMap or its key must be defined

        - **spec.consulSDConfigs.oauth2.clientId.secret**
          object

          Secret containing data to use for the targets.

            - **spec.consulSDConfigs.oauth2.clientId.secret.key**
              string

              Required value

The key of the secret to select from. Must be a valid secret key.

- **spec.consulSDConfigs.oauth2.clientId.secret.name**
  string

  Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.consulSDConfigs.oauth2.clientId.secret.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.oauth2.clientSecret**
  object

  Required value

  The secret containing the OAuth2 client secret

  - **spec.consulSDConfigs.oauth2.clientSecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.consulSDConfigs.oauth2.clientSecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.consulSDConfigs.oauth2.clientSecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.oauth2.endpointParams**
  object

  Parameters to append to the token URL

- **spec.consulSDConfigs.oauth2.scopes**
  array of strings

  OAuth2 scopes used for the token request

- **spec.consulSDConfigs.oauth2.tokenUrl**
  string

  Required value

  The URL to fetch the token from

- **spec.consulSDConfigs.partition**
  string

  Admin Partitions are only supported in Consul Enterprise.

- **spec.consulSDConfigs.proxy_connect_header**
  object

  Specifies headers to send to proxies during CONNECT requests.

  - **spec.consulSDConfigs.proxy_connect_header.<KEY_NAME>**
    object

    `<KEY_NAME>` — item (key) name.

    SecretKeySelector selects a key of a Secret.

    - **spec.consulSDConfigs.proxy_connect_header.<KEY_NAME>.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.consulSDConfigs.proxy_connect_header.<KEY_NAME>.name**
      string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.consulSDConfigs.proxy_connect_header.<KEY_NAME>.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.proxy_from_environment**
  boolean

  Use proxy URL indicated by environment variables (HTTP_PROXY, https_proxy, HTTPs_PROXY, https_proxy, and no_proxy) If unset, Prometheus uses its default value.

- **spec.consulSDConfigs.proxy_url**
  string

  Optional proxy URL.

- **spec.consulSDConfigs.refresh_interval**
  string

  The time after which the provided names are refreshed. On large setup it might be a good idea to increase this value because the catalog will change all the time. If unset, Prometheus uses its default value.

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.consulSDConfigs.scheme**
  string

  HTTP Scheme default “http”

  Allowed values: `HTTP`, `HTTPS`

- **spec.consulSDConfigs.server**
  string

  Required value

  A valid string consisting of a hostname or IP followed by an optional port number.

- **spec.consulSDConfigs.services**
  array of strings

  A list of services for which targets are retrieved. If omitted, all services are scraped.

- **spec.consulSDConfigs.tag_separator**
  string

  The string by which Consul tags are joined into the tag label. If unset, Prometheus uses its default value.

- **spec.consulSDConfigs.tags**
  array of strings

  An optional list of tags used to filter nodes for a given service. Services must contain all tags in the list.

- **spec.consulSDConfigs.tlsConfig**
  object

  TLS Config

  - **spec.consulSDConfigs.tlsConfig.ca**
    object

    Certificate authority used when verifying server certificates.

    - **spec.consulSDConfigs.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.consulSDConfigs.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.consulSDConfigs.tlsConfig.ca.configMap.name**

string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.consulSDConfigs.tlsConfig.ca.configMap.optional**
boolean

Specify whether the ConfigMap or its key must be defined

- **spec.consulSDConfigs.tlsConfig.ca.secret**
object

Secret containing data to use for the targets.

- **spec.consulSDConfigs.tlsConfig.ca.secret.key**
string

Required value

The key of the secret to select from. Must be a valid secret key.

- **spec.consulSDConfigs.tlsConfig.ca.secret.name**
string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.consulSDConfigs.tlsConfig.ca.secret.optional**
boolean

Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.tlsConfig.cert**
object

Client certificate to present when doing client-authentication.

- **spec.consulSDConfigs.tlsConfig.cert.configMap**
object

ConfigMap containing data to use for the targets.

- **spec.consulSDConfigs.tlsConfig.cert.configMap.key**
string

Required value

The key to select.

- **spec.consulSDConfigs.tlsConfig.cert.configMap.name**
string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.consulSDConfigs.tlsConfig.cert.configMap.optional**
boolean

Specify whether the ConfigMap or its key must be defined

- **spec.consulSDConfigs.tlsConfig.cert.secret**
object

Secret containing data to use for the targets.

- **spec.consulSDConfigs.tlsConfig.cert.secret.key**
string

Required value

The key of the secret to select from. Must be a valid secret key.

- **spec.consulSDConfigs.tlsConfig.cert.secret.name**
string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.consulSDConfigs.tlsConfig.cert.secret.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.consulSDConfigs.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.consulSDConfigs.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.consulSDConfigs.tlsConfig.keySecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.consulSDConfigs.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.consulSDConfigs.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.consulSDConfigs.tokenRef**
  object

  Consul ACL TokenRef, if not provided it will use the ACL from the local Consul Agent.

  - **spec.consulSDConfigs.tokenRef.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.consulSDConfigs.tokenRef.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.consulSDConfigs.tokenRef.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.dnsSDConfigs**
  array of objects

  DNSSDConfigs defines a list of DNS service discovery configurations.

  DNSSDConfig allows specifying a set of DNS domain names which are periodically queried to discover a list of targets. The DNS servers to be contacted are read from /etc/resolv.conf. See https://prometheus.io/docs/prometheus/latest/configuration/configuration/#dns_sd_config

  - **spec.dnsSDConfigs.names**
    array of strings

    Required value

    A list of DNS domain names to be queried.

  - **spec.dnsSDConfigs.port**
    integer

    The port number used if the query type is not SRV Ignored for SRV records

  - **spec.dnsSDConfigs.refreshInterval**

string

RefreshInterval configures the time after which the provided names are refreshed. If not set, Prometheus uses its default value.

Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.dnsSDConfigs.type**
  string

  The type of DNS query to perform. One of SRV, A, AAAA or MX. If not set, Prometheus uses its default value.

  Allowed values: `SRV`, `A`, `AAAA`, `MX`

- **spec.fileSDConfigs**
  array of objects

  FileSDConfigs defines a list of file service discovery configurations.

  FileSDConfig defines a Prometheus file service discovery configuration See https://prometheus.io/docs/prometheus/latest/configuration/configuration/#file_sd_config

  - **spec.fileSDConfigs.files**
    array of strings

    Required value

    List of files to be used for file discovery. Recommendation: use absolute paths. While relative paths work, the prometheus-operator project makes no guarantees about the working directory where the configuration file is stored. Files must be mounted using Prometheus.ConfigMaps or Prometheus.Secrets.

    - **Element of the array**
      string

      SDFile represents a file used for service discovery

      Pattern: `^[^*]*(\*[^/]*)?\.(json|yml|yaml|JSON|YML|YAML)$`

  - **spec.fileSDConfigs.refreshInterval**
    string

    RefreshInterval configures the refresh interval at which Prometheus will reload the content of the files.

    Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.honorLabels**
  boolean

  HonorLabels chooses the metric’s labels on collisions with target labels.

- **spec.honorTimestamps**
  boolean

  HonorTimestamps controls whether Prometheus respects the timestamps present in scraped data.

- **spec.httpSDConfigs**
  array of objects

  HTTPSDConfigs defines a list of HTTP service discovery configurations.

  HTTPSDConfig defines a prometheus HTTP service discovery configuration See https://prometheus.io/docs/prometheus/latest/configuration/configuration/#http_sd_config

  - **spec.httpSDConfigs.authorization**
    object

    Authorization header configuration to authenticate against the target HTTP endpoint.

    - **spec.httpSDConfigs.authorization.credentials**
      object

      Selects a key of a Secret in the namespace that contains the credentials for authentication.

      - **spec.httpSDConfigs.authorization.credentials.key**
        string

        Required value

The key of the secret to select from. Must be a valid secret key.

- **spec.httpSDConfigs.authorization.credentials.name**
  string

  Name of the referent. More info:
  https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.httpSDConfigs.authorization.credentials.optional**
  boolean

  Specify whether the Secret or its key must be defined

- **spec.httpSDConfigs.authorization.type**
  string

  Defines the authentication type. The value is case-insensitive. “Basic” is not a supported value. Default: “Bearer”

- **spec.httpSDConfigs.basicAuth**
  object

  BasicAuth information to authenticate against the target HTTP endpoint. More info:
  https://prometheus.io/docs/operating/configuration/#endpoints

  - **spec.httpSDConfigs.basicAuth.password**
    object

    The secret in the service monitor namespace that contains the password for authentication.

    - **spec.httpSDConfigs.basicAuth.password.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.httpSDConfigs.basicAuth.password.name**
      string

      Name of the referent. More info:
      https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.httpSDConfigs.basicAuth.password.optional**
      boolean

      Specify whether the Secret or its key must be defined

  - **spec.httpSDConfigs.basicAuth.username**
    object

    The secret in the service monitor namespace that contains the username for authentication.

    - **spec.httpSDConfigs.basicAuth.username.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.httpSDConfigs.basicAuth.username.name**
      string

      Name of the referent. More info:
      https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.httpSDConfigs.basicAuth.username.optional**
      boolean

      Specify whether the Secret or its key must be defined

- **spec.httpSDConfigs.refreshInterval**
  string

  RefreshInterval configures the refresh interval at which Prometheus will re-query the endpoint to update the target list.

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.httpSDConfigs.tlsConfig**

object

TLS configuration applying to the target HTTP endpoint.

- **spec.httpSDConfigs.tlsConfig.ca**
  object

  Certificate authority used when verifying server certificates.

  - **spec.httpSDConfigs.tlsConfig.ca.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.httpSDConfigs.tlsConfig.ca.configMap.key**
      string

      Required value

      The key to select.

    - **spec.httpSDConfigs.tlsConfig.ca.configMap.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.httpSDConfigs.tlsConfig.ca.configMap.optional**
      boolean

      Specify whether the ConfigMap or its key must be defined

  - **spec.httpSDConfigs.tlsConfig.ca.secret**
    object

    Secret containing data to use for the targets.

    - **spec.httpSDConfigs.tlsConfig.ca.secret.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.httpSDConfigs.tlsConfig.ca.secret.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.httpSDConfigs.tlsConfig.ca.secret.optional**
      boolean

      Specify whether the Secret or its key must be defined

- **spec.httpSDConfigs.tlsConfig.cert**
  object

  Client certificate to present when doing client-authentication.

  - **spec.httpSDConfigs.tlsConfig.cert.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.httpSDConfigs.tlsConfig.cert.configMap.key**
      string

      Required value

      The key to select.

    - **spec.httpSDConfigs.tlsConfig.cert.configMap.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.httpSDConfigs.tlsConfig.cert.configMap.optional**
      boolean

Specify whether the ConfigMap or its key must be defined

- **spec.httpSDConfigs.tlsConfig.cert.secret**
  object

  Secret containing data to use for the targets.

  - **spec.httpSDConfigs.tlsConfig.cert.secret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.httpSDConfigs.tlsConfig.cert.secret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.httpSDConfigs.tlsConfig.cert.secret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.httpSDConfigs.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.httpSDConfigs.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.httpSDConfigs.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.httpSDConfigs.tlsConfig.keySecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.httpSDConfigs.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.httpSDConfigs.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.httpSDConfigs.url**
  string

  Required value

  URL from which the targets are fetched.

  Pattern: `^http(s)?://.+$`

- **spec.keepDroppedTargets**
  integer

  Per-scrape limit on the number of targets dropped by relabeling that will be kept in memory. 0 means no limit. It requires Prometheus >= v2.47.0.

- **spec.kubernetesSDConfigs**
  array of objects

  KubernetesSDConfigs defines a list of Kubernetes service discovery configurations.

  KubernetesSDConfig allows retrieving scrape targets from Kubernetes' REST API. See https://prometheus.io/docs/prometheus/latest/configuration/configuration/#kubernetes_sd_config

  - **spec.kubernetesSDConfigs.role**

string

Required value

Role of the Kubernetes entities that should be discovered. Currently the only supported role is “Node”.

Allowed values: `Node`

- **spec.labelLimit**
  integer

  Per-scrape limit on number of labels that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelNameLengthLimit**
  integer

  Per-scrape limit on length of labels name that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelValueLengthLimit**
  integer

  Per-scrape limit on length of labels value that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.metricRelabelings**
  array of objects

  MetricRelabelConfigs to apply to samples before ingestion.

  RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  - **spec.metricRelabelings.action**
    string

    Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: “Replace”

    Default: `replace`

    Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

  - **spec.metricRelabelings.modulus**
    integer

    Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

  - **spec.metricRelabelings.regex**
    string

    Regular expression against which the extracted value is matched.

  - **spec.metricRelabelings.replacement**
    string

    Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

  - **spec.metricRelabelings.separator**
    string

    Separator is the string between concatenated SourceLabels.

  - **spec.metricRelabelings.sourceLabels**
    array of strings

    The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

    - **Element of the array**
      string

      LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

- **spec.metricRelabelings.targetLabel**
  string

  Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.metricsPath**
  string

  MetricsPath HTTP path to scrape for metrics. If empty, Prometheus uses the default value (e.g. /metrics).

- **spec.params**
  object

  Optional HTTP URL parameters

- **spec.relabelings**
  array of objects

  RelabelConfigs defines how to rewrite the target's labels before scraping. Prometheus Operator automatically adds relabelings for a few standard Kubernetes fields. The original scrape job's name is available via the `__tmp_prometheus_job_name` label. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  - **spec.relabelings.action**
    string

    Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: "Replace"

    Default: `replace`

    Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

  - **spec.relabelings.modulus**
    integer

    Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

  - **spec.relabelings.regex**
    string

    Regular expression against which the extracted value is matched.

  - **spec.relabelings.replacement**
    string

    Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

  - **spec.relabelings.separator**
    string

    Separator is the string between concatenated SourceLabels.

  - **spec.relabelings.sourceLabels**
    array of strings

    The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

    - **Element of the array**
      string

      LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

      Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

  - **spec.relabelings.targetLabel**

string

Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.sampleLimit**
integer

SampleLimit defines per-scrape limit on number of scraped samples that will be accepted.

- **spec.scheme**
string

Configures the protocol scheme used for requests. If empty, Prometheus uses HTTP by default.

Allowed values: `HTTP`, `HTTPS`

- **spec.scrapeInterval**
string

ScrapeInterval is the interval between consecutive scrapes.

Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.scrapeTimeout**
string

ScrapeTimeout is the number of seconds to wait until a scrape request times out.

Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.staticConfigs**
array of objects

StaticConfigs defines a list of static targets with a common label set.

StaticConfig defines a Prometheus static configuration. See https://prometheus.io/docs/prometheus/latest/configuration/configuration/#scrape_config

  - **spec.staticConfigs.labels**
  object

  Labels assigned to all metrics scraped from the targets.

  - **spec.staticConfigs.targets**
  array of strings

  List of targets for this static configuration.

    - **Element of the array**
    string

    Target represents a target for Prometheus to scrape

- **spec.targetLimit**
integer

TargetLimit defines a limit on the number of scraped targets that will be accepted.

- **spec.tlsConfig**
object

TLS configuration to use on every scrape request

  - **spec.tlsConfig.ca**
  object

  Certificate authority used when verifying server certificates.

    - **spec.tlsConfig.ca.configMap**
    object

    ConfigMap containing data to use for the targets.

      - **spec.tlsConfig.ca.configMap.key**
      string

      Required value

      The key to select.

- **spec.tlsConfig.ca.configMap.name**
  string

  Name of the referent. More info:
  https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.tlsConfig.ca.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must be defined

- **spec.tlsConfig.ca.secret**
  object

  Secret containing data to use for the targets.

  - **spec.tlsConfig.ca.secret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.tlsConfig.ca.secret.name**
    string

    Name of the referent. More info:
    https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.tlsConfig.ca.secret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.tlsConfig.cert**
  object

  Client certificate to present when doing client-authentication.

  - **spec.tlsConfig.cert.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.tlsConfig.cert.configMap.key**
      string

      Required value

      The key to select.

    - **spec.tlsConfig.cert.configMap.name**
      string

      Name of the referent. More info:
      https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.tlsConfig.cert.configMap.optional**
      boolean

      Specify whether the ConfigMap or its key must be defined

  - **spec.tlsConfig.cert.secret**
    object

    Secret containing data to use for the targets.

    - **spec.tlsConfig.cert.secret.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.tlsConfig.cert.secret.name**
      string

      Name of the referent. More info:
      https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.tlsConfig.cert.secret.optional**
      boolean

Specify whether the Secret or its key must be defined

- **spec.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.tlsConfig.keySecret.name**
    string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must be defined

- **spec.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

ServiceMonitor

Short names: smon

Scope: Namespaced
Version: v1

ServiceMonitor defines monitoring for a set of services.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds

- **metadata**
  object
- **spec**
  object

  Required value

  Specification of desired Service selection for target discovery by Prometheus.

  - **spec.attachMetadata**
    object

    Attaches node metadata to discovered targets. Requires Prometheus v2.37.0 and above.

    - **spec.attachMetadata.node**
      boolean

      When set to true, Prometheus must have permissions to get Nodes.

  - **spec.endpoints**
    array of objects

    Required value

A list of endpoints allowed as part of this ServiceMonitor.

Endpoint defines a scrapeable endpoint serving Prometheus metrics.

- **spec.endpoints.authorization**
  object

  Authorization section for this endpoint

  - **spec.endpoints.authorization.credentials**
    object

    Selects a key of a Secret in the namespace that contains the credentials for authentication.

    - **spec.endpoints.authorization.credentials.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.endpoints.authorization.credentials.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.endpoints.authorization.credentials.optional**
      boolean

      Specify whether the Secret or its key must be defined

  - **spec.endpoints.authorization.type**
    string

    Defines the authentication type. The value is case-insensitive. “Basic” is not a supported value. Default: “Bearer”

- **spec.endpoints.basicAuth**
  object

  BasicAuth allow an endpoint to authenticate over basic authentication More info: https://prometheus.io/docs/operating/configuration/#endpoints

  - **spec.endpoints.basicAuth.password**
    object

    The secret in the service monitor namespace that contains the password for authentication.

    - **spec.endpoints.basicAuth.password.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.endpoints.basicAuth.password.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.endpoints.basicAuth.password.optional**
      boolean

      Specify whether the Secret or its key must be defined

  - **spec.endpoints.basicAuth.username**
    object

    The secret in the service monitor namespace that contains the username for authentication.

    - **spec.endpoints.basicAuth.username.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.endpoints.basicAuth.username.name**

string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.endpoints.basicAuth.username.optional**
boolean

Specify whether the Secret or its key must be defined

- **spec.endpoints.bearerTokenFile**
string

File to read bearer token for scraping targets.

- **spec.endpoints.bearerTokenSecret**
object

Secret to mount to read bearer token for scraping targets. The secret needs to be in the same namespace as the service monitor and accessible by the Prometheus Operator.

- **spec.endpoints.bearerTokenSecret.key**
string

Required value

The key of the secret to select from. Must be a valid secret key.

- **spec.endpoints.bearerTokenSecret.name**
string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.endpoints.bearerTokenSecret.optional**
boolean

Specify whether the Secret or its key must be defined

- **spec.endpoints.enableHttp2**
boolean

Whether to enable HTTP2.

- **spec.endpoints.filterRunning**
boolean

Drop pods that are not running. (Failed, Succeeded). Enabled by default. More info: https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle/#pod-phase

- **spec.endpoints.followRedirects**
boolean

FollowRedirects configures whether scrape requests follow HTTP 3xx redirects.

- **spec.endpoints.honorLabels**
boolean

HonorLabels chooses the metric’s labels on collisions with target labels.

- **spec.endpoints.honorTimestamps**
boolean

HonorTimestamps controls whether Prometheus respects the timestamps present in scraped data.

- **spec.endpoints.interval**
string

Interval at which metrics should be scraped If not specified Prometheus’ global scrape interval is used.

Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.endpoints.metricRelabelings**
array of objects

MetricRelabelConfigs to apply to samples before ingestion.

RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

- **spec.endpoints.metricRelabelings.action**
  string

  Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: “Replace”

  Default: `replace`

  Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

- **spec.endpoints.metricRelabelings.modulus**
  integer

  Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

- **spec.endpoints.metricRelabelings.regex**
  string

  Regular expression against which the extracted value is matched.

- **spec.endpoints.metricRelabelings.replacement**
  string

  Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

- **spec.endpoints.metricRelabelings.separator**
  string

  Separator is the string between concatenated SourceLabels.

- **spec.endpoints.metricRelabelings.sourceLabels**
  array of strings

  The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

  - **Element of the array**
    string

    LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

    Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

- **spec.endpoints.metricRelabelings.targetLabel**
  string

  Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.endpoints.oauth2**
  object

  OAuth2 for the URL. Only valid in Prometheus versions 2.27.0 and newer.

  - **spec.endpoints.oauth2.clientId**
    object

    Required value

    The secret or configmap containing the OAuth2 client id

    - **spec.endpoints.oauth2.clientId.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.endpoints.oauth2.clientId.configMap.key**
        string

        Required value

        The key to select.

      - **spec.endpoints.oauth2.clientId.configMap.name**
        string

Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

- **spec.endpoints.oauth2.clientId.configMap.optional**
boolean

  Specify whether the ConfigMap or its key must be defined

- **spec.endpoints.oauth2.clientId.secret**
object

  Secret containing data to use for the targets.

  - **spec.endpoints.oauth2.clientId.secret.key**
string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.endpoints.oauth2.clientId.secret.name**
string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.endpoints.oauth2.clientId.secret.optional**
boolean

    Specify whether the Secret or its key must be defined

- **spec.endpoints.oauth2.clientSecret**
object

  Required value

  The secret containing the OAuth2 client secret

  - **spec.endpoints.oauth2.clientSecret.key**
string

    Required value

    The key of the secret to select from. Must be a valid secret key.

  - **spec.endpoints.oauth2.clientSecret.name**
string

    Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

  - **spec.endpoints.oauth2.clientSecret.optional**
boolean

    Specify whether the Secret or its key must be defined

- **spec.endpoints.oauth2.endpointParams**
object

  Parameters to append to the token URL

- **spec.endpoints.oauth2.scopes**
array of strings

  OAuth2 scopes used for the token request

- **spec.endpoints.oauth2.tokenUrl**
string

  Required value

  The URL to fetch the token from

- **spec.endpoints.params**
object

  Optional HTTP URL parameters

- **spec.endpoints.path**
string

HTTP path to scrape for metrics. If empty, Prometheus uses the default value (e.g. `/metrics`).

- **spec.endpoints.port**
  string

  Name of the service port this endpoint refers to. Mutually exclusive with targetPort.

- **spec.endpoints.proxyUrl**
  string

  ProxyURL eg http://proxyserver:2195 Directs scrapes to proxy through this endpoint.

- **spec.endpoints.relabelings**
  array of objects

  RelabelConfigs to apply to samples before scraping. Prometheus Operator automatically adds relabelings for a few standard Kubernetes fields. The original scrape job's name is available via the `__tmp_prometheus_job_name` label. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  RelabelConfig allows dynamic rewriting of the label set for targets, alerts, scraped samples and remote write samples. More info: https://prometheus.io/docs/prometheus/latest/configuration/configuration/#relabel_config

  - **spec.endpoints.relabelings.action**
    string

    Action to perform based on the regex matching. `Uppercase` and `Lowercase` actions require Prometheus >= v2.36.0. `DropEqual` and `KeepEqual` actions require Prometheus >= v2.41.0. Default: "Replace"

    Default: `replace`

    Allowed values: `replace`, `Replace`, `keep`, `Keep`, `drop`, `Drop`, `hashmod`, `HashMod`, `labelmap`, `LabelMap`, `labeldrop`, `LabelDrop`, `labelkeep`, `LabelKeep`, `lowercase`, `Lowercase`, `uppercase`, `Uppercase`, `keepequal`, `KeepEqual`, `dropequal`, `DropEqual`

  - **spec.endpoints.relabelings.modulus**
    integer

    Modulus to take of the hash of the source label values. Only applicable when the action is `HashMod`.

  - **spec.endpoints.relabelings.regex**
    string

    Regular expression against which the extracted value is matched.

  - **spec.endpoints.relabelings.replacement**
    string

    Replacement value against which a Replace action is performed if the regular expression matches. Regex capture groups are available.

  - **spec.endpoints.relabelings.separator**
    string

    Separator is the string between concatenated SourceLabels.

  - **spec.endpoints.relabelings.sourceLabels**
    array of strings

    The source labels select values from existing labels. Their content is concatenated using the configured Separator and matched against the configured regular expression.

    - **Element of the array**
      string

      LabelName is a valid Prometheus label name which may only contain ASCII letters, numbers, as well as underscores.

      Pattern: `^[a-zA-Z_][a-zA-Z0-9_]*$`

  - **spec.endpoints.relabelings.targetLabel**
    string

    Label to which the resulting string is written in a replacement. It is mandatory for `Replace`, `HashMod`, `Lowercase`, `Uppercase`, `KeepEqual` and `DropEqual` actions. Regex capture groups are available.

- **spec.endpoints.scheme**
  string

  HTTP scheme to use for scraping. `http` and `https` are the expected values unless you rewrite the `__scheme__` label via relabeling. If empty, Prometheus uses the default value `http`.

  Allowed values: `http`, `https`

- **spec.endpoints.scrapeTimeout**
  string

  Timeout after which the scrape is ended If not specified, the Prometheus global scrape timeout is used unless it is less than `Interval` in which the latter is used.

  Pattern: `^(0|(([0-9]+)y)?(([0-9]+)w)?(([0-9]+)d)?(([0-9]+)h)?(([0-9]+)m)?(([0-9]+)s)?(([0-9]+)ms)?)$`

- **spec.endpoints.targetPort**
  integer or string

  Name or number of the target port of the Pod behind the Service, the port must be specified with container port property. Mutually exclusive with port.

- **spec.endpoints.tlsConfig**
  object

  TLS configuration to use when scraping the endpoint

  - **spec.endpoints.tlsConfig.ca**
    object

    Certificate authority used when verifying server certificates.

    - **spec.endpoints.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.endpoints.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.endpoints.tlsConfig.ca.configMap.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.endpoints.tlsConfig.ca.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must be defined

    - **spec.endpoints.tlsConfig.ca.secret**
      object

      Secret containing data to use for the targets.

      - **spec.endpoints.tlsConfig.ca.secret.key**
        string

        Required value

        The key of the secret to select from. Must be a valid secret key.

      - **spec.endpoints.tlsConfig.ca.secret.name**
        string

        Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

      - **spec.endpoints.tlsConfig.ca.secret.optional**
        boolean

        Specify whether the Secret or its key must be defined

  - **spec.endpoints.tlsConfig.caFile**

string

Path to the CA cert in the Prometheus container to use for the targets.

- **spec.endpoints.tlsConfig.cert**
  object

  Client certificate to present when doing client-authentication.

  - **spec.endpoints.tlsConfig.cert.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.endpoints.tlsConfig.cert.configMap.key**
      string

      Required value

      The key to select.

    - **spec.endpoints.tlsConfig.cert.configMap.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.endpoints.tlsConfig.cert.configMap.optional**
      boolean

      Specify whether the ConfigMap or its key must be defined

  - **spec.endpoints.tlsConfig.cert.secret**
    object

    Secret containing data to use for the targets.

    - **spec.endpoints.tlsConfig.cert.secret.key**
      string

      Required value

      The key of the secret to select from. Must be a valid secret key.

    - **spec.endpoints.tlsConfig.cert.secret.name**
      string

      Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

    - **spec.endpoints.tlsConfig.cert.secret.optional**
      boolean

      Specify whether the Secret or its key must be defined

- **spec.endpoints.tlsConfig.certFile**
  string

  Path to the client cert file in the Prometheus container for the targets.

- **spec.endpoints.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.endpoints.tlsConfig.keyFile**
  string

  Path to the client key file in the Prometheus container for the targets.

- **spec.endpoints.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.endpoints.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from. Must be a valid secret key.

        - **spec.endpoints.tlsConfig.keySecret.name**
          string

          Name of the referent. More info:
          https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names

        - **spec.endpoints.tlsConfig.keySecret.optional**
          boolean

          Specify whether the Secret or its key must be defined

      - **spec.endpoints.tlsConfig.serverName**
        string

        Used to verify the hostname for the targets.

- **spec.jobLabel**
  string

  JobLabel selects the label from the associated Kubernetes service which will be used as the `job` label for all metrics. For example: If in `ServiceMonitor.spec.jobLabel: foo` and in `Service.metadata.labels.foo: bar`, then the `job="bar"` label is added to all metrics. If the value of this field is empty or if the label doesn't exist for the given Service, the `job` label of the metrics defaults to the name of the Kubernetes Service.

- **spec.keepDroppedTargets**
  integer

  Per-scrape limit on the number of targets dropped by relabeling that will be kept in memory. 0 means no limit. It requires Prometheus >= v2.47.0.

- **spec.labelLimit**
  integer

  Per-scrape limit on number of labels that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelNameLengthLimit**
  integer

  Per-scrape limit on length of labels name that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.labelValueLengthLimit**
  integer

  Per-scrape limit on length of labels value that will be accepted for a sample. Only valid in Prometheus versions 2.27.0 and newer.

- **spec.namespaceSelector**
  object

  Selector to select which namespaces the Kubernetes Endpoints objects are discovered from.

    - **spec.namespaceSelector.any**
      boolean

      Boolean describing whether all namespaces are selected in contrast to a list restricting them.

    - **spec.namespaceSelector.matchNames**
      array of strings

      List of namespace names to select from.

- **spec.podTargetLabels**
  array of strings

  PodTargetLabels transfers labels on the Kubernetes `Pod` onto the created metrics.

- **spec.sampleLimit**
  integer

  SampleLimit defines per-scrape limit on number of scraped samples that will be accepted.

- **spec.selector**
  object

  Required value

  Selector to select Endpoints objects.

    - **spec.selector.matchExpressions**
      array of objects

matchExpressions is a list of label selector requirements. The requirements are ANDed.

A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

- **spec.selector.matchExpressions.key**
  string

  Required value

  key is the label key that the selector applies to.

- **spec.selector.matchExpressions.operator**
  string

  Required value

  operator represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

- **spec.selector.matchExpressions.values**
  array of strings

  values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **spec.selector.matchLabels**
  object

  matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is "key", the operator is "In", and the values array contains only "value". The requirements are ANDed.

- **spec.targetLabels**
  array of strings

  TargetLabels transfers labels from the Kubernetes `Service` onto the created metrics.

- **spec.targetLimit**
  integer

  TargetLimit defines a limit on the number of scraped targets that will be accepted.

The Prometheus monitoring module

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

> **i** Web interfaces associated with the module: grafana

The module expands the monitoring stack with preset parameters for DKP and applications, which simplifies the initial configuration.

Module features:

- The package includes ready—made triggers and dashboards, and supports push and pull models for collecting metrics. The load is optimized by using caches and Dekhouse Prom++.
- It is possible to store historical data using downsampling.
- The module covers all the basic tasks of basic monitoring of the platform and applications.

Monitoring hardware resources

Prometheus tracks hardware resources and displays the corresponding utilization graphs for:

- CPU
- Memory
- Disk drive
- Network

The graphs can be grouped by:

- Pods
- Controllers
- Namespaces
- Nodes

Kubernetes monitoring

Deckhouse configures monitoring of Kubernetes “health” parameters and its components such as:

- General cluster utilization.
- Connectivity of Kubernetes nodes to each other (RTT between all nodes is measured).
- Availability and operability of control plane components:
  - `etcd`.
  - `coredns`.
  - `kube-dns`.
  - `kube-apiserver` and others.
- Time synchronization on nodes and other parameters.

Ingress monitoring

The detailed description is available here.

Advanced monitoring mode

Deckhouse also provides the advanced monitoring mode that implements additional metrics-based alerts, such as: free space and inode-related, the node usage, the availability of Pods and container images, certificates expiration and other Kubernetes cluster events.

Alerting in advanced monitoring mode

Deckhouse allows you to flexibly configure alerts for each namespace and specify different levels of severity based on the threshold. You can set thresholds in various namespaces for the following parameters:

- Empty space and inodes on a disk.
- CPU usage for a node and a container.
- Percent of `5xx` errors on `ingress-nginx`.
- Number of unavailable Pods in a `Deployment`, `StatefulSet`, `DaemonSet`.

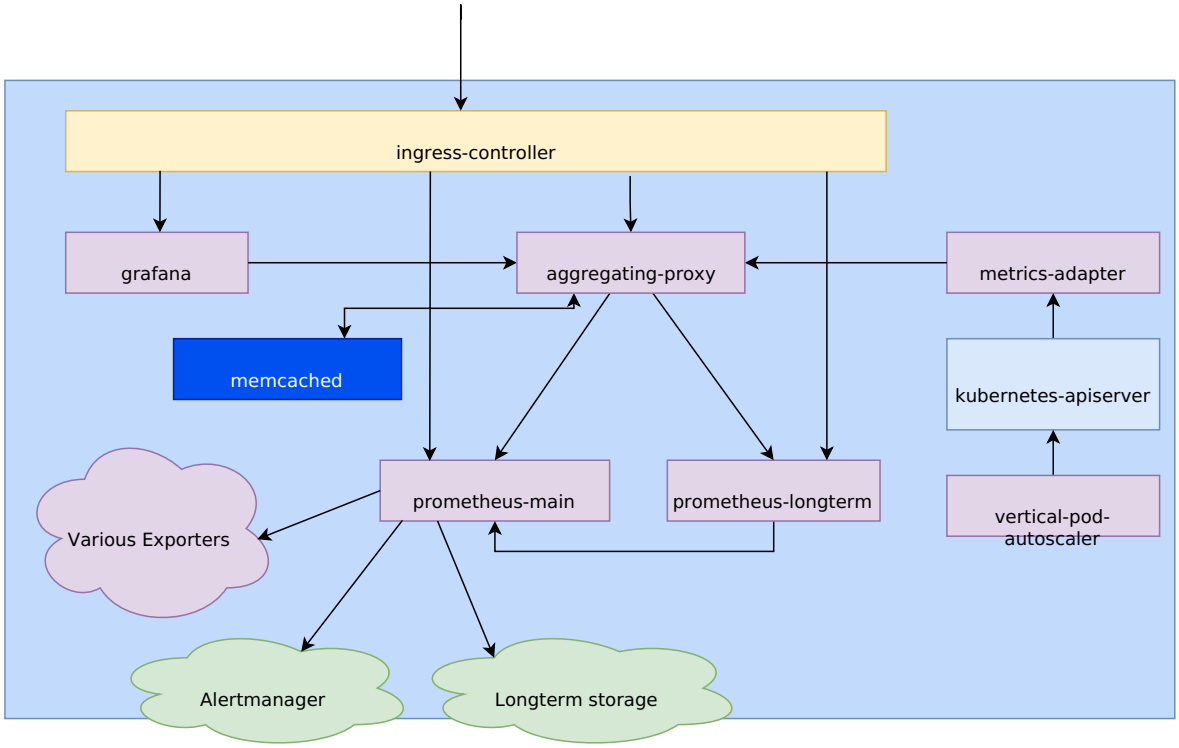
Monitoring Management as code (IaC approach)

The capabilities of the DKP monitoring system can be expanded by using the Observability module. It is used to implement:

- managing alerts;
- differentiation of access rights to settings and monitoring data;
- centralized dashboard management.

Alerts

The Deckhouse monitoring includes event notifications. The standard edition includes a set of basic alerts covering the health of the cluster and its components. Also, you can add custom alerts.



For the list of all available alerts in the Deckhouse Kubernetes Platform monitoring system, refer to the corresponding documentation page.

Sending alerts to external systems

Deckhouse supports sending alerts using `Alertmanager`:

- Via the SMTP protocol
- To PagerDuty
- To Slack
- To Telegram
- Via the Webhook mechanism
- By any other means supported in Alertmanager

Architecture

Basic monitoring components

Name	Description
prometheus-main	The primary Prometheus instance that scrapes metrics every 30 seconds (you can change this value using the `scrapeInterval` parameter). It processes all the rules, sends alerts, and serves as the main data source.
prometheus-longterm	The secondary Prometheus instance that scrapes the data of the primary Prometheus instance (`prometheus-main`) every 5 minutes (you can change this value using the `longtermScrapeInterval` parameter). It is used for long-term history storage and displaying data for large periods.
trickster	The caching proxy that reduces the load on Prometheus.
aggregating-proxy	An aggregating and caching proxy that reduces the load on Prometheus and aggregate both main and longterm in single datasource.
memcached	Distributed memory caching system.
grafana	The managed observability platform with ready-to-use dashboards for all Deckhouse modules and popular applications. Grafana instances are highly available, stateless, and configured by CRDs.
metrics-adapter	The component connecting Prometheus and Kubernetes metrics API. It enables HPA support in a Kubernetes cluster.
vertical-pod-autoscaler	An autoscaling tool to help size Pods for the optimal CPU and memory resources required by the Pods.
Various Exporters	Precooked exporters connected to Prometheus. The list includes exporters for all necessary metrics: `kube-state-metrics`, `node-exporter`, `oomkill-exporter`, `image-availability-exporter`, and many more.

Name	Description
Push/pull the metric collection model	Monitoring uses a pull model by default. Data is collected from applications at the initiative of the monitoring system. The push model is also supported: metrics can be transmitted via the Prometheus Remote Write protocol or using the Prometheus Pushgateway.

Fault Tolerance and High Availability Monitoring (HA) mode

The monitoring module provides built-in fault tolerance for all key DKP components. All monitoring services (Prometheus servers, storage systems, proxies, and other important components) are deployed in multiple copies by default. This ensures that in the event of a failure of a separate instance, the service will continue to work without loss of data and availability.

Prometheus, the main component of metric collection, runs in at least two copies (if there are enough nodes in the cluster). Both Prometheus instances use the same configuration and receive the same data. To ensure seamless operation in case of failure of one of the copies, a special component, the aggregation proxy, is used to access Prometheus. It allows you to combine metrics from both Prometheus instances and always return the most complete and up-to-date data, even if one of the copies is temporarily unavailable.

Third-party components

List of third-party software used in the `prometheus` module:

- Prometheus

  License: Apache License 2.0

  A systems and service monitoring system.

- Grafana

  License: GNU Affero General Public License v3.0

  An open-source platform for monitoring and observability.

- Trickster

  License: Apache License 2.0

  A HTTP reverse proxy/cache for http applications and a dashboard query accelerator for time series databases.

- Mimir

  License: AGPL-3.0 license

  A HTTP reverse proxy/cache for http applications and a dashboard query accelerator for time series databases.

- Promxy

  License: MIT License

  Promxy is a prometheus proxy that makes many shards of prometheus appear as a single API endpoint to the user. This significantly simplifies operations and use of prometheus at scale (when you have more than one prometheus host).

- Memcached

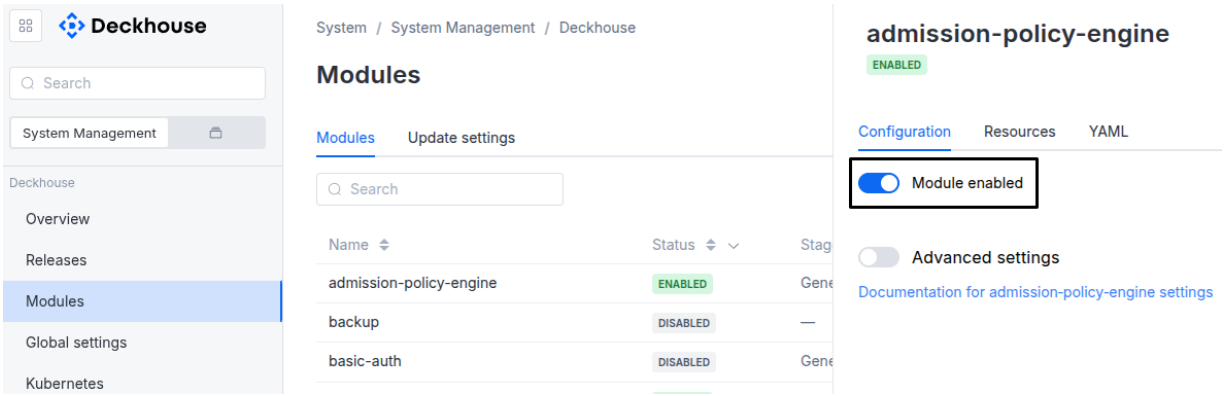
  License: BSD-3-Clause license

  High performance multithreaded event-based key/value cache store intended to be used in a distributed system.

Configuration

> The module lifecycle stage: General Availability
> The module has requirements for installation

The module does not require any configuration – it works right out-of-the-box.



The module has 28 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `prometheus` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

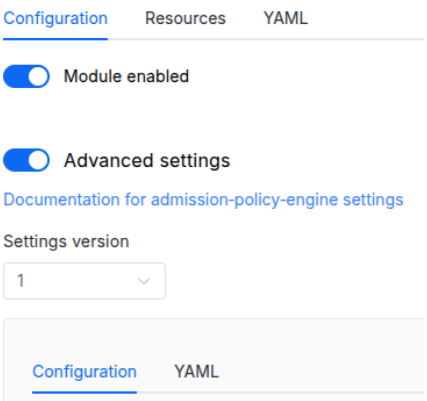
```
d8 system module enable prometheus
```

- **Using ModuleConfig `prometheus`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `prometheus` (create it if necessary);

  Example of a manifest to enable module `prometheus`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `prometheus` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `prometheus` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `prometheus`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

Edit the existing ModuleConfig `prometheus` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc prometheus
```

Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `prometheus` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `prometheus`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus
spec:
  version: 2
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Requirements

To the versions of other modules:

- `operator-prometheus`: any version.

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Remove the `.auth.password` field. If the `.auth` object becomes empty after this change, delete it.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.auth**
    object

    Options related to authentication or authorization in the application.

    - **settings.auth.allowedUserEmails**
      array of strings

      An array of emails of users that can access module’s public web interfaces.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.
    - **settings.auth.allowedUserGroups**
      array of strings

      An array of user groups that can access Grafana & Prometheus.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

      Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.
    - **settings.auth.externalAuthentication**
      object

      Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the NGINX auth_request module.

      > **i** External authentication is enabled automatically if the user-authn module is enabled.

      - **settings.auth.externalAuthentication.authSignInURL**
        string

        The URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

        Example:

        ```
        authSignInURL: https://example.com/dex/sign_in
        ```
      - **settings.auth.externalAuthentication.authURL**
        string

        The URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

        Example:

        ```
        authURL: https://example.com/dex/auth
        ```

- **settings.auth.satisfyAny**
  boolean

  Enables single authentication.

  If used together with the whitelistSourceRanges parameter, it authorizes all the users from above networks (no need to enter a username and password).

  Default: `false`

  Example:

  ```
  satisfyAny: true
  ```

- **settings.auth.whitelistSourceRanges**
  array of strings

  An array if CIDRs that are allowed to authenticate in Grafana & Prometheus.

  Example:

  ```
  whitelistSourceRanges:
  - 1.1.1.1/32
  ```

- **settings.externalLabels**
  object

  The set of external labels to add to the metrics.

  It's possible to expand the environment variables of the `config-reloader` container in external labels such as:

  - `HOSTNAME`/`POD_NAME` - contains the name of the pod (for example `prometheus-main-0`, `prometheus-main-1`, etc.).
  - `SHARD` - contains the shard number.

  Example:

  ```
  externalLabels:
    prometheus_replica: "$(POD_NAME)"
    shard: "$(SHARD)"
    hostname: "$(HOSTNAME)"
  ```

- **settings.grafana**
  object

  Grafana installation-related settings.

  - **settings.grafana.customPlugins**
    array of strings

    A list of custom Grafana plugins. Contains plugin names from the official repository.

    Here is how you can add custom plugins (in this case, clickhouse-datasource and flowcharting-panel plugins are used):

    ```
    grafana:
      customPlugins:
      - agenty-flowcharting-panel
      - vertamedia-clickhouse-datasource
    ```

    You can also install plugins from other sources by passing a link to the plugin zip archive in the format `<url to plugin zip>;<plugin name>`:

    ```
    grafana:
      customPlugins:
      - http://10.241.32.16:3000/netsage-bumpchart-panel-1.1.1.zip;netsage-bumpchart-panel
    ```

    Example:

    ```
    customPlugins:
    - agenty-flowcharting-panel
    - vertamedia-clickhouse-datasource
    ```

  - **settings.grafana.enabled**
    boolean

    Enables Grafana deploy in the cluster.

    Default: `true`

    Example:

    ```
    enabled: false
    ```

  - **settings.grafana.useDarkTheme**
    boolean

    The dark theme is enabled by default.

    Default: `false`

    Example:

    ```
    useDarkTheme: true
    ```

- **settings.highAvailability**
  boolean

  Manually enable the high availability mode.

By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

Example:

```
highAvailability: true
```

- **settings.https**
  object

  What certificate type to use with Grafana/Prometheus.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

  ```
  https:
    mode: CustomCertificate
    customCertificate:
      secretName: foobar
  ```

  ```
  https:
    mode: CertManager
    certManager:
      clusterIssuerName: letsencrypt
  ```

  - **settings.https.certManager**
    object
    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for Grafana/Prometheus.

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`
  - **settings.https.customCertificate**
    object
    - **settings.https.customCertificate.secretName**
      string

      The name of the secret in the `d8-system` namespace to use with Grafana/Prometheus.

      This secret must have the kubernetes.io/tls format.

      Default: `false`
  - **settings.https.mode**
    string

    The HTTPS usage mode:

    - `Disabled` — Grafana/Prometheus will work over HTTP only;
    - `CertManager` — Grafana/Prometheus will use HTTPS and get a certificate from the clusterissuer defined in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate` — Grafana/Prometheus will use HTTPS using the certificate from the `d8-system` namespace.
    - `OnlyInURI` — Grafana/Prometheus will work over HTTP (thinking that there is an external HTTPS load balancer in front that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

    Default: `Disabled`

    Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for Grafana/Prometheus.

  An optional parameter. By default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  ingressClass: public
  ```

- **settings.longtermMaxDiskSizeGigabytes**
  Deprecated
  integer

  Deprecated and will be removed. Doesn’t affect anything.

- **settings.longtermNodeSelector**
  object

  The same as in the Pods’ `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  longtermNodeSelector:
    disktype: ssd
  ```

- **settings.longtermPodAntiAffinity**
  string

  Defines the podAntiAffinity configuration for the Prometheus longterm instance relative to the Prometheus main instance.

  - `Preferred` — allows scheduling Prometheus longterm instance alongside the Prometheus main instance if it is not possible to

place them on different nodes.
- `Required` — does not allow scheduling Prometheus longterm instance on the same node as the Prometheus main instance.

Default: `Preferred`

Allowed values: `Preferred`, `Required`

- **settings.longtermRetentionDays**
integer

  How long to keep the data in longterm Prometheus.

  Setting this parameter to `0` will result in Longterm Prometheus not running in the cluster.

  Default: `1095`

- **settings.longtermScrapeInterval**
string

  Sets the interval for making “data snapshots” of the main Prometheus by the longterm Prometheus.

  Default: `5m`

- **settings.longtermStorageClass**
string

  The name of the StorageClass to use for Longterm Prometheus.

  If omitted, the StorageClass of the existing Longterm Prometheus PVC is used. If there is no PVC yet, the StorageClass will be used according to the global storageClass parameter setting.

  The global `storageClass` parameter is only considered when the module is enabled. Changing the global `storageClass` parameter while the module is enabled will not trigger disk re-provisioning.

  Warning. Specifying a value different from the one currently used (in the existing PVC) will result in disk re-provisioning and all data will be deleted.

  Warning. When migrating Prometheus with local storage to other nodes, the pod will hang in the Pending state. In this case, it will be necessary to save the Prometheus database, delete the old PVC and restart the pod manually. Local storage refers to a StorageClass that is associated not with network storage, but with a local volume on a node (for example, StorageClass created by the local-path-provider module).

  If `false` is specified, emptyDir will be forced to be used.

  Example:

  ```
  longtermStorageClass: ceph-ssd
  ```

- **settings.longtermTolerations**
array of objects

  The same as in the Pods’ `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  longtermTolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.longtermTolerations.effect**
  string
  - **settings.longtermTolerations.key**
  string
  - **settings.longtermTolerations.operator**
  string
  - **settings.longtermTolerations.tolerationSeconds**
  integer
  - **settings.longtermTolerations.value**
  string
- **settings.mainMaxDiskSizeGigabytes**
Deprecated
integer

  Deprecated and will be removed. Doesn’t affect anything.

- **settings.nodeSelector**
object

  The same as in the Pods’ `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.retentionDays**
integer

  How long to keep the data.

  Default: `15`

- **settings.scrapeInterval**
string

  Sets the interval for scraping metrics from targets.

  Evaluation Interval is always equal to scrapeInterval.

Default: `30s`

Pattern: `^([\d]*y)?([\d]*w)?([\d]*d)?([\d]*h)?([\d]*m)?([\d]*s)?$`

- **settings.storageClass**
  string

  The name of the StorageClass to use for Prometheus.

  If omitted, the StorageClass of the existing Prometheus PVC is used. If there is no PVC yet, the StorageClass will be used according to the global storageClass parameter setting.

  The global `storageClass` parameter is only considered when the module is enabled. Changing the global `storageClass` parameter while the module is enabled will not trigger disk re-provisioning.

  Warning. Specifying a value different from the one currently used (in the existing PVC) will result in disk re-provisioning and all data will be deleted.

  If `false` is specified, `emptyDir` will be forced to be used.

  Examples:

  ```
  storageClass: ceph-ssd
  ```

  ```
  storageClass: 'false'
  ```

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string
- **settings.vpa**
  object

  VPA settings for pods.

  Default: `{"updateMode":"Initial"}`

  Examples:

  ```
  vpa:
    updateMode: Initial
    longtermMaxCPU: '1'
    longtermMaxMemory: 1500Mi
    maxCPU: 1000m
    maxMemory: 1500Mi
  ```

  ```
  vpa:
    updateMode: 'Off'
  ```

  - **settings.vpa.longtermMaxCPU**
    string or number

    The maximum value that the VPA can set for the Longterm Prometheus Pods.

    The default value is chosen automatically based on the maximum number of Pods that can be created in the cluster considering the current number of nodes and their settings. For more information, see the `detect_vpa_max` hook of the module.

    Pattern: `^[0-9]+m?$`

    Example:

    ```
    longtermMaxCPU: 0.1
    ```

  - **settings.vpa.longtermMaxMemory**
    string or number

    The maximum memory requests the VPA can set for the longterm Prometheus Pods.

    The default value is chosen automatically based on the maximum number of Pods that can be created in the cluster considering the current number of nodes and their settings. For more information, see the `detect_vpa_max` hook of the module.

    Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

    Example:

    ```
    longtermMaxMemory: 4Mi
    ```

- **settings.vpa.maxCPU**
  string or number

  The maximum value that the VPA can set for the CPU requests for the main Prometheus Pods.

  The default value is chosen automatically based on the maximum number of Pods that can be created in the cluster considering the current number of nodes and their settings. For more information, see the `detect_vpa_max` hook of the module.

  Pattern: `^[0-9]+m?$`

  Example:

  ```
  maxCPU: '3'
  ```

- **settings.vpa.maxMemory**
  string or number

  The maximum memory requests the VPA can set for the main Prometheus Pods.

  The default value is chosen automatically based on the maximum number of Pods that can be created in the cluster considering the current number of nodes and their settings. For more information, see the `detect_vpa_max` hook of the module.

  Pattern: `^[0-9]+(\.[0-9]+)?(E|P|T|G|M|k|Ei|Pi|Ti|Gi|Mi|Ki)?$`

  Example:

  ```
  maxMemory: 3Mi
  ```

- **settings.vpa.updateMode**
  string

  The VPA usage mode.

  Default: `Initial`

  Allowed values: `Initial`, `Auto`, `Off`

Authentication

user-authn module provides authentication by default. Also, externalAuthentication can be configured (see below). If these options are disabled, the module will use basic auth with the auto-generated password and the user `admin`.

Use d8 k to see password:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values prometheus -o json | jq
'.internal.auth.password'
```

Delete the Secret to re-generate password:

```
d8 k -n d8-monitoring delete secret/basic-auth
```

> **Note!** The `auth.password` parameter is deprecated.

Notes

- `retentionSize` for the `main` and `longterm` Prometheus is **calculated automatically; you cannot set this value manually!**
  - The following calculation algorithm is used:
    - `pvc size * 0.85` — if the PVC exists;
    - `10 GiB` — if there is no PVC and if the StorageClass supports resizing;
    - `25 GiB` — if there is no PVC and if the StorageClass does not support resizing;
  - If the `local-storage` is used, and you have to change the `retentionSize`, then you need to manually change the size of the PV and PVC. **Caution!** Note that the value from `.status.capacity.storage` PVC is used for the calculation since it reflects the actual size of the PV in the case of manual resizing.
- `40 GiB` — size of PersistentVolumeClaim created by default.
- You can change the size of Prometheus disks in the standard Kubernetes way (if the StorageClass permits this) by editing the `.spec.resources.requests.storage` field of the PersistentVolumeClaim resource.

Custom resources

> The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability
> The module has requirements for installation

ClusterAlert

Scope: Cluster
Version: v1alpha1

Resource to display Prometheus alerts.

- **metadata**
  object
  - **metadata.name**
    string

    Alert identifier (fingerprint) as it calculated by Alertmanager.

    Pattern: `^[a-z0-9]+$`

    Maximum length: `64`

- **status**
  object
  - **status.alertStatus**
    string

    Current alert status.
  - **status.lastUpdateTime**
    string

    Timestamp of last status update for operation.
  - **status.startsAt**
    string

    Timestamp of alert creation.
- **alert**
  object

  Required value

  Alert description.
  - **alert.annotations**
    object

    Similar to the standard `metadata.annotations` field.

    Example:

    ```
    annotations:
      summary: Certificate has expired.
    ```
  - **alert.description**
    string

    Alert description.

    Optional.
  - **alert.labels**
    object

    Required value

    Similar to the standard `metadata.labels` field.

    Example:

    ```
    labels:
      alertname: NginxIngressSslExpired
      class: ingress-nginx.deckhouse.io/nginx
    ```
  - **alert.name**
    string

    Required value

    Alert name.
  - **alert.severityLevel**
    integer or string

    Severity level.

    Optional.

    Example:

    ```
    severityLevel: '4'
    ```
  - **alert.summary**
    string

    Alert summary.

    Optional.

CustomAlertmanager

Scope: Cluster
Version: v1alpha1

The resource for connecting additional Alertmanagers to Prometheus.

- **status**
  object
  - **status.deckhouse**
    object
    - **status.deckhouse.observed**
      object

      Contains last timestamp when the resource change was noted by the operator and its checksum.

      - **status.deckhouse.observed.checkSum**
        string

        The checksum of last observed resource.
      - **status.deckhouse.observed.lastTimestamp**
        string

        Last timestamp when a change of the resource was noted by the operator.

- **status.deckhouse.processed**
  object

  Contains last timestamp when the resource was applied in the cluster by the operator and its checksum.

  - **status.deckhouse.processed.checkSum**
    string

    The checksum of last processed resource.

  - **status.deckhouse.processed.lastTimestamp**
    string

    Last timestamp when a change of the resource was processed by the operator.

- **status.deckhouse.synced**
  string

  True if last observed version of the resource was successfully applied in the cluster.

- **spec**
  object

  Required value

  - **spec.external**
    object

    Parameters for connecting an external Alertmanager.

    - **spec.external.address**
      string

      URL of an external Alertmanager.

      Pattern: `^https?://[^\s/$.?#].[^\s]*$`

      Examples:

      ```
      address: http://alerts.mycompany.com
      ```

      ```
      address: https://alerts.company.com
      ```

      ```
      address: http://192.168.1.1
      ```

    - **spec.external.auth**
      object

      Authorization properties.

      - **spec.external.auth.basic**
        object

        Basic authorization properties.

        - **spec.external.auth.basic.bearerToken**
          string

          Bearer token authorization.

        - **spec.external.auth.basic.password**
          string

          User password.

        - **spec.external.auth.basic.username**
          string

          User name.

    - **spec.external.service**
      object

      Kubernetes cluster service, which leads to deployed Alertmanager.

      - **spec.external.service.name**
        string

        Required value

        Name of an Alertmanager service.

      - **spec.external.service.namespace**
        string

        Required value

        Namespace of an Alertmanager service.

      - **spec.external.service.path**
        string

        URL prefix in a service to send alerts for.

        Default: `/`

    - **spec.external.tls**
      object

      TLS settings.

      - **spec.external.tls.ca**
        string

        CA cert to use.

      - **spec.external.tls.cert**

string

Client certificate.

- **spec.external.tls.insecureSkipVerify**
boolean

Disable certificate validation.

Default: `false`

- **spec.external.tls.key**
string

Client key.

- **spec.internal**
object

Internal Alertmanager parameters.

- **spec.internal.inhibitRules**
array of objects

List of inhibition rules.

InhibitRule defines an inhibition rule that allows to mute alerts when other alerts are already firing (details...).

- **spec.internal.inhibitRules.equal**
array of strings

Labels that must have an equal value in the source and target alert for the inhibition to take effect.

- **spec.internal.inhibitRules.sourceMatch**
array of objects

Matchers for which one or more alerts have to exist for the inhibition to take effect.

Matcher defines how to match on alert’s labels.

- **spec.internal.inhibitRules.sourceMatch.name**
string

Required value

Label to match.

- **spec.internal.inhibitRules.sourceMatch.regex**
boolean

Whether to match on equality (false) or regular-expression (true).

- **spec.internal.inhibitRules.sourceMatch.value**
string

Label value to match.

- **spec.internal.inhibitRules.targetMatch**
array of objects

Matchers that have to be fulfilled in the alerts to be muted.

Matcher defines how to match on alert’s labels.

- **spec.internal.inhibitRules.targetMatch.name**
string

Required value

Label to match.

- **spec.internal.inhibitRules.targetMatch.regex**
boolean

Whether to match on equality (false) or regular-expression (true).

- **spec.internal.inhibitRules.targetMatch.value**
string

Label value to match.

- **spec.internal.receivers**
array of objects

List of receivers.

Receiver defines one or more notification integrations.

- **spec.internal.receivers.emailConfigs**
array of objects

List of Email configurations.

EmailConfig configures notifications via Email.

- **spec.internal.receivers.emailConfigs.authIdentity**
string

The identity to use for authentication.

- **spec.internal.receivers.emailConfigs.authPassword**
object

The secret’s key that contains the password to use for authentication.

The secret needs to be in the `d8-monitoring` namespace.

- **spec.internal.receivers.emailConfigs.authPassword.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.emailConfigs.authPassword.name**
  string

  Name of the secret.

- **spec.internal.receivers.emailConfigs.authPassword.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.emailConfigs.authSecret**
  object

  The secret's key that contains the CRAM-MD5 secret.

  The secret needs to be in the `d8-monitoring` namespace.

  - **spec.internal.receivers.emailConfigs.authSecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.emailConfigs.authSecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.emailConfigs.authSecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.emailConfigs.authUsername**
  string

  The username to use for authentication.

- **spec.internal.receivers.emailConfigs.from**
  string

  The sender address.

- **spec.internal.receivers.emailConfigs.headers**
  array of objects

  Further headers email header key/value pairs. Overrides any headers previously set by the notification implementation.

  KeyValue defines a (key, value) tuple.

  - **spec.internal.receivers.emailConfigs.headers.key**
    string

    Required value

    Key of the tuple.

  - **spec.internal.receivers.emailConfigs.headers.value**
    string

    Required value

    Value of the tuple.

- **spec.internal.receivers.emailConfigs.hello**
  string

  The hostname to identify to the SMTP server.

- **spec.internal.receivers.emailConfigs.html**
  string

  The HTML body of the email notification.

- **spec.internal.receivers.emailConfigs.requireTLS**
  boolean

  The SMTP TLS requirement.

- **spec.internal.receivers.emailConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.emailConfigs.smarthost**
  string

  The SMTP host through which emails are sent.

- **spec.internal.receivers.emailConfigs.text**
  string

  The text body of the email notification.

- **spec.internal.receivers.emailConfigs.tlsConfig**
  object

  TLS configuration.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca**
    object

    Struct containing the CA cert to use for the targets.

- **spec.internal.receivers.emailConfigs.tlsConfig.ca.configMap**
  object

  ConfigMap containing data to use for the targets.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca.configMap.key**
    string

    Required value

    The key to select.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca.configMap.name**
    string

    Name of the ConfigMap.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca.configMap.optional**
    boolean

    Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.emailConfigs.tlsConfig.ca.secret**
  object

  Secret containing data to use for the targets.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca.secret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca.secret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.emailConfigs.tlsConfig.ca.secret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.emailConfigs.tlsConfig.cert**
  object

  Struct containing the client cert file for the targets.

  - **spec.internal.receivers.emailConfigs.tlsConfig.cert.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.internal.receivers.emailConfigs.tlsConfig.cert.configMap.key**
      string

      Required value

      The key to select.

    - **spec.internal.receivers.emailConfigs.tlsConfig.cert.configMap.name**
      string

      Name of the ConfigMap.

    - **spec.internal.receivers.emailConfigs.tlsConfig.cert.configMap.optional**
      boolean

      Specify whether the ConfigMap or its key must exist.

  - **spec.internal.receivers.emailConfigs.tlsConfig.cert.secret**
    object

    Secret containing data to use for the targets.

    - **spec.internal.receivers.emailConfigs.tlsConfig.cert.secret.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.emailConfigs.tlsConfig.cert.secret.name**
      string

      Name of the secret.

    - **spec.internal.receivers.emailConfigs.tlsConfig.cert.secret.optional**
      boolean

      Specify whether the Secret or its key must exist.

- **spec.internal.receivers.emailConfigs.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.emailConfigs.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.internal.receivers.emailConfigs.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from.

        - **spec.internal.receivers.emailConfigs.tlsConfig.keySecret.name**
          string

          Name of the secret.

        - **spec.internal.receivers.emailConfigs.tlsConfig.keySecret.optional**
          boolean

          Specify whether the Secret or its key must exist.

      - **spec.internal.receivers.emailConfigs.tlsConfig.serverName**
        string

        Used to verify the hostname for the targets.

    - **spec.internal.receivers.emailConfigs.to**
      string

      The email address to send notifications to.

- **spec.internal.receivers.name**
  string

  Required value

  Name of the receiver. Must be unique across all items from the list.

- **spec.internal.receivers.opsgenieConfigs**
  array of objects

  List of OpsGenie configurations.

  OpsGenieConfig configures notifications via OpsGenie. Details...

  - **spec.internal.receivers.opsgenieConfigs.apiKey**
    object

    The secret's key that contains the OpsGenie API key.

    The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.opsgenieConfigs.apiKey.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.opsgenieConfigs.apiKey.name**
      string

      Name of the secret.

    - **spec.internal.receivers.opsgenieConfigs.apiKey.optional**
      boolean

      Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.opsgenieConfigs.apiURL**
    string

    The URL to send OpsGenie API requests to.

  - **spec.internal.receivers.opsgenieConfigs.description**
    string

    Description of the incident.

  - **spec.internal.receivers.opsgenieConfigs.details**
    array of objects

    A set of arbitrary key/value pairs that provide further detail about the incident.

    - **spec.internal.receivers.opsgenieConfigs.details.key**
      string

      Required value

      Key of the tuple.

    - **spec.internal.receivers.opsgenieConfigs.details.value**
      string

      Required value

      Value of the tuple.

  - **spec.internal.receivers.opsgenieConfigs.httpConfig**
    object

    HTTP client configuration.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth**
      object

      BasicAuth for the client.

      - **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.password**
        object

        The secret in the `d8-monitoring` namespace that contains the password for authentication.

        - **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.password.key**
          string

          Required value

          The key of the secret to select from.

        - **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.password.name**

string

Name of the secret.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.password.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.username**
object

The secret in the `d8-monitoring` namespace that contains the username for authentication.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.username.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.username.name**
string

Name of the secret.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.basicAuth.username.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.bearerTokenSecret**
object

The secret's key that contains the bearer token to be used by the client for authentication.

The secret needs to be in the `d8-monitoring` namespace.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.bearerTokenSecret.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.bearerTokenSecret.name**
string

Name of the secret.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.bearerTokenSecret.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.proxyURL**
string

Optional proxy URL.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig**
object

TLS configuration.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca**
object

Struct containing the CA cert to use for the targets.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.configMap**
object

ConfigMap containing data to use for the targets.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.configMap.key**
string

Required value

The key to select.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.configMap.name**
string

Name of the ConfigMap.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.configMap.optional**
boolean

Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.secret**
object

Secret containing data to use for the targets.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.secret.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.secret.name**
string

Name of the secret.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.ca.secret.optional**

boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert**
  object

  Struct containing the client cert file for the targets.

  - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.configMap**
    object

    ConfigMap containing data to use for the targets.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.configMap.key**
      string

      Required value

      The key to select.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.configMap.name**
      string

      Name of the ConfigMap.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.configMap.optional**
      boolean

      Specify whether the ConfigMap or its key must exist.

  - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.secret**
    object

    Secret containing data to use for the targets.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.secret.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.secret.name**
      string

      Name of the secret.

    - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.cert.secret.optional**
      boolean

      Specify whether the Secret or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.keySecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.opsgenieConfigs.httpConfig.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.internal.receivers.opsgenieConfigs.message**
  string

  Alert text limited to 130 characters.

- **spec.internal.receivers.opsgenieConfigs.note**
  string

  Additional alert note.

- **spec.internal.receivers.opsgenieConfigs.priority**
  string

  Priority level of alert. Possible values are P1, P2, P3, P4, and P5.

- **spec.internal.receivers.opsgenieConfigs.responders**
  array of objects

  List of responders responsible for notifications.

  OpsGenieConfigResponder defines a responder to an incident. One of `id`, `name` or `username` has to be defined.

  - **spec.internal.receivers.opsgenieConfigs.responders.id**
    string

ID of the responder.

- **spec.internal.receivers.opsgenieConfigs.responders.name**
  string

  Name of the responder.

- **spec.internal.receivers.opsgenieConfigs.responders.type**
  string

  Required value

  Type of responder.

- **spec.internal.receivers.opsgenieConfigs.responders.username**
  string

  Username of the responder.

- **spec.internal.receivers.opsgenieConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.opsgenieConfigs.source**
  string

  Backlink to the sender of the notification.

- **spec.internal.receivers.opsgenieConfigs.tags**
  string

  Comma separated list of tags attached to the notifications.

- **spec.internal.receivers.pagerdutyConfigs**
  array of objects

  List of PagerDuty configurations.

  PagerDutyConfig configures notifications via PagerDuty. Details...

  - **spec.internal.receivers.pagerdutyConfigs.class**
    string

    The class/type of the event.

  - **spec.internal.receivers.pagerdutyConfigs.client**
    string

    Client identification.

  - **spec.internal.receivers.pagerdutyConfigs.clientURL**
    string

    Backlink to the sender of notification.

  - **spec.internal.receivers.pagerdutyConfigs.component**
    string

    The part or component of the affected system that is broken.

  - **spec.internal.receivers.pagerdutyConfigs.description**
    string

    Description of the incident.

  - **spec.internal.receivers.pagerdutyConfigs.details**
    array of objects

    Arbitrary key/value pairs that provide further detail about the incident.

    - **spec.internal.receivers.pagerdutyConfigs.details.key**
      string

      Required value

      Key of the tuple.

    - **spec.internal.receivers.pagerdutyConfigs.details.value**
      string

      Required value

      Value of the tuple.

  - **spec.internal.receivers.pagerdutyConfigs.group**
    string

    A cluster or grouping of sources.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig**
    object

    HTTP client configuration.

    - **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth**
      object

      BasicAuth for the client.

      - **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.password**
        object

        The secret in the `d8-monitoring` namespace that contains the password for authentication.

        - **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.password.key**
          string

          Required value

The key of the secret to select from.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.password.name**
  string

  Name of the secret.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.password.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.username**
  object

  The secret in the `d8-monitoring` namespace that contains the username for authentication.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.username.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.username.name**
    string

    Name of the secret.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.basicAuth.username.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.bearerTokenSecret**
  object

  The secret's key that contains the bearer token to be used by the client for authentication.

  The secret needs to be in the `d8-monitoring` namespace.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.bearerTokenSecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.bearerTokenSecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.bearerTokenSecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.proxyURL**
  string

  Optional proxy URL.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig**
  object

  TLS configuration.

  - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca**
    object

    Struct containing the CA cert to use for the targets.

    - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.secret**
      object

      Secret containing data to use for the targets.

      - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.secret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.secret.name**
        string

Name of the secret.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.ca.secret.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert**
object

Struct containing the client cert file for the targets.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.configMap**
object

ConfigMap containing data to use for the targets.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.configMap.key**
string

Required value

The key to select.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.configMap.name**
string

Name of the ConfigMap.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.configMap.optional**
boolean

Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.secret**
object

Secret containing data to use for the targets.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.secret.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.secret.name**
string

Name of the secret.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.cert.secret.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.insecureSkipVerify**
boolean

Disable target certificate validation.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.keySecret**
object

Secret containing the client key file for the targets.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.keySecret.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.keySecret.name**
string

Name of the secret.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.keySecret.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.httpConfig.tlsConfig.serverName**
string

Used to verify the hostname for the targets.

- **spec.internal.receivers.pagerdutyConfigs.routingKey**
object

The secret’s key that contains the PagerDuty integration key (when using Events API v2).

Either this field or `serviceKey` needs to be defined.

The secret needs to be in the `d8-monitoring` namespace.

- **spec.internal.receivers.pagerdutyConfigs.routingKey.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.pagerdutyConfigs.routingKey.name**
string

Name of the secret.

- **spec.internal.receivers.pagerdutyConfigs.routingKey.optional**

boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.sendResolved**
boolean

Whether or not to notify about resolved alerts.

- **spec.internal.receivers.pagerdutyConfigs.serviceKey**
object

The secret's key that contains the PagerDuty service key (when using integration type "Prometheus").

Either this field or `routingKey` needs to be defined.

The secret needs to be in the `d8-monitoring` namespace.

- **spec.internal.receivers.pagerdutyConfigs.serviceKey.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.pagerdutyConfigs.serviceKey.name**
string

Name of the secret.

- **spec.internal.receivers.pagerdutyConfigs.serviceKey.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pagerdutyConfigs.severity**
string

Severity of the incident.

- **spec.internal.receivers.pagerdutyConfigs.url**
string

The URL to send requests to.

- **spec.internal.receivers.pushoverConfigs**
array of objects

List of Pushover configurations.

PushoverConfig configures notifications via Pushover. Details...

- **spec.internal.receivers.pushoverConfigs.expire**
string

How long your notification will continue to be retried for, unless the user acknowledges the notification.

- **spec.internal.receivers.pushoverConfigs.html**
boolean

Whether notification message is HTML or plain text.

- **spec.internal.receivers.pushoverConfigs.httpConfig**
object

HTTP client configuration.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth**
object

BasicAuth for the client.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.password**
object

The secret in the `d8-monitoring` namespace that contains the password for authentication.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.password.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.password.name**
string

Name of the secret.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.password.optional**
boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.username**
object

The secret in the `d8-monitoring` namespace that contains the username for authentication.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.username.key**
string

Required value

The key of the secret to select from.

- **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.username.name**
string

Name of the secret.

        - **spec.internal.receivers.pushoverConfigs.httpConfig.basicAuth.username.optional**
          boolean

          Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pushoverConfigs.httpConfig.bearerTokenSecret**
  object

  The secret's key that contains the bearer token to be used by the client for authentication.

  The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.pushoverConfigs.httpConfig.bearerTokenSecret.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.pushoverConfigs.httpConfig.bearerTokenSecret.name**
      string

      Name of the secret.

    - **spec.internal.receivers.pushoverConfigs.httpConfig.bearerTokenSecret.optional**
      boolean

      Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pushoverConfigs.httpConfig.proxyURL**
  string

  Optional proxy URL.

- **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig**
  object

  TLS configuration.

    - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca**
      object

      Struct containing the CA cert to use for the targets.

        - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.configMap**
          object

          ConfigMap containing data to use for the targets.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.configMap.key**
              string

              Required value

              The key to select.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.configMap.name**
              string

              Name of the ConfigMap.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.configMap.optional**
              boolean

              Specify whether the ConfigMap or its key must exist.

        - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.secret**
          object

          Secret containing data to use for the targets.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.secret.key**
              string

              Required value

              The key of the secret to select from.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.secret.name**
              string

              Name of the secret.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.ca.secret.optional**
              boolean

              Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert**
      object

      Struct containing the client cert file for the targets.

        - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.configMap**
          object

          ConfigMap containing data to use for the targets.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.configMap.key**
              string

              Required value

              The key to select.

            - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.configMap.name**
              string

              Name of the ConfigMap.

- **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.secret**
  object

  Secret containing data to use for the targets.

  - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.secret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.secret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.cert.secret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.keySecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pushoverConfigs.httpConfig.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.internal.receivers.pushoverConfigs.message**
  string

  Notification message.

- **spec.internal.receivers.pushoverConfigs.priority**
  string

  Priority. Details…

- **spec.internal.receivers.pushoverConfigs.retry**
  string

  How often the Pushover servers will send the same notification to the user. Must be at least 30 seconds.

- **spec.internal.receivers.pushoverConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.pushoverConfigs.sound**
  string

  The name of one of the sounds supported by device clients to override the user’s default sound choice.

- **spec.internal.receivers.pushoverConfigs.title**
  string

  Notification title.

- **spec.internal.receivers.pushoverConfigs.token**
  object

  The secret’s key that contains the registered application’s API token (details…).

  The secret needs to be in the `d8-monitoring` namespace.

  - **spec.internal.receivers.pushoverConfigs.token.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.pushoverConfigs.token.name**
    string

    Name of the secret.

  - **spec.internal.receivers.pushoverConfigs.token.optional**
    boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.pushoverConfigs.url**
  string

  A supplementary URL shown alongside the message.

- **spec.internal.receivers.pushoverConfigs.urlTitle**
  string

  A title for supplementary URL, otherwise just the URL is shown.

- **spec.internal.receivers.pushoverConfigs.userKey**
  object

  The secret’s key that contains the recipient user’s user key.

  The secret needs to be in the `d8-monitoring` namespace.

  - **spec.internal.receivers.pushoverConfigs.userKey.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.pushoverConfigs.userKey.name**
    string

    Name of the secret.

  - **spec.internal.receivers.pushoverConfigs.userKey.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.slackConfigs**
  array of objects

  List of Slack configurations.

  Configures notifications via Slack. Details...

  - **spec.internal.receivers.slackConfigs.actions**
    array of objects

    A list of Slack actions that are sent with each notification.

    Configures a single Slack action that is sent with each notification.

    More information here... and here.

    - **spec.internal.receivers.slackConfigs.actions.confirm**
      object

      Protects users from destructive actions or particularly distinguished decisions by asking them to confirm their button click one more time. Details....

      - **spec.internal.receivers.slackConfigs.actions.confirm.dismissText**
        string

        The text label for the button to cancel the action.

      - **spec.internal.receivers.slackConfigs.actions.confirm.okText**
        string

        The text label for the button to continue with an action.

      - **spec.internal.receivers.slackConfigs.actions.confirm.text**
        string

        Required value

        Describe in detail the consequences of the action and contextualize your button text choices.

        Use a maximum of 30 characters or so for best results across form factors.

      - **spec.internal.receivers.slackConfigs.actions.confirm.title**
        string

        Brief title of the pop up window.

    - **spec.internal.receivers.slackConfigs.actions.name**
      string
    - **spec.internal.receivers.slackConfigs.actions.style**
      string
    - **spec.internal.receivers.slackConfigs.actions.text**
      string

      Required value

    - **spec.internal.receivers.slackConfigs.actions.type**
      string

      Required value

    - **spec.internal.receivers.slackConfigs.actions.url**
      string
    - **spec.internal.receivers.slackConfigs.actions.value**
      string
  - **spec.internal.receivers.slackConfigs.apiURL**
    object

    The secret’s key that contains the Slack webhook URL.

    The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.slackConfigs.apiURL.key**
      string

Required value

The key of the secret to select from.

- **spec.internal.receivers.slackConfigs.apiURL.name**
  string

  Name of the secret.

- **spec.internal.receivers.slackConfigs.apiURL.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.slackConfigs.callbackId**
  string
- **spec.internal.receivers.slackConfigs.channel**
  string

  The channel or user to send notifications to.

- **spec.internal.receivers.slackConfigs.color**
  string
- **spec.internal.receivers.slackConfigs.fallback**
  string
- **spec.internal.receivers.slackConfigs.fields**
  array of objects

  A list of Slack fields that are sent with each notification.

  Configures a single Slack field that is sent with each notification.

  Each field must contain a title, value, and optionally, a boolean value to indicate if the field is short enough to be displayed next to other fields designated as short. More information…

  - **spec.internal.receivers.slackConfigs.fields.short**
    boolean
  - **spec.internal.receivers.slackConfigs.fields.title**
    string

    Required value

  - **spec.internal.receivers.slackConfigs.fields.value**
    string

    Required value

- **spec.internal.receivers.slackConfigs.footer**
  string
- **spec.internal.receivers.slackConfigs.httpConfig**
  object

  HTTP client configuration.

  - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth**
    object

    BasicAuth for the client.

    - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.password**
      object

      The secret in the `d8-monitoring` namespace that contains the password for authentication.

      - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.password.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.password.name**
        string

        Name of the secret.

      - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.password.optional**
        boolean

        Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.username**
      object

      The secret in the `d8-monitoring` namespace that contains the username for authentication.

      - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.username.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.username.name**
        string

        Name of the secret.

      - **spec.internal.receivers.slackConfigs.httpConfig.basicAuth.username.optional**
        boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.slackConfigs.httpConfig.bearerTokenSecret**
    object

    The secret's key that contains the bearer token to be used by the client for authentication.

    The secret needs to be in the `d8-monitoring` namespace.

- **spec.internal.receivers.slackConfigs.httpConfig.bearerTokenSecret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.slackConfigs.httpConfig.bearerTokenSecret.name**
  string

  Name of the secret.

- **spec.internal.receivers.slackConfigs.httpConfig.bearerTokenSecret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.slackConfigs.httpConfig.proxyURL**
  string

  Optional proxy URL.

- **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig**
  object

  TLS configuration.

  - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca**
    object

    Struct containing the CA cert to use for the targets.

    - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.secret**
      object

      Secret containing data to use for the targets.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.secret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.secret.name**
        string

        Name of the secret.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.ca.secret.optional**
        boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert**
    object

    Struct containing the client cert file for the targets.

    - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.secret**
      object

      Secret containing data to use for the targets.

      - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.secret.key**
        string

Required value

The key of the secret to select from.

- **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.secret.name**
  string

  Name of the secret.

- **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.cert.secret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.keySecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.slackConfigs.httpConfig.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.internal.receivers.slackConfigs.iconEmoji**
  string
- **spec.internal.receivers.slackConfigs.iconURL**
  string
- **spec.internal.receivers.slackConfigs.imageURL**
  string
- **spec.internal.receivers.slackConfigs.linkNames**
  boolean
- **spec.internal.receivers.slackConfigs.mrkdwnIn**
  array of strings
- **spec.internal.receivers.slackConfigs.pretext**
  string
- **spec.internal.receivers.slackConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.slackConfigs.shortFields**
  boolean
- **spec.internal.receivers.slackConfigs.text**
  string
- **spec.internal.receivers.slackConfigs.thumbURL**
  string
- **spec.internal.receivers.slackConfigs.title**
  string
- **spec.internal.receivers.slackConfigs.titleLink**
  string
- **spec.internal.receivers.slackConfigs.username**
  string

- **spec.internal.receivers.telegramConfigs**
  array of objects

  List of Telegram configurations.

  Configures notifications via Telegram.

  Read more in the Prometheus documentation.

  - **spec.internal.receivers.telegramConfigs.apiURL**
    string

    The Telegram API URL i.e. `https://api.telegram.org`.

    If not specified, the default API URL will be used.

  - **spec.internal.receivers.telegramConfigs.botToken**
    object

    The Secret in the `d8-monitoring` namespace that contains Telegram bot token.

    - **spec.internal.receivers.telegramConfigs.botToken.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.telegramConfigs.botToken.name**
      string

      Name of the secret.

- **spec.internal.receivers.telegramConfigs.botToken.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.telegramConfigs.chatID**
  integer

  The Telegram chat ID.

- **spec.internal.receivers.telegramConfigs.disableNotifications**
  boolean

  Disable telegram notifications

- **spec.internal.receivers.telegramConfigs.httpConfig**
  object

  HTTP client configuration.

  - **spec.internal.receivers.telegramConfigs.httpConfig.authorization**
    object

    Authorization header configuration for the client. This is mutually exclusive with BasicAuth and is only available starting from Alertmanager v0.22+.

    - **spec.internal.receivers.telegramConfigs.httpConfig.authorization.credentials**
      object

      The Secret in the `d8-monitoring` namespace that contains the credentials of the request.

      - **spec.internal.receivers.telegramConfigs.httpConfig.authorization.credentials.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.telegramConfigs.httpConfig.authorization.credentials.name**
        string

        Name of the secret.

      - **spec.internal.receivers.telegramConfigs.httpConfig.authorization.credentials.optional**
        boolean

        Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.telegramConfigs.httpConfig.authorization.type**
      string

      Set the authentication type. Defaults to Bearer, Basic will cause an error

  - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth**
    object

    BasicAuth for the client. This is mutually exclusive with Authorization. If both are defined, BasicAuth takes precedence.

    - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.password**
      object

      The Secret in the `d8-monitoring` namespace that contains the password for authentication.

      - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.password.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.password.name**
        string

        Name of the secret.

      - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.password.optional**
        boolean

        Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.username**
      object

      The Secret in the `d8-monitoring` namespace that contains the username for authentication.

      - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.username.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.username.name**
        string

        Name of the secret.

      - **spec.internal.receivers.telegramConfigs.httpConfig.basicAuth.username.optional**
        boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.telegramConfigs.httpConfig.bearerTokenSecret**
    object

    The Secret in the `d8-monitoring` namespace that contains the bearer token to be used by the client for authentication.

    - **spec.internal.receivers.telegramConfigs.httpConfig.bearerTokenSecret.key**

string

Required value

The key of the secret to select from.

- **spec.internal.receivers.telegramConfigs.httpConfig.bearerTokenSecret.name**
string

  Name of the secret.

- **spec.internal.receivers.telegramConfigs.httpConfig.bearerTokenSecret.optional**
boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.telegramConfigs.httpConfig.followRedirects**
boolean

  FollowRedirects specifies whether the client should follow HTTP 3xx redirects.

- **spec.internal.receivers.telegramConfigs.httpConfig.oauth2**
object

  OAuth2 client credentials used to fetch a token for the targets.

  - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId**
object

    Required value

    The Secret or configMap containing the OAuth2 client id

    - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.configMap**
object

      The ConfigMap in the `d8-monitoring` namespace that contains data to use for the targets.

      - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.configMap.key**
string

        Required value

        The key to select.

      - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.configMap.name**
string

        Name of the ConfigMap.

      - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.configMap.optional**
boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.secret**
object

      The Secret in the `d8-monitoring` namespace that contains data to use for the targets.

      - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.secret.key**
string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.secret.name**
string

        Name of the secret.

      - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientId.secret.optional**
boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientSecret**
object

    Required value

    The secret in the `d8-monitoring` namespace that contains OAuth2 client data.

    - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientSecret.key**
string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientSecret.name**
string

      Name of the secret.

    - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.clientSecret.optional**
boolean

      Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.endpointParams**
object

    Parameters to append to the token URL

  - **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.scopes**
array of strings

    OAuth2 scopes used for the token request

- **spec.internal.receivers.telegramConfigs.httpConfig.oauth2.tokenUrl**
  string

  Required value

  The URL to fetch the token from

- **spec.internal.receivers.telegramConfigs.httpConfig.proxyURL**
  string

  Optional proxy URL.

- **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig**
  object

  TLS configuration for the client.

  - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca**
    object

    Certificate authority used when verifying server certificates.

    - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.configMap**
      object

      The ConfigMap in the `d8-monitoring` namespace that contains data to use for the targets.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.secret**
      object

      The Secret in the `d8-monitoring` namespace that contains data to use for the targets.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.secret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.secret.name**
        string

        Name of the secret.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.ca.secret.optional**
        boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert**
    object

    Client certificate to present when doing client-authentication.

    - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.configMap**
      object

      The ConfigMap in the `d8-monitoring` namespace that contains data to use for the targets.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.secret**
      object

      The Secret in the `d8-monitoring` namespace that contains data to use for the targets.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.secret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.secret.name**
        string

        Name of the secret.

- **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.cert.secret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.keySecret**
  object

  The Secret in the `d8-monitoring` namespace that contains the client key file for the targets.

  - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.keySecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.telegramConfigs.httpConfig.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.internal.receivers.telegramConfigs.message**
  string

  Message template

- **spec.internal.receivers.telegramConfigs.parseMode**
  string

  Parse mode for telegram message

  Allowed values: `MarkdownV2`, `Markdown`, `HTML`

- **spec.internal.receivers.telegramConfigs.sendResolved**
  boolean

  Whether to notify about resolved alerts.

- **spec.internal.receivers.victoropsConfigs**
  array of objects

  List of VictorOps configurations.

  VictorOpsConfig configures notifications via VictorOps. Details...

  - **spec.internal.receivers.victoropsConfigs.apiKey**
    object

    The secret's key that contains the API key to use when talking to the VictorOps API.

    The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.victoropsConfigs.apiKey.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.victoropsConfigs.apiKey.name**
      string

      Name of the secret.

    - **spec.internal.receivers.victoropsConfigs.apiKey.optional**
      boolean

      Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.victoropsConfigs.apiUrl**
    string

    The VictorOps API URL.

  - **spec.internal.receivers.victoropsConfigs.customFields**
    array of objects

    Additional custom fields for notification.

    KeyValue defines a (key, value) tuple.

    - **spec.internal.receivers.victoropsConfigs.customFields.key**
      string

      Required value

      Key of the tuple.

    - **spec.internal.receivers.victoropsConfigs.customFields.value**
      string

      Required value

      Value of the tuple.

- **spec.internal.receivers.victoropsConfigs.entityDisplayName**
  string

  Contains summary of the alerted problem.

- **spec.internal.receivers.victoropsConfigs.httpConfig**
  object

  The HTTP client’s configuration.

  - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth**
    object

    BasicAuth for the client.

    - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.password**
      object

      The secret in the `d8-monitoring` namespace that contains the password for authentication.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.password.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.password.name**
        string

        Name of the secret.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.password.optional**
        boolean

        Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.username**
      object

      The secret in the `d8-monitoring` namespace that contains the username for authentication.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.username.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.username.name**
        string

        Name of the secret.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.basicAuth.username.optional**
        boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.victoropsConfigs.httpConfig.bearerTokenSecret**
    object

    The secret’s key that contains the bearer token to be used by the client for authentication.

    The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.victoropsConfigs.httpConfig.bearerTokenSecret.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.victoropsConfigs.httpConfig.bearerTokenSecret.name**
      string

      Name of the secret.

    - **spec.internal.receivers.victoropsConfigs.httpConfig.bearerTokenSecret.optional**
      boolean

      Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.victoropsConfigs.httpConfig.proxyURL**
    string

    Optional proxy URL.

  - **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig**
    object

    TLS configuration.

    - **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca**
      object

      Struct containing the CA cert to use for the targets.

      - **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.configMap**
        object

        ConfigMap containing data to use for the targets.

        - **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.configMap.key**
          string

          Required value

          The key to select.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.configMap.name**
  string

  Name of the ConfigMap.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.secret**
  object

  Secret containing data to use for the targets.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.secret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.secret.name**
  string

  Name of the secret.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.ca.secret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert**
  object

  Struct containing the client cert file for the targets.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.configMap**
  object

  ConfigMap containing data to use for the targets.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.configMap.key**
  string

  Required value

  The key to select.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.configMap.name**
  string

  Name of the ConfigMap.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.secret**
  object

  Secret containing data to use for the targets.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.secret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.secret.name**
  string

  Name of the secret.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.cert.secret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.keySecret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.keySecret.name**
  string

  Name of the secret.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.keySecret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.victoropsConfigs.httpConfig.tlsConfig.serverName**
  string

Used to verify the hostname for the targets.

- **spec.internal.receivers.victoropsConfigs.messageType**
  string

  Describes the behavior of the alert (CRITICAL, WARNING, INFO).

- **spec.internal.receivers.victoropsConfigs.monitoringTool**
  string

  The monitoring tool the state message is from.

- **spec.internal.receivers.victoropsConfigs.routingKey**
  string

  A key used to map the alert to a team.

- **spec.internal.receivers.victoropsConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.victoropsConfigs.stateMessage**
  string

  Contains long explanation of the alerted problem.

- **spec.internal.receivers.webhookConfigs**
  array of objects

  List of webhook configurations.

  WebhookConfig configures notifications via a generic receiver supporting the webhook payload. Details...

  - **spec.internal.receivers.webhookConfigs.httpConfig**
    object

    HTTP client configuration.

    - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth**
      object

      BasicAuth for the client.

      - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.password**
        object

        The secret in the `d8-monitoring` namespace that contains the password for authentication.

        - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.password.key**
          string

          Required value

          The key of the secret to select from.

        - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.password.name**
          string

          Name of the secret.

        - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.password.optional**
          boolean

          Specify whether the Secret or its key must exist.

      - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.username**
        object

        The secret in the `d8-monitoring` namespace that contains the username for authentication.

        - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.username.key**
          string

          Required value

          The key of the secret to select from.

        - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.username.name**
          string

          Name of the secret.

        - **spec.internal.receivers.webhookConfigs.httpConfig.basicAuth.username.optional**
          boolean

          Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.webhookConfigs.httpConfig.bearerTokenSecret**
      object

      The secret's key that contains the bearer token to be used by the client for authentication.

      The secret needs to be in the `d8-monitoring` namespace.

      - **spec.internal.receivers.webhookConfigs.httpConfig.bearerTokenSecret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.webhookConfigs.httpConfig.bearerTokenSecret.name**
        string

        Name of the secret.

      - **spec.internal.receivers.webhookConfigs.httpConfig.bearerTokenSecret.optional**
        boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.webhookConfigs.httpConfig.proxyURL**
  string

  Optional proxy URL.

- **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig**
  object

  TLS configuration.

  - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca**
    object

    Struct containing the CA cert to use for the targets.

    - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.secret**
      object

      Secret containing data to use for the targets.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.secret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.secret.name**
        string

        Name of the secret.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.ca.secret.optional**
        boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert**
    object

    Struct containing the client cert file for the targets.

    - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.configMap**
      object

      ConfigMap containing data to use for the targets.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.configMap.key**
        string

        Required value

        The key to select.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.configMap.name**
        string

        Name of the ConfigMap.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.configMap.optional**
        boolean

        Specify whether the ConfigMap or its key must exist.

    - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.secret**
      object

      Secret containing data to use for the targets.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.secret.key**
        string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.secret.name**
        string

        Name of the secret.

      - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.cert.secret.optional**
        boolean

        Specify whether the Secret or its key must exist.

- **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

  - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.keySecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.keySecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.keySecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.webhookConfigs.httpConfig.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.internal.receivers.webhookConfigs.maxAlerts**
  integer

  Maximum number of alerts to be sent per webhook message.

  When 0, all alerts are included.

  Allowed values: `0 <= X`

- **spec.internal.receivers.webhookConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.webhookConfigs.url**
  string

  The URL to send HTTP POST requests to.

  `urlSecret` takes precedence over `url`.

  One of `urlSecret` and `url` should be defined.

- **spec.internal.receivers.webhookConfigs.urlSecret**
  object

  The secret’s key that contains the webhook URL to send HTTP requests to.

  `urlSecret` takes precedence over `url`. One of `urlSecret` and `url` should be defined.

  The secret needs to be in the `d8-monitoring` namespace.

  - **spec.internal.receivers.webhookConfigs.urlSecret.key**
    string

    Required value

    The key of the secret to select from.

  - **spec.internal.receivers.webhookConfigs.urlSecret.name**
    string

    Name of the secret.

  - **spec.internal.receivers.webhookConfigs.urlSecret.optional**
    boolean

    Specify whether the Secret or its key must exist.

- **spec.internal.receivers.wechatConfigs**
  array of objects

  List of WeChat configurations.

  WeChatConfig configures notifications via WeChat. Details…

  - **spec.internal.receivers.wechatConfigs.agentID**
    string
  - **spec.internal.receivers.wechatConfigs.apiSecret**
    object

    The secret’s key that contains the WeChat API key.

    The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.wechatConfigs.apiSecret.key**
      string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.wechatConfigs.apiSecret.name**
      string

      Name of the secret.

    - **spec.internal.receivers.wechatConfigs.apiSecret.optional**

boolean

Specify whether the Secret or its key must exist.

- **spec.internal.receivers.wechatConfigs.apiURL**
string

  The WeChat API URL.

- **spec.internal.receivers.wechatConfigs.corpID**
string

  The corp id for authentication.

- **spec.internal.receivers.wechatConfigs.httpConfig**
object

  HTTP client configuration.

  - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth**
  object

    BasicAuth for the client.

    - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.password**
    object

      The secret in the `d8-monitoring` namespace that contains the password for authentication.

      - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.password.key**
      string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.password.name**
      string

        Name of the secret.

      - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.password.optional**
      boolean

        Specify whether the Secret or its key must exist.

    - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.username**
    object

      The secret in the `d8-monitoring` namespace that contains the username for authentication.

      - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.username.key**
      string

        Required value

        The key of the secret to select from.

      - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.username.name**
      string

        Name of the secret.

      - **spec.internal.receivers.wechatConfigs.httpConfig.basicAuth.username.optional**
      boolean

        Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.wechatConfigs.httpConfig.bearerTokenSecret**
  object

    The secret's key that contains the bearer token to be used by the client for authentication.

    The secret needs to be in the `d8-monitoring` namespace.

    - **spec.internal.receivers.wechatConfigs.httpConfig.bearerTokenSecret.key**
    string

      Required value

      The key of the secret to select from.

    - **spec.internal.receivers.wechatConfigs.httpConfig.bearerTokenSecret.name**
    string

      Name of the secret.

    - **spec.internal.receivers.wechatConfigs.httpConfig.bearerTokenSecret.optional**
    boolean

      Specify whether the Secret or its key must exist.

  - **spec.internal.receivers.wechatConfigs.httpConfig.proxyURL**
  string

    Optional proxy URL.

  - **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig**
  object

    TLS configuration.

    - **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca**
    object

      Struct containing the CA cert to use for the targets.

      - **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.configMap**
      object

ConfigMap containing data to use for the targets.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.configMap.key**
  string

  Required value

  The key to select.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.configMap.name**
  string

  Name of the ConfigMap.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.secret**
  object

  Secret containing data to use for the targets.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.secret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.secret.name**
  string

  Name of the secret.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.ca.secret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert**
  object

  Struct containing the client cert file for the targets.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.configMap**
  object

  ConfigMap containing data to use for the targets.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.configMap.key**
  string

  Required value

  The key to select.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.configMap.name**
  string

  Name of the ConfigMap.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.configMap.optional**
  boolean

  Specify whether the ConfigMap or its key must exist.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.secret**
  object

  Secret containing data to use for the targets.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.secret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.secret.name**
  string

  Name of the secret.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.cert.secret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.insecureSkipVerify**
  boolean

  Disable target certificate validation.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.keySecret**
  object

  Secret containing the client key file for the targets.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.keySecret.key**
  string

  Required value

  The key of the secret to select from.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.keySecret.name**
  string

Name of the secret.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.keySecret.optional**
  boolean

  Specify whether the Secret or its key must exist.

- **spec.internal.receivers.wechatConfigs.httpConfig.tlsConfig.serverName**
  string

  Used to verify the hostname for the targets.

- **spec.internal.receivers.wechatConfigs.message**
  string

  API request data as defined by the WeChat API.

- **spec.internal.receivers.wechatConfigs.messageType**
  string
- **spec.internal.receivers.wechatConfigs.sendResolved**
  boolean

  Whether or not to notify about resolved alerts.

- **spec.internal.receivers.wechatConfigs.toParty**
  string
- **spec.internal.receivers.wechatConfigs.toTag**
  string
- **spec.internal.receivers.wechatConfigs.toUser**
  string

- **spec.internal.route**
  object

  Required value

  The Alertmanager route definition for alerts matching the resource’s namespace. If present, it will be added to the generated Alertmanager configuration as a first-level route.

  - **spec.internal.route.continue**
    boolean

    Whether an alert should continue matching subsequent sibling nodes.

    It will always be overridden to true for the first-level route by the Prometheus operator.

  - **spec.internal.route.groupBy**
    array of strings

    List of labels to group by.

  - **spec.internal.route.groupInterval**
    string

    How long to wait before sending an updated notification.

    Must match the regular expression `[0-9]+(ms|s|m|h)` (milliseconds, seconds, minutes, hours).

  - **spec.internal.route.groupWait**
    string

    How long to wait before sending the initial notification.

    Must match the regular expression `[0-9]+(ms|s|m|h)` (milliseconds, seconds, minutes, hours).

  - **spec.internal.route.matchers**
    array of objects

    List of matchers that the alert’s labels should match.

    For the first level route, the operator removes any existing equality and regexp matcher on the `namespace` label and adds a `namespace: <object namespace>` matcher.

    Matcher defines how to match on alert’s labels.

    - **spec.internal.route.matchers.name**
      string

      Required value

      Label to match.

    - **spec.internal.route.matchers.regex**
      boolean

      Whether to match on equality (false) or regular-expression (true).

    - **spec.internal.route.matchers.value**
      string

      Label value to match.

  - **spec.internal.route.receiver**
    string

    Name of the receiver for this route.

    If not empty, it should be listed in the `receivers` field.

  - **spec.internal.route.repeatInterval**
    string

    How long to wait before repeating the last notification.

    Must match the regular expression `[0-9]+(ms|s|m|h)` (milliseconds, seconds, minutes, hours).

  - **spec.internal.route.routes**
    array

    Child routes.

    - **spec.type**
      string

      Type of the Alertmanager.

      Allowed values: `External`, `Internal`

CustomPrometheusRules

Scope: Cluster

- v1
- v1alpha1

Resource to store `PrometheusRule`. Details....

- **spec**
  object

  Required value

    - **spec.groups**
      array of objects

      Required value

      Alert group description.

      The structure of the groups is similar to that of prometheus-operator.

      RuleGroup is a list of sequentially evaluated recording and alerting rules.

        - **spec.groups.interval**
          string
        - **spec.groups.name**
          string

          Required value

        - **spec.groups.rules**
          array of objects

          Required value

            - **spec.groups.rules.alert**
              string
            - **spec.groups.rules.annotations**
              object
            - **spec.groups.rules.expr**
              integer or string

              Required value

            - **spec.groups.rules.for**
              string
            - **spec.groups.rules.labels**
              object
            - **spec.groups.rules.record**
              string

Deprecated resource. Support for the resource might be removed in a later release.

Resource to store `PrometheusRule`. Details....

- **spec**
  object

  Required value

    - **spec.groups**
      array of objects

      Required value

      Alert group description.

      The structure of the groups is similar to that of prometheus-operator.

      RuleGroup is a list of sequentially evaluated recording and alerting rules.

        - **spec.groups.interval**
          string
        - **spec.groups.name**
          string

          Required value

        - **spec.groups.rules**
          array of objects

          Required value

            - **spec.groups.rules.alert**
              string
            - **spec.groups.rules.annotations**
              object
            - **spec.groups.rules.expr**
              integer or string

              Required value

            - **spec.groups.rules.for**
              string
            - **spec.groups.rules.labels**
              object
            - **spec.groups.rules.record**
              string

GrafanaAdditionalDatasource

Scope: Cluster

- v1
- v1alpha1

The resource for connecting additional datasources to Grafana.

The resource parameters are described in details in the Grafana documentation.

- **spec**
  object

  Required value

  - **spec.access**
    string

    Required value

    Access mode.

    Allowed values: `Proxy`, `Direct`

  - **spec.basicAuth**
    boolean

    Enable/disable basic auth.

  - **spec.basicAuthUser**
    string

    Basic auth username.

  - **spec.database**
    string

    Database name (if used).

  - **spec.jsonData**
    object

    Fields to be converted to JSON and stored in jsonData.

  - **spec.secureJsonData**
    object

    JSON-data object to be saved encrypted.

  - **spec.type**
    string

    Required value

    Datasource type.

  - **spec.url**
    string

    Datasource URL.

    Example:

    ```
    url: http://localhost:8080
    ```

  - **spec.user**
    string

    Database username.

  - **spec.withCredentials**
    boolean

    Enable/disable with credentials headers (details...).

Deprecated resource. Support for the resource might be removed in a later release.

The resource for connecting additional datasources to Grafana.

The resource parameters are described in details in the Grafana documentation.

- **spec**
  object

  Required value

  - **spec.access**
    string

    Required value

    Access mode.

    Allowed values: `proxy`, `direct`

  - **spec.basicAuth**
    boolean

    Enable/disable basic auth.

  - **spec.basicAuthUser**
    string

    Basic auth username.

  - **spec.database**
    string

Database name (if used).

- **spec.jsonData**
  object

  Fields to be converted to JSON and stored in jsonData.

- **spec.secureJsonData**
  object

  JSON-data object to be saved encrypted.

- **spec.type**
  string

  Required value

  Datasource type.

- **spec.url**
  string

  Datasource URL.

  Example:

  ```
  url: http://localhost:8080
  ```

- **spec.user**
  string

  Database username.

- **spec.withCredentials**
  boolean

  Enable/disable with credentials headers (details...).

GrafanaAlertsChannel

Scope: Cluster
Version: v1alpha1

The resource for adding alert notification channels to Grafana.

- **spec**
  object

  Required value

  - **spec.alertManager**
    object

    Required value

    Alert manager settings.

    - **spec.alertManager.address**
      string

      Required value

      URL of an external Alertmanager.

      Pattern: `^https?://[^\s/$.?#].[^\s]*$`

      Examples:

      ```
      address: http://alerts.mycompany.com
      ```

      ```
      address: https://alerts.company.com
      ```

      ```
      address: http://192.168.1.1
      ```

    - **spec.alertManager.auth**
      object

      Authorization properties.

      - **spec.alertManager.auth.basic**
        object

        Required value

        Basic authorization properties.

        - **spec.alertManager.auth.basic.password**
          string

          Required value

          Password.

        - **spec.alertManager.auth.basic.username**
          string

          Required value

          User name.

  - **spec.description**
    string

    Small and optional description about this alerts channel.

Default:

- **spec.disableResolveMessage**
  boolean

  When true, this option disables the resolve message [OK] that is sent when the alerting state returns to false.

  Default: `false`

- **spec.isDefault**
  boolean

  Use this notification channel for all alerts.

  Default: `false`

- **spec.type**
  string

  Required value

  Allowed values: `PrometheusAlertManager`

GrafanaDashboardDefinition

Scope: Cluster

- v1
- v1alpha1

The resource for storing and managing Grafana dashboards.

- **spec**
  object

  Required value

  - **spec.definition**
    string

    Required value

    The dashboard’s JSON manifest.

    > **Caution!** Make sure that there is no “local” `id` (at the `.id` address) in the manifest in addition to the `uid`.

    Pattern: `^[ \t\n]*\{(.|\n)*\}[ \t\n]*$`

  - **spec.folder**
    string

    Required value

    What folder to use for a dashboard. If the folder does not exist, it will be created.

    Example:

    ```
    folder: My Folder
    ```

Deprecated resource. Support for the resource might be removed in a later release.

The resource for storing and managing Grafana dashboards.

- **spec**
  object

  Required value

  - **spec.definition**
    string

    Required value

    The dashboard’s JSON manifest.

    > **Caution!** Make sure that there is no “local” `id` (at the `.id` address) in the manifest in addition to the `uid`.

    Pattern: `^[ \t\n]*\{(.|\n)*\}[ \t\n]*$`

  - **spec.folder**
    string

    Required value

    What folder to use for a dashboard. If the folder does not exist, it will be created.

    Example:

    ```
    folder: My Folder
    ```

PrometheusRemoteWrite

Scope: Cluster

- v1
- v1alpha1

Resource for including ‘remote_write’ data from the local Prometheus into a separate longterm storage (E.g: VictoriaMetrics).

A cluster can have any number of such resources.

- **spec**
  object

  Required value

  - **spec.basicAuth**
    object

    BasicAuth for the URL.

    - **spec.basicAuth.password**
      string

      Required value

      Password for the authentication.

    - **spec.basicAuth.username**
      string

      Required value

      Username for the authentication.

  - **spec.bearerToken**
    string

    Bearer token.

  - **spec.customAuthToken**
    string

    Custom token sent as a value of the X-Auth-Token header.

  - **spec.headers**
    object

    HTTP headers to include in the request.

    - **spec.headers.X-Scope-OrgID**
      string

      Required value

      The `X-Scope-OrgID` header specifying the tenant ID.

  - **spec.tlsConfig**
    object

    TLS Config to use for remote write.

    - **spec.tlsConfig.ca**
      string

      The CA certificate used when verifying the API server certificate.

      Default:

    - **spec.tlsConfig.insecureSkipVerify**
      boolean

      Disable target certificate validation.

      Default: `false`

  - **spec.url**
    string

    Required value

    The URL of the endpoint to send samples to.

    Example:

    ```
    url: https://victoriametrics-test.domain.com/api/v1/write
    ```

  - **spec.writeRelabelConfigs**
    array of objects

    The list of remote write relabel configurations.

    For example, if you need to remove unnecessary metrics or perform data relabeling.

    - **spec.writeRelabelConfigs.action**
      string

      Action to perform based on regex matching.

      Default: `replace`

    - **spec.writeRelabelConfigs.modulus**
      integer

      Modulus to take of the hash of the source label values.

    - **spec.writeRelabelConfigs.regex**
      string

      Regular expression against which the extracted value is matched. Default is '(.*)'

      Default: `(.*)`

    - **spec.writeRelabelConfigs.replacement**
      string

      Replacement value against which a regex replace is performed if the regular expression matches.

      Regex capture groups are available.

Default: `$1`

- **spec.writeRelabelConfigs.separator**
  string

  Separator placed between concatenated source label values.

  Default: `;`

- **spec.writeRelabelConfigs.sourceLabels**
  array of strings

  The source labels select values from existing labels.

  Their content is concatenated using the configured separator and matched against the configured regular expression for the replace, keep, and drop actions.

- **spec.writeRelabelConfigs.targetLabel**
  string

  Label to which the resulting value is written in a replace action. It is mandatory for replace actions.

  Regex capture groups are available.

Deprecated resource. Support for the resource might be removed in a later release.

Resource for including ‘remote_write’ data from the local Prometheus into a separate longterm storage (E.g: VictoriaMetrics).

A cluster can have any number of such resources.

- **spec**
  object

  Required value

  - **spec.basicAuth**
    object

    BasicAuth for the URL.

    - **spec.basicAuth.password**
      string

      Required value

      Password for the authentication.

    - **spec.basicAuth.username**
      string

      Required value

      Username for the authentication.

  - **spec.bearerToken**
    string

    Bearer token.

  - **spec.customAuthToken**
    string

    Custom token sent as a value of the X-Auth-Token header.

  - **spec.headers**
    object

    HTTP headers to include in the request.

    - **spec.headers.X-Scope-OrgID**
      string

      Required value

      The `X-Scope-OrgID` header specifying the tenant ID.

  - **spec.tlsConfig**
    object

    TLS Config to use for remote write.

    - **spec.tlsConfig.ca**
      string

      The CA certificate used when verifying the API server certificate.

      Default:

    - **spec.tlsConfig.insecureSkipVerify**
      boolean

      Disable target certificate validation.

      Default: `false`

  - **spec.url**
    string

    Required value

    The URL of the endpoint to send samples to.

    Example:

    ```
    url: https://victoriametrics-test.domain.com/api/v1/write
    ```

  - **spec.writeRelabelConfigs**
    array of objects

The list of remote write relabel configurations.

For example, if you need to remove unnecessary metrics or perform data relabeling.

- **spec.writeRelabelConfigs.action**
  string

  Action to perform based on regex matching.

  Default: `replace`
- **spec.writeRelabelConfigs.modulus**
  integer

  Modulus to take of the hash of the source label values.
- **spec.writeRelabelConfigs.regex**
  string

  Regular expression against which the extracted value is matched. Default is '(.*)'

  Default: `(.*)`
- **spec.writeRelabelConfigs.replacement**
  string

  Replacement value against which a regex replace is performed if the regular expression matches.

  Regex capture groups are available.

  Default: `$1`
- **spec.writeRelabelConfigs.separator**
  string

  Separator placed between concatenated source label values.

  Default: `;`
- **spec.writeRelabelConfigs.sourceLabels**
  array of strings

  The source labels select values from existing labels.

  Their content is concatenated using the configured separator and matched against the configured regular expression for the replace, keep, and drop actions.
- **spec.writeRelabelConfigs.targetLabel**
  string

  Label to which the resulting value is written in a replace action. It is mandatory for replace actions.

  Regex capture groups are available.

Usage

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

An example of the module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus
spec:
  version: 2
  enabled: true
  settings:
    auth:
      password: xxxxxx
    retentionDays: 7
    storageClass: rbd
    nodeSelector:
      node-role/monitoring: ""
    tolerations:
    - key: dedicated.deckhouse.io
      operator: Equal
      value: monitoring
```

Writing Prometheus data to the longterm storage

Prometheus supports remote_write'ing data from the local Prometheus to a separate longterm storage (e.g., VictoriaMetrics). In Deckhouse, this mechanism is implemented using the `PrometheusRemoteWrite` custom resource.

> **i** For VictoriaMetrics detailed information about how to send data to vmagent can be found in the VictoriaMetrics documentation.

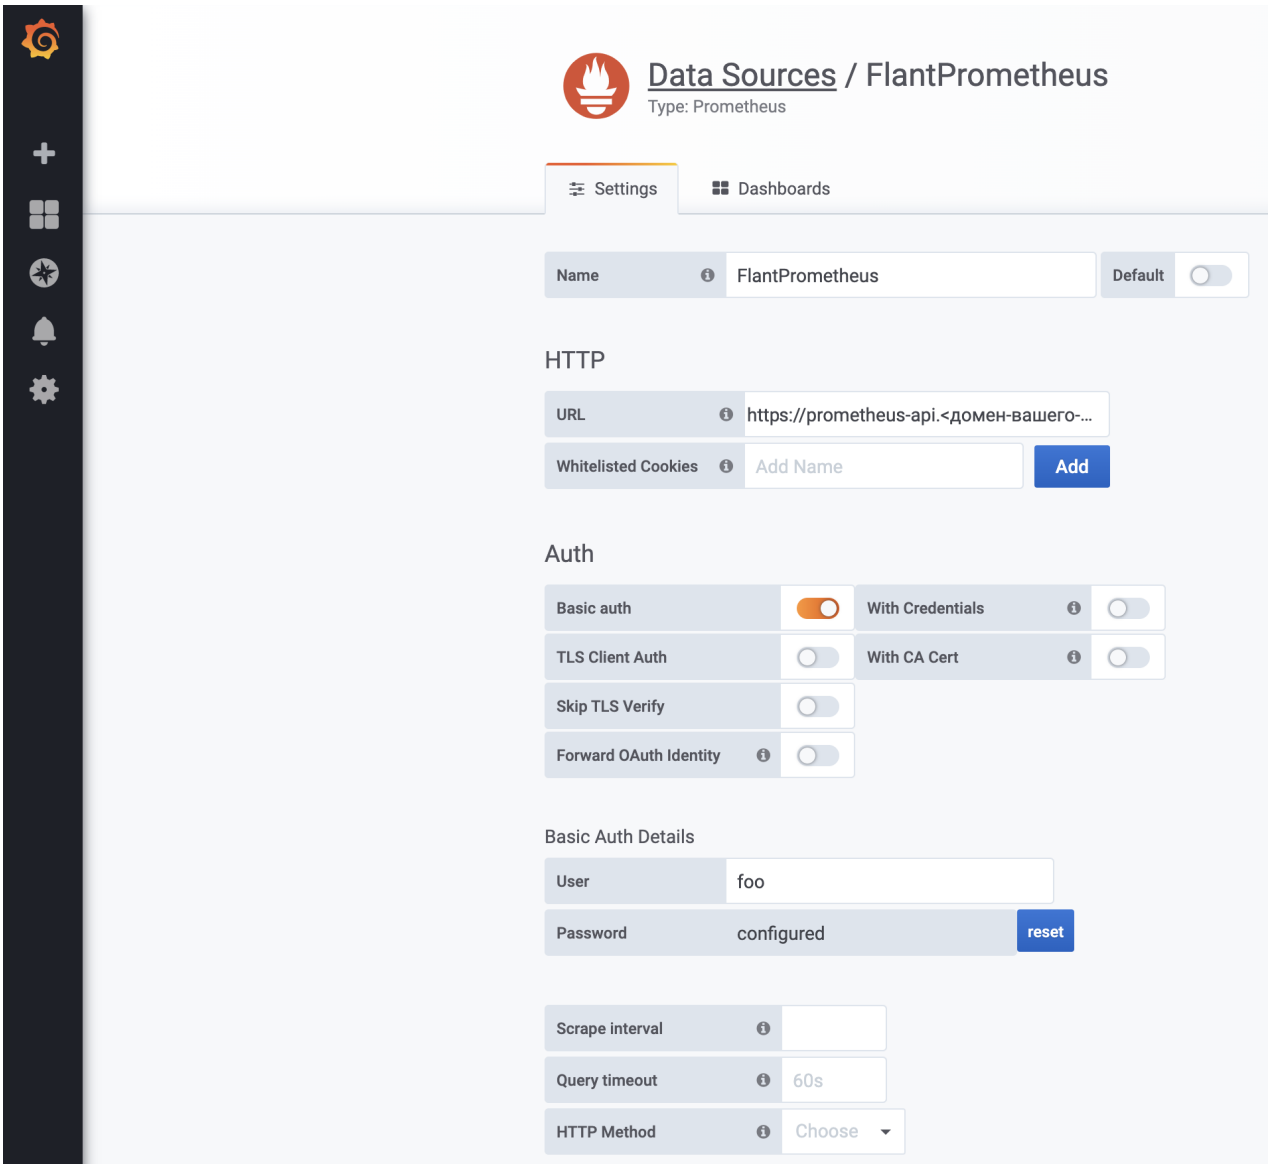
Example of the basic PrometheusRemoteWrite

```
apiVersion: deckhouse.io/v1
kind: PrometheusRemoteWrite
metadata:
  name: test-remote-write
spec:
  url: https://victoriametrics-test.domain.com/api/v1/write
```

Example of the expanded PrometheusRemoteWrite

```
apiVersion: deckhouse.io/v1
kind: PrometheusRemoteWrite
metadata:
  name: test-remote-write
spec:
  url: https://victoriametrics-test.domain.com/api/v1/write
  basicAuth:
    username: username
    password: password
  writeRelabelConfigs:
  - sourceLabels: [__name__]
    action: keep
    regex: prometheus_build_.*|my_cool_app_metrics_.*
  - sourceLabels: [__name__]
    action: drop
    regex: my_cool_app_metrics_with_sensitive_data
```

Connecting Prometheus to an external Grafana instance



Each `ingress-nginx-controller` has certificates that can be used to connect to Prometheus. All you need is to create an additional `Ingress` resource.

> **i**
>
> For the example below, it is presumed that Secret `example-com-tls` already exist in namespace d8-monitoring.
>
> Names for Ingress `my-prometheus-api` and Secret `my-basic-auth-secret` are there for example. Change them to the most suitable names for your case.

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: my-prometheus-api
  namespace: d8-monitoring
  annotations:
    nginx.ingress.kubernetes.io/backend-protocol: HTTPS
    nginx.ingress.kubernetes.io/auth-type: basic
    nginx.ingress.kubernetes.io/auth-secret: my-basic-auth-secret
    nginx.ingress.kubernetes.io/app-root: /graph
    nginx.ingress.kubernetes.io/configuration-snippet: |
      proxy_ssl_certificate /etc/nginx/ssl/client.crt;
      proxy_ssl_certificate_key /etc/nginx/ssl/client.key;
      proxy_ssl_protocols TLSv1.2;
      proxy_ssl_session_reuse on;
spec:
  ingressClassName: nginx
  rules:
  - host: prometheus-api.example.com
    http:
      paths:
      - backend:
          service:
            name: prometheus
            port:
              name: https
        path: /
        pathType: ImplementationSpecific
  tls:
  - hosts:
    - prometheus-api.example.com
    secretName: example-com-tls
---
apiVersion: v1
kind: Secret
metadata:
  name: my-basic-auth-secret
  namespace: d8-monitoring
type: Opaque
data:
  # Basic-auth string is hashed using htpasswd.
  auth: Zm9vOiRhcHIxJE9GRzNYeWJwJGNrTDBGSERBa29YWUlsSDkuY3lzVDAK  # foo:bar
```

Next, you only need to add the data source to Grafana:

> Specify `https://prometheus-api.<cluster-domain>` as the URL.

- Note that **basic authorization** is not sufficiently secure and safe. You are encouraged to implement additional safety measures, e.g., attach the `nginx.ingress.kubernetes.io/whitelist-source-range` annotation.
- It is **not recommended** connecting this way since you have to create an Ingress resource in the system namespace. Deckhouse does **not guarantee** the functionality of this connection method due to its regular updates.
- This Ingress resource can be used to access the Prometheus API not only from Grafana but for other integrations, e.g., the Prometheus federation.

Connecting an external app to Prometheus

The connection to Prometheus is protected using kube-rbac-proxy. To connect, you need to create a `ServiceAccount` with the necessary permissions.

```
---
apiVersion: v1
kind: ServiceAccount
metadata:
  name: app
  namespace: default
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: app:prometheus-access
rules:
- apiGroups: ["monitoring.coreos.com"]
  resources: ["prometheuses/http"]
  resourceNames: ["main", "longterm"]
  verbs: ["get"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: app:prometheus-access
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: app:prometheus-access
subjects:
- kind: ServiceAccount
  name: app
  namespace: default
```

Define the following job containing the `curl` request:

```
apiVersion: batch/v1
kind: Job
metadata:
  name: app-curl
  namespace: default
spec:
  template:
    metadata:
      name: app-curl
    spec:
      serviceAccountName: app
      containers:
      - name: app-curl
        image: curlimages/curl:7.69.1
        command: ["sh", "-c"]
        args:
        - >-
          curl -H "Authorization: Bearer $(cat /var/run/secrets/kubernetes.io/serviceaccount/token)" -k -f
          https://prometheus.d8-monitoring:9090/api/v1/query_range?query=up\&start=1584001500\&end=1584023100\&step=30
      restartPolicy: Never
  backoffLimit: 4
```

The `job` must complete successfully.

Sending alerts to Telegram

Alertmanager supports sending alerts to Telegram directly.

Create the Secret in the `d8-monitoring` namespace:

```
apiVersion: v1
kind: Secret
metadata:
  name: telegram-bot-secret
  namespace: d8-monitoring
stringData:
  token: "562696849:AAExcuJ8H6z4pTlPuocbrXXXXXXXXXXx"
```

Deploy CustomAlertManager CR:

```
apiVersion: deckhouse.io/v1alpha1
kind: CustomAlertmanager
metadata:
  name: telegram
spec:
  type: Internal
  internal:
    receivers:
      - name: telegram
        telegramConfigs:
          - botToken:
              name: telegram-bot-secret
              key: token
            chatID: -30490XXXXX
    route:
      groupBy:
        - job
      groupInterval: 5m
      groupWait: 30s
      receiver: telegram
      repeatInterval: 12h
```

The fields `token` in the Secret and `chatID` in the `CustomAlertmanager` custom resource must be set on your own. Read more about Telegram API.

Example of sending alerts to Slack with a filter

```
apiVersion: deckhouse.io/v1alpha1
kind: CustomAlertmanager
metadata:
  name: slack
spec:
  internal:
    receivers:
    - name: devnull
    - name: slack
      slackConfigs:
      - apiURL:
          key: apiURL
          name: slack-apiurl
        channel: {{ dig .Values.werf.env .Values.slack.channel._default .Values.slack.channel }}
        fields:
        - short: true
          title: Severity
          value: '{{`{{  .CommonLabels.severity_level }}`}}'
        - short: true
          title: Status
          value: '{{`{{ .Status }}`}}'
        - title: Summary
          value: '{{`{{ range .Alerts }}`}}{{`{{ .Annotations.summary }}`}} {{`{{ end }}`}}'
        - title: Description
          value: '{{`{{ range .Alerts }}`}}{{`{{ .Annotations.description }}`}} {{`{{ end }}`}}'
        - title: Labels
          value: '{{`{{ range .Alerts }}`}} {{`{{ range .Labels.SortedPairs }}`}}{{`{{ printf "%s:
            %s\n" .Name .Value }}`}}{{`{{ end }}`}}{{`{{ end }}`}}'
        - title: Links
          value: '{{`{{ (index .Alerts 0).GeneratorURL }}`}}'
        title: '{{`{{ .CommonLabels.alertname }}`}}'
    route:
      groupBy:
      - '...'
      receiver: devnull
      routes:
        - matchers:
          - matchType: =~
            name: severity_level
            value: "^[4-9]$"
          receiver: slack
      repeatInterval: 12h
  type: Internal
```

Example of sending alerts to Opsgenie

```
- name: opsgenie
      opsgenieConfigs:
        - apiKey:
            key: data
            name: opsgenie
          description: |
            {{ range .Alerts }}{{ .Annotations.summary }} {{ end }}
            {{ range .Alerts }}{{ .Annotations.description }} {{ end }}
          message: '{{ .CommonLabels.alertname }}'
          priority: P1
          responders:
            - id: team_id
              type: team
```

Example of sending alert by Email

Create a Secret with base64 encoded password for email account as value of `password`:

```
apiVersion: v1
kind: Secret
metadata:
  name: am-mail-server-pass
  namespace: d8-monitoring
data:
  password: BASE64_ENCODED_PASSWORD_HERE
```

Change values in `CustomAlertManager` manifest as you need and apply the resource:

```
apiVersion: deckhouse.io/v1alpha1
kind: CustomAlertmanager
metadata:
  name: mail
spec:
  type: Internal
  internal:
    receivers:
      - name: devnull
      - name: mail
        emailConfigs:
          - to: oncall@example.com
            from: prom@example.com
            smarthost: mx.example.com:587
            authIdentity: prom@example.com
            authUsername: prom@example.com
            authPassword:
              key: password
              name: am-mail-server-pass
            # In case you have custom TLS certificates, you can put public part of your CA in a ConfigMap and deploy it
in d8-monitoring namespace
            # tlsConfig:
            #   insecureSkipVerify: true
            #   ca:
            #     configMap:
            #       key: ca.pem
            #       name: alertmanager-mail-server-ca
            sendResolved: true
            requireTLS: true
    route:
      groupBy:
        - job
      groupInterval: 5m
      groupWait: 30s
      receiver: devnull
      repeatInterval: 24h
      routes:
        - matchers:
          - matchType: =~
            name: severity_level
            value: "^[1-4]$"
          receiver: mail
```

FAQ

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

How do I collect metrics from applications running outside of the cluster?

1. Configure a Service similar to the one that collects metrics from your application (but do not set the `spec.selector` parameter).
2. Create Endpoints for this Service and explicitly specify the `IP:PORT` pairs that your applications use to expose metrics.

> **i** Port names in Endpoints must match those in the Service.

An example

Application metrics are freely available (no TLS involved) at `http://10.182.10.5:9114/metrics`.

```
apiVersion: v1
kind: Service
metadata:
  name: my-app
  namespace: my-namespace
  labels:
    prometheus.deckhouse.io/custom-target: my-app
spec:
  ports:
  - name: http-metrics
    port: 9114
---
apiVersion: v1
kind: Endpoints
metadata:
  name: my-app
  namespace: my-namespace
subsets:
  - addresses:
    - ip: 10.182.10.5
    ports:
    - name: http-metrics
      port: 9114
```

How do I create custom Grafana dashboards?

Custom Grafana dashboards can be added to the project using the Infrastructure as a Code approach. To add your dashboard to Grafana, create the dedicated `GrafanaDashboardDefinition` Custom Resource in the cluster.

An example:

```
apiVersion: deckhouse.io/v1
kind: GrafanaDashboardDefinition
metadata:
  name: my-dashboard
spec:
  folder: My folder # The folder where the custom dashboard will be located.
  definition: |
    {
      "annotations": {
        "list": [
          {
            "builtIn": 1,
            "datasource": "-- Grafana --",
            "enable": true,
            "hide": true,
            "iconColor": "rgba(0, 211, 255, 1)",
            "limit": 100,
...
```

> **⚠** System dashboards and dashboards added using GrafanaDashboardDefinition cannot be modified via the Grafana interface.
>
> Alerts configured in the dashboard do not work with datasource templates - such a dashboard is invalid and cannot be imported. In Grafana 9.0, the legacy alerting functionality was deprecated and replaced with Grafana Alerting. Therefore, we do not recommend using legacy alerting in dashboards.

> **i** If the dashboard does not appear in Grafana after being applied, there might be an error in the dashboard's JSON file. To identify the source of the problem, use the command `d8 k logs -n d8-monitoring deployments/grafana-v10 dashboard-provisioner` to view the logs of the component responsible for applying dashboards.

How do I add alerts and/or recording rules?

There are two ways to add alerts:

- **Recommended**: Using the ClusterObservabilityMetricsRulesGroup and ObservabilityMetricsRulesGroup resources of the `observability` module.
- **Outdated**: Using the CustomPrometheusRules resource. The following is an example configuration for this resource.

Parameters:

- `groups` — is the only parameter where you need to define alert groups. The structure of the groups is similar to that of prometheus-operator.

An example:

```
apiVersion: deckhouse.io/v1
kind: CustomPrometheusRules
metadata:
  name: my-rules
spec:
  groups:
  - name: cluster-state-alert.rules
    rules:
    - alert: CephClusterErrorState
      annotations:
        description: Storage cluster is in error state for more than 10m.
        summary: Storage cluster is in error state
        plk_markup_format: markdown
      expr: |
        ceph_health_status{job="rook-ceph-mgr"} > 1
```

How do I provision additional Grafana data sources?

The `GrafanaAdditionalDatasource` allows you to provision additional Grafana data sources.

A detailed description of the resource parameters is available in the Grafana documentation.

See the datasource type in the documentation for the specific datasource.

An example:

```
apiVersion: deckhouse.io/v1
kind: GrafanaAdditionalDatasource
metadata:
  name: another-prometheus
spec:
  type: prometheus
  access: Proxy
  url: https://another-prometheus.example.com/prometheus
  basicAuth: true
  basicAuthUser: foo
  jsonData:
    timeInterval: 30s
    httpMethod: POST
  secureJsonData:
    basicAuthPassword: bar
```

How do I enable secure access to metrics?

To enable secure access to metrics, we strongly recommend using **kube-rbac-proxy**.

An example of collecting metrics securely from an application inside a cluster

To set up application metrics protection using `kube-rbac-proxy` and then collect metrics using Prometheus, follow these steps:

1. Create a new `ServiceAccount` with the following permissions:

   ```
   ---
   apiVersion: v1
   kind: ServiceAccount
   metadata:
     name: rbac-proxy-test
   ---
   apiVersion: rbac.authorization.k8s.io/v1
   kind: ClusterRoleBinding
   metadata:
     name: rbac-proxy-test
   roleRef:
     apiGroup: rbac.authorization.k8s.io
     kind: ClusterRole
     name: d8:rbac-proxy
   subjects:
   - kind: ServiceAccount
     name: rbac-proxy-test
     namespace: default
   ```

   > **i** The example uses the `d8:rbac-proxy` built-in Deckhouse `ClusterRole`.

2. Create a configuration for the `kube-rbac-proxy`:

```
---
apiVersion: v1
kind: ConfigMap
metadata:
  name: rbac-proxy-config-test
  namespace: rbac-proxy-test
data:
  config-file.yaml: |+
    authorization:
      resourceAttributes:
        namespace: default
        apiVersion: v1
        resource: services
        subresource: proxy
        name: rbac-proxy-test
```

> **i** Get more information on authorization attributes in the Kubernetes documentation.

3. Create `Service` and `Deployment` for your application with the `kube-rbac-proxy` as a sidecar container:

```
---
apiVersion: v1
kind: Service
metadata:
  name: rbac-proxy-test
  labels:
    prometheus.deckhouse.io/custom-target: rbac-proxy-test
spec:
  ports:
  - name: https-metrics
    port: 8443
    targetPort: https-metrics
  selector:
    app: rbac-proxy-test
---
apiVersion: apps/v1
kind: Deployment
metadata:
  name: rbac-proxy-test
spec:
  replicas: 1
  selector:
    matchLabels:
      app: rbac-proxy-test
  template:
    metadata:
      labels:
        app: rbac-proxy-test
    spec:
      securityContext:
        runAsUser: 65532
      serviceAccountName: rbac-proxy-test
      containers:
      - name: kube-rbac-proxy
        image: quay.io/brancz/kube-rbac-proxy:v0.14.0
        args:
        - "--secure-listen-address=0.0.0.0:8443"
        - "--upstream=http://127.0.0.1:8081/"
        - "--config-file=/kube-rbac-proxy/config-file.yaml"
        - "--logtostderr=true"
        - "--v=10"
        ports:
        - containerPort: 8443
          name: https-metrics
        volumeMounts:
        - name: config
          mountPath: /kube-rbac-proxy
      - name: prometheus-example-app
        image: quay.io/brancz/prometheus-example-app:v0.1.0
        args:
        - "--bind=127.0.0.1:8081"
      volumes:
      - name: config
        configMap:
          name: rbac-proxy-config-test
```

4. Add the necessary resource permissions to Prometheus:

```
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: rbac-proxy-test-client
rules:
- apiGroups: [""]
  resources: ["services/proxy"]
  verbs: ["get"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: rbac-proxy-test-client
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: rbac-proxy-test-client
subjects:
- kind: ServiceAccount
  name: prometheus
  namespace: d8-monitoring
```

After step 4, your application's metrics should become available in Prometheus.

An example of collecting metrics securely from an application outside a cluster

Suppose there is a server exposed to the Internet on which the `node-exporter` is running. By default, the `node-exporter` listens on port `9100` and is available on all interfaces. One needs to ensure access control to the `node-exporter` so that metrics can be collected securely. Below is an example of how you can set this up.

Requirements:

- There must be network access from the cluster to the `kube-rbac-proxy` service running on the *remote server*.
- The *remote server* must have access to the Kubernetes API server.

Follow these steps:

1. Create a new `ServiceAccount` with the following permissions:

```
---
apiVersion: v1
kind: ServiceAccount
metadata:
  name: prometheus-external-endpoint-server-01
  namespace: d8-service-accounts
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: prometheus-external-endpoint
rules:
- apiGroups: ["authentication.k8s.io"]
  resources:
  - tokenreviews
  verbs: ["create"]
- apiGroups: ["authorization.k8s.io"]
  resources:
  - subjectaccessreviews
  verbs: ["create"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: prometheus-external-endpoint-server-01
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: prometheus-external-endpoint
subjects:
- kind: ServiceAccount
  name: prometheus-external-endpoint-server-01
  namespace: d8-service-accounts
```

2. Generate a `kubeconfig` file for the created `ServiceAccount` (refer to the example on how to generate `kubeconfig` for `ServiceAccount`).
3. Copy the `kubeconfig` file to the *remote server*. You will also have to specify the `kubeconfig` path in the `kube-rbac-proxy` settings (our example uses `${PWD}/.kube/config`).
4. Configure `node-exporter` on the *remote server* to be accessible only on the local interface (i.e., listening on `127.0.0.1:9100`).
5. Run `kube-rbac-proxy` on the *remote server*:

```
docker run --network host -d -v ${PWD}/.kube/config:/config quay.io/brancz/kube-rbac-proxy:v0.14.0 --secure-listen-
address=0.0.0.0:8443 \
  --upstream=http://127.0.0.1:9100 --kubeconfig=/config --logtostderr=true --v=10
```

6. Check that port `8443` is accessible at the remote server's external address.

7. Create `Service` and `Endpoint`, specifying the external address of the *remote server* as `<server_ip_address>`:

```
---
apiVersion: v1
kind: Service
metadata:
  name: prometheus-external-endpoint-server-01
  labels:
    prometheus.deckhouse.io/custom-target: prometheus-external-endpoint-server-01
spec:
  ports:
  - name: https-metrics
    port: 8443
---
apiVersion: v1
kind: Endpoints
metadata:
  name: prometheus-external-endpoint-server-01
subsets:
  - addresses:
    - ip: <server_ip_address>
    ports:
    - name: https-metrics
      port: 8443
```

How do I add Alertmanager?

Create a custom resource `CustomAlertmanager` with type `Internal`.

Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: CustomAlertmanager
metadata:
  name: webhook
spec:
  type: Internal
  internal:
    route:
      groupBy: ['job']
      groupWait: 30s
      groupInterval: 5m
      repeatInterval: 12h
      receiver: 'webhook'
    receivers:
    - name: 'webhook'
      webhookConfigs:
      - url: 'http://webhookserver:8080/'
```

Refer to the description of the CustomAlertmanager custom resource for more information about the parameters.

How do I add an additional Alertmanager?

Create a custom resource `CustomAlertmanager` with the type `External`, it can point to Alertmanager through the FQDN or Kubernetes service.

FQDN Alertmanager example:

```
apiVersion: deckhouse.io/v1alpha1
kind: CustomAlertmanager
metadata:
  name: my-fqdn-alertmanager
spec:
  external:
    address: https://alertmanager.mycompany.com/myprefix
  type: External
```

Alertmanager with a Kubernetes service:

```
apiVersion: deckhouse.io/v1alpha1
kind: CustomAlertmanager
metadata:
  name: my-service-alertmanager
spec:
  external:
    service:
      namespace: myns
      name: my-alertmanager
      path: /myprefix/
  type: External
```

Refer to the description of the CustomAlertmanager Custom Resource for more information about the parameters.

How do I ignore unnecessary alerts in Alertmanager?

The solution comes down to configuring alert routing in the Alertmanager.

You will need to:

1. Create a parameterless receiver.
2. Route unwanted alerts to this receiver.

Below are samples for configuring `CustomAlertmanager`.

Receive all alerts with labels `service: foo|bar|baz`:

```
receivers:
 # The parameterless receiver is similar to "/dev/null".
 - name: blackhole
 # Your valid receiver.
 - name: some-other-receiver
   # ...
route:
 # Default receiver.
 receiver: blackhole
 routes:
   # Child receiver.
   - matchers:
       - matchType: =~
         name: service
         value: ^(foo|bar|baz)$
     receiver: some-other-receiver
```

Receive all alerts except for `DeadMansSwitch`:

```
receivers:
 # The parameterless receiver is similar to "/dev/null".
 - name: blackhole
 # Your valid receiver.
 - name: some-other-receiver
   # ...
route:
 # default receiver
 receiver: some-other-receiver
 routes:
   # Child receiver.
   - matchers:
       - matchType: =
         name: alertname
         value: DeadMansSwitch
     receiver: blackhole
```

A detailed description of all parameters can be found in the official documentation.

Why can’t different scrape Intervals be set for individual targets?

The Prometheus developer Brian Brazil provides, probably, the most comprehensive answer to this question. In short, different scrapeIntervals are likely to cause the following complications:

- Increasing configuration complexity;
- Problems with writing queries and creating graphs;
- Short intervals are more like profiling an app, and Prometheus isn’t the best tool to do this in most cases.

The most appropriate value for scrapeInterval is in the range of 10-60s.

How do I limit Prometheus resource consumption?

To avoid situations when VPA requests more resources for Prometheus or Longterm Prometheus than those available on the corresponding node, you can explicitly limit VPA using module parameters:

- `vpa.longtermMaxCPU`
- `vpa.longtermMaxMemory`
- `vpa.maxCPU`
- `vpa.maxMemory`

How do I set up a ServiceMonitor or PodMonitor to work with Prometheus?

Add the `prometheus: main` label to the PodMonitor or ServiceMonitor. Add the label `prometheus.deckhouse.io/monitor-watcher-enabled: "true"` to the namespace where the PodMonitor or ServiceMonitor was created.

Example:

```
---
apiVersion: v1
kind: Namespace
metadata:
  name: frontend
  labels:
    prometheus.deckhouse.io/monitor-watcher-enabled: "true"
---
apiVersion: monitoring.coreos.com/v1
kind: ServiceMonitor
metadata:
  name: example-app
  namespace: frontend
  labels:
    prometheus: main
spec:
  selector:
    matchLabels:
      app: example-app
  endpoints:
    - port: web
```

How do I set up a Probe to work with Prometheus?

Add the `prometheus: main` to Probe. Add the label `prometheus.deckhouse.io/probe-watcher-enabled: "true"` to the namespace where the Probe was created.

Example:

```
---
apiVersion: v1
kind: Namespace
metadata:
  name: frontend
  labels:
    prometheus.deckhouse.io/probe-watcher-enabled: "true"
---
apiVersion: monitoring.coreos.com/v1
kind: Probe
metadata:
  labels:
    app: prometheus
    component: probes
    prometheus: main
  name: cdn-is-up
  namespace: frontend
spec:
  interval: 30s
  jobName: httpGet
  module: http_2xx
  prober:
    path: /probe
    scheme: http
    url: blackbox-exporter.blackbox-exporter.svc.cluster.local:9115
  targets:
    staticConfig:
      static:
      - https://example.com/status
```

How do I set up a PrometheusRules to work with Prometheus?

Add the label `prometheus.deckhouse.io/rules-watcher-enabled: "true"` to the namespace where the PrometheusRules was created.

Example:

```
---
apiVersion: v1
kind: Namespace
metadata:
  name: frontend
  labels:
    prometheus.deckhouse.io/rules-watcher-enabled: "true"
```

How to expand disk size

1. To request a larger volume for a PVC, edit the PVC object and specify a larger size in `spec.resources.requests.storage` field.
   - You can only expand a PVC if its storage class's `allowVolumeExpansion` field is set to true.
2. If storage doesn't support online resize, the message `Waiting for user to (re-)start a pod to finish file system resize of volume on node.` will appear in the PersistentVolumeClaim status.
3. Restart the Pod to complete the file system resizing.

How to get information about alerts in a cluster?

You can get information about active alerts not only in the Grafana/Prometheus web interface but in the CLI. This can be useful if you only have access to the cluster API server and there is no way to open the Grafana/Prometheus web interface.

Run the following command to get cluster alerts:

```
d8 k get clusteralerts
```

Example:

```
# d8 k get clusteralerts
NAME              ALERT                                      SEVERITY   AGE     LAST RECEIVED   STATUS
086551aeee5b5b24  ExtendedMonitoringDeprecatatedAnnotation   4          3h25m   38s             firing
226d35c886464d6e  ExtendedMonitoringDeprecatatedAnnotation   4          3h25m   38s             firing
235d4efba7df6af4  D8SnapshotControllerPodIsNotReady          8          5d4h    44s             firing
27464763f0aa857c  D8PrometheusOperatorPodIsNotReady          7          5d4h    43s             firing
ab17837fffa5e440  DeadMansSwitch                             4          5d4h    41s             firing
```

Run the following command to view a specific alert:

```
d8 k get clusteralerts <ALERT_NAME> -o yaml
```

Example:

```
# d8 k get clusteralerts 235d4efba7df6af4 -o yaml
alert:
  description: |
    The recommended course of action:
    1. Retrieve details of the Deployment: `kubectl -n d8-snapshot-controller describe deploy snapshot-controller`
    2. View the status of the Pod and try to figure out why it is not running: `kubectl -n d8-snapshot-controller describe pod -l app=snapshot-
controller`
  labels:
    pod: snapshot-controller-75bd776d76-xhb2c
    prometheus: deckhouse
    tier: cluster
  name: D8SnapshotControllerPodIsNotReady
  severityLevel: "8"
  summary: The snapshot-controller Pod is NOT Ready.
apiVersion: deckhouse.io/v1alpha1
kind: ClusterAlert
metadata:
  creationTimestamp: "2023-05-15T14:24:08Z"
  generation: 1
  labels:
    app: prometheus
    heritage: deckhouse
  name: 235d4efba7df6af4
  resourceVersion: "36262598"
  uid: 817f83e4-d01a-4572-8659-0c0a7b6ca9e7
status:
  alertStatus: firing
  lastUpdateTime: "2023-05-15T18:10:09Z"
  startsAt: "2023-05-10T13:43:09Z"
```

> The presence of a special alert `MissingDeadMansSwitch` in the cluster indicates problems in the performance of the monitoring components.

For the list of all available alerts in the Deckhouse Kubernetes Platform monitoring system, refer to the corresponding documentation page.

How do I add additional endpoints to a scrape config?

Add the label `prometheus.deckhouse.io/scrape-configs-watcher-enabled: "true"` to the namespace where the ScrapeConfig was created.

Example:

```
---
apiVersion: v1
kind: Namespace
metadata:
  name: frontend
  labels:
    prometheus.deckhouse.io/scrape-configs-watcher-enabled: "true"
```

Add the ScrapeConfig with the required label `prometheus: main`:

```
apiVersion: monitoring.coreos.com/v1alpha1
kind: ScrapeConfig
metadata:
  name: example-scrape-config
  namespace: frontend
  labels:
    prometheus: main
spec:
  honorLabels: true
  staticConfigs:
    - targets: ['example-app.frontend.svc.{{ .Values.global.discovery.clusterDomain }}.:8080']
  relabelings:
    - regex: endpoint|namespace|pod|service
      action: labeldrop
    - targetLabel: scrape_endpoint
      replacement: main
    - targetLabel: job
      replacement: kube-state-metrics
  metricsPath: '/metrics'
```

The prometheus-metrics-adapter module

> i
> The module lifecycle stage: General Availability
> The module has requirements for installation

This module allows HPA and VPA autoscalers base their decisions on various metrics.

It installs an implementation of the Kubernetes resource metrics API, custom metrics API, and external metrics API to get Prometheus metrics.

As a result:

- `kubectl top` can collect Prometheus metrics via the adapter;
- autoscaling/v2 can be used for scaling applications (HPA);
- Prometheus data can be obtained using the Kubernetes API and utilized in other modules (Vertical Pod Autoscaler, etc.).

The following parameters serve as a basis for scaling:

- CPU (of the Pod),
- memory (of the Pod),
- rps (of the Ingress) — over 1,5,15 minutes (`rps Nm`),
- CPU (of the Pod) — over 1,5,15 minutes (`cpu Nm`) — average CPU utilization over N minutes,
- memory (of the Pod) — over 1,5,15 minutes (`memory_Nm`) — average Memory utilization over N minutes,
- any Prometheus metrics and any queries based on them.

How does it work?

This module registers `k8s-prometheus-adapter` as an external API service that extends the capabilities of the Kubernetes API. When some Kubernetes component (VPA, HPA) needs information about the resources consumed, it requests the Kubernetes API, which, in turn, proxies that request to the adapter. The adapter figures out (using its configuration file) how to calculate the metric and sends a request to Prometheus.

Third-party components

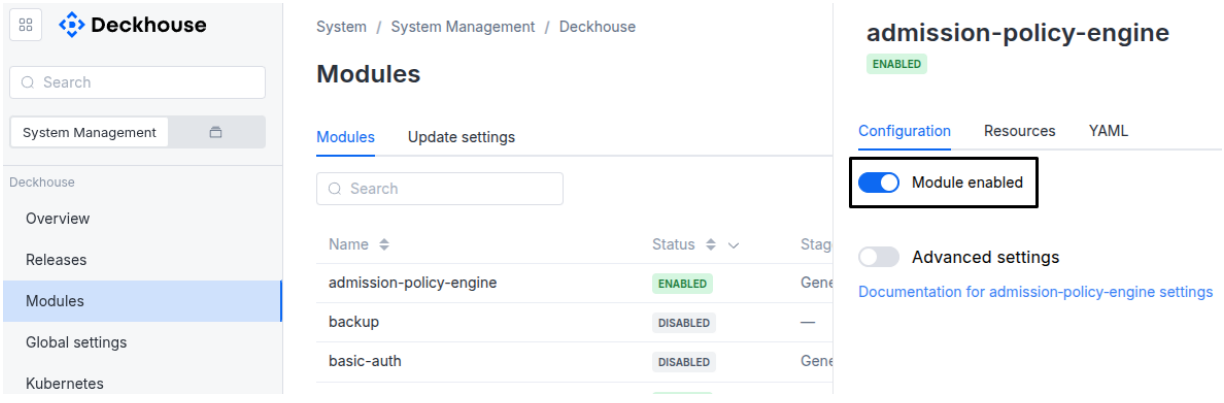
List of third-party software used in the `prometheus-metrics-adapter` module:

- Kubernetes Metrics Server

  License: Apache License 2.0

  A scalable, efficient source of container resource metrics for Kubernetes built-in autoscaling pipelines.

Configuration



> i
> The module lifecycle stage: General Availability
> The module has requirements for installation

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `prometheus-metrics-adapter` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

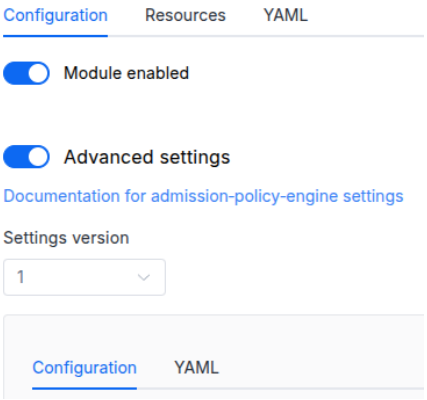
  ```
  d8 system module enable prometheus-metrics-adapter
  ```

- **Using ModuleConfig `prometheus-metrics-adapter`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `prometheus-metrics-adapter` (create it if necessary);

  Example of a manifest to enable module `prometheus-metrics-adapter`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: prometheus-metrics-adapter
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `prometheus-metrics-adapter` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `prometheus-metrics-adapter` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `prometheus-metrics-adapter`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `prometheus-metrics-adapter` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc prometheus-metrics-adapter
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `prometheus-metrics-adapter` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `prometheus-metrics-adapter`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: prometheus-metrics-adapter
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `prometheus`: any version.

Generally, no configuration is required.

Parameters

- `highAvailability` — manually enable/disable the high availability mode. By default, this parameter is configured automatically (additional information about the HA mode for modules is available here).

Custom resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

ClusterDaemonSetMetric

Scope: Cluster

- v1beta1
- v1alpha1

ClusterDaemonSetMetric is handy interface for configuring custom DaemonSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterDaemonSetMetric is handy interface for configuring custom DaemonSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterDeploymentMetric

Scope: Cluster

- v1beta1
- v1alpha1

ClusterDeploymentMetric is handy interface for configuring custom Deployment-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterDeploymentMetric is handy interface for configuring custom Deployment-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterIngressMetric

Scope: Cluster

- v1beta1
- v1alpha1

ClusterIngressMetric is handy interface for configuring custom Ingress-related metrics in prometheus-metrics-adapter.

- **spec**
  object

Required value

- **spec.query**
  string

  Required value

  PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterIngressMetric is handy interface for configuring custom Ingress-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterPodMetric

Scope: Cluster

- v1beta1
- v1alpha1

ClusterPodMetric is handy interface for configuring custom Pod-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

Deprecated resource. Support for the resource might be removed in a later release.

ClusterPodMetric is handy interface for configuring custom Pod-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterServiceMetric

Scope: Cluster

- v1beta1
- v1alpha1

ClusterServiceMetric is handy interface for configuring custom Service-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterServiceMetric is handy interface for configuring custom Service-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterStatefulSetMetric

Scope: Cluster

- v1beta1
- v1alpha1

ClusterStatefulSetMetric is handy interface for configuring custom StatefulSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ClusterStatefulSetMetric is handy interface for configuring custom StatefulSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

DaemonSetMetric

Scope: Namespaced

- v1beta1
- v1alpha1

DaemonSetMetric is handy interface for configuring custom DaemonSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

DaemonSetMetric is handy interface for configuring custom DaemonSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

DeploymentMetric

Scope: Namespaced

- v1beta1
- v1alpha1

DeploymentMetric is handy interface for configuring custom Deployment-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

DeploymentMetric is handy interface for configuring custom Deployment-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

    - **spec.query**
      string

      Required value

      PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

IngressMetric

Scope: Namespaced

- v1beta1
- v1alpha1

IngressMetric is handy interface for configuring custom Ingress-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

    - **spec.query**
      string

      Required value

      PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

IngressMetric is handy interface for configuring custom Ingress-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

    - **spec.query**
      string

      Required value

      PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

NamespaceMetric

Scope: Namespaced

- v1beta1
- v1alpha1

NamespaceMetric is handy interface for configuring custom Namespace-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

    - **spec.query**
      string

      Required value

      PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

NamespaceMetric is handy interface for configuring custom Namespace-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

    - **spec.query**
      string

      Required value

      PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

PodMetric

Scope: Namespaced

- v1beta1
- v1alpha1

PodMetric is handy interface for configuring custom Pod-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

    - **spec.query**
      string

      Required value

      PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use

keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

PodMetric is handy interface for configuring custom Pod-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ServiceMetric

Scope: Namespaced

- v1beta1
- v1alpha1

ServiceMetric is handy interface for configuring custom Service-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

ServiceMetric is handy interface for configuring custom Service-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

StatefulSetMetric

Scope: Namespaced

- v1beta1
- v1alpha1

StatefulSetMetric is handy interface for configuring custom StatefulSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

StatefulSetMetric is handy interface for configuring custom StatefulSet-related metrics in prometheus-metrics-adapter.

- **spec**
  object

  Required value

  - **spec.query**
    string

    Required value

    PromQL-query which returns unambiguous value for your metric. Use grouping operators like sum() by(), max() by() etc. Also use keywords: «.LabelMatchers» with your optional applied comma-separated labels as label selector and «.GroupBy» as group-by-labels. Example: max(mymetric{«.LabelMatchers»,queue=”messages”}) by(«.GroupBy»)

Usage

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

Note that only HPA (Horizontal Pod Autoscaling) with apiVersion: autoscaling/v2, whose support has been available since Kubernetes v1.12, is discussed below.

Configuring HPA requires:

- defining what is being scaled (`.spec.scaleTargetRef`);
- defining the scaling range (`.spec.minReplicas` , `.scale.maxReplicas`);
- defining metrics to be used as the basis for scaling (`.spec.metrics`) and registering them with the Kubernetes API.

Metrics in terms of HPA are of three types:

- classic — of type (`.spec.metrics[].type`) “Resource”; these are used for simple scaling based on CPU and memory consumption;
- custom — of type (`.spec.metrics[].type`) “Pods” or “Object”;
- external — of type (`.spec.metrics[].type`) “External”.

Caution! By default, HPA uses different approaches for scaling:

- If the metrics indicate that scaling **up** is required, it is done immediately (`spec.behavior.scaleUp.stabilizationWindowSeconds` = 0). The only limitation is the rate of increase: pods can double in 15 seconds, but if there are less than 4 pods, 4 new pods will be added.
- If the metrics indicate that scaling **down** is required, it happens within 5 minutes (`spec.behavior.scaleUp.stabilizationWindowSeconds` = 300): suggestions for a new number of replicas are calculated, then the largest value is selected. There is no limit on the number of pods to be removed at once.

If metrics are subject to fluctuations that result in a surge of unnecessary application replicas, the following approaches are used:

- Wrapping the metric with an aggregation function (e. g., `avg_over_time()`) if the metric is defined by a PromQL query. For more details, see. example.
- Increasing the stabilization window (parameter `spec.behavior.scaleUp.stabilizationWindowSeconds`) in the *HorizontalPodAutoscaler* resource. During the this period, requests to increase the number of replicas will be accumulated, then the most modest request will be selected. This method is identical to applying the `min_over_time(<stabilizationWindowSeconds>)` aggregation function, but only if the metric is increasing and scaling **up** is required. For scaling **down**, the default settings usually work good enough. For more details, see example.
- Limiting the rate of increase of the new replica count with `spec.behavior.scaleUp.policies` .

Scaling types

The following metrics can be used to scale applications:

1. Classic metrics.
2. Custom namespace-scoped metrics. This type is suitable if you have a single application, the source of the metrics is in the namespace and it is tied to one of the objects.
3. Custom cluster-wide metrics. This type is suitable if you have many applications using the same metric, whose source is in the application namespace, and it is associated with one of the objects. Such metrics let you put common infrastructure components into a separate deployment (“infra”).
4. If the metric source is not tied to the application namespace, you can use external metrics. For example, metrics provided by a cloud provider or an external SaaS service.

Caution! We recommend using option 1 (classic metrics), or option 2 (custom metrics defined in the *Namespace*). In this case, we suggest defining the application configuration (including its autoscaling) in the app repository. You should consider options 3 and 4 only if you have a large collection of identical microservices.

Classic resource consumption-based scaling

Below is an example HPA configuration for scaling based on the classic metrics from `metrics.k8s.io` : CPU and memory utilization for pods. The `averageUtulization` value reflects the target percentage of resources that have been **requested**.

```
apiVersion: autoscaling/v2
kind: HorizontalPodAutoscaler
metadata:
  name: app-hpa
  namespace: app-prod
spec:
  # Indicates the controller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: app
  # Controller scaling limits.
  minReplicas: 1
  maxReplicas: 10
  # If the application is prone to short-term spikes in CPU consumption,
  # you can postpone the scaling decision to see if it is necessary.
  # By default, scaling up occurs immediately.
  behavior:
    scaleUp:
      stabilizationWindowSeconds: 300
  metrics:
  # CPU- and memory-based scaling.
  - type: Resource
    resource:
      name: cpu
      target:
        # Scaling will occur when the average CPU utilization of all pods in scaleTargetRef exceeds the specified value.
        # For a metric with type: Resource, only type: Utilization is available.
        type: Utilization
        # Scaling will occur if 1 core is requested for all Deployment pods and if over 700m is already in use on
average.
        averageUtilization: 70
  - type: Resource
    resource:
      name: memory
      target:
        # Example of a scaling rule when the average memory usage of all pods in scaleTargetRef exceeds the given value.
        type: Utilization
        # Scaling will occur if 1 GB of memory is requested for the pods and more than 800 MB is already in use on
average.
        averageUtilization: 80
```

Scaling based on custom metrics

Registering custom metrics with Kubernetes API

Custom metrics must be registered with the `/apis/custom.metrics.k8s.io/` API, this registration is done by prometheus-metrics-adapter (and it also implements the API). The metrics can then be referenced using the *HorizontalPodAutoscaler* object. Customizing a vanilla prometheus-metrics-adapter is a time-consuming process. We made it easier by defining a set of Custom Resources with different Scopes:

- Namespaced:
  - `ServiceMetric`;
  - `IngressMetric`;
  - `PodMetric`;
  - `DeploymentMetric`;
  - `StatefulsetMetric`;
  - `NamespaceMetric`;
  - `DaemonSetMetric` (unavailable to users).
- Cluster:
  - `ClusterServiceMetric` (unavailable to users);
  - `ClusterIngressMetric` (unavailable to users);
  - `ClusterPodMetric` (unavailable to users);
  - `ClusterDeploymentMetric` (unavailable to users);
  - `ClusterStatefulsetMetric` (unavailable to users);
  - `ClusterDaemonSetMetric` (unavailable to users).

You can use the cluster-wide resource to define the metric globally, and use the *Namespace* to redefine it locally. Format is the same for all custom resources.

Using custom metrics in HPA

Once a custom metric is registered, it can be referenced. In terms of HPA, custom metrics can be of two types — `Pods` and `Object`.

`Object` refers to an object in the cluster that has metrics in Prometheus with corresponding labels (`namespace=XXX,ingress=YYYYY`). These labels will be substituted in place of `<<.LabelMatchers>>` in your custom request.

```
apiVersion: deckhouse.io/v1beta1
kind: IngressMetric
metadata:
  name: mymetric
  namespace: mynamespace
spec:
  query: sum(rate(ingress_nginx_detail_requests_total{<<.LabelMatchers>>}[2m])) by (<<.GroupBy>>) OR on() vector(0)
---
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: myhpa
  namespace: mynamespace
spec:
  # Specifies the controller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: myapp
  minReplicas: 1
  maxReplicas: 2
  # Metrics to use for scaling.
  # An example of using custom metrics.
  metrics:
  - type: Object
    object:
      # An object that has metrics in Prometheus.
      describedObject:
        apiVersion: networking.k8s.io/v1
        kind: Ingress
        name: myingress
      metric:
        # A metric registered with the IngressMetric or ClusterIngressMetric custom resource.
        # You can use rps_1m, rps_5m, or rps_15m that come with the prometheus-metrics-adapter module.
        name: mymetric
      target:
        # You can use `Value` or `AverageValue` for metrics of type Object.
        type: AverageValue
        # Scaling occurs if the average value of the custom metric for all pods in the Deployment deviates significantly
from 10.
        averageValue: 10
```

`Pods` — all pods will be selected from the resource managed by HPA and metrics will be collected for each pod with the relevant labels (`namespace=XXX`, `pod=YYYY-sadiq`, `namespace=XXX`, `pod=YYYY-e3adf`, etc.). Then the HPA will calculate an average value based on these metrics and will use it for scaling.

Using custom metrics with the RabbitMQ queue size

In the example below, scaling is performed based on the `send_forum_message` queue in RabbitMQ for which the `rmq` service is registered. If the number of messages in this queue exceeds 42, scaling is carried out.

```
apiVersion: deckhouse.io/v1beta1
kind: ServiceMetric
metadata:
  name: rmq-queue-forum-messages
  namespace: mynamespace
spec:
  query: sum (rabbitmq_queue_messages{<<.LabelMatchers>>,queue=~"send_forum_message",vhost="/"}) by (<<.GroupBy>>)
---
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: myhpa
  namespace: mynamespace
spec:
  # The controller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: myconsumer
  minReplicas: 1
  maxReplicas: 5
  metrics:
  - type: Object
    object:
      describedObject:
        apiVersion: v1
        kind: Service
        name: rmq
      metric:
        name: rmq-queue-forum-messages
      target:
        type: Value
        value: 42
```

Using volatile custom metrics

This example improves on the previous one.

In the example below, scaling is based on the `send_forum_message` queue in RabbitMQ, for which the `rmq` service is registered. If the number of messages in this queue exceeds 42, scaling takes place. The MQL function `avg_over_time()` smooths (averages the metric) to avoid over-scaling due to short-term spikes in the number of messages.

```
apiVersion: deckhouse.io/v1beta1
kind: ServiceMetric
metadata:
  name: rmq-queue-forum-messages
  namespace: mynamespace
spec:
  query: sum (avg_over_time(rabbitmq_queue_messages{<<.LabelMatchers>>,queue=~"send_forum_message",vhost="/"}[5m])) by
(<<.GroupBy>>)
---
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: myhpa
  namespace: mynamespace
spec:
  # The controller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: myconsumer
  minReplicas: 1
  maxReplicas: 5
  metrics:
  - type: Object
    object:
      describedObject:
        apiVersion: v1
        kind: Service
        name: rmq
      metric:
        name: rmq-queue-forum-messages
      target:
        type: Value
        value: 42
```

Examples involving custom metrics of type `Pods`

In the example below, the number of workers is scaled based on the percentage of active php-fpm workers. The trigger is the average number of php-fpm-workers in `mybackend` *Deployment*, which should not exceed 5.

```
apiVersion: deckhouse.io/v1beta1
kind: PodMetric
metadata:
  name: php-fpm-active-workers
spec:
  query: sum (phpfpm_processes_total{state="active",<<.LabelMatchers>>}) by (<<.GroupBy>>)
---
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: myhpa
  namespace: mynamespace
spec:
  # The controller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: mybackend
  minReplicas: 1
  maxReplicas: 5
  metrics:
  # HPA has to loop through all the Deployment pods and collect metrics from them.
  - type: Pods
    # Unlike type: Object, you don't have to specify describedObject.
    pods:
      metric:
        # A custom metric registered using the PodMetric custom resource.
        name: php-fpm-active-workers
      target:
        # For metrics of type: Pods, only AverageValue can be used.
        type: AverageValue
        # The scaling will take place if the average metric value of all Deployment pods exceeds 5.
        averageValue: 5
```

Scaling the Deployment based on the percentage number of active php-fpm-workers:

```
---
apiVersion: deckhouse.io/v1beta1
kind: PodMetric
metadata:
  name: php-fpm-active-worker
spec:
  # Percentage of active php-fpm-workers. The round() function gets rid of millipercentages in HPA.
  query: round(sum by(<<.GroupBy>>) (phpfpm_processes_total{state="active",<<.LabelMatchers>>}) / sum by(<<.GroupBy>>)
(phpfpm_processes_total{<<.LabelMatchers>>}) * 100)
---
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: {{ .Chart.Name }}-hpa
spec:
  # The cpntroller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1beta1
    kind: Deployment
    name: {{ .Chart.Name }}
  minReplicas: 4
  maxReplicas: 8
  metrics:
  - type: Pods
    pods:
      metric:
        name: php-fpm-active-worker
      target:
        type: AverageValue
        # Scaling will take place if, on average, the Deployment has 80% of the workers in use.
        averageValue: 80
```

Registering external metrics with the Kubernetes API

The `prometheus-metrics-adapter` module supports the `externalRules` mechanism. It allows you to define custom PromQL queries and register them as metrics.

A universal rule that allows you to create your own metrics without customization in `prometheus-metrics-adapter` has been added in the installation examples — “any metric in Prometheus with the name `kube_adapter_metric_<name>` will be registered in the API under the name `<name>`”. Then, you just need to write an exporter that will export such a metric or create a recording rule in Prometheus that will aggregate your metric based on other metrics.

Below is an example of *CustomPrometheusRules*:

The example showcases Prometheus custom rules for the `mymetric` metric.

```
apiVersion: deckhouse.io/v1
kind: CustomPrometheusRules
metadata:
  # The recommended template for naming your CustomPrometheusRules.
  name: prometheus-metrics-adapter-mymetric
spec:
  groups:
  # The recommended template
  - name: prometheus-metrics-adapter.mymetric
    rules:
    # The name of your new metric
    # Note that the 'kube_adapter_metric_' prefix is mandatory.
    - record: kube_adapter_metric_mymetric
      # A request with results that will end up in the final metric; there's no point in attaching extra labels to it.
      expr: sum(ingress_nginx_detail_sent_bytes_sum) by (namespace,ingress)
```

Using external metrics in HPA

Once an external metric is registered, you can refer to it.

```
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: myhpa
  namespace: mynamespace
spec:
  # The controller to be scaled (reference to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: myapp
  minReplicas: 1
  maxReplicas: 2
  metrics:
  # Scaling based on the external metrics
  - type: External
    external:
      metric:
        # The metric we registered by creating a metric in Prometheus (kube_adapter_metric_mymetric), but without the
prefix 'kube_adapter_metric_'.
        name: mymetric
        selector:
          # For external metrics, you can and should refine the request with labels.
          matchLabels:
            namespace: mynamespace
            ingress: myingress
      target:
        # Only `type: Value` can be used for metrics of type External.
        type: Value
        # Scaling will take place if the value of our metric exceeds 10.
        value: 10
```

Using the queue size in Amazon SQS

To install an exporter to integrate with SQS:

1. Create a dedicated “service” Git repository (alternatively, you could use, e.g., an “infrastructure” repository).
2. Copy the exporter installation and the script to it — these will be used to create the necessary *CustomPrometheusRules*.

That’s it, you have integrated the cluster. In case you need to configure autoscaling for just one application (in a single namespace), we recommend installing the exporter together with that application and using `NamespaceMetrics`.

The following is an example of an exporter (e. g., sqs-exporter) to retrieve metrics from Amazon SQS if:

- a `send_forum_message` queue is running in Amazon SQS;
- scaling is done when the number of messages in that queue exceeds 42.

```
apiVersion: deckhouse.io/v1
kind: CustomPrometheusRules
metadata:
  # The recommended name — prometheus-metrics-adapter-<metric name>.
  name: prometheus-metrics-adapter-sqs-messages-visible
  # Pay attention!
  namespace: d8-monitoring
  labels:
    # Pay attention!
    prometheus: main
    # Pay attention!
    component: rules
spec:
  groups:
  - name: prometheus-metrics-adapter.sqs_messages_visible # the recommended template
    rules:
    - record: kube_adapter_metric_sqs_messages_visible # Pay attention! The 'kube_adapter_metric_' prefix is required.
      expr: sum (sqs_messages_visible) by (queue)
---
kind: HorizontalPodAutoscaler
apiVersion: autoscaling/v2
metadata:
  name: myhpa
  namespace: mynamespace
spec:
  # The targets of scaling (link to a deployment or statefulset).
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: myconsumer
  minReplicas: 1
  maxReplicas: 5
  metrics:
  - type: External
    external:
      metric:
        # Must match CustomPrometheusRules record name without 'kube_adapter_metric_' prefix.
        name: sqs_messages_visible
        selector:
          matchLabels:
            queue: send_forum_messages
      target:
        type: Value
        value: 42
```

Debugging

How do I get a list of custom metrics?

```
d8 k get --raw /apis/custom.metrics.k8s.io/v1beta1/
```

How do I get the value of a metric associated with an object?

```
d8 k get --raw /apis/custom.metrics.k8s.io/v1beta1/namespaces/my-namespace/services/*/my-service-metric
d8 k get --raw /apis/custom.metrics.k8s.io/v1beta1/namespaces/my-namespace/ingresses/*/rps_1m
d8 k get --raw /apis/custom.metrics.k8s.io/v1beta1/namespaces/my-namespace/ingresses/*/mymetric
```

How do I get the value of a metric created via `NamespaceMetric`?

```
d8 k get --raw /apis/custom.metrics.k8s.io/v1beta1/namespaces/my-namespace/metrics/my-ns-metric
```

How do I get external metrics?

```
d8 k get --raw /apis/external.metrics.k8s.io/v1beta1
d8 k get --raw /apis/external.metrics.k8s.io/v1beta1/namespaces/d8-ingress-nginx/d8_ingress_nginx_ds_cpu_utilization
```

The Prometheus Pushgateway module

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

This module installs Prometheus Pushgateway into the cluster. It gets metrics from the app and pushes them to Prometheus.

Additional information:

- When to use `Prometheus Pushgateway`.
- How to collect metrics using `Prometheus Pushgateway`.

Third-party components

List of third-party software used in the `prometheus-pushgateway` module:

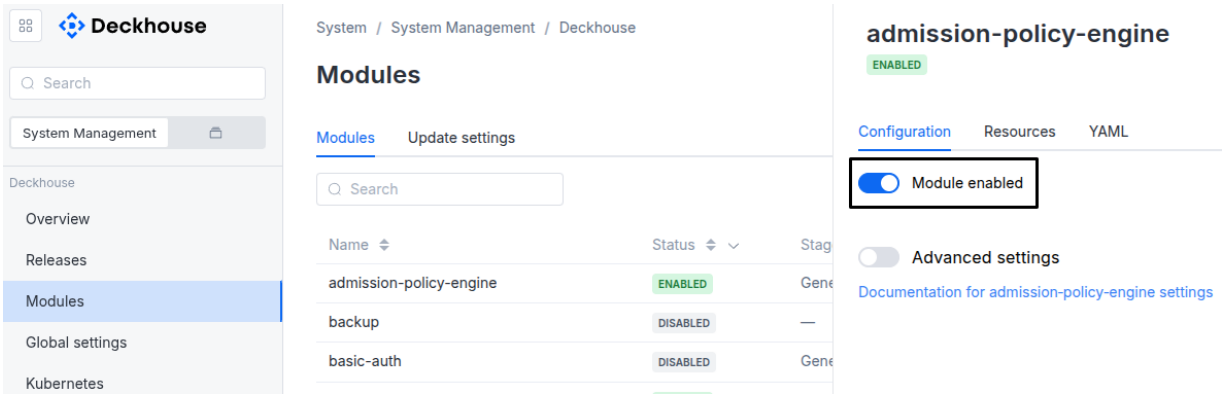
- Prometheus Pushgateway

  License: Apache License 2.0

  A tool to allow ephemeral and batch jobs to expose their metrics to Prometheus.

Configuration

> The module lifecycle stage: General Availability
> The module has requirements for installation



This module installs Prometheus Pushgateway into the cluster. It receives metrics from the app and pushes them to Prometheus.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `prometheus-pushgateway` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

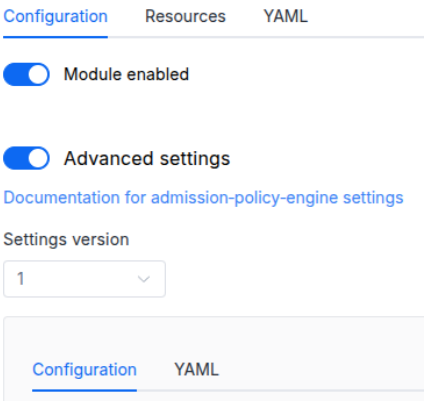
```
d8 system module enable prometheus-pushgateway
```

- **Using ModuleConfig `prometheus-pushgateway`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `prometheus-pushgateway` (create it if necessary);

  Example of a manifest to enable module `prometheus-pushgateway`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus-pushgateway
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `prometheus-pushgateway` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `prometheus-pushgateway` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `prometheus-pushgateway`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `prometheus-pushgateway` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc prometheus-pushgateway
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `prometheus-pushgateway` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `prometheus-pushgateway`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: prometheus-pushgateway
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `prometheus`: any version.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.instances**
    array of strings

    Required value

    This parameter contains a list of instances; a separate PushGateway will be created for each instance.

    Example:

    ```
    instances:
    - first
    - second
    ```
  - **settings.nodeSelector**
    object

    The same as in the pods’ `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.
  - **settings.tolerations**
    array of objects

    The same as in the pods’ `spec.tolerations` parameter in Kubernetes;

    If the parameter is omitted or `false`, it will be determined automatically.

    - **settings.tolerations.effect**
      string
    - **settings.tolerations.key**
      string
    - **settings.tolerations.operator**
      string
    - **settings.tolerations.tolerationSeconds**
      integer
    - **settings.tolerations.value**
      string

Examples

> **i**
> The module lifecycle stage: General Availability
> The module has requirements for installation

Example of the module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus-pushgateway
spec:
  version: 1
  enabled: true
  settings:
    instances:
    - first
    - second
    - another
```

PushGateway address (from a container pod): `http://first.kube-prometheus-pushgateway:9091`.

Pushing a metric

An example of pushing a metric using curl:

```
echo "test_metric{env="dev"} 3.14" | curl --data-binary @- http://first.kube-prometheus-pushgateway:9091/metrics/job/myapp
```

The metrics will be available in Prometheus in 30 seconds (after the data are scraped). An example:

```
test_metric{container="prometheus-pushgateway", env="dev", exported_job="myapp",
    instance="10.244.1.155:9091", job="prometheus-pushgateway", pushgateway="prometheus-pushgateway", tier="cluster"} 3.14
```

i The job name (`myapp` in the example) will be available in Prometheus in the label `exported_job`, and not `job` (because the label `job` already exists in Prometheus and is renamed when receiving metrics from PushGateway).

i You may need to get a list of all available job names to choose a unique name (in order not to spoil existing graphs and alerts). Use the following query to get a list of all existing jobs: `count({__name__=~".+"}) by (job)`.

Deleting metrics

An example of deleting all metrics of a group `{instance="10.244.1.155:9091",job="myapp"}` using curl:

```
curl -X DELETE http://first.kube-prometheus-pushgateway:9091/metrics/job/myapp/instance/10.244.1.155:9091
```

Since PushGateway stores the scraped metrics in memory, **all metrics will be lost when the Pod is restarted**.

Registry Module

⚠ The module lifecycle stage: Preview

Description

The module manages the registry settings for DKP components.

The module can operate in the following modes:

- `Direct`: Provides direct access to an external registry via the fixed address `registry.d8-system.svc:5001/system/deckhouse`. This fixed address prevents Deckhouse images from being re-downloaded and components from being restarted when registry parameters are changed. Switching between modes and registries is done through the `deckhouse` ModuleConfig. The switching process is automatic — see the usage examples for more information.
- `Proxy`: Using an internal caching proxy registry that accesses an external registry, with the caching proxy registry running on control-plane (master) nodes. This mode reduces the number of requests to the external registry by caching images. Cached data is stored on the control-plane (master) nodes. Access to the internal registry is via the fixed address `registry.d8-system.svc:5001/system/deckhouse`, similar to the `Direct` mode. Switching between modes and registries is done through the `deckhouse` ModuleConfig. The switching process is automatic — see the usage examples for more information.
- `Local`: Using a local internal registry, with the registry running on control-plane (master) nodes. This mode allows the cluster to operate in an isolated environment. All data is stored on the control-plane (master) nodes. Access to the internal registry is via the fixed address `registry.d8-system.svc:5001/system/deckhouse`, similar to the `Direct` and `Proxy` modes. Switching between modes and registries is done through the `deckhouse` ModuleConfig. The switching process is automatic — see the usage examples for more information.
- `Unmanaged`: Operation without using the internal registry. Access within the cluster is performed directly to the external registry. There are two types of the `Unmanaged` mode:
  - Configurable: A mode managed via the `registry` module. Switching between modes and registries is handled through the `deckhouse` ModuleConfig. The switch is performed automatically (see usage examples for details).
  - Non-configurable (deprecated): The default mode. Configuration parameters are set during cluster installation or changed in a running cluster using the (deprecated) `helper change registry` command.

Restrictions and features of using the module

The `registry` module has a number of limitations and features related to installation, operating conditions, and mode switching.

Cluster installation limitations

- DKP cluster bootstrap is supported only in `Direct`, `Unmanaged`, and `Proxy` modes (bootstrap in `Local` mode is not supported). Registry settings during cluster installation are configured via the `deckhouse` ModuleConfig.
- To launch a cluster in the non-configurable `Unmanaged` mode (Legacy), registry parameters must be specified in `initConfiguration`.

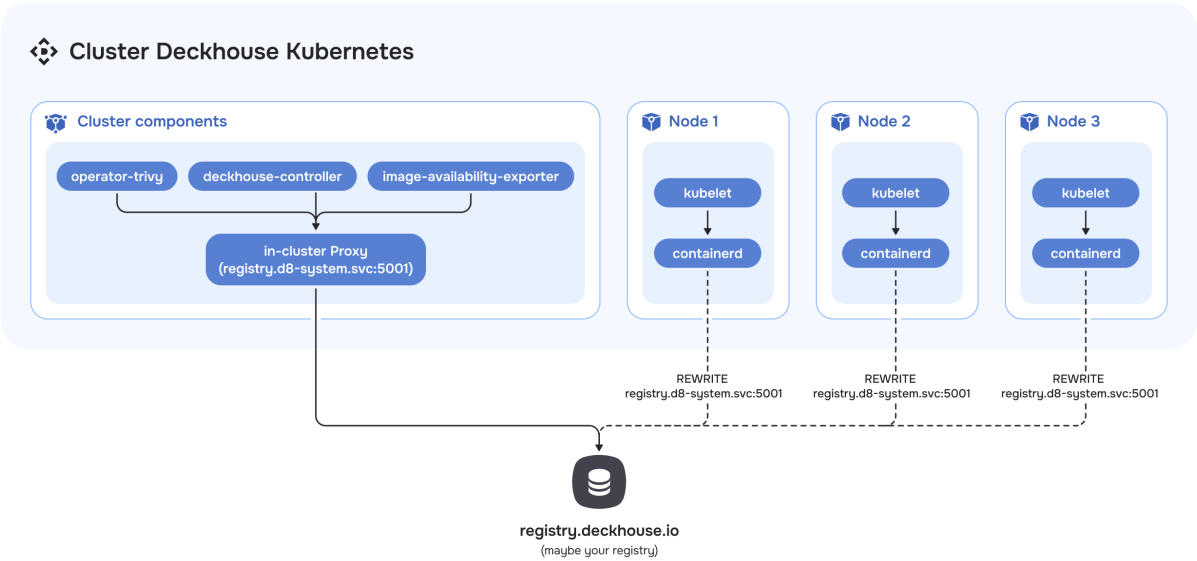
Operating conditions restrictions

The module works under the following conditions:

- If CRI containerd or containerd v2 is used on the cluster nodes. To configure CRI, refer to the `ClusterConfiguration` configuration.
- The cluster is fully managed by DKP. The module will not work in Managed Kubernetes clusters.
- The `Local` and `Proxy` modes are only supported on static clusters.

Mode switching restrictions

Mode switching restrictions are as follows:



- Changing registry parameters and switching modes is only available after the bootstrap phase is fully complete.
- For the first switch, migration of user registry configurations must be performed. For more details, see the Registry Module: FAQ section.
- Switching to the non-configurable `Unmanaged` mode is only available from the `Unmanaged` mode. For more details, see the Registry Module: FAQ section.
- Switching between `Local` and `Proxy` modes is only possible via the intermediate `Direct` or `Unmanaged` modes. Example switching sequence: `Local/Proxy` → `Direct` → `Proxy/Local`.

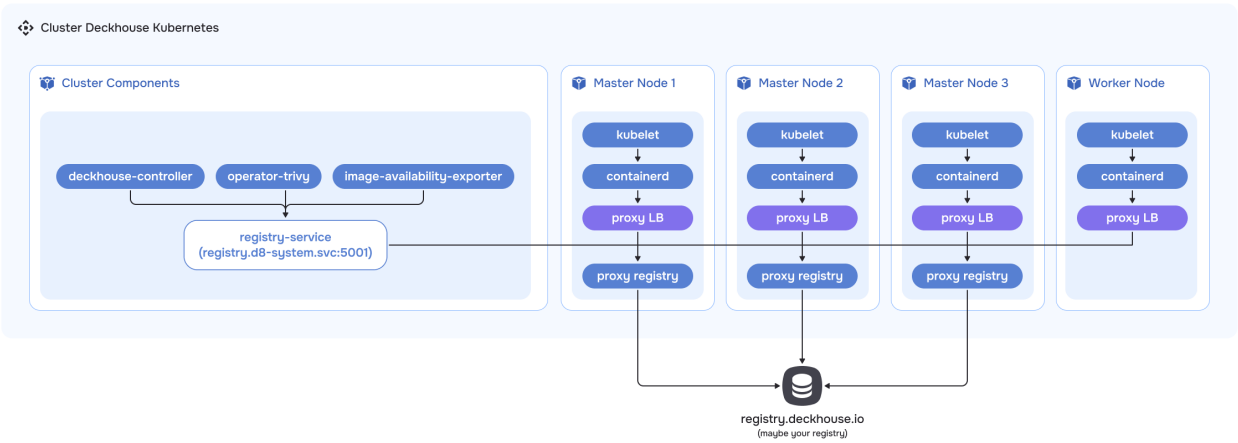
Direct Mode Architecture

In Direct mode, registry requests are processed directly, without intermediate caching.

CRI requests to the registry are redirected based on its configuration, which is defined in the `containerd` configuration.

For components such as `operator-trivy`, `image-availability-exporter`, `deckhouse-controller`, and others that access the registry directly, requests will go through the in-cluster proxy located on the master nodes.

Proxy Mode Architecture



> ⚠ It is recommended to use separate disks for storing registry (`/opt/deckhouse/registry`) and etcd data. Using a single disk may lead to etcd performance degradation during registry operations.

The `Proxy` mode allows the registry to act as an intermediate proxy server between the client and the remote registry.

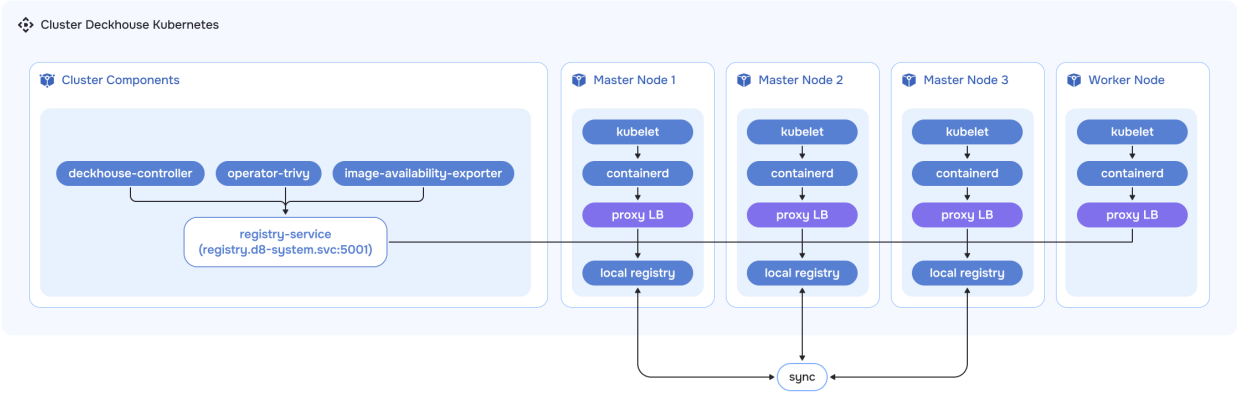
The caching proxy registry is launched as static pods on control-plane (master) nodes. Cached data is stored on the control-plane (master) nodes in the `/opt/deckhouse/registry` directory.

To ensure high availability of the caching proxy registry, a load balancer is deployed on each cluster node. Access to the proxy registry from CRI goes through this load balancer. The configuration for accessing the load balancer is set in the `containerd` configuration.

For components such as `operator-trivy`, `image-availability-exporter`, `deckhouse-controller`, and others that access the registry directly, requests will go through the caching proxy registry.

Local Mode Architecture

⚠ It is recommended to use separate disks for storing registry (`/opt/deckhouse/registry`) and etcd data. Using a single disk may lead to etcd performance degradation during registry operations.



The `Local` mode allows creating a local copy of the registry inside the cluster. Images from the remote registry are fully copied to local storage and synchronized between replicas of the local registry.

The operation of the local registry is identical to that of the caching proxy registry. The local registry is launched as static pods on control-plane (master) nodes. Registry data is stored on the control-plane (master) nodes in the `/opt/deckhouse/registry` directory.

To ensure high availability of the local registry, a load balancer is deployed on each cluster node. Access to the local registry from CRI goes through this load balancer. The configuration for accessing the load balancer is set in the `containerd` configuration.

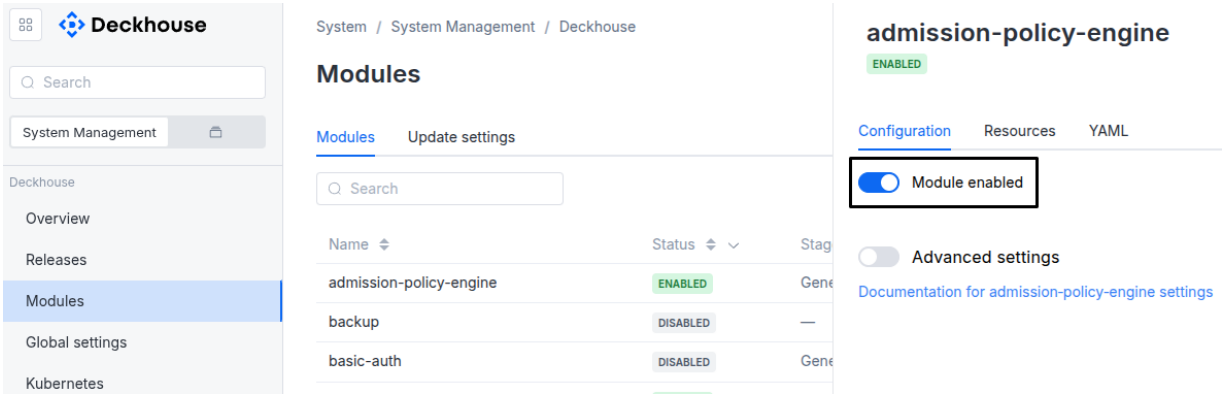
For components such as `operator-trivy`, `image-availability-exporter`, `deckhouse-controller`, and others that access the registry directly, requests will go to the local registry.

The local registry is populated using the `d8` tool with the `d8 mirror push/pull` commands. For more details, see the «Registry Module: Usage Examples» section.

Module registry: configuration

⚠ The module lifecycle stage: Preview

⚠ To configure connection parameters to the container registry and manage the container registry operating mode, use the `registry` section of the `deckhouse` module configuration.



The parameters of the `registry` module itself are specified in ModuleConfig `registry`.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

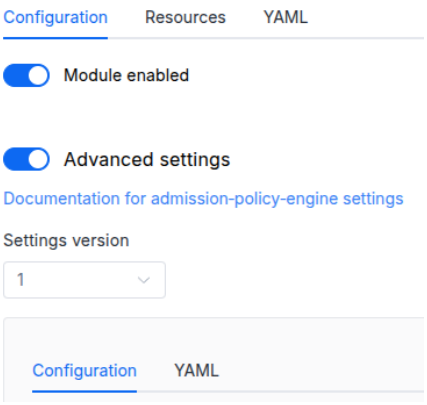
```
d8 system module enable registry
```

- **Using ModuleConfig `registry`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `registry` (create it if necessary);

  Example of a manifest to enable module `registry`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `registry` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `registry`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `registry` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc registry
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `registry` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `registry`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: registry
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.https**
    object

    What certificate type to use.

    This parameter completely overrides the `global.modules.https` settings.

    Examples:

    ```
    https:
      mode: Disabled
    ```

    ```
    https:
      mode: OnlyInURI
    ```

```
https:
  mode: CustomCertificate
  customCertificate:
    secretName: foobar
```

```
https:
  mode: CertManager
  certManager:
    clusterIssuerName: letsencrypt
```

- **settings.https.certManager**
  object

  Parameters for certmanager.

  - **settings.https.certManager.clusterIssuerName**
    string

    What ClusterIssuer to use for getting an SSL certificate (currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available; also, you can define your own).

    Default: `letsencrypt`

    Example:

    ```
    clusterIssuerName: letsencrypt
    ```

- **settings.https.customCertificate**
  object

  Parameters for custom certificate usage.

  - **settings.https.customCertificate.secretName**
    string

    The name of the secret in the `d8-system` namespace to use with the registry ingress.

    This secret must have the kubernetes.io/tls format.

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager`: The registry ingress is accessed over HTTPS using a certificate obtained from a clusterIssuer specified in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate`: The registry ingress is accessed over HTTPS using a certificate from the `d8-system` namespace.
  - `Disabled`: In this mode, the registry ingress can only be accessed over HTTP.
  - `OnlyInURI`: The registry ingress will work over HTTP (thinking that there is an external HTTPS load balancer in front of it that terminates HTTPS traffic). Load balancer should provide a redirect from HTTP to HTTPS.

  Default: `CertManager`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for the registry.

  Optional. By default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.whitelistSourceRanges**
  array of strings

  A list of CIDR-formatted addresses allowed to connect to the registry. If not specified, connections from any address are allowed.

  Example:

  ```
  whitelistSourceRanges:
  - 10.0.0.0/10
  - 192.168.0.0/16
  ```

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))?$`

FAQ

⚠ The module lifecycle stage: Preview

How to Migrate to the registry module?

During the migration, Containerd v1 will switch to the new registry configuration format. Containerd v2 uses the new format by default. For more details, see the section with a description of configuration methods.

For containerd v2

1. Switch to using the `registry` module. To do this, specify the `Unmanaged` mode parameters in the `deckhouse` `moduleConfig`. If you are using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for proper configuration.

   You can view the current registry settings using the following command:

```
d8 k -n d8-system exec -it svc/deckhouse-leader -c deckhouse -- deckhouse-controller global values | yq e '.modulesImages.registry' -
```

Specify this configuration when setting up the `Unmanaged` mode:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Unmanaged
      unmanaged:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY> # Replace with your license key
```

2. Wait for the switch to complete. Example status output:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

For Containerd v1

- During the switch, containerd v1 will be restarted.
- During the switch, containerd v1 will be migrated to the new registry configuration scheme.
- During the switch, custom registry configurations for containerd v1 will be temporarily unavailable.

1. Make sure that nodes with containerd v1 do not have any custom registry configurations located in the `/etc/containerd/conf.d` directory.
2. If configurations are present, you need to migrate to the new registry configuration format in containerd. To do this, add new configuration files to the `/etc/containerd/registry.d` directory. These configurations will take effect after switching to the `registry` module. To add configurations, prepare a `NodeGroupConfiguration`. For more details, see the section with a description of configuration methods. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # The step can be arbitrary, as restarting the containerd service is not required
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p "/etc/containerd/registry.d/${REGISTRY_URL}"
    bb-sync-file "/etc/containerd/registry.d/${REGISTRY_URL}/hosts.toml" - << EOF
    [host]
      [host."https://${REGISTRY_URL}"]
        capabilities = ["pull", "resolve"]
        [host."https://${REGISTRY_URL}".auth]
          username = "username"
          password = "password"
    EOF
```

3. Apply the NodeGroupConfiguration. Wait until the configuration files appear in the `/etc/containerd/registry.d` directory on all nodes.
4. Verify that the configurations are working correctly. To do this, use the following command:

```
# For HTTPS:
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/ private.registry.example/registry/path:tag

# For HTTP:
ctr -n k8s.io images pull --hosts-dir=/etc/containerd/registry.d/ --plain-http private.registry.example/registry/path:tag
```

5. Switch to using the `registry` module. To do this, specify the `Unmanaged` mode parameters in the `deckhouse` `moduleConfig`. If you are using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for proper configuration.

   You can view the current registry settings using the following command:

```
d8 k -n d8-system exec -it svc/deckhouse-leader -c deckhouse -- deckhouse-controller global values | yq e '.modulesImages.registry' -
```

   Specify this configuration when setting up the `Unmanaged` mode:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Unmanaged
      unmanaged:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY> # Replace with your license key
```

6. After applying, wait for the following message to appear in the switch status:

   Example output:

```
conditions:
# ...
- lastTransitionTime: "2025-08-13T15:22:34Z"
  message: |
    Check current nodes configuration
    2/2 node(s) Unready:
    - master-0: has custom toml merge containerd configuration
    - worker-5e389be0-578df-s5sm5: has custom toml merge containerd configuration
  reason: Processing
  status: "False"
  type: ContainerdConfigPreflightReady
```

   This message means that there are old registry configurations on the nodes located in the `/etc/containerd/conf.d` directory. The switch to the new containerd configuration is currently blocked. To allow the switch, you need to remove the old configuration files.

7. Remove the old configuration files to allow switching to the `registry` module. To do this, create a NodeGroupConfiguration. Example of a NodeGroupConfiguration manifest:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth-delete.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step
  weight: 0
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    file="/etc/containerd/conf.d/old-config.toml"

    [ -f "$file" ] && rm -f "$file"
```

8. After removing the old configurations, make sure that the switch has resumed. Example of the switch status:

```
conditions:
# ...
- lastTransitionTime: "2025-08-13T16:42:09Z"
  message: ""
  reason: ""
  status: "True"
  type: ContainerdConfigPreflightReady
```

9. Wait for the switch to complete. Example of the switch status:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

10. Delete the NodeGroupConfiguration created in the step for deleting old configuration files:

```
d8 k delete nodegroupconfiguration containerd-additional-config-auth-delete.sh
```

To verify that NodeGroupConfiguration has been deleted, use the command:

```
d8 k get nodegroupconfiguration
```

The list should not contain the NodeGroupConfiguration to be deleted (for this example, `containerd-additional-config-auth-delete.sh`).

How to Migrate Back from the Registry Module?

- This is a deprecated registry management format.
- During the switch, containerd v1 will be restarted.
- During the switch, containerd v1 will be migrated to the legacy registry configuration scheme.
- During the switch, custom registry configurations for containerd v1 will be temporarily unavailable.

1. Switch the registry to `Unmanaged` mode. If you are using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for proper configuration.

   Example configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Unmanaged
      unmanaged:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY>
```

2. Check the switch status using the instruction. Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: ""
  reason: ""
  status: "True"
  type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

3. Switch the registry to the non-configurable `Unmanaged` mode. Example configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Unmanaged
```

4. Check the switch status using the instruction. Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: ""
  reason: ""
  status: "True"
  type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

5. If containerd v1 is used and custom registry configurations are applied in the cluster, they must be replaced with the old format. To do this, prepare the registry configurations in the old format. These configurations do not need to be applied at this stage. Example configuration:

```
apiVersion: deckhouse.io/v1alpha1
kind: NodeGroupConfiguration
metadata:
  name: containerd-additional-config-auth.sh
spec:
  # To add a file before the '032_configure_containerd.sh' step
  weight: 31
  bundles:
    - '*'
  nodeGroups:
    - "*"
  content: |
    # Copyright 2023 Flant JSC
    #
    # Licensed under the Apache License, Version 2.0 (the "License");
    # you may not use this file except in compliance with the License.
    # You may obtain a copy of the License at
    #
    #     http://www.apache.org/licenses/LICENSE-2.0
    #
    # Unless required by applicable law or agreed to in writing, software
    # distributed under the License is distributed on an "AS IS" BASIS,
    # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    # See the License for the specific language governing permissions and
    # limitations under the License.

    REGISTRY_URL=private.registry.example

    mkdir -p /etc/containerd/conf.d
    bb-sync-file /etc/containerd/conf.d/additional_registry.toml - << EOF
    [plugins]
      [plugins."io.containerd.grpc.v1.cri"]
        [plugins."io.containerd.grpc.v1.cri".registry]
          [plugins."io.containerd.grpc.v1.cri".registry.mirrors]
            [plugins."io.containerd.grpc.v1.cri".registry.mirrors."${REGISTRY_URL}"]
              endpoint = ["https://${REGISTRY_URL}"]
          [plugins."io.containerd.grpc.v1.cri".registry.configs]
            [plugins."io.containerd.grpc.v1.cri".registry.configs."${REGISTRY_URL}".auth]
              username = "username"
              password = "password"
              # OR
              auth = "dXNlcm5hbWU6cGFzc3dvcmQ="
    EOF
```

6. Delete the `registry-bashible-config` secret. This will trigger containerd v1 to switch back to the legacy registry format:

```
d8 k -n d8-system delete secret registry-bashible-config
```

7. After deletion, wait for the switch to complete. Use the instruction to track the progress. Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: ""
  reason: ""
  status: "True"
  type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

8. If containerd v1 is used, apply the previously prepared `NodeGroupConfiguration` with custom registry configurations.
9. Disable the `registry` module. Example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry
spec:
  enabled: false
  settings: {}
  version: 1
```

How to check the registry mode switch status?

The status of the registry mode switch can be retrieved using the following command:

```
d8 k -n d8-system -o yaml get secret registry-state | yq -C -P '.data | del .state | map_values(@base64d) | .conditions =
(.conditions | from_yaml)'
```

Example output:

```
conditions:
  - lastTransitionTime: "2025-07-15T12:52:46Z"
    message: 'registry.deckhouse.io: all 157 items are checked'
    reason: Ready
    status: "True"
    type: RegistryContainsRequiredImages
  - lastTransitionTime: "2025-07-11T11:59:03Z"
    message: ""
    reason: ""
    status: "True"
    type: ContainerdConfigPreflightReady
  - lastTransitionTime: "2025-07-15T12:47:47Z"
    message: ""
    reason: ""
    status: "True"
    type: TransitionContainerdConfigReady
  - lastTransitionTime: "2025-07-15T12:52:48Z"
    message: ""
    reason: ""
    status: "True"
    type: InClusterProxyReady
  - lastTransitionTime: "2025-07-15T12:54:53Z"
    message: ""
    reason: ""
    status: "True"
    type: DeckhouseRegistrySwitchReady
  - lastTransitionTime: "2025-07-15T12:55:48Z"
    message: ""
    reason: ""
    status: "True"
    type: FinalContainerdConfigReady
  - lastTransitionTime: "2025-07-15T12:55:48Z"
    message: ""
    reason: ""
    status: "True"
    type: Ready
mode: Direct
target_mode: Direct
```

The output displays the status of the switch process. Each condition can have a status of `True` or `False`, and may contain a `message` field with additional details.

Description of conditions:

Condition	Description
`ContainerdConfigPreflightReady`	State of the containerd configuration preflight check. Verifies there are no custom containerd auth configurations on the nodes.
`TransitionContainerdConfigReady`	State of preparing the containerd configuration for the new mode. Verifies that the configuration contains both the old and new mode settings.

Condition	Description
`FinalContainerdConfigReady`	State of finalizing the switch to the new containerd mode. Verifies that the containerd configuration has been successfully applied and contains only the new mode settings.
`DeckhouseRegistrySwitchReady`	State of switching Deckhouse and its components to use the new registry. `True` means Deckhouse successfully switched and is ready to operate.
`InClusterProxyReady`	State of In-Cluster Proxy readiness. Checks that the In-Cluster Proxy has started successfully and is running.
`CleanupInClusterProxy`	State of cleaning up the In-Cluster Proxy if it is not needed in the selected mode. Verifies that all related resources have been removed.
`NodeServicesReady`	State of Node Services Manager and Static-Pod registry readiness. Verifies that the Node Services Manager is successfully launched and operational, and that the Static-Pod registry has been successfully deployed by it.
`CleanupNodeServices`	State of cleaning up the Node Services Manager and Static-Pod registry if they are not needed in the selected mode. Verifies that all related resources have been removed.
`RegistryContainsRequiredImages`	State of checking the registry for the presence of required images.
`Ready`	Overall state of registry readiness in the selected mode. Indicates that all other conditions are met and the `module` is ready to operate.

Module registry: usage example

⚠ The module lifecycle stage: Preview

⚠ If, during the switching process, the image of a module did not reload and the module did not reinstall, use the instructions to resolve the issue.

Switching to the `Direct` Mode

To switch an already running cluster to `Direct` mode, follow these steps:

✖ The first switch from `Unmanaged` to `Direct` mode will result in a full restart of all DKP components.

1. Before switching, perform the migration to use the `registry` module.
2. Make sure the `registry` module is enabled and running. To do this, execute the following command:

   ```
   d8 k get module registry -o wide
   ```

   Example output:

   ```
   NAME       WEIGHT ...  PHASE   ENABLED   DISABLED MESSAGE   READY
   registry   38     ...  Ready   True                         True
   ```

3. Make sure all master nodes are in the `Ready` state and do not have the `SchedulingDisabled` status, using the following command:

   ```
   d8 k get nodes
   ```

   Example output:

   ```
   NAME       STATUS   ROLES                ...
   master-0   Ready    control-plane,master  ...
   master-1   Ready    control-plane,master  ...
   master-2   Ready    control-plane,master  ...
   ```

   Example of output when the master node (`master-2` in the example) is in the `SchedulingDisabled` status:

   ```
   NAME       STATUS                     ROLES                ...
   master-0   Ready    control-plane,master  ...
   master-1   Ready    control-plane,master  ...
   master-2   Ready,SchedulingDisabled    control-plane,master  ...
   ```

4. Ensure the Deckhouse job queue is empty and contains no errors:

   ```
   d8 system queue list
   ```

   Example output:

   ```
   Summary:
   - 'main' queue: empty.
   - 107 other queues (0 active, 107 empty): 0 tasks.
   - no tasks to handle.
   ```

5. Set the `Direct` mode configuration in the ModuleConfig `deckhouse`. If you're using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for correct configuration.

Configuration example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Direct
      direct:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY> # Replace with your license key
```

6. Check the registry switch status in the `registry-state` secret using this guide.

   Example output:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Direct
target_mode: Direct
```

Switching to the `Proxy` Mode

To switch an already running cluster to `Proxy` mode, follow these steps:

- The first switch from `Unmanaged` to `Proxy` mode will result in a full restart of all DKP components.
- Switching from `Local` mode to `Proxy` mode is not available. To switch from `Local` mode, you must switch the registry to another available mode (for example: `Direct`).

1. Before switching, perform the migration to use the `registry` module.
2. Make sure the `registry` module is enabled and running. To do this, execute the following command:

```
d8 k get module registry -o wide
```

   Example output:

```
NAME       WEIGHT ...  PHASE   ENABLED   DISABLED MESSAGE   READY
registry   38     ...  Ready   True                         True
```

3. Make sure all master nodes are in the `Ready` state and do not have the `SchedulingDisabled` status, using the following command:

```
d8 k get nodes
```

   Example output:

```
NAME       STATUS   ROLES                ...
master-0   Ready    control-plane,master  ...
master-1   Ready    control-plane,master  ...
master-2   Ready    control-plane,master  ...
```

   Example of output when the master node (`master-2` in the example) is in the `SchedulingDisabled` status:

```
NAME       STATUS                     ROLES                ...
master-0   Ready    control-plane,master  ...
master-1   Ready    control-plane,master  ...
master-2   Ready,SchedulingDisabled    control-plane,master  ...
```

4. Ensure the Deckhouse job queue is empty and contains no errors:

```
d8 system queue list
```

   Example output:

```
Summary:
- 'main' queue: empty.
- 107 other queues (0 active, 107 empty): 0 tasks.
- no tasks to handle.
```

5. Set the `Proxy` mode configuration in the ModuleConfig `deckhouse`. If you're using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for correct configuration.

   Configuration example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Proxy
      proxy:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY> # Replace with your license key
```

6. Check the registry switch status in the `registry-state` secret using this guide.

   Example output:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Proxy
target_mode: Proxy
```

Switching to the `Local` Mode

To switch an already running cluster to `Local` mode, follow these steps:

- The first switch from `Unmanaged` to `Local` mode will result in a full restart of all DKP components.
- Switching from `Proxy` mode to `Local` mode is not available. To switch from `Proxy` mode, you must switch the registry to another available mode (for example: `Direct`).

1. Before switching, perform the migration to use the `registry` module.
2. Make sure the `registry` module is enabled and running. To do this, execute the following command:

```
d8 k get module registry -o wide
```

   Example output:

```
NAME       WEIGHT ...  PHASE   ENABLED   DISABLED MESSAGE   READY
registry   38     ...  Ready   True                         True
```

3. Make sure all master nodes are in the `Ready` state and do not have the `SchedulingDisabled` status, using the following command:

```
d8 k get nodes
```

   Example output:

```
NAME       STATUS   ROLES                ...
master-0   Ready    control-plane,master  ...
master-1   Ready    control-plane,master  ...
master-2   Ready    control-plane,master  ...
```

   Example of output when the master node (`master-2` in the example) is in the `SchedulingDisabled` status:

```
NAME       STATUS                     ROLES                ...
master-0   Ready    control-plane,master  ...
master-1   Ready    control-plane,master  ...
master-2   Ready,SchedulingDisabled    control-plane,master  ...
```

4. Ensure the Deckhouse job queue is empty and contains no errors:

```
d8 system queue list
```

   Example output:

```
Summary:
- 'main' queue: empty.
- 107 other queues (0 active, 107 empty): 0 tasks.
- no tasks to handle.
```

5. Prepare archives with DKP images of the current version. To do this, use the `d8 mirror` command.

   Example:

```
TAG=$(
 d8 k -n d8-system get deployment/deckhouse -o yaml \
 | yq -r '.spec.template.spec.containers[] | select(.name == "deckhouse").image | split(":")[-1]'
) && echo "TAG: $TAG"

EDITION=$(
 d8 k -n d8-system exec -it svc/deckhouse-leader -- deckhouse-controller global values -o yaml \
 | yq .deckhouseEdition
) && echo "EDITION: $EDITION"
```

```
d8 mirror pull \
--license="<LICENSE_KEY>" \
--source="registry.deckhouse.io/deckhouse/$EDITION" \
--deckhouse-tag="$TAG" \
/home/user/d8-bundle
```

6. Set the `Local` mode configuration in the ModuleConfig `deckhouse`.

   Configuration example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Local
```

7. Check the registry switch status in the `registry-state` secret using this guide. In the status, you need to wait for the `RegistryContainsRequiredImages` check to start. The condition will show the absence or presence of images in the running local registry.

   Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: |-
    Mode: Default
    master-1: 0 of 166 items processed, 166 items with errors:
    - source: module/control-plane-manager/control-plane-manager133
      image:
10.128.0.5:5001/system/deckhouse@sha256:00202db19b40930f764edab5695f450cf709d50736e012055393447b3379414a
      error: HEAD
https://10.128.0.5:5001/v2/system/deckhouse/manifests/sha256:00202db19b40930f764edab5695f450cf709d50736e012055393
447b3379414a: unexpected status code 404 Not Found (HEAD responses have no body, use GET for details)
    - source: module/cloud-provider-yandex/cloud-metrics-exporter
      image:
10.128.0.5:5001/system/deckhouse@sha256:05517a86fcf0ec4a62d14ed7dc4f9ffd91c05716b8b0e28263da59edf11f0fad
      error: HEAD
https://10.128.0.5:5001/v2/system/deckhouse/manifests/sha256:05517a86fcf0ec4a62d14ed7dc4f9ffd91c05716b8b0ed86d6a1
f465f4556fb8: unexpected status code 404 Not Found (HEAD responses have no body, use GET for details)
    - source: module/control-plane-manager/kube-controller-manager132
      image:
10.128.0.5:5001/system/deckhouse@sha256:13f24cc717698682267ed2b428e7399b145a4d8ffe96ad1b7a0b3269b17c7e61
      error: HEAD
https://10.128.0.5:5001/v2/system/deckhouse/manifests/sha256:13f24cc717698682267ed2b428e7399b145a4d8ffe96ad1b7a0b
3269b17c7e61: unexpected status code 404 Not Found (HEAD responses have no body, use GET for details)

      ...and more
  reason: Processing
  status: "False"
  type: RegistryContainsRequiredImages
```

8. Upload the images to the local registry using the `d8 mirror` command. Image upload to the local registry is performed via Ingress at `registry.${PUBLIC_DOMAIN}`.

   Get the password for the read-write user of the local registry:

```
$ d8 k -n d8-system get secret/registry-user-rw -o json | jq -r '.data | to_entries[] | "\(.key): \(.value | @base64d)"'
name: rw
password: KFVxXZGuqKkkumPz
passwordHash: $2a$10$Phjbr6iinLf00ZZDD2Y7O.p9H3nDOgYzFmpYKW5eydGvIsdaHQY0a
```

   Upload images to the local registry:

```
d8 mirror push \
--registry-login="rw" \
--registry-password="KFVxXZGuqKkkumPz" \
/home/user/d8-bundle \
registry.${PUBLIC_DOMAIN}/system/deckhouse
```

9. Check the registry switch status in the `registry-state` secret using this guide. After uploading the images, the `RegistryContainsRequiredImages` status should be in the `Ready` state.

Example output:

```
conditions:
# ...
- lastTransitionTime: "..."
  message: |-
    Mode: Default
    master-1: all 166 items are checked
  reason: Ready
  status: "True"
  type: RegistryContainsRequiredImages
hash: ..
mode: Direct
target_mode: Local
```

10. Wait for the switch to complete. To check the switch status, use this guide.

    Example output:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Local
target_mode: Local
```

Switching to the `Unmanaged` Mode

To switch an already running cluster to `Unmanaged` mode, follow these steps:

✖ Changing the registry in `Unmanaged` mode will result in a full restart of all DKP components.

1. Before switching, perform the migration to use the `registry` module.
2. Make sure the `registry` module is enabled and running. To do this, execute the following command:

```
d8 k get module registry -o wide
```

   Example output:

```
NAME       WEIGHT ...  PHASE   ENABLED   DISABLED MESSAGE   READY
registry   38     ...  Ready   True                         True
```

3. Ensure the Deckhouse job queue is empty and contains no errors:

```
d8 system queue list
```

   Example output:

```
Summary:
- 'main' queue: empty.
- 107 other queues (0 active, 107 empty): 0 tasks.
- no tasks to handle.
```

4. Set the `Unmanaged` mode configuration in the ModuleConfig `deckhouse`. If you're using a registry other than `registry.deckhouse.io`, refer to the `deckhouse` module documentation for correct configuration.

   Configuration example:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: deckhouse
spec:
  version: 1
  enabled: true
  settings:
    registry:
      mode: Unmanaged
      unmanaged:
        imagesRepo: registry.deckhouse.io/deckhouse/ee
        scheme: HTTPS
        license: <LICENSE_KEY> # Replace with your license key
```

5. Check the registry switch status in the `registry-state` secret using this guide.

   Example output:

```
conditions:
# ...
  - lastTransitionTime: "..."
    message: ""
    reason: ""
    status: "True"
    type: Ready
hash: ..
mode: Unmanaged
target_mode: Unmanaged
```

6. If you need to switch back to the old registry management method, refer to the instruction.

⚠ This is a deprecated format for registry management.

The registry-packages-proxy module

i The module lifecycle stage: General Availability

The `registry-packages-proxy` module provides an in-cluster HTTP proxy service for accessing packages from container registries. It acts as an intermediary between cluster components and external or internal registries, offering caching capabilities to optimize bandwidth usage and improve package retrieval performance.

This module is a critical infrastructure component that runs on master nodes and is used during cluster bootstrap and runtime operations to fetch packages from container registries.

The module deploys a highly-available proxy service that:

- Runs as a deployment on master nodes with `hostNetwork` enabled to ensure availability during bootstrap when CNI is not yet available.
- Listens on port `4219` (HTTPS) on each master node's IP address.
- Provides a `/package` endpoint for retrieving registry packages by digest.
- Implements local caching of retrieved packages (up to 1 GB) to reduce network traffic and improve performance.
- Watches ModuleSource custom resources to obtain registry credentials for different repositories.
- Uses `kube-rbac-proxy` to secure access to the proxy and metrics endpoints.
- Exposes a public HTTPS API (via Ingress) for Deckhouse CLI binaries.
- Exposes an in-cluster HTTPS API for package icons (no public Ingress).

Architecture

The proxy service consists of two containers:

1. **registry-packages-proxy**: The main proxy application that:
   - Fetches packages from remote registries using digests.
   - Caches packages locally in an ephemeral volume (1 GB max).
   - Supports authentication to registries via credentials from ModuleSource resources.
   - Provides health checks and Prometheus metrics.
   - Listens on `127.0.0.1:5080` (HTTP, internal).
2. **kube-rbac-proxy**: Provides RBAC-based access control:
   - Exposes the service on port `4219` (HTTPS).
   - Secures `/metrics` endpoint with Kubernetes RBAC authorization.
   - Secures `/package` endpoint requiring appropriate permissions.
   - Secures `/v1/images/*` (Deckhouse CLI downloads) with Kubernetes RBAC authorization.
   - Allows unauthenticated access to `/healthz`.

HTTP API

After the cluster is bootstrapped and the DNS name template is configured in the publicDomainTemplate parameter, the module creates an Ingress for `registry-packages-proxy` using that template (for example, `registry-packages-proxy.company.my` for `publicDomainTemplate: "%s.company.my"`).

The endpoints listed below are reachable in two ways:

- **Public** (via the Ingress on the `registry-packages-proxy` public host): only `/v1/images/*`.
- **In-cluster only** (via the `registry-packages-proxy.d8-cloud-instance-manager.svc` Service on port `443`, or `:4219` on each master node for bootstrap): all routes, including `/v1/packages/*`.

Package icons (`/v1/packages/`) — in-cluster only

Package icons are served **without authentication** (`kube-rbac-proxy` excludes these paths from RBAC) but are **only reachable from inside the cluster**. They are intentionally **not** routed through the public Ingress, so the public domain `registry-packages-proxy.<publicDomain>` will not serve them.

Method	Path	Description
`GET`, `HEAD`	`/v1/packages/<PACKAGE-REPOSITORY>/<PACKAGE-NAME>/metadata/icon/`	Icon of the latest semver tag
`GET`, `HEAD`	`/v1/packages/<PACKAGE-REPOSITORY>/<PACKAGE-NAME>/metadata/icon`	Same as above
`GET`, `HEAD`	`/v1/packages/<PACKAGE-REPOSITORY>/<PACKAGE-NAME>/metadata/icon/<VERSION>`	Icon of a specific version (`<VERSION>` is a semantic version, e.g. `v1.0.1`)

`<PACKAGE-REPOSITORY>` is the `metadata.name` of a PackageRepository custom resource; its `spec.registry.repo` field tells the proxy which registry path to pull the icon from. The proxy reads the icon from the OCI image `<spec.registry.repo>/<PACKAGE-NAME>:<TAG>`.

The proxy looks for the following files inside the package image, in this priority order, and returns the first one it finds:

Path	Content-Type
`docs/icon.svg`	`image/svg+xml`
`docs/icon.png`	`image/png`
`docs/icon.jpg`	`image/jpeg`
`docs/icon.jpeg`	`image/jpeg`

If none of these are present (or the file is larger than 4 MiB), the proxy returns `404 Not Found`; callers should fall back to a default icon. SVG is preferred because it is resolution-independent.

Example request from a pod in the cluster:

```
curl -fsSk "https://registry-packages-proxy.d8-cloud-instance-manager.svc/v1/packages/my-repo/my-module/metadata/icon/"
```

Example response headers (when the image ships `docs/icon.svg`):

```
Content-Type: image/svg+xml
Content-Disposition: attachment; filename="<PACKAGE-NAME>.svg"
```

Deckhouse CLI downloads (`/v1/images/`) — public

These endpoints are reachable through the public Ingress (`registry-packages-proxy.<publicDomain>`) and require a valid Kubernetes token (or client certificate accepted by `kube-rbac-proxy`) and RBAC permission to `get` the `deployments/cli-binary` subresource `registry-packages-proxy` in namespace `d8-cloud-instance-manager`.

Grant access with the ClusterRole `d8:registry-packages-proxy:cli-download` (bind it to users or ServiceAccounts via ClusterRoleBinding or RoleBinding).

Method	Path	Description
`GET`	`/v1/images/<IMAGE>/tags`	JSON list of tags
`GET`, `HEAD`	`/v1/images/<IMAGE>/tags/<TAG>`	OCI image as `application/x-gzip` (flattened layers)

Allowed `<IMAGE>` values:

- `deckhouse-cli`
- `deckhouse-cli/plugins/<PLUGIN>` (single path segment for `<PLUGIN>`)

Example:

```
curl -fsS -H "Authorization: Bearer ${TOKEN}" \
  "https://registry-packages-proxy.example.com/v1/images/deckhouse-cli/tags"
```

Internal `/package` endpoint

The legacy `/package?digest=...` endpoint (used during bootstrap and by internal components) remains protected by RBAC (`deployments/http` subresource). It is not exposed through the public Ingress.

Package retrieval flow

When a component requests a package:

1. The request includes a `digest` parameter (required) and optional `repository` and `path` parameters.
2. The proxy checks its local cache for the requested digest.
3. If cached, the package is served directly from cache.
4. If not cached:
   - The proxy fetches credentials for the specified registry from watched ModuleSource resources.
   - The package is retrieved from the remote registry.
   - The package is streamed to the client while simultaneously being cached for future requests.
5. Responses include appropriate HTTP headers for caching (`Cache-Control`, `ETag`, `Content-Length`).

High availability

The module ensures high availability through:

- Running multiple replicas on master nodes (in HA configurations).
- Pod anti-affinity rules to distribute pods across different masters.
- PodDisruptionBudget to prevent simultaneous disruption of all replicas.
- Vertical Pod Autoscaler support for automatic resource adjustments.

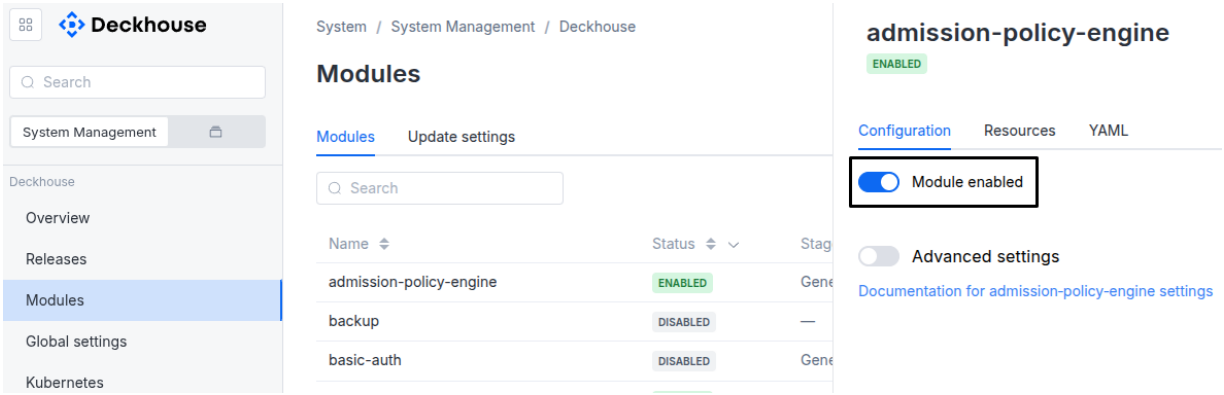
RBAC roles provided by the module

ClusterRole	Purpose
`d8:registry-packages-proxy:cli-download`	Access to `/v1/images/*`
`d8:registry-packages-proxy:packages-download`	Reserved for future authenticated `/v1/packages/*` routes (icons are served anonymously, in-cluster only)

Limitations

- The module runs exclusively on master nodes.
- It requires `hostNetwork: true` to function during bootstrap phase.
- Cache size is limited to 1 GB per pod.
- Most HTTP endpoints require Kubernetes RBAC; only health checks (healthz) and package icons are anonymous. Package icons are additionally limited to in-cluster access (no public Ingress route).
- Package icons are read from fixed paths inside the package image (`docs/icon.svg`, `docs/icon.png`, `docs/icon.jpg`, `docs/icon.jpeg`) with SVG preferred. Maximum icon size is 4 MiB.

The registry-packages-proxy: configuration



> The module lifecycle stage: General Availability

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry-packages-proxy` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

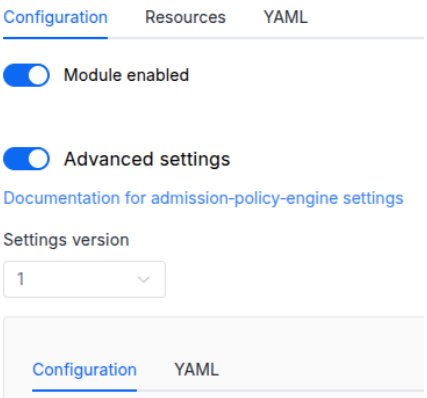
```
d8 system module enable registry-packages-proxy
```

- **Using ModuleConfig `registry-packages-proxy`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `registry-packages-proxy` (create it if necessary);

  Example of a manifest to enable module `registry-packages-proxy`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry-packages-proxy
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `registry-packages-proxy` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `registry-packages-proxy` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `registry-packages-proxy`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `registry-packages-proxy` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

```
d8 k edit mc registry-packages-proxy
```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

You can also create a file with manifest for ModuleConfig `registry-packages-proxy` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

Apply the manifest using the following command (indicate the manifest file name):

```
d8 k apply -f <FILENAME>
```

Example of a manifest for ModuleConfig `registry-packages-proxy`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: registry-packages-proxy
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

The module does not have any settings.

The secret-copier module

> **i** The module lifecycle stage: General Availability

This module copies Secrets to all namespaces.

It facilitates the copying of Secrets required to pull images and to provision Ceph's RBDs as part of the CI process.

> **⚠** The `secret-copier` module cannot be used together with `multitenancy-manager`.
>
> `multitenancy-manager` creates isolated environments for users within their projects, while `secret-copier` automatically distributes secrets across all namespaces. This may lead to sensitive data leaks if important secrets end up in a user's isolated environment, violating the security model.
>
> If you need to provide a shared certificate (e.g., a WC certificate for an internal environment) or a shared registry access token, do not use `secret-copier`. Instead, place such secrets in the project template in `multitenancy-manager` — the cluster administrator should define them in the project configuration.

How does it work?

This module monitors the Secrets (with the `secret-copier.deckhouse.io/enabled: ""` label) in the `default` namespace for changes.

- The module copies such a Secret to all namespaces after it is created.
- When a Secret is changed, its new contents are also propagated to all namespaces.
- When a Secret is deleted, its copies are deleted from all namespaces.
- The module restores the original content of a copy of a Secret in the application namespace if it gets modified.
- The module copies all the Secrets (that have the `secret-copier.deckhouse.io/enabled: ""` label) of the `default` namespace to any newly created namespace.

Additionally, it synchronizes the Secrets every night, ensuring they are identical to those in the `default` namespace.

What do I need to configure?

All you need to do is to create a Secret with the `secret-copier.deckhouse.io/enabled: ""` label in the `default` namespace.

> **i** **Note!** The working namespace for the module is `default`, Secrets will be copied only from it. Secrets with the secret-copier.deckhouse.io/enabled: "" label created in other namespaces will be automatically deleted when the module is enabled.

How to synchronize Secret to some selected namespaces instead of all namespaces?

Specify namespace label-selector in the value of the `secret-copier.deckhouse.io/target-namespace-selector` annotation. For example: `secret-copier.deckhouse.io/target-namespace-selector: "app=custom"`. The module will create a copy of that Secret in all namespaces that matches the label-selector.

The service-with-healthchecks module

> **i** The module lifecycle stage: General Availability

Limitations of the built-in Service load balancer

In Kubernetes, the `Service` resource handles the internal and external load balancing of requests. It routes requests between the application's worker pods and excludes failed instances from load balancing. The readiness probes defined in the specs of the containers running in this pod make sure that the pod can handle incoming traffic.

The built-in Service load balancer is suitable for most cloud application tasks, but it has two limitations:

- If at least one container in a pod fails the readiness probe, the entire pod is marked as `NotReady` and is excluded from load balancing.
- You can only define one probe for each container, so it is not possible to create independent probes to check, for example, whether reads and writes are available.

The following are examples of scenarios where the capabilities of the regular load balancer are inadequate:

- Database:
  - Runs like a service consisting of three pods, `db-0`, `db-1`, and `db-2`. Each pod contains one container with a running database process.
  - You would like to create two Services, `db-write` for writing and `db-read` for reading.
  - Read queries must be load balanced across all pods.
  - Write queries are only routed to the database's master pod.

- Virtual machine:
  - The pod contains a single container running the `qemu` process, which acts as a hypervisor for the guest virtual machine.
  - The guest virtual machine is running some independent processes, such as a web server and an SMTP server.
  - You would like to create two Services, `web` and `smtp`, and define a separate readiness probe for each service.

ServiceWithHealthcheck load balancer capabilities

Unlike the regular load balancer, in which readiness probes are tied to the container state, `ServiceWithHealthcheck` allows you to set up active probes on individual TCP ports. In this way, each of the load balancers dealing with the same pod can operate independently of the others.

You can configure this balancing method using the ServiceWithHealthchecks resource:

- Its specification is the same as the regular `Service` except for the `healthcheck` section, which contains a set of probes.
- Currently, three types of probes are supported:
  - `TCP` — a regular probe that establishes a TCP connection.
  - `HTTP` — a probe that sends an HTTP request and waits for a specific response code.
  - `PostgreSQL` — a probe that sends an SQL query and waits for it to complete successfully.

Examples can be found in the documentation.

How the ServiceWithHealthcheck load balancer works

The load balancer is made up of two components:

- The **controller** runs on the cluster master nodes and manages `ServiceWithHealthcheck` resources,
- The agents operate on each cluster node and carry out probing for pods that run on that node.

The ServiceWithHealthcheck load balancer is designed to be CNI implementation agnostic. It uses the built-in K8s `Service` and `EndpointSlice` resources:

- When creating a `ServiceWithHealthcheck` resource, the controller automatically creates an eponymous Service resource in the same namespace with an empty `selector` field. This prevents the default controller from creating `EndpointSlice`, which are used to configure load balancing.
- When pods subject to `ServiceWithHealthcheck` are scheduled to a particular node, the agent running on that node runs the pre-configured probes and creates an `EndpointSlice` for them with a list of IP addresses and ports to be checked. This `EndpointSlice` is bound to the `Service` child resource created above.
- CNI maps all `EndpointSlice` to the regular services created above and performs load balancing across probed IP addresses and ports on all nodes in the cluster.

Migrating from a Service to a ServiceWithHealthchecks resource, for example within the framework of CI/CD, should not cause difficulties. The ServiceWithHealthchecks specification basically repeats the Service specification, but contains an additional healthchecks section. During the lifecycle of the ServiceWithHealthchecks resource, a service of the same name is created in the same namespace in order to direct traffic to workloads in the cluster in the usual way (kube-proxy or cni).

Configuration

i The module lifecycle stage: General Availability

i For the ServiceWithHealthchecks load balancers you create to work, the following conditions must be met:

- The network policy of the custom project in which the ServiceWithHealthchecks will be created must include a rule allowing incoming traffic from all pods in the `d8-service-with-healthchecks` namespace:

  ```
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: d8-service-with-healthchecks
  ```

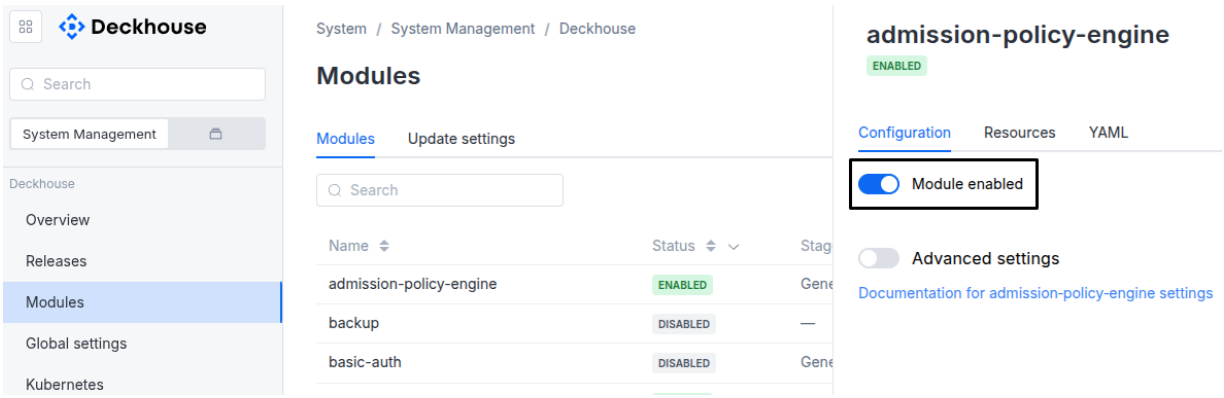
  For more information on network policies, see the Configuring Network Policies section.

- The cluster role used in ClusterRoleBinding and RoleBinding when assigning permissions to users and service accounts for the ServiceWithHealthchecks resource must be extended with the following rules:

  - `get`
  - `list`
  - `watch`
  - `create`
  - `update`
  - `patch`
  - `delete`.

  For more details, see the section Granting permissions to users and service accounts.

⚠ Enabling the module does not automatically replace existing Service resources with ServiceWithHealthcheck resources. To replace existing services with ServiceWithHealthcheck, follow these steps:



- Create ServiceWithHealthcheck resources with the same names and parameters as the existing Service resources you want to replace. When creating a ServiceWithHealthcheck, specify the required `healthchecks` parameters.
- Delete the Service resources that you want to replace with ServiceWithHealthcheck.

The module is not enabled by default in any bundles.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `service-with-healthchecks` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

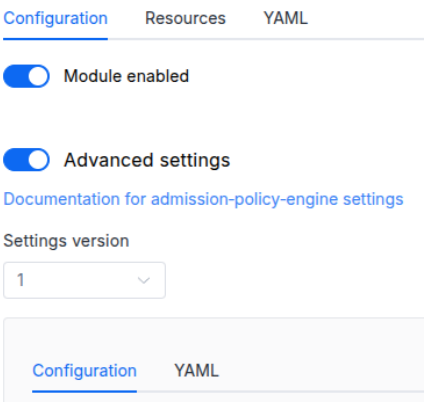
  ```
  d8 system module enable service-with-healthchecks
  ```

- **Using ModuleConfig `service-with-healthchecks`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `service-with-healthchecks` (create it if necessary);

  Example of a manifest to enable module `service-with-healthchecks`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: service-with-healthchecks
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `service-with-healthchecks` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `service-with-healthchecks` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `service-with-healthchecks`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `service-with-healthchecks` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc service-with-healthchecks
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `service-with-healthchecks` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `service-with-healthchecks`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: service-with-healthchecks
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.debug**
    boolean

    Option to instruct the logger to output stacktraces for warnings and errors.

    Default: `false`

The service-with-healthchecks: Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

ServiceWithHealthchecks

Short names: swh

Scope: Namespaced
Version: v1alpha1

ServiceWithHealthchecks is the schema for the `servicewithhealthchecks` API.

- **apiVersion**
  string
- **kind**
  string
- **metadata**
  object
- **spec**
  object

  Defines the desired state of ServiceWithHealthchecks.

  For the ServiceWithHealthchecks load balancers you create to work, the following conditions must be met:

  - The network policy of the custom project in which the ServiceWithHealthchecks will be created must include a rule allowing incoming traffic from all pods in the `d8-service-with-healthchecks` namespace:

    ```
    ingress:
    - from:
      - namespaceSelector:
          matchLabels:
            kubernetes.io/metadata.name: d8-service-with-healthchecks
    ```

    For more information on network policies, see the Configuring Network Policies section.

  - The cluster role used in ClusterRoleBinding and RoleBinding when assigning permissions to users and service accounts for the ServiceWithHealthchecks resource must be extended with the following rules:

    - `get`
    - `list`
    - `watch`
    - `create`
    - `update`
    - `patch`
    - `delete`.

    For more details, see the section Granting permissions to users and service accounts.

  - **spec.allocateLoadBalancerNodePorts**
    boolean

    Determines whether NodePort should be automatically allocated for services of LoadBalancer type. Default is `true`. It may be set to `false` if the cluster load-balancer does not rely on NodePorts.

    If the caller requests specific NodePorts (by specifying a value), those requests will be respected, regardless of this field. This parameter can be set only for services of LoadBalancer type and is automatically reset when the type is changed to another.

  - **spec.clusterIP**
    string

    The IP address of the service.

    Normally, the IP address is randomly assigned to the service. If the IP address is manually specified, it must be within the valid range (specified by the system configuration) and free for assignment; otherwise, service creation will fail.

    This field may not be changed through updates unless the type field is also being changed to `ExternalName` (which requires this field to be blank) or the type field is being changed from `ExternalName` (in which case this field may optionally be specified, as describe above).

Valid values are `None`, empty string (“”), or a valid IP address. Setting this to `None` makes a “headless service” (no virtual IP), which is useful when direct endpoint connections are preferred and proxying is not required. Only applies to types ClusterIP, NodePort, and LoadBalancer. If this field is specified when creating a Service of type ExternalName, creation will fail. This field will be wiped when updating a Service to type ExternalName. More info.

- **spec.externalIPs**
  array of strings

  A list of IP addresses where nodes in the cluster will also accept traffic for this service. These IPs are not managed by Kubernetes. The user is responsible for ensuring that traffic arrives at a node with this IP.

  A common example is external load-balancers that are not part of the Kubernetes system.

- **spec.externalName**
  string

  An external reference that discovery mechanisms will return as an alias for this service (e.g., a DNS record CNAME).

  Must be a lowercase RFC-1123 hostname and requires `type` to be “ExternalName”.

- **spec.externalTrafficPolicy**
  string

  Describes how nodes distribute service traffic they receive on one of the Service’s “externally-facing” addresses (NodePorts, ExternalIPs, and LoadBalancer IPs). If set to `Local`, the proxy will configure the service in a way that assumes that external load balancers will take care of balancing the service traffic between nodes, and so each node will deliver traffic only to the node-local endpoints of the service, without masquerading the client source IP. Traffic mistakenly sent to a node with no endpoints will be dropped.

  The default value, `Cluster`, uses the standard behavior of routing to all endpoints evenly (possibly modified by topology and other features).

  Note that traffic sent to an External IP or LoadBalancer IP from within the cluster will always get `Cluster` semantics, but clients sending to a NodePort from within the cluster may need to take traffic policy into account when picking a node.

- **spec.healthCheckNodePort**
  integer

  Specifies the healthcheck nodePort for the service. This only applies when type is set to LoadBalancer and `externalTrafficPolicy` is set to `Local`. If a value is specified, is in-range, and is not in use, it will be used.

  If not specified, a value will be automatically allocated. External systems (e.g. load-balancers) can use this port to determine if a given node holds endpoints for this service or not.

  If this field is specified when creating a Service which does not need it, creation will fail. This field will be wiped when updating a Service to no longer need it (e.g. changing type).

  This field cannot be updated once set.

- **spec.healthcheck**
  object

  Required value

  - **spec.healthcheck.initialDelaySeconds**
    integer

    Number of seconds after the container has started before liveness probes are initiated.

    Default: `10`

    Allowed values: `0 <= X <= 108000`

  - **spec.healthcheck.periodSeconds**
    integer

    How often (in seconds) to perform the probe.

    Default: `10`

    Allowed values: `1 <= X <= 108000`

  - **spec.healthcheck.probes**
    array of objects
    - **spec.healthcheck.probes.failureThreshold**
      integer

      Minimum consecutive failures for the probe to be considered failed after having succeeded.

      Default: `3`

      Allowed values: `1 <= X`

    - **spec.healthcheck.probes.http**
      object
      - **spec.healthcheck.probes.http.caCert**
        string

        CA certificate for HTTPS connection.

      - **spec.healthcheck.probes.http.host**
        string

        Hostname to connect to, defaults to the pod’s IP address.

      - **spec.healthcheck.probes.http.httpHeaders**
        array of objects

        Custom headers that will be added to the HTTP request and used when performing the probe. Duplicate headers are allowed.

        - **spec.healthcheck.probes.http.httpHeaders.name**
          string

          Required value

          The header name.

          This will be canonicalized upon output, so case-variant names will be understood as the same header.

        - **spec.healthcheck.probes.http.httpHeaders.value**
          string

          Required value

          The header value.
      - **spec.healthcheck.probes.http.insecureSkipTLSVerify**
        boolean

        Indicates if the client should skip verifying the server's TLS certificate chain and hostname.

        Default: `false`
      - **spec.healthcheck.probes.http.method**
        string

        Method to use for the request.

        Default: `GET`

        Allowed values: `GET`, `HEAD`
      - **spec.healthcheck.probes.http.path**
        string

        Path to access on the HTTP server.
      - **spec.healthcheck.probes.http.scheme**
        string

        Scheme to use for connecting to the host.

        Default: `HTTP`

        Allowed values: `HTTP`, `HTTPS`
      - **spec.healthcheck.probes.http.targetPort**
        integer

        Required value

        Number of the port to access on the container.

        Allowed values: `1 <= X <= 65535`
  - **spec.healthcheck.probes.mode**
    string

    The mode for the probe.

    Allowed values: `HTTP`, `TCP`, `PostgreSQL`
  - **spec.healthcheck.probes.postgreSQL**
    object
    - **spec.healthcheck.probes.postgreSQL.authSecretName**
      string

      The name of the secret located in the same namespace as this resource.

      The secret can contain the following authentication fields: `tlsMode`, `clientCert`, `clientKey`, `caCert`, `password`, `user`.

      > **Warining.** The type of the secret must be `network.deckhouse.io/postgresql-credentials`.
    - **spec.healthcheck.probes.postgreSQL.dbName**
      string

      Optional Database Name.
    - **spec.healthcheck.probes.postgreSQL.query**
      string

      Query to PostgreSQL for testing.

      Must return one of the values `TRUE`: `t`, `true`, `y`, `yes`, `1`. to be considered successful.

      > **Warining.** The privileges for the user under whom the requests are executed should be minimal.

      Default: `select 1`
    - **spec.healthcheck.probes.postgreSQL.targetPort**
      integer

      Required value

      Number of the port to access on the container.

      Allowed values: `1 <= X <= 65535`
  - **spec.healthcheck.probes.successThreshold**
    integer

    Minimum consecutive successes for the probe to be considered successful after having failed.

    Default: `1`

    Allowed values: `1 <= X`
  - **spec.healthcheck.probes.tcp**
    object
    - **spec.healthcheck.probes.tcp.targetPort**
      integer

      Required value

Number of the port to access on the container.

Allowed values: `1 <= X <= 65535`

- **spec.healthcheck.probes.timeoutSeconds**
  integer

  Number of seconds after which the probe times out.

  Default: `1`

  Allowed values: `1 <= X`

- **spec.internalTrafficPolicy**
  string

  Describes how nodes distribute service traffic they receive on the ClusterIP.

  If set to `Local`, the proxy will assume that pods only want to talk to endpoints of the service on the same node as the pod, dropping the traffic if there are no local endpoints.

  The default value, `Cluster`, uses the standard behavior of routing to all endpoints evenly (possibly modified by topology and other features).

- **spec.ipFamilies**
  array of strings

  A family of IP addresses (e.g., IPv4, IPv6) assigned to a service. This field is usually assigned automatically based on cluster configuration and the `ipFamilyPolicy` field.

  If this field is specified manually, the requested family is available in the cluster, and `ipFamilyPolicy` allows it, it will be used; otherwise creation of the service will fail. This field is conditionally mutable: it allows for adding or removing a secondary IP family, but it does not allow changing the primary IP family of the Service.

  Valid values are `IPv4` and `IPv6`.This field only applies to Services of types ClusterIP, NodePort, and LoadBalancer, and does apply to “headless” services.

  This field will be wiped when updating a Service to type `ExternalName`.

  This field may hold a maximum of two entries (dual-stack families, in either order). These families must correspond to the values of the `clusterIPs` field, if specified. Both `clusterIPs` and `ipFamilies` are governed by the `ipFamilyPolicy` field.

  - **Element of the array**
    string

    Represents the IP Family (IPv4 or IPv6).

    This type is used to express the family of an IP expressed by a type (e.g. service.spec.ipFamilies).

- **spec.ipFamilyPolicy**
  string

  Required or requested dual stack support for the service.

  If there is no value provided, then this field will be set to `SingleStack`. Services can be `SingleStack` (a single IP family), `PreferDualStack` (two IP families on dual-stack configured clusters or a single IP family on single-stack clusters), or `RequireDualStack` (two IP families on dual-stack configured clusters, otherwise fail).

  The `ipFamilies` and `clusterIPs` fields depend on the value of this field. This field will be wiped when updating a service to type `ExternalName`.

- **spec.loadBalancerClass**
  string

  The class of the load balancer implementation this Service belongs to. If specified, the value of this field must be a label-style identifier, with an optional prefix, e.g. `internal-vip` or `example.com/internal-vip`. Unprefixed names are reserved for end-users.

  This field can only be set when the Service type is `LoadBalancer`.

  If not set, the default load balancer implementation is used, today this is typically done through the cloud provider integration, but should apply for any default implementation.

  If set, it is assumed that a load balancer implementation is watching for Services with a matching class. Any default load balancer implementation (e.g. cloud providers) should ignore Services that set this field. This field can only be set when creating or updating a Service to type `LoadBalancer`.

  Once set, it can not be changed. This field will be wiped when a service is updated to a non `LoadBalancer` type.

- **spec.loadBalancerIP**
  string

  Only applies to Service Type: LoadBalancer. This feature depends on whether the underlying cloud-provider supports specifying the loadBalancerIP when a load balancer is created.

  This field will be ignored if the cloud-provider does not support the feature.

- **spec.loadBalancerSourceRanges**
  array of strings

  If specified and supported by the platform, this will restrict traffic through the cloud-provider load-balancer will be restricted to the specified client IPs.

  This field will be ignored if the cloud-provider does not support the feature. More info.

- **spec.ports**
  array of objects

  The list of ports that are exposed by this service. More info.

  ServicePort contains information on service’s port.

  - **spec.ports.appProtocol**
    string

    The application protocol for this port. This is used as a hint for implementations to offer richer behavior for protocols that they understand. This field follows standard Kubernetes label syntax. Valid values are either:

    - Un-prefixed protocol names - reserved for IANA standard service names as RFC-6335.
    - Kubernetes-defined prefixed names:

        - `kubernetes.io/h2c` — HTTP/2 prior knowledge over cleartext as described in RFC;
        - `kubernetes.io/ws` — WebSocket over cleartext as described in RFC;
        - `kubernetes.io/wss` — WebSocket over TLS as described in RFC.
      - Other protocols should use implementation-defined prefixed names such as `mycompany.com/my-custom-protocol`.
    - **spec.ports.name**
      string

      The name of this port within the service. This must be a `DNS_LABEL`.

      All ports within a ServiceSpec must have unique names. When considering the endpoints for a Service, this must match the 'name' field in the `EndpointPort`. Optional if only one `ServicePort` is defined on this service.

    - **spec.ports.nodePort**
      integer

      The port on each node on which this service is exposed when type is NodePort or LoadBalancer. Usually assigned by the system. If a value is specified, in-range, and not in use it will be used, otherwise the operation will fail.

      If not specified, a port will be allocated if this Service requires one.

      If this field is specified when creating a Service which does not need it, creation will fail.

      This field will be wiped when updating a Service to no longer need it (e.g. changing type from NodePort to ClusterIP). More info.

    - **spec.ports.port**
      integer

      Required value

      The port that will be exposed by this service.

    - **spec.ports.protocol**
      string

      The IP protocol for this port. Supports `TCP`, `UDP`, and `SCTP`.

      Default: `TCP`

    - **spec.ports.targetPort**
      integer

      Number of the port to access on the pods targeted by the service.

      If this is not specified, the value of the `port` field is used (an identity map).

      This field is ignored for services with `clusterIP=None`, and should be omitted or set equal to the `port` field. More info.

- **spec.publishNotReadyAddresses**
  boolean

  Indicates that any agent which deals with endpoints for this Service should disregard any indications of ready/not-ready. The primary use case for setting this field is for a StatefulSet's Headless Service to propagate SRV DNS records for its Pods for the purpose of peer discovery.

  The Kubernetes controllers that generate `Endpoints` and `EndpointSlice` resources for Services interpret this to mean that all endpoints are considered "ready" even if the Pods themselves are not. Agents which consume only Kubernetes generated endpoints through the `Endpoints` or `EndpointSlice` resources can safely assume this behavior.

- **spec.selector**
  object

  Route service traffic to pods with label keys and values matching this selector. If empty or not present, the service is assumed to have an external process managing its endpoints, which Kubernetes will not modify.

  Only applies to types ClusterIP, NodePort, and LoadBalancer.

  Ignored if type is `ExternalName`. More info.

- **spec.sessionAffinity**
  string

  Used to maintain session affinity. Enable client IP based session affinity. Must be `ClientIP` or `None`. More info.

- **spec.sessionAffinityConfig**
  object

  Contains the configurations of session affinity.

  - **spec.sessionAffinityConfig.clientIP**
    object

    Contains the configurations of `ClientIP` based session affinity.

    - **spec.sessionAffinityConfig.clientIP.timeoutSeconds**
      integer

      Specifies the seconds of `ClientIP` type session sticky time. The value must be `>0 && <=86400` (for 1 day) if `ServiceAffinity == ClientIP`.

- **spec.trafficDistribution**
  string

  Offers a way to express preferences for how traffic is distributed to Service endpoints. Implementations can use this field as a hint, but are not required to guarantee strict adherence.

  If the field is not set, the implementation will apply its default routing strategy. If set to `PreferClose`, implementations should prioritize endpoints that are topologically close (e.g., same zone).

- **spec.type**
  string

  Determines how the Service is exposed.

  Defaults to ClusterIP. Valid options are ExternalName, ClusterIP, NodePort, and LoadBalancer.

  ClusterIP allocates a cluster-internal IP address for load-balancing to endpoints. Endpoints are determined by the `selector` or if that is not specified, by manual construction of an `Endpoints` object or `EndpointSlice` objects.

  If `clusterIP` is `None`, no virtual IP is allocated and the endpoints are published as a set of endpoints rather than a virtual IP.

NodePort builds on ClusterIP and allocates a port on every node which routes to the same endpoints as the `clusterIP`.

LoadBalancer builds on NodePort and creates an external load-balancer (if supported in the current cloud) which routes to the same endpoints as the `clusterIP`.

ExternalName aliases this service to the specified `externalName`. Several other fields do not apply to ExternalName services. More info.

- **status**
  object

  Defines the observed state of ServiceWithHealthchecks

  - **status.conditions**
    array of objects

    Current service state

    Condition contains details for one aspect of the current state of this API Resource. This struct is intended for direct use as an array at the field path `.status.conditions`.

    - **status.conditions.lastTransitionTime**
      string

      Required value

      Is the last time the condition transitioned from one status to another. This should be when the underlying condition changed.

      If that is not known, then using the time when the API field changed is acceptable.

    - **status.conditions.message**
      string

      Required value

      Is a human readable message indicating details about the transition.

      This may be an empty string.

      Maximum length: `32768`

    - **status.conditions.observedGeneration**
      integer

      Represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

      Allowed values: `0 <= X`

    - **status.conditions.reason**
      string

      Required value

      Contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API.

      The value should be a CamelCase string.

      This field may not be empty.

      Pattern: `^[A-Za-z]([A-Za-z0-9_,:]*[A-Za-z0-9_])?$`

      Length: `1..1024`

    - **status.conditions.status**
      string

      Required value

      status of the condition, one of `True`, `False`, `Unknown`.

      Allowed values: `True`, `False`, `Unknown`

    - **status.conditions.type**
      string

      Required value

      Condition in CamelCase or in `foo.example.com/CamelCase`.

      Many `.condition.type` values are consistent across resources like Available, but because arbitrary conditions can be useful (see .node.status.conditions), the ability to deconflict is important. The regex it matches is `(dns1123SubdomainFmt/)?(qualifiedNameFmt)`.

      Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

      Maximum length: `316`

  - **status.endpointStatuses**
    array of objects

    Current service state

    - **status.endpointStatuses.failedProbes**
      array of strings
    - **status.endpointStatuses.lastProbeTime**
      string
    - **status.endpointStatuses.nodeName**
      string
    - **status.endpointStatuses.podName**
      string

      Required value

    - **status.endpointStatuses.probesSuccessful**
      boolean

        - **status.endpointStatuses.ready**
          boolean
    - **status.healthcheckCondition**
      object
        - **status.healthcheckCondition.activeNodeName**
          string
        - **status.healthcheckCondition.endpoints**
          integer
        - **status.healthcheckCondition.observedGeneration**
          integer
        - **status.healthcheckCondition.readyEndpoints**
          integer
    - **status.loadBalancer**
      object

      Contains the current status of the load-balancer, if one is present.

        - **status.loadBalancer.ingress**
          array of objects

          Is a list containing ingress points for the load-balancer. Traffic intended for the service should be sent to these ingress points.

          LoadBalancerIngress represents the status of a load-balancer ingress point: traffic intended for the service should be sent to an ingress point.

            - **status.loadBalancer.ingress.hostname**
              string

              Is set for load-balancer ingress points that are DNS based (typically AWS load-balancers)

            - **status.loadBalancer.ingress.ip**
              string

              Is set for load-balancer ingress points that are IP based (typically GCE or OpenStack load-balancers)

            - **status.loadBalancer.ingress.ipMode**
              string

              Specifies how the load-balancer IP behaves, and may only be specified when the ip field is specified. Setting this to `VIP` indicates that traffic is delivered to the node with the destination set to the load-balancer's IP and port.

              Setting this to `Proxy` indicates that traffic is delivered to the node or pod with the destination set to the node's IP and node port or the pod's IP and port.

              Service implementations may use this information to adjust traffic routing.

            - **status.loadBalancer.ingress.ports**
              array of objects

              Is a list of records of service ports

              If used, every port defined in the service should have an entry in it

                - **status.loadBalancer.ingress.ports.error**
                  string

                  Error is to record the problem with the service NodePorts.

                  The format of the error shall comply with the following rules:

                    - built-in error values shall be specified in this file and those shall use CamelCase names
                    - cloud provider specific error values must have names that comply with the format `foo.example.com/CamelCase`.

                  The regex it matches is `(dns1123SubdomainFmt/)?(qualifiedNameFmt)`.

                  Pattern: `^([a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*/)?(([A-Za-z0-9][-A-Za-z0-9_.]*)?[A-Za-z0-9])$`

                  Maximum length: `316`

                - **status.loadBalancer.ingress.ports.port**
                  integer

                  Required value

                  Is the port number of the service port of which status is recorded here

                - **status.loadBalancer.ingress.ports.protocol**
                  string

                  Required value

                  Is the protocol of the service port of which status is recorded here

                  The supported values are: `TCP`, `UDP`, `SCTP`

                  Default: `TCP`

Module service-with-healthchecks: examples

> **i** The module lifecycle stage: General Availability

i For the ServiceWithHealthchecks load balancers you create to work, the following conditions must be met:

- The network policy of the custom project in which the ServiceWithHealthchecks will be created must include a rule allowing incoming traffic from all pods in the `d8-service-with-healthchecks` namespace:

  ```
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: d8-service-with-healthchecks
  ```

  For more information on network policies, see the Configuring Network Policies section.

- The cluster role used in ClusterRoleBinding and RoleBinding when assigning permissions to users and service accounts for the ServiceWithHealthchecks resource must be extended with the following rules:
  - `get`
  - `list`
  - `watch`
  - `create`
  - `update`
  - `patch`
  - `delete`.

  For more details, see the section Granting permissions to users and service accounts.

⚠ Enabling the module does not automatically replace existing Service resources with ServiceWithHealthcheck resources. To replace existing services with ServiceWithHealthcheck, follow these steps:

- Create ServiceWithHealthcheck resources with the same names and parameters as the existing Service resources you want to replace. When creating a ServiceWithHealthcheck, specify the required `healthchecks` parameters.
- Delete the Service resources that you want to replace with ServiceWithHealthcheck.

Running two independent balancers on the same virtual machine

Suppose that there are two applications running on a Linux virtual machine — an HTTP server (TCP 8080) and an SMTP server (TCP 2525). You need to set up two separate balancers for these services, a web balancer and an SMTP balancer.

Creating a virtual machine

Create a `my-vm` virtual machine by following the examples in the DVP documentation.

In the manifest example below, the `vm: my-vm` label is included so that the virtual machine can be bound to load balancers.

```
apiVersion: virtualization.deckhouse.io/v1alpha2
kind: VirtualMachine
metadata:
  name: my-vm
  namespace: my-ns
  labels:
    vm: my-vm
spec:
  virtualMachineClassName: generic
  cpu:
    cores: 1
  memory:
    size: 1Gi
  provisioning:
    type: UserData
    userData: |
      #cloud-config
      ssh_pwauth: True
      users:
      - name: cloud
        passwd:
'$6$rounds=4096$saltsalt$fPmUsbjAuA7mnQNTajQM6ClhesyG0.yyQhvahas02ejfMAq1ykBo1RquzS0R6GgdIDlvS.kbUwDablGZKZcTP/'
        shell: /bin/bash
        sudo: ALL=(ALL) NOPASSWD:ALL
        lock_passwd: False
  blockDeviceRefs:
    - kind: VirtualDisk
      name: linux-disk
```

Web service and SMTP load balancer manifests

Below is an example of a manifest of a web service load balancer:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: ServiceWithHealthchecks
metadata:
  name: web
  namespace: my-ns
spec:
  ports:
  - port: 80
    protocol: TCP
    targetPort: 8080
  selector:
    vm: my-vm
  healthcheck:
    probes:
    - mode: HTTP
      http:
        targetPort: 8080
        method: GET
        path: /healthz
```

Below is an example of a manifest of a SMTP load balancer:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: ServiceWithHealthchecks
metadata:
  name: smtp
  namespace: my-ns
spec:
  ports:
  - port: 25
    protocol: TCP
    targetPort: 2525
  selector:
    vm: my-vm
  healthcheck:
    probes:
    - mode: TCP
      tcp:
        targetPort: 2525
```

Load balancers for working with a PostgreSQL cluster

Creating a StatefulSet for PostgreSQL

In order for `StatefulSet` to operate properly, you will have to create a regular Service to generate the pod DNS names. This service will not be used for direct access to the database.

```
apiVersion: v1
kind: Service
metadata:
  name: postgres
spec:
  selector:
    app: postgres
  ports:
    - protocol: TCP
      port: 5432
      targetPort: 5432
```

Below is an example of a `StatefulSet` manifest:

```
apiVersion: apps/v1
kind: StatefulSet
metadata:
  name: postgres
  name: my-ns
spec:
  serviceName: postgres
  replicas: 3
  selector:
    matchLabels:
      app: postgres
  template:
    metadata:
      labels:
        app: postgres
    spec:
      containers:
        - name: postgres
          image: postgres:13
          ports:
            - containerPort: 5432
          env:
            - name: POSTGRES_USER
              value: postgres
            - name: POSTGRES_PASSWORD
              value: example
```

Configuring ServiceWithHealthchecks load balancers

Create a Secret to store credentials so that probes can access the database:

```
d8 k -n my-ns create secret generic cred-secret --from-literal=user=postgres --from-literal=password=example cred-secret
```

Below is an example of a load balancer manifest for reading:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: ServiceWithHealthchecks
metadata:
  name: postgres-read
spec:
  ports:
  - port: 5432
    protocol: TCP
    targetPort: 5432
  selector:
    app: postgres
  healthcheck:
    probes:
    - mode: PostgreSQL
      postgreSQL:
        targetPort: 5432
        dbName: postgres
        authSecretName: cred-secret
        query: "SELECT 1"
```

And here is an example of a load balancer manifest for writing:

```
apiVersion: network.deckhouse.io/v1alpha1
kind: ServiceWithHealthchecks
metadata:
  name: postgres-write
spec:
  ports:
  - port: 5432
    protocol: TCP
    targetPort: 5432
  selector:
    app: postgres
  healthcheck:
    probes:
    - mode: PostgreSQL
      postgreSQL:
        targetPort: 5432
        dbName: postgres
        authSecretName: cred-secret
        query: "SELECT NOT pg_is_in_recovery()"
```

The terraform-manager module

> **i** The module lifecycle stage: General Availability

The module is responsible for monitoring and synchronizing the state of the underlying infrastructure and persistent nodes in the cloud

environment. The implementation is based on Terraform and is used in the Deckhouse Kubernetes Platform for interaction with supported cloud providers.

- The module consists of 2 parts:
  - `terraform-auto-converger` — checks the Terraform state and applies non-destructive changes;
  - `terraform-state-exporter` — checks the Terraform state and exports cluster metrics.
- The module is enabled by default if the following secrets are present in the cluster:
  - `kube-system/d8-provider-cluster-configuration`;
  - `d8-system/d8-cluster-terraform-state`.

Third-party components

List of third-party software used in the `terraform-manager` module:

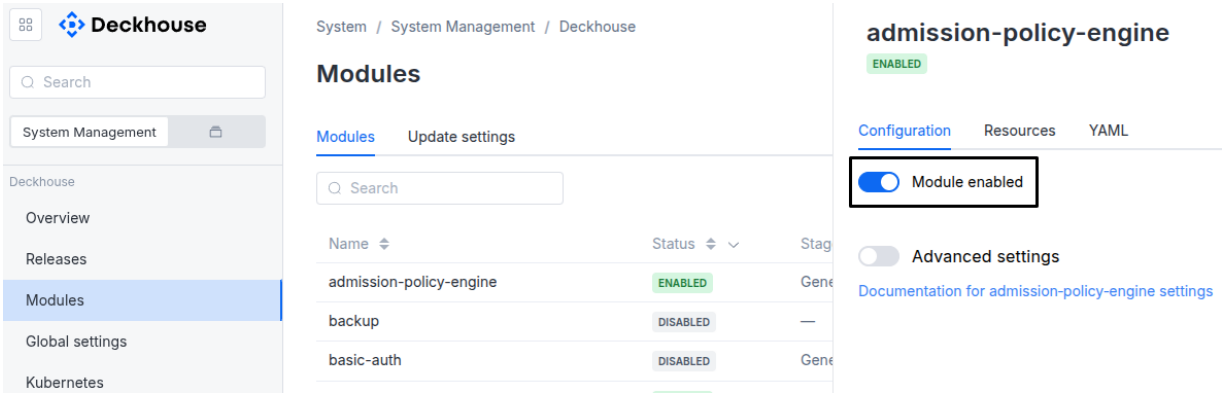
- Terraform

  License: Mozilla Public License 2.0

  A tool for building, changing, and versioning infrastructure safely and efficiently.

Configuration

> **i** The module lifecycle stage: General Availability



The module has 10 alerts.

The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `terraform-manager` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

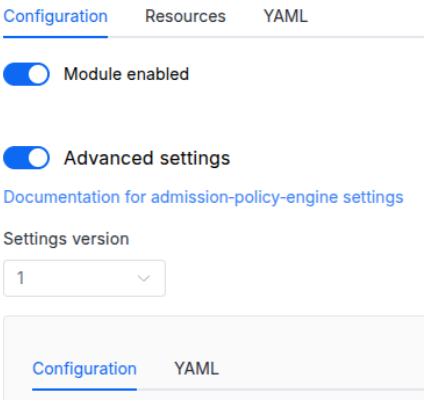
```
d8 system module enable terraform-manager
```

- **Using ModuleConfig `terraform-manager`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `terraform-manager` (create it if necessary);

  Example of a manifest to enable module `terraform-manager`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: terraform-manager
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `terraform-manager` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `terraform-manager` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `terraform-manager`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `terraform-manager` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc terraform-manager
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `terraform-manager` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `terraform-manager`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: terraform-manager
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.autoConvergerEnabled**
    boolean

    Enables periodic checking of Terraform state and applying non-destructive changes.

    The frequency of the check is set by the autoConvergerPeriod parameter.

    Default: `true`
  - **settings.autoConvergerPeriod**
    string

    The time interval after which the state of Terraform is checked and applied.

    It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    Default: `1h`

    Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`
  - **settings.nodeSelector**
    object

    The same as in the Pod’s `spec.nodeSelector` parameter in Kubernetes.

    If the parameter is omitted or `false`, it will be determined automatically.
  - **settings.tolerations**
    array of objects

    The same as in the Pods’ `spec.tolerations` parameter in Kubernetes;

    If the parameter is omitted or `false`, it will be determined automatically.
    - **settings.tolerations.effect**
      string
    - **settings.tolerations.key**
      string
    - **settings.tolerations.operator**
      string
    - **settings.tolerations.tolerationSeconds**
      integer

- **settings.tolerations.value**
  string

Cluster SLA Monitoring

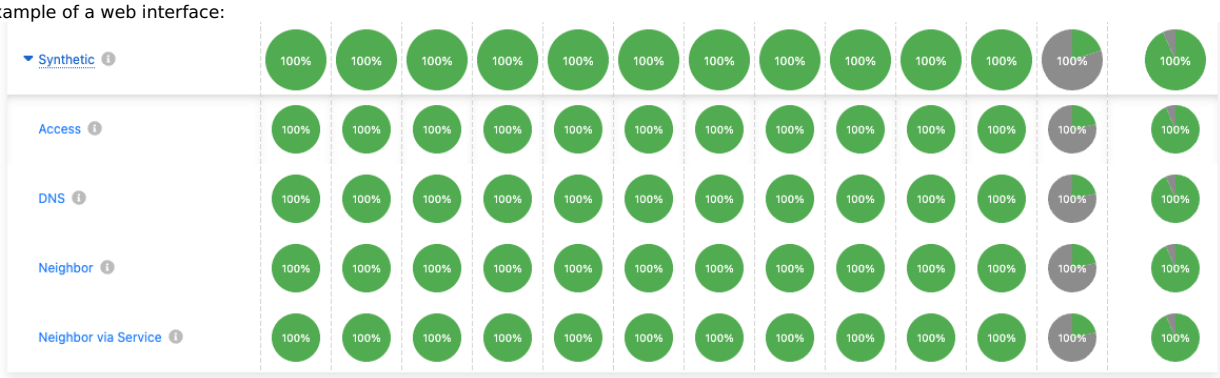
> **i** The module lifecycle stage: General Availability

> **i** Web interfaces associated with the module: status, upmeter

The module tests the availability of the platform and the status of cluster components in real time, and outputs information in the form of corresponding dashboards.

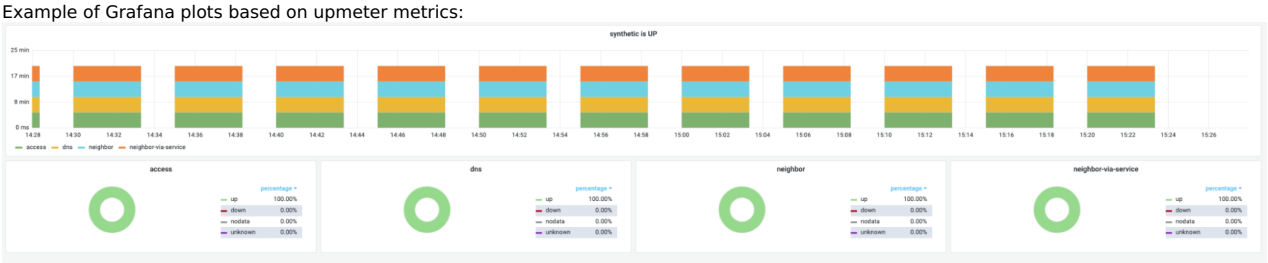
Module features:

- continuous testing scenarios have been developed for all major cluster components;
- the test results are saved as metrics;
- displays a dashboard showing the functionality of the components;
- the data can be exported to any external Prometheus-compatible monitoring system.



Module composition:

- **agent** — runs on master nodes, performs availability tests, and sends results to the server.
- **upmeter** — collects results and supports an API server to retrieve them.
- **front**
  - **status** — shows the availability level for the last 10 minutes (requires authorization, but it can be disabled);
  - **webui** — shows a dashboard with statistics on probes and availability groups (requires authorization).
- **smoke-mini** — supports continuous *smoke testing* using StatefulSet.



The module sends about 100 metric readings every 5 minutes. This figure depends on the number of Deckhouse Kubernetes Platform modules enabled.

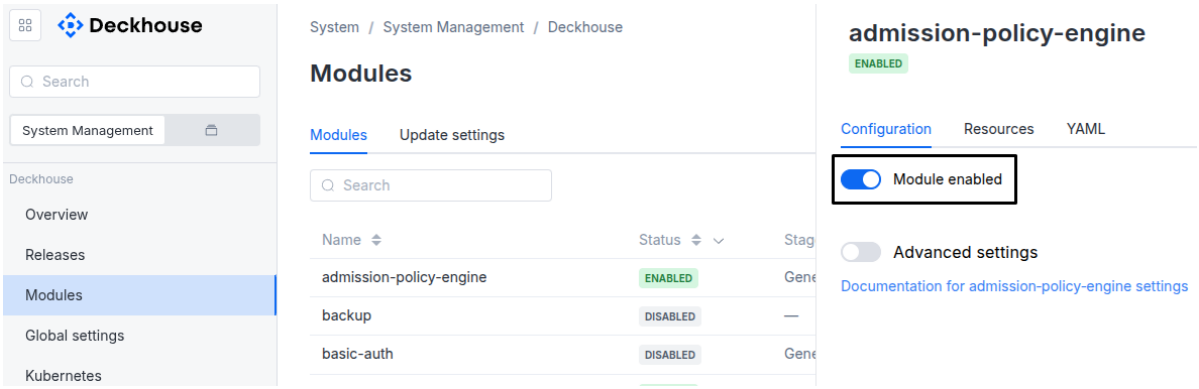
Interface

Example of a web interface:

Example of Grafana plots based on upmeter metrics:

Configuration

> The module lifecycle stage: General Availability



The module has 15 alerts.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `upmeter` module and enable (or disable) the “Module enabled” toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

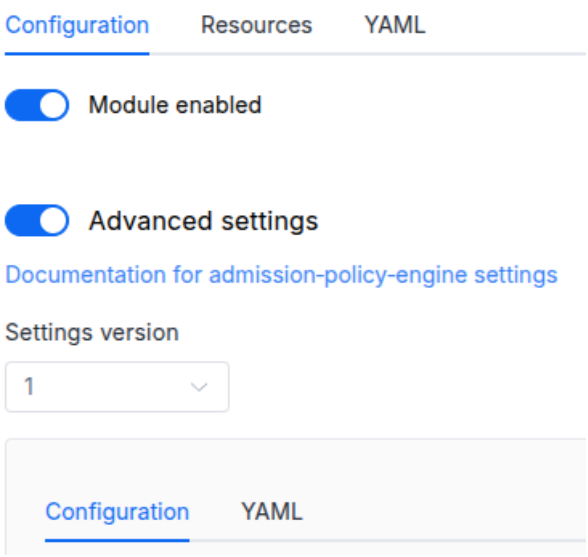
```
d8 system module enable upmeter
```

- **Using ModuleConfig `upmeter`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `upmeter` (create it if necessary);

  Example of a manifest to enable module `upmeter`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: upmeter
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `upmeter` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `upmeter` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `upmeter`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `upmeter` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc upmeter
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `upmeter` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `upmeter`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: upmeter
  spec:
    version: 3
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Conversion description is missing.

  Actions performed by the conversion (jq syntax)...

  - `del(.auth.status.password) | if .auth.status == {} then del(.auth.status) end | if .auth == {} then del(.auth) end`

    - `del(.auth.webui.password) | if .auth.webui == {} then del(.auth.webui) end | if .auth == {} then del(.auth) end`

- Updates from version **2** to **3**:

  Conversion description is missing.

  Actions performed by the conversion (jq syntax)...

    - `del(.smokeMini.ingressClass) | if .smokeMini == {} then del(.smokeMini) end`

Parameters

Schema version: 3

- **settings**
  object
    - **settings.auth**
      object

      Required value

      Configuration of authentication for Upmeter frontends.

        - **settings.auth.status**
          object

          Required value

          Authentication configuration.

            - **settings.auth.status.allowedUserEmails**
              array of strings

              An array of emails of users that can access module’s public web interfaces.

              This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

            - **settings.auth.status.allowedUserGroups**
              array of strings

              An array of user groups that can access Grafana & Prometheus.

              This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

              Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

            - **settings.auth.status.externalAuthentication**
              object

              Parameters to enable external authentication based on the Ingress NGINX external-auth mechanism that uses the NGINX auth_request module.

              > **i** External authentication is enabled automatically if the user-authn module is enabled.

                - **settings.auth.status.externalAuthentication.authSignInURL**
                  string

                  URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

                - **settings.auth.status.externalAuthentication.authURL**
                  string

                  URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

            - **settings.auth.status.whitelistSourceRanges**
              array of strings

              An array if CIDRs that are allowed to authenticate.

Example:

```
whitelistSourceRanges:
- 1.1.1.1/32
```

- **settings.auth.webui**
  object

  Required value

  Authentication configuration.

  - **settings.auth.webui.allowedUserEmails**
    array of strings

    An array of emails of users that can access module’s public web interfaces.

    This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

  - **settings.auth.webui.allowedUserGroups**
    array of strings

    An array of user groups that can access Grafana & Prometheus.

    This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

    Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

  - **settings.auth.webui.externalAuthentication**
    object

    Parameters to enable external authentication. Uses Ingress NGINX external-auth mechanism which is based on the the NGINX auth_request module.

    - **settings.auth.webui.externalAuthentication.authSignInURL**
      string

      URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

    - **settings.auth.webui.externalAuthentication.authURL**
      string

      URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

  - **settings.auth.webui.password**
    string

    Password for http authorization of the `admin` user. It is generated automatically, but you can change it.

    This parameter is used if the `externalAuthentication` is not enabled.

  - **settings.auth.webui.whitelistSourceRanges**
    array of strings

    An array if CIDRs that are allowed to authenticate.

    Example:

    ```
    whitelistSourceRanges:
    - 1.1.1.1/32
    ```

- **settings.disabledProbes**
  array of strings

  Group names or specific probes from a group. You can view the names in the web UI.

  For example:

```
disabledProbes:
  - "synthetic/api" # disable a specific probe
  - "synthetic/"   # disable a group of probes
  - control-plane  # / can be omitted
```

Default: `[]`

- **settings.https**
  object

  What certificate type to use with webui and status apps.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

```
https:
  mode: CustomCertificate
  customCertificate:
    secretName: foobar
```

```
https:
  mode: CertManager
  certManager:
    clusterIssuerName: letsencrypt
```

  - **settings.https.certManager**
    object
    - **settings.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for webui/status.

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.https.customCertificate**
    object
    - **settings.https.customCertificate.secretName**
      string

      The name of the secret in the `d8-system` namespace to use with webui/status.

      This secret must have the kubernetes.io/tls format.

      Default: `false`

  - **settings.https.mode**
    string

    The HTTPS usage mode:

    - `Disabled` — webui/status will work over HTTP only;
    - `CertManager` — webui/status will use HTTPS and get a certificate from the clusterissuer defined in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate` — webui/status will use HTTPS using the certificate from the `d8-system` namespace.
    - `OnlyInURI` — webui/status will work over HTTP (thinking that there is an external HTTPS load balancer in front that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

    Default: `Disabled`

    Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.ingressClass**
  string

  The class of the Ingress controller used for the Upmeter.

Optional. By default, the `modules.ingressClass` global value is used

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.nodeSelector**
  object

  Node selector for Upmeter server. The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  nodeSelector:
    disktype: ssd
  ```

- **settings.smokeMini**
  object

  Configuration of authentication for smoke-mini.

  - **settings.smokeMini.auth**
    object

    Required value

    Authentication configuration.

    - **settings.smokeMini.auth.allowedUserGroups**
      array of strings

      An array of user groups that can access Grafana & Prometheus.

      This parameter is used if the `user-authn` module is enabled or the `externalAuthentication` parameter is set.

      Caution! Note that you must add those groups to the appropriate field in the DexProvider config if this module is used together with the user-authn one.

    - **settings.smokeMini.auth.externalAuthentication**
      object

      Parameters to enable external authentication. Uses Ingress NGINX external-auth mechanism which is based on the the NGINX auth_request module.

      - **settings.smokeMini.auth.externalAuthentication.authSignInURL**
        string

        URL to redirect the user for authentication (if the authentication service returned a non-200 HTTP response code).

      - **settings.smokeMini.auth.externalAuthentication.authURL**
        string

        URL of the authentication service. If the user is authenticated, the service should return an HTTP 200 response code.

    - **settings.smokeMini.auth.password**
      string

      Password for http authorization of the `admin` user. It is generated automatically, but you can change it.

      This parameter is used if the `externalAuthentication` is not enabled.

    - **settings.smokeMini.auth.whitelistSourceRanges**
      array of strings

      An array if CIDRs that are allowed to authenticate.

      Example:

      ```
      whitelistSourceRanges:
      - 1.1.1.1/32
      ```

- **settings.smokeMini.https**
  object

  What certificate type to use with smoke-mini.

  This parameter completely overrides the `global.modules.https` settings.

  Examples:

```
https:
  mode: CustomCertificate
  customCertificate:
    secretName: foobar
```

```
https:
  mode: CertManager
  certManager:
    clusterIssuerName: letsencrypt
```

  - **settings.smokeMini.https.certManager**
    object
    - **settings.smokeMini.https.certManager.clusterIssuerName**
      string

      What ClusterIssuer to use for smoke-mini.

      Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

      Default: `letsencrypt`

  - **settings.smokeMini.https.customCertificate**
    object
    - **settings.smokeMini.https.customCertificate.secretName**
      string

      The name of the secret in the `d8-system` namespace to use with smoke-mini.

      This secret must have the kubernetes.io/tls format.

      Default: `false`

  - **settings.smokeMini.https.mode**
    string

    The HTTPS usage mode:

    - `Disabled` — smoke-mini will work over HTTP only;
    - `CertManager` — smoke-mini will use HTTPS and get a certificate from the clusterissuer defined in the `certManager.clusterIssuerName` parameter.
    - `CustomCertificate` — smoke-mini will use HTTPS using the certificate from the `d8-system` namespace.
    - `OnlyInURI` — smoke-mini will work over HTTP (thinking that there is an external HTTPS load balancer in front that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

    Default: `Disabled`

    Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.smokeMini.storageClass**
  string or boolean

  A StorageClass to use when checking the health of disks.

  If omitted, the StorageClass of the existing PVC is used. If there is no PVC yet, either the global StorageClass or `global.discovery.defaultStorageClass` is used, and if those are undefined, the emptyDir volume is used to store the data.

  `global.discovery.defaultStorageClass` is applied during module activation, changing default StorageClass in cluster won't result in disk re-provisioning.

Setting it to `false` forces the use of an emptyDir volume.

Default: `false`

Allowed values: `false`

Examples:

```
storageClass: false
```

```
storageClass: default
```

- **settings.smokeMiniDisabled**
  boolean

  Disables smokeMini.

  Disables “synthetic” probe group in Upmeter as well.

  Default: `false`

- **settings.statusPageAuthDisabled**
  boolean

  Disables authorization for the status domain.

  Default: `false`

- **settings.storageClass**
  string or boolean

  The name of the StorageClass to use for Upmeter storage (PVC).

  If omitted, the StorageClass of the existing PVC is used. If there is no PVC yet, the StorageClass will be used according to the global storageClass parameter setting.

  The global `storageClass` parameter is only considered when the module is enabled. Changing the global `storageClass` parameter while the module is enabled will not trigger disk re-provisioning.

  If `false` is specified, `emptyDir` will be forced to be used.

  Warning. Specifying a value different from the one currently used (in the existing PVC) will result in disk re-provisioning and all data will be deleted.

  Warning. When migrating Upmeter with local storage to other nodes, the pods will enter a Pending state. In this situation, it will be necessary to back up the Upmeter database, delete the old PVCs, and manually restart the pod. Here, local storage refers to a StorageClass associated not with network storage but with a local volume on a node (for example, a StorageClass created by the local-path-provisioner module).

  Allowed values: `false`

  Examples:

  ```
  storageClass: false
  ```

  ```
  storageClass: default
  ```

- **settings.tolerations**
  array of objects

  Node tolerations for Upmeter server. The same as in the Pods’ `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

```
tolerations:
- key: key1
  operator: Equal
  value: value1
  effect: NoSchedule
```

- **settings.tolerations.effect**
  string
- **settings.tolerations.key**
  string
- **settings.tolerations.operator**
  string
- **settings.tolerations.tolerationSeconds**
  integer
- **settings.tolerations.value**
  string

Authentication

user-authn module provides authentication by default. Also, externalAuthentication can be configured (see below). If these options are disabled, the module will use basic auth with the auto-generated password.

Use d8 k to see password:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values upmeter -o json | jq '.upmeter.internal.auth.webui.password'
```

Delete the Secret to re-generate password:

```
d8 k -n d8-upmeter delete secret/basic-auth-webui
```

Use d8 k to see password for status page:

```
d8 k -n d8-system exec svc/deckhouse-leader -c deckhouse -- deckhouse-controller module values upmeter -o json | jq '.upmeter.internal.auth.status.password'
```

Delete the Secret to re-generate password for status page:

```
d8 k -n d8-upmeter delete secret/basic-auth-status
```

> **Note!** The `auth.status.password` and `auth.webui.password` parameters are deprecated.

Custom Resources

> The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> The module lifecycle stage: General Availability

Downtime

Scope: Cluster
Version: v1alpha1

Downtime incident records

- **spec**
  array of objects

Required value

- **spec.affected**
  array of strings

  A list of affected groups.

- **spec.description**
  string

  Human readable incident information.

- **spec.endDate**
  string

  End of downtime (Unix time or RFC3339 date 2020-09-07T17:24:55Z).

- **spec.startDate**
  string

  Start of downtime (Unix time or RFC3339 date 2020-09-07T17:24:55Z).

- **spec.type**
  string

  Type of downtime incident.

  Allowed values: `Accident`, `Maintenance`, `InfrastructureMaintenance`, `InfrastructureAccident`

UpmeterHookProbe

Scope: Cluster
Version: v1

Upmeter CRD for deckhouse-configuration probe.

- **spec**
  object

  Required value

  - **spec.inited**
    string

    Required value

    The initial value set by upmeter agent

  - **spec.mirror**
    string

    Required value

    The mirrored value set by hook

UpmeterRemoteWrite

Scope: Cluster

- v1
- v1alpha1

Upmeter `remote_write` configuration.

- **spec**
  object

  Required value

  - **spec.additionalLabels**
    object

    Additional labels to add to all metrics.

  - **spec.config**
    object

Required value

Config defines the `remote_write` configuration for Prometheus.

- **spec.config.basicAuth**
  object

  BasicAuth for the URL.

  - **spec.config.basicAuth.password**
    string

    Required value

    The password for authentication.

  - **spec.config.basicAuth.username**
    string

    Required value

    The username for authentication.

- **spec.config.bearerToken**
  string

  Bearer token.

- **spec.config.headers**
  object

  Additional HTTP headers to send with each remote write request.

  - **spec.config.headers.X-Auth-Token**
    string

    The `X-Auth-Token` header specifying the authentication token.

  - **spec.config.headers.X-Scope-OrgID**
    string

    The `X-Scope-OrgID` header specifying the tenant ID.

- **spec.config.tlsConfig**
  object

  TLS Config to use for remote write.

  - **spec.config.tlsConfig.ca**
    string

    The CA certificate used when verifying the API server certificate.

    Default:

  - **spec.config.tlsConfig.insecureSkipVerify**
    boolean

    Disable target certificate validation.

    Default: `false`

- **spec.config.url**
  string

  Required value

  The URL of the endpoint to send samples to.

- **spec.intervalSeconds**
  number

  The size of timeslot to send.

  Default: `300`

  Allowed values: `30`, `300`

Deprecated resource. Support for the resource might be removed in a later release.

Upmeter `remote_write` configuration.

- **spec**
  object

  Required value

  - **spec.additionalLabels**
    object

    Additional labels to add to all metrics.

  - **spec.config**
    object

    Required value

    Config defines the `remote_write` configuration for Prometheus.

    - **spec.config.basicAuth**
      object

      BasicAuth for the URL.

      - **spec.config.basicAuth.password**
        string

        Required value

        The password for authentication.

      - **spec.config.basicAuth.username**
        string

        Required value

        The username for authentication.

    - **spec.config.bearerToken**
      string

      Bearer token.

    - **spec.config.headers**
      object

      Additional HTTP headers to send with each remote write request.

      - **spec.config.headers.X-Auth-Token**
        string

        The `X-Auth-Token` header specifying the authentication token.

      - **spec.config.headers.X-Scope-OrgID**
        string

        The `X-Scope-OrgID` header specifying the tenant ID.

    - **spec.config.tlsConfig**
      object

      TLS Config to use for remote write.

      - **spec.config.tlsConfig.ca**
        string

        The CA certificate used when verifying the API server certificate.

        Default:

      - **spec.config.tlsConfig.insecureSkipVerify**
        boolean

        Disable target certificate validation.

        Default: `false`

    - **spec.config.url**
      string

Required value

The URL of the endpoint to send samples to.

- **spec.intervalSeconds**
  number

  The size of timeslot to send.

  Default: `300`

  Allowed values: `30`, `300`

FAQ

> **i** The module lifecycle stage: General Availability

Why can't `upmeter-probe-*` pods be placed in the cluster, why are some pods constantly deleted?

The module implements tests for the availability of the functionality of some Kubernetes controllers.

The tests are performed by creating and deleting temporary pods.

`upmeter-probe-scheduler` objects implement a test for the functionality of placing pods on nodes. As part of the test, a Pod is created and placed on a node. Then this pod is deleted.

`upmeter-probe-controller-manager` objects implement a test for the health of `kube-controller-manager`.

`StatefulSet` is created for the test, and it is checked that this object has spawned a Pod (since the actual placement of the pod is not required and is checked as part of another test, a Pod is created that is guaranteed not to be placed, i.e. is in the `Pending` state). Deletes the StatefulSet, checks that the Pod it spawned has been deleted.

`smoke-mini` objects implement network connectivity testing between nodes. Five `StatefulSet` with one replica are deployed for testing. The test checks connectivity between `smoke-mini` Pods as well as network connectivity with `upmeter-agent` Pods running on master nodes.
Once per minute, one of the `smoke-mini` Pods is migrated to another node.

Examples

> **i** The module lifecycle stage: General Availability

An example of the `UpmeterRemoteWrite` configuration

```
apiVersion: deckhouse.io/v1
kind: UpmeterRemoteWrite
metadata:
  labels:
    heritage: upmeter
    module: upmeter
  name: victoriametrics
spec:
  additionalLabels:
    cluster: cluster-name
    some: fun
  config:
    url: https://upmeter-victoriametrics.whatever/api/v1/write
    basicAuth:
      password: "Cdp#Cd.OxfZsx4*89SZ"
      username: upmeter
  intervalSeconds: 300
```

The user-authn module

> **i** The module lifecycle stage: General Availability

> **i** Web interfaces associated with the module: kubeconfig

The module sets up a unified authentication system integrated with Kubernetes and Web interfaces used in other modules (Grafana, Dashboard, etc.).

It consists of the following components:

- dex — is a federated OpenID Connect provider that acts as an identity service for static users and can be linked to one or more ID providers (e.g., SAML providers, GitHub, and Gitlab);
- `kubeconfig-generator` (in fact, dex-k8s-authenticator) — is a helper web application that (being authorized with dex) generates kubectl commands for creating and modifying a kubeconfig;
- `dex-authenticator` (in fact, `oauth2-proxy`) is an application that receives Ingress NGINX requests (via the `auth_request` module) and authenticates them with Dex.

Management of static users is performed using the User and Group resources:

- The User object stores user information, including the email address and an encrypted password hash (the plain-text password is not stored);
- The Group object defines a list of users grouped together for easier access management.

The following external authentication protocols/providers are supported:

- GitHub;
- GitLab;
- BitBucket Cloud;
- Crowd;
- LDAP;
- OIDC.

You can use several external authentication providers simultaneously.

Integration features

Basic authentication for the Kubernetes API requests

Basic authentication for the Kubernetes API requests is currently only available for the Crowd provider (with the `enableBasicAuth` parameter).

> **i** You can also connect to the Kubernetes API via other supported external providers.

Application integration

To enable authentication for any web application running in Kubernetes, create a *DexAuthenticator* resource in the application's *Namespace* and add several annotations to the *Ingress* resource. This will enable you to:

- limit the list of groups with access;
- limit the list of addresses for which authentication is allowed;
- integrate the application into a unified authentication system if the application supports OIDC. For that, Kubernetes will create a resource *DexClient* in the application *Namespace*. A secret with data for connecting to Dex via OIDC will also be created in that *Namespace*.

Following such an integration, you can:

- limit the list of groups for which the connection is allowed;
- define a list of clients with trusted OIDC tokens (`trustedPeers`).

Web interface for generating ready-made kubeconfig files

The module allows you to automatically generate configuration for kubectl or other Kubernetes tools.

The user will be presented with a set of commands to configure kubectl once authorized in the

generator's web interface. These commands can be copied and pasted into the console to use kubectl. The authentication mechanism for kubeconfig uses an OIDC token. The OIDC session can be extended automatically if the authentication provider used in Dex supports session extension. For this, the `refresh token` is specified in kubeconfig.

On top of that, you can configure multiple `kube-apiserver` addresses and CA certificates for each of them. This may come in handy, e. g., if access to the Kubernetes cluster is via VPN or direct connection.

Exposing the Kubernetes API over Ingress

The kube-apiserver component (without advanced configuration) is only accessible in the internal cluster network. This module enables easy and secure access to Kubernetes API from outside the cluster. The API server is exposed on a dedicated domain (for more details, see the section on service domains in the documentation).

When configuring, you can:

- list network addresses from which connection is allowed;
- list groups that are allowed to access the API server;
- specify Ingress-controller to authenticate on.

By default, a special CA certificate will be generated and the kubeconfig generator will be automatically configured.

Extensions by Flant

The module uses a modified version of Dex to support:

- groups for static user accounts and Bitbucket Cloud provider (parameter `bitbucketCloud`);
- passing the `group` parameter to clients;
- the `obsolete tokens` mechanism to avoid a race condition when an OIDC client renews a token.
- Kerberos (SPNEGO) support for the LDAP connector. When enabled, Dex accepts `Authorization: Negotiate` tickets, validates them with a service keytab, and completes the login without rendering the password form.

High availability mode

The module also supports the `highAvailability` mode. When this mode is enabled, all components responding to the `auth requests` are deployed with the redundancy required to operate continuously without failure. Thus, the user authentication sessions are kept alive even if any of the authenticator instances fail.

Third-party components

List of third-party software used in the `user-authn` module:

- Dex 2.44.0

  License: Apache License 2.0

  A Federated OpenID Connect Provider with pluggable connectors.

- OAuth2 Proxy 7.5.1

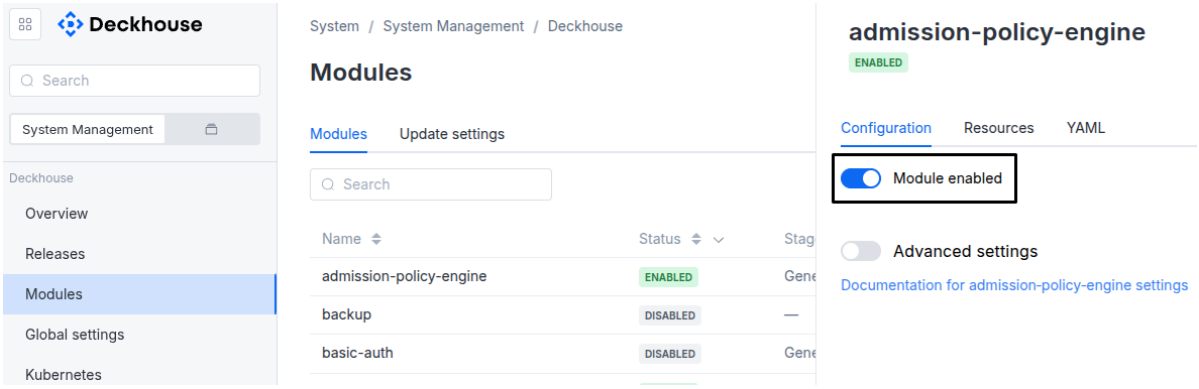
  License: MIT License

  A reverse proxy and static file server that provides authentication using Providers (Google, GitHub, and others) to validate accounts by email, domain or group.

Configuration

> **i** The module lifecycle stage: General Availability

The module has 3 alerts.



The module is **enabled** by default in the `Default` bundle. The module is **disabled** by default in the following bundles: `Managed`, `Minimal`.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `user-authn` module and enable (or disable) the "Module enabled" toggle. Save

changes.

Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

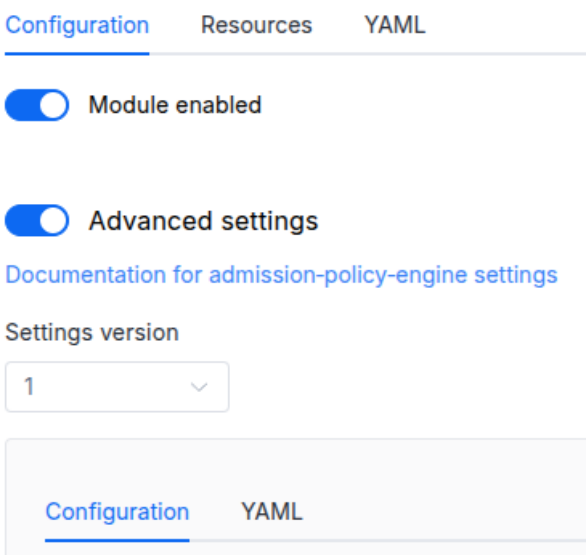
  ```
  d8 system module enable user-authn
  ```

- **Using ModuleConfig `user-authn`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `user-authn` (create it if necessary);

  Example of a manifest to enable module `user-authn`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: user-authn
  spec:
    enabled: true
  ```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `user-authn` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `user-authn` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `user-authn`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `user-authn` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc user-authn
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `user-authn` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `user-authn`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: user-authn
  spec:
    version: 2
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Conversions

The module is configured using the ModuleConfig resource, the schema of which contains a version number. When you apply an *old* version of the ModuleConfig schema in a cluster, automatic transformations are performed. To manually update the ModuleConfig schema version, the following steps must be completed **sequentially** for each version :

- Updates from version **1** to **2**:

  Replace `publishAPI.enable` with `publishAPI.enabled`.

Parameters

Schema version: 2

- **settings**
  object
  - **settings.controlPlaneConfigurator**
    object

    Parameters of the `control-plane-manager` module for automatic configuration of `kube-apiserver`.

    - **settings.controlPlaneConfigurator.dexCAMode**
      string

      How to determine the CA that will be used when configuring `kube-apiserver`.

      - `Custom` — use the CA explicitly set via the `dexCustomCA` parameter (see below). This option comes in handy if you use an external HTTPS load balancer in front of Ingresses, and this load balancer relies on a self-signed certificate.
      - `DoNotNeed` — a CA is not required (e.g., when using a public LE or other TLS providers).
      - `FromIngressSecret` — extract the CA of certificate from the Secret that is used in the Ingress. This option comes in handy if you use self-signed certificates with Ingresses.

      Default: `DoNotNeed`

      Allowed values: `Custom`, `DoNotNeed`, `FromIngressSecret`

    - **settings.controlPlaneConfigurator.dexCustomCA**
      string

      The CA to use if `dexCAMode` is `Custom`. Plain text (no base64).

    - **settings.controlPlaneConfigurator.enabled**
      boolean

      Defines if the `control-plane-manager` module should be used to configure OIDC for the `kube-apiserver`.

      Default: `true`

  - **settings.highAvailability**
    boolean

    Manually enable the high availability mode.

    By default, Deckhouse automatically decides whether to enable the HA mode. Click here to learn more about the HA mode for modules.

    Examples:

    ```
    highAvailability: true
    ```

    ```
    highAvailability: false
    ```

  - **settings.https**
    object

    What certificate type to use with Dex/kubeconfig-generator.

    This parameter completely overrides the `global.modules.https` settings.

    Examples:

    ```
    https:
      mode: CustomCertificate
      customCertificate:
        secretName: foobar
    ```

    ```
    https:
      mode: CertManager
      certManager:
        clusterIssuerName: letsencrypt
    ```

- **settings.https.certManager**
  object
  - **settings.https.certManager.clusterIssuerName**
    string

    What ClusterIssuer to use for Dex/kubeconfig-generator.

    Currently, `letsencrypt`, `letsencrypt-staging`, `selfsigned` are available. Also, you can define your own.

    Default: `letsencrypt`

- **settings.https.customCertificate**
  object
  - **settings.https.customCertificate.secretName**
    string

    The name of the Secret in the `d8-system` namespace to use with Dex/kubeconfig-generator.

    This Secret must have the `kubernetes.io/tls` format.

    Default: `false`

- **settings.https.mode**
  string

  The HTTPS usage mode:

  - `CertManager` — Dex/kubeconfig-generator will use HTTPS and get a certificate from the ClusterIssuer defined in the `certManager.clusterIssuerName` parameter.
  - `CustomCertificate` — Dex/kubeconfig-generator will use HTTPS using the certificate from the `d8-system` namespace.
  - `Disabled` — Dex/kubeconfig-generator will work over HTTP only;
  - `OnlyInURI` — Dex/kubeconfig-generator will work over HTTP (thinking that there is an external HTTPS load balancer in front that terminates HTTPS traffic). All the links in the `user-authn` will be generated using the HTTPS scheme. Load balancer should provide a redirect from HTTP to HTTPS.

  Default: `Disabled`

  Allowed values: `Disabled`, `CertManager`, `CustomCertificate`, `OnlyInURI`

- **settings.idTokenTTL**
  string

  TTL of the ID token.

  Set as a string specifying hours, minutes, or seconds: `30m`, `20s`, `2h30m10s`, `24h`.

  Defines the minimum possible user session lifetime (via `keepUsersLoggedInFor` in the DexAuthenticator resource and parameters like `auth.sessionTTL`, for example, in the `console` module).

  If the session TTL is less than or equal to `idTokenTTL`, the effective logout time is `idTokenTTL + 1s`.

  To force logout sooner than the default `idTokenTTL`, decrease this parameter value as well.

  Default: `10m`

  Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.ingressClass**
  string

  The class of the Ingress controller that will be used for Dex/kubeconfig-generator.

  An optional parameter; by default, the `modules.ingressClass` global value is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.kubeconfigGenerator**
  array of objects

  An array in which additional possible methods for accessing the API server are specified.

This option comes in handy if you prefer not to grant access to the cluster's API via Ingress but rather do it by other means (e.g., using a bastion host or over OpenVPN).

- **settings.kubeconfigGenerator.description**
  string

  A couple of words how this authentication method differs from others.

- **settings.kubeconfigGenerator.id**
  string

  Required value

  The name of the method for accessing the API server (no spaces, lowercase letters).

  Pattern: `^[\@\.\:0-9a-z._-]+$`

- **settings.kubeconfigGenerator.masterCA**
  string

  A CA for accessing the API:

  - If the parameter is not set, Kubernetes CA is used.
  - We recommend using a self-signed certificate (and specify it as masterCA) if an HTTP proxy (that terminates HTTPS traffic) is used for exposing.
- **settings.kubeconfigGenerator.masterURI**
  string

  Required value

  If you plan to use a TCP proxy, then you must configure a certificate on the API server's side for the TCP proxy address. Suppose your API servers use three different addresses (`192.168.0.10`, `192.168.0.11`, and `192.168.0.12`) while the client uses a TCP load balancer (say, `192.168.0.15`). In this case, you have to re-generate the API server certificates:

  - edit `kubeadm-config`: `d8 k -n kube-system edit configmap kubeadm-config` and add `192.168.0.15` to `.apiServer.certSANs`;
  - save the resulting config: `kubeadm config view > kubeadmconf.yaml`;
  - delete old API server certificates: `mv /etc/kubernetes/pki/apiserver.* /tmp/`;
  - reissue new certificates: `kubeadm init phase certs apiserver --config=kubeadmconf.yaml`;
  - restart the API server's container: `docker ps -a | grep 'kube-apiserver' | grep -v pause| awk '{print $1}' | xargs docker restart`;
  - repeat this step for all master nodes.

- **settings.nodeSelector**
  object

  The same as in the Pods' `spec.nodeSelector` parameter in Kubernetes.

  If the parameter is omitted or `false`, it will be determined automatically.

- **settings.passwordPolicy**
  object

  Default:

  - **settings.passwordPolicy.complexityLevel**
    string

    Password complexity level.

    Depending on the complexity level, a password must meet the following minimum requirements:

    - `None`: 1 character.
    - `Low`: 8 characters.
    - `Fair`: 8 characters, 1 uppercase letter (`A`–`Z`), 1 lowercase letter (`a`–`z`), 1 digit.
    - `Good`: 8 characters, 1 uppercase letter (`A`–`Z`), 1 lowercase letter (`a`–`z`), 1 digit, 1 special character (`!@#$%^&*`).
    - `Excellent`: 8 characters, 1 uppercase letter (`A`–`Z`), 1 lowercase letter (`a`–`z`), 1 digit, 1 special character (`!@#$%^&*`), no more than 2 identical characters in a row.

    Default: `Fair`

    Allowed values: `None`, `Low`, `Fair`, `Good`, `Excellent`

- **settings.passwordPolicy.lockout**
  object

  Temporary user lockout settings after consecutive failed login attempts.

  - **settings.passwordPolicy.lockout.lockDuration**
    string

    Required value

    Temporary lockout duration. Can be set in seconds, minutes, hours, or days: `10s`, `5m`, `1h`, `3d`.

    Pattern: `^(?:(?:[1-9]|[1-9][0-9]+)d)?(?:(?:[1-9]|[1-9][0-9]+)h)?(?:(?:[1-9]|[1-9][0-9]+)m)?(?:(?:[1-9]|[1-9][0-9]+)s)?$`

  - **settings.passwordPolicy.lockout.maxAttempts**
    integer

    Required value

    Number of consecutive failed login attempts after which the user will be temporarily locked out.

- **settings.passwordPolicy.passwordHistoryLimit**
  integer

  Number of the user’s previous passwords stored in history to prevent their reuse.

  Default: `5`

  Allowed values: `0 <= X`

- **settings.passwordPolicy.rotation**
  object

  Password rotation settings.

  - **settings.passwordPolicy.rotation.interval**
    string

    Required value

    Time interval after which the password must be changed. Can be set in seconds, minutes, hours or days: `10s`, `5m`, `1h`, `3d`.

    Pattern: `^(?:(?:[1-9]|[1-9][0-9]+)d)?(?:(?:[1-9]|[1-9][0-9]+)h)?(?:(?:[1-9]|[1-9][0-9]+)m)?(?:(?:[1-9]|[1-9][0-9]+)s)?$`

- **settings.publishAPI**
  object

  Settings for exposing the API server using Ingress.

  - **settings.publishAPI.addKubeconfigGeneratorEntry**
    boolean

    Setting it to `false` will remove an entry in kubeconfig-generator.

    Default: `true`

  - **settings.publishAPI.enabled**
    boolean

    Setting it to `true` will create an Ingress resource in the `d8-user-authn` namespace in the cluster (it exposes the Kubernetes API).

    Default: `false`

  - **settings.publishAPI.https**
    object

    The HTTPS mode for the API server Ingress.

    Examples:

```
https:
  mode: SelfSigned
```

```
https:
  mode: Global
  global:
    kubeconfigGeneratorMasterCA: plainstring
```

- **settings.publishAPI.https.global**
  object

  An additional parameter for the `Global` mode.

  - **settings.publishAPI.https.global.kubeconfigGeneratorMasterCA**
    string

    If there is an external load balancer in front of the Ingress that terminates HTTPS traffic using non-public CA, then you need to specify the CA so it will be included in kubectl-config.

    If you are using certificates issued by the `cert-manager` module and Let's Encrypt in your cluster, you should set an empty string `""` as the value.

    Also, you can set the external LB's certificate itself as a CA if you can't get the CA that signed it for some reason. Note that after the certificate is updated on the LB, all the previously generated kubeconfigs will stop working.

- **settings.publishAPI.https.mode**
  string

  The mode of issuing certificates for the Ingress resource.

  In the `SelfSigned` mode, a CA-signed certificate will be issued for the Ingress resource.

  Use the following command to get the certificate: `d8 k -n d8-user-authn get secrets kubernetes-api-ca-key-pair -oyaml`.

  In the `Global` mode, the policies specified in the `global.modules.https.mode` global parameter will be applied. Thus, if the global parameter has the `CertManager` mode set (with `letsencrypt` as the ClusterIssuer), then the Let's Encrypt certificate will be issued for the Ingress resource.

  Default: `SelfSigned`

  Allowed values: `SelfSigned`, `Global`

- **settings.publishAPI.ingressClass**
  string

  The Ingress class that will be used to expose the Kubernetes API via Ingress.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **settings.publishAPI.whitelistSourceRanges**
  array of strings

  An array of CIDRs that are allowed to connect to the API server.

  - **Element of the array**
    string

    Pattern: `^(([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])\.){3}([0-9]|[1-9][0-9]|1[0-9]{2}|2[0-4][0-9]|25[0-5])(\/(3[0-2]|[1-2][0-9]|[0-9]))?$`

- **settings.refreshTokenAbsoluteLifetime**
  string

  Maximum lifetime of refresh tokens (maps to Dex `expiry.refreshTokens.absoluteLifetime`).

  This setting controls how long user sessions can persist. After this period expires, users will need to re-authenticate, even if they have active refresh tokens.

It is specified as a string containing the time unit in hours, minutes and seconds: 30m, 20s, 2h30m10s, 24h.

Default: `4380h`

Pattern: `^([0-9]+h)?([0-9]+m)?([0-9]+s)?$`

- **settings.staticUsers2FA**
  object
  - **settings.staticUsers2FA.enabled**
    boolean

    Required value

    If set to `true`, the static users will be required to use two-factor authentication (2FA) when logging in. This option is useful for enhancing security by requiring an additional verification step during the login process.

    Default: `false`

  - **settings.staticUsers2FA.issuerName**
    string

    The issuer name for the two-factor authentication (2FA) tokens. This name is visible to users in the 2FA application (e.g., Google Authenticator).

    Default: `Deckhouse`

- **settings.tolerations**
  array of objects

  The same as in the Pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  Example:

  ```
  tolerations:
  - key: key1
    operator: Equal
    value: value1
    effect: NoSchedule
  ```

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

The creation of the `DexAuthenticator` Custom Resource leads to the automatic deployment of oauth2-proxy to your application's namespace and connecting it to Dex.

Caution! Since using OpenID Connect over HTTP poses a significant threat to security (the fact that Kubernetes API server doesn't support OICD over HTTP confirms that), this module can only be installed if HTTPS is enabled (to do this, set the `https.mode` parameter to the value other than `Disabled` either at the cluster level or in the module).

Caution! When this module is enabled, authentication in all web interfaces will be switched from HTTP Basic Auth to Dex (the latter, in turn, will use the external providers that you have defined). To configure kubectl, go to `https://kubeconfig.<modules.publicDomainTemplate>/`, log in to your external provider's account and copy the shell commands to your console.

Caution! The API server requires additional configuration to use authentication for dashboard and kubectl. The control-plane-manager module (enabled by default) automates this process.

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

DexAuthenticator

Short names: dex-auth

Scope: Namespaced

- v1
- v2alpha1
- v1alpha1

After the `DexAuthenticator` object appears in the namespace, the following objects will be created:

- Deployment containing OAuth2-Proxy and Redis containers;
- Service, pointing to OAuth2-Proxy;
- Ingress resource, configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- HTTPRoute resource (optional), configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- Secrets, needed to access Dex.

Warning. DexAuthenticator only works with HTTPS. The application Ingress must have TLS configured.

Warning. After restarting a pod with an OAuth2-Proxy, the current Access Token and ID Token will be queried (using the refresh token) and stored in a Redis memory.

Example:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-name
  namespace: app-namespace
spec:
  applicationDomain: app-name.kube.my-domain.com
  sendAuthorizationHeader: false
  applicationIngressCertificateSecretName: ingress-tls
  applicationIngressClassName: nginx
  keepUsersLoggedInFor: 720h
  allowedGroups:
  - everyone
  - admins
  whitelistSourceRanges:
  - 1.1.1.1/32
  - 192.168.0.0/24
  additionalApplications:
  - domain: additional-app-name.kube.my-domain.com
    ingressSecretName: ingress-tls
    ingressClassName: nginx
    signOutURL: "/logout"
    whitelistSourceRanges:
    - 2.2.2.2/32
```

- **spec**
  object

  Required value

  - **spec.additionalApplications**
    array of objects

A list of additional applications for which user authentication is required.

- **spec.additionalApplications.domain**
  string

  Required value

  An application domain from which the user request will be redirected for authentication in Dex.

  > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.ingressClassName**
  string

  Required value

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.ingressSecretName**
  string

  The name of the Secret containing the TLS certificate (from the domain) used in the applications Ingress resource. The Secret must be in the same namespace as DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

- **spec.additionalApplications.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.additionalApplications.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec.allowedEmails**
  array of strings

  A list of emails of users are allowed to connect to the client.

  By default, all users can connect.

  Values must not contain line breaks.

Default: `All emails are allowed.`

- **Element of the array**
  string

  Pattern: `^[^\r\n]*$`

  Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client.

  By default, all groups can connect.

  Values must not contain line breaks.

  Default: `All groups are allowed.`

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `512`

- **spec.applicationDomain**
  string

  Required value

  An address for the application (DNS domain for Ingress resource) from which the user request will be redirected for authentication in Dex.

  > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  applicationDomain: my-app.domain.com
  ```

- **spec.applicationIngressCertificateSecretName**
  string

  The name of the Secret containing the TLS certificate for the application domain (is used in the Ingress resource). The Secret must be located in the same namespace as the DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

  Example:

  ```
  applicationIngressCertificateSecretName: ingress-tls
  ```

- **spec.applicationIngressClassName**
  string

  Required value

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  applicationIngressClassName: nginx
  ```

- **spec.gatewayAPI**
  object

A set of parameters to use in HTTPRoute object.

> **Warning.** Only applicable in clusters with Gateway API support.

> **Warning.** Define the same ListenerSet object which is used to publish the application domain.

- **spec.gatewayAPI.applicationHTTPRouteListenerSetName**
  string

  Required value

  Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `253`

  Example:

  ```
  applicationHTTPRouteListenerSetName: default-listenerset
  ```

- **spec.gatewayAPI.applicationHTTPRouteListenerSetNamespace**
  string

  Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `63`

  Example:

  ```
  applicationHTTPRouteListenerSetNamespace: default
  ```

- **spec.gatewayAPI.applicationHTTPRouteListenerSetSectionName**
  string

  Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `253`

  Example:

  ```
  applicationHTTPRouteListenerSetSectionName: default-listener
  ```

- **spec.highAvailability**
  boolean

  Enables high availability mode for `dex-authenticator`.

  When this mode is enabled, multiple pod replicas will be deployed to ensure fault tolerance.

  Default: `false`

- **spec.keepUsersLoggedInFor**
  string

  Maximum period of user inactivity during which the user session remains active.

  Set as a string specifying hours, minutes, or seconds: `30m`, `20s`, `2h30m10s`, `24h`.

  Specified value can’t be shorter or equal to the `idTokenTTL` value set in the module settings. If you set a value that is shorter or equal to `idTokenTTL`, the effective logout time will be `idTokenTTL + 1s`.

  To force logout sooner than the default `idTokenTTL`, decrease the `idTokenTTL` parameter

value in the module settings as well.

Default: `168h`

Example:

```
keepUsersLoggedInFor: 24h
```

- **spec.nodeSelector**
  object

  If specified, the `dex-authenticator` pods nodeSelector.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resources**
  object

  Container resources (CPU/memory) — requests/limits.

  If this field is set, the specified values are applied and VPA is disabled for this instance. If the field is not set, behavior remains the same: when the VPA module is enabled, resources are managed by VPA, when it is disabled, default values are used.

  Resources can be specified either directly for the `dex-authenticator` container (for backward compatibility) or in nested objects — separately for each container.

  - **spec.resources.limits**
    object

    Upper limit of resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

  - **spec.resources.redis**
    object

    Resources of the `redis` container (CPU/memory) — requests/limits.

    - **spec.resources.redis.limits**
      object

      Upper limit of resources for the `redis` container (CPU/memory)

    - **spec.resources.redis.requests**
      object

      Guaranteed minimum resources for the `redis` container (CPU/memory).

  - **spec.resources.requests**
    object

    Guaranteed minimum resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.sendAuthorizationHeader**
  boolean

  Request to application will be sent with `Authorization: Bearer` header when the option is switched to true.

- **spec.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.tolerations**
  array of objects

If specified the `dex-authenticator` pods tolerations.

Format: the standard toleration list. Instance pods inherit this field as is.

- **spec.tolerations.effect**
  string

  Defines the taint's effect this toleration is associated with (it matches any effect if empty).

  Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

- **spec.tolerations.key**
  string

  Defines the taint's key this toleration is associated with (it matches any key if empty).

  If the key is omitted (emplty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

- **spec.tolerations.operator**
  string

  Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

  Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

  Default: `Equal`

  Allowed values: `Exists`, `Equal`

- **spec.tolerations.tolerationSeconds**
  integer

  Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

  If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

  The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the `operator` parameter is set to `Exists`.

- **spec.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec**
  object

  Required value

  - **spec.allowedEmails**
    array of strings

A list of emails of users are allowed to connect to the client.

By default, all users can connect.

Values must not contain line breaks.

Default: `All users are allowed.`

- **Element of the array**
  string

  Pattern: `^[^\r\n]*$`

  Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client.

  By default, all groups can connect.

  Values must not contain line breaks.

  Default: `All groups are allowed.`

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `512`

- **spec.applications**
  array of objects

  Required value

  A list of applications for which user authentication is required.

  - **spec.applications.domain**
    string

    Required value

    An application domain (for Ingress resources) from which the user request will be redirected for authentication in Dex.

    > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  - **spec.applications.gatewayAPI**
    object

    A set of parameters to use in HTTPRoute object.

    > **Warning.** Only applicable in clusters with Gateway API support.

    > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

    - **spec.applications.gatewayAPI.httpRouteListenerSetName**
      string

      Required value

      Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-`

9])?)*$`

Maximum length: `253`

Example:

```
httpRouteListenerSetName: default-listener-set
```

- **spec.applications.gatewayAPI.httpRouteListenerSetNamespace**
  string

  Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

  If not set, the namespace of the `DeAuthenticator` is used.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `63`

  Example:

  ```
  httpRouteListenerSetNamespace: default
  ```

- **spec.applications.gatewayAPI.httpRouteListenerSetSectionName**
  string

  Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `253`

  Example:

  ```
  httpRouteListenerSetSectionName: web-listener
  ```

- **spec.applications.ingressClassName**
  string

  Required value

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.applications.ingressSecretName**
  string

  The name of the Secret containing the TLS certificate for the application domain (is used in the Ingress resource). The Secret must be located in the same namespace as the DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

- **spec.applications.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.applications.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, if not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec.highAvailability**
  boolean

  Enables high availability mode for `dex-authenticator`.

  When this mode is enabled, multiple pod replicas will be deployed to ensure fault tolerance.

  Default: `false`

- **spec.keepUsersLoggedInFor**
  string

  Maximum period of user inactivity during which the user session remains active.

  Set as a string specifying hours, minutes, or seconds: `30m`, `20s`, `2h30m10s`, `24h`.

  Specified value can’t be shorter or equal to the `idTokenTTL` value set in the module settings. If you set a value that is shorter or equal to `idTokenTTL`, the effective logout time will be `idTokenTTL + 1s`.

  To force logout sooner than the default `idTokenTTL`, decrease the `idTokenTTL` parameter value in the module settings as well.

  Default: `168h`

- **spec.nodeSelector**
  object

  If specified, the `dex-authenticator` pods nodeSelector.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resources**
  object

  Container resources (CPU/memory) — requests/limits.

  If this field is set, the specified values are applied and VPA is disabled for this instance. If the field is not set, behavior remains the same: when the VPA module is enabled, resources are managed by VPA, when it is disabled, default values are used.

  Resources can be specified either directly for the `dex-authenticator` container (for backward compatibility) or in nested objects — separately for each container.

  - **spec.resources.limits**
    object

    Upper limit of resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

  - **spec.resources.redis**
    object

    Resources of the `redis` container (CPU/memory) — requests/limits.

    - **spec.resources.redis.limits**
      object

      Upper limit of resources for the `redis` container (CPU/memory).

    - **spec.resources.redis.requests**

object

Guaranteed minimum resources for the `redis` container (CPU/memory).

- **spec.resources.requests**
  object

  Guaranteed minimum resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.sendAuthorizationHeader**
  boolean

  Request to application will be sent with `Authorization: Bearer` header when the option is switched to true.

- **spec.tolerations**
  array of objects

  If specified the `dex-authenticator` pods tolerations.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Defines the taint's effect this toleration is associated with (it matches any effect if empty).

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string

    Defines the taint's key this toleration is associated with (it matches any key if empty).

    If the key is omitted (emplty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

  - **spec.tolerations.operator**
    string

    Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

    Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

    Default: `Equal`

    Allowed values: `Exists`, `Equal`

  - **spec.tolerations.tolerationSeconds**
    integer

    Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

    If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

    The default is: not set.

  - **spec.tolerations.value**
    string

    The value that the toleration must match.

    Must be empty if the `operator` parameter is set to `Exists`.

Deprecated resource. Support for the resource might be removed in a later release.

After the `DexAuthenticator` object appears in the namespace, the following objects will be created:

- Deployment containing OAuth2-Proxy and Redis containers;
- Service, pointing to OAuth2-Proxy;
- Ingress resource, configured to receive requests on `https://<applicationDomain>/dex-`

`authenticator` and send it to a service side;
- HTTPRoute resource (optional), configured to receive requests on `https://<applicationDomain>/dex-authenticator` and send it to a service side;
- Secrets, needed to access Dex.

Warning. DexAuthenticator only works with HTTPS. The application Ingress must have TLS configured.

Warning. After restarting a pod with an OAuth2-Proxy, the current Access Token and ID Token will be queried (using the refresh token) and stored in a Redis memory.

Example:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  name: app-name
  namespace: app-namespace
spec:
  applicationDomain: app-name.kube.my-domain.com
  sendAuthorizationHeader: false
  applicationIngressCertificateSecretName: ingress-tls
  applicationIngressClassName: nginx
  keepUsersLoggedInFor: 720h
  allowedGroups:
  - everyone
  - admins
  whitelistSourceRanges:
  - 1.1.1.1/32
  - 192.168.0.0/24
  additionalApplications:
  - domain: additional-app-name.kube.my-domain.com
    ingressSecretName: ingress-tls
    ingressClassName: nginx
    signOutURL: "/logout"
    whitelistSourceRanges:
    - 2.2.2.2/32
```

- **spec**
  object

  Required value

  - **spec.additionalApplications**
    array of objects

    A list of additional applications for which user authentication is required.

    - **spec.additionalApplications.domain**
      string

      Required value

      An application domain from which the user request will be redirected for authentication in Dex.

      > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

      Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    - **spec.additionalApplications.ingressClassName**
      string

      Required value

      The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

- **spec.additionalApplications.ingressSecretName**
  string

  The name of the Secret containing the TLS certificate (from the domain) used in the applications Ingress resource. The Secret must be in the same namespace as DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

- **spec.additionalApplications.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.additionalApplications.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

  ```
  whitelistSourceRanges:
  - 192.168.42.0/24
  ```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

- **spec.allowedEmails**
  array of strings

  A list of emails of users are allowed to connect to the client.

  By default, all users can connect.

  Values must not contain line breaks.

  Default: `All emails are allowed.`

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client.

  By default, all groups can connect.

  Values must not contain line breaks.

  Default: `All groups are allowed.`

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

Maximum length: `512`

- **spec.applicationDomain**
  string

  Required value

  An address for the application (DNS domain for Ingress resource) from which the user request will be redirected for authentication in Dex.

  > **Warning.** Specify a DNS name that complies with RFC 1123 (subdomain) and does not include an HTTP scheme. IP addresses are not allowed.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  applicationDomain: my-app.domain.com
  ```

- **spec.applicationIngressCertificateSecretName**
  string

  The name of the Secret containing the TLS certificate for the application domain (is used in the Ingress resource). The Secret must be located in the same namespace as the DexAuthenticator.

  Pattern: `^(|[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)$`

  Example:

  ```
  applicationIngressCertificateSecretName: ingress-tls
  ```

- **spec.applicationIngressClassName**
  string

  Required value

  The name of the Ingress class to be used in the Ingress resource (it must match the Ingress class name for the application domain).

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Example:

  ```
  applicationIngressClassName: nginx
  ```

- **spec.gatewayAPI**
  object

  A set of parameters to use in HTTPRoute object.

  > **Warning.** Only applicable in clusters with Gateway API support.

  > **Warning.** Define the same ListenerSet object which is used to publish the application domain.

  - **spec.gatewayAPI.applicationHTTPRouteListenerSetName**
    string

    Required value

    Name of the ListenerSet object from the Gateway API to be referred to from the HTTPRoute.

    Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

    Maximum length: `253`

Example:

```
applicationHTTPRouteListenerSetName: default-listenerset
```

- **spec.gatewayAPI.applicationHTTPRouteListenerSetNamespace**
  string

  Namespace where the ListenerSet object from the Gateway API is deployed to be referred to from the HTTPRoute.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `63`

  Example:

  ```
  applicationHTTPRouteListenerSetNamespace: default
  ```

- **spec.gatewayAPI.applicationHTTPRouteListenerSetSectionName**
  string

  Section name from the ListenerSet object in the Gateway API the HTTPRoute refers to.

  Pattern: `^[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*$`

  Maximum length: `253`

  Example:

  ```
  applicationHTTPRouteListenerSetSectionName: default-listener
  ```

- **spec.highAvailability**
  boolean

  Enables high availability mode for `dex-authenticator`.

  When this mode is enabled, multiple pod replicas will be deployed to ensure fault tolerance.

  Default: `false`

- **spec.keepUsersLoggedInFor**
  string

  Maximum period of user inactivity during which the user session remains active.

  Set as a string specifying hours, minutes, or seconds: `30m`, `20s`, `2h30m10s`, `24h`.

  Specified value can’t be shorter or equal to the `idTokenTTL` value set in the module settings. If you set a value that is shorter or equal to `idTokenTTL`, the effective logout time will be `idTokenTTL + 1s`.

  To force logout sooner than the default `idTokenTTL`, decrease the `idTokenTTL` parameter value in the module settings as well.

  Default: `168h`

  Example:

  ```
  keepUsersLoggedInFor: 24h
  ```

- **spec.nodeSelector**
  object

  If specified, the `dex-authenticator` pods nodeSelector.

  Format: the standard `nodeSelector` list. Instance pods inherit this field as is.

- **spec.resources**
  object

  Container resources (CPU/memory) — requests/limits.

  If this field is set, the specified values are applied and VPA is disabled for this instance. If the field is not set, behavior remains the same: when the VPA module is enabled, resources are managed by VPA, when it is disabled, default values are used.

Resources can be specified either directly for the `dex-authenticator` container (for backward compatibility) or in nested objects — separately for each container.

- **spec.resources.limits**
  object

  Upper limit of resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.resources.redis**
  object

  Resources of the `redis` container (CPU/memory) — requests/limits.

  - **spec.resources.redis.limits**
    object

    Upper limit of resources for the `redis` container (CPU/memory)

  - **spec.resources.redis.requests**
    object

    Guaranteed minimum resources for the `redis` container (CPU/memory).

- **spec.resources.requests**
  object

  Guaranteed minimum resources for the `dex-authenticator` container (CPU/memory). This field is kept for backward compatibility.

- **spec.sendAuthorizationHeader**
  boolean

  Request to application will be sent with `Authorization: Bearer` header when the option is switched to true.

- **spec.signOutURL**
  string

  The URL of the application from which requests will be redirected to the sign-out URL of the `dex-authenticator`.

  It is used in the application to direct logout requests. A separate Ingress resource will be created for the specified URL, and requests to it will be redirected to `dex-authenticator`.

  The value must not contain line breaks.

  Pattern: `^[^\r\n]*$`

  Maximum length: `2048`

- **spec.tolerations**
  array of objects

  If specified the `dex-authenticator` pods tolerations.

  Format: the standard toleration list. Instance pods inherit this field as is.

  - **spec.tolerations.effect**
    string

    Defines the taint’s effect this toleration is associated with (it matches any effect if empty).

    Allowed values: `NoSchedule`, `PreferNoSchedule`, `NoExecute`

  - **spec.tolerations.key**
    string

    Defines the taint’s key this toleration is associated with (it matches any key if empty).

    If the key is omitted (emplty), then `operator` must be set to `Exists` (which means it matches any `value` and `key`).

  - **spec.tolerations.operator**
    string

    Defines how the key and its value are linked — whether the key must be `Equal` to the value or can have any value.

Setting it to `Exists` is equivalent to the value having any value so that the pod with the specified toleration can match the corresponding taint.

Default: `Equal`

Allowed values: `Exists`, `Equal`

- **spec.tolerations.tolerationSeconds**
  integer

  Specifies the period (in seconds) that the scheduler waits before evicting a Pod from a node if the toleration no longer matches the taint (**only** applicable to the `NoExecute` effect, otherwise ignored).

  If the parameter **is not set**, the Pod will not be evicted from the node if the toleration no longer matches the taint. If the parameter **is set to zero** (or negative), the Pod will be evicted immediately if the toleration no longer matches the taint.

  The default is: not set.

- **spec.tolerations.value**
  string

  The value that the toleration must match.

  Must be empty if the `operator` parameter is set to `Exists`.

- **spec.whitelistSourceRanges**
  array of strings

  CIDRs that are allowed to authenticate. Authentication is allowed without IP address restrictions, If not specified.

  Example:

```
whitelistSourceRanges:
- 192.168.42.0/24
```

  - **Element of the array**
    string

    Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}/[0-9]{1,2}$`

DexClient

Scope: Namespaced

- v1
- v1alpha1

Allows applications that support DC authentication to interact with Dex.

After the `DexClient` object appears in the cluster:

- Dex will register a client with a `dex-client-<NAME>@<NAMESPACE>` **clientID**, where `<NAME>` and `<NAMESPACE>` are `metadata.name` and `metadata.namespace` of the DexClient object, respectively.
- A `dex-client-<NAME>` Secret containing the client access password (**clientSecret**) will be created in the corresponding namespace (where `<NAME>` is `metadata.name` of the DexClient object).

Usage example...

- **spec**
  object

  Required value

  - **spec.allowedEmails**
    array of strings

    A list of emails of users are allowed to connect to the client.

    By default, all users can connect.

    Values must not contain line breaks.

Default: `All users are allowed.`

- **Element of the array**
  string

  Pattern: `^[^\r\n]*$`

  Maximum length: `320`

- **spec.allowedGroups**
  array of strings

  A list of groups whose members are allowed to connect to the client; **By default**, all groups can connect.

  Values must not contain line breaks.

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `512`

- **spec.redirectURIs**
  array of strings

  Array or urls that Dex can redirect to after successful authentication.

  Values must not contain line breaks.

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `2048`

- **spec.secretMetadata**
  object

  A list of labels and an annotations that will be transferred to the metadata secrets of the DexClient resource.

  - **spec.secretMetadata.annotations**
    object
  - **spec.secretMetadata.labels**
    object

- **spec.trustedPeers**
  array of strings

  OAuth2 client IDs that allowed cross authentication with the current client.

  Values must not contain line breaks.

  Details...

  - **Element of the array**
    string

    Pattern: `^[^\r\n]*$`

    Maximum length: `256`

Deprecated resource. Support for the resource might be removed in a later release.

Allows applications that support DC authentication to interact with Dex.

After the `DexClient` object appears in the cluster:

- Dex will register a client with a `dex-client-<NAME>@<NAMESPACE>` **clientID**, where `<NAME>` and `<NAMESPACE>` are `metadata.name` and `metadata.namespace` of the DexClient object, respectively.
- A `dex-client-<NAME>` Secret containing the client access password (**clientSecret**) will be created in the corresponding namespace (where `<NAME>` is `metadata.name` of the DexClient object).

Usage example...

- **spec**
  object

  Required value

  - **spec.allowedEmails**
    array of strings

    A list of emails of users are allowed to connect to the client.

    By default, all users can connect.

    Values must not contain line breaks.

    Default: `All users are allowed.`

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `320`

  - **spec.allowedGroups**
    array of strings

    A list of groups whose members are allowed to connect to the client; **By default**, all groups can connect.

    Values must not contain line breaks.

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `512`

  - **spec.redirectURIs**
    array of strings

    Array or urls that Dex can redirect to after successful authentication.

    Values must not contain line breaks.

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `2048`

  - **spec.secretMetadata**
    object

    A list of labels and an annotations that will be transferred to the metadata secrets of the DexClient resource.

    - **spec.secretMetadata.annotations**
      object
    - **spec.secretMetadata.labels**
      object
  - **spec.trustedPeers**
    array of strings

    OAuth2 client IDs that allowed cross authentication with the current client.

    Values must not contain line breaks.

    Details…

    - **Element of the array**
      string

      Pattern: `^[^\r\n]*$`

      Maximum length: `256`

DexProvider

Scope: Cluster

- v1
- v1alpha1

Defines the configuration for connecting a third-party provider.

With it, you can flexibly configure the integration of the account directory with Kubernetes.

Usage example…

Warning. It is forbidden to use users and groups with the `system:` prefix. Authentication attempts by such users or members of such groups will be rejected, and a corresponding warning will appear in the `kube-apiserver` logs.

- **spec**
  object

  Required value

  - **spec.bitbucketCloud**
    object

    Parameters of the Bitbucket Cloud (intended for the `type: BitbucketCloud`).

    - **spec.bitbucketCloud.clientID**
      string

      Required value

      Team application ID from BitbucketCloud (Key).

    - **spec.bitbucketCloud.clientSecret**
      string

      Required value

      Team application secret key from BitbucketCloud.

    - **spec.bitbucketCloud.includeTeamGroups**
      boolean

      Optional parameter to include team groups.

      If enabled, the groups claim of Dex id_token will looks like this:

      ```
      ["my_team", "my_team/administrators", "my_team/members"]
      ```

      Default: `false`

    - **spec.bitbucketCloud.teams**
      array of strings

      A list of allowed Bitbucket Cloud teams (filter).

      The user token will contain a set intersection of Bitbucket Cloud teams and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

      The user token will contain the user teams in the `groups` claim (similar to other providers).

  - **spec.crowd**
    object

    Parameters of the Crowd (intended for the `type: Crowd`).

    - **spec.crowd.baseURL**
      string

      Required value

      Base part of Attlassian Crowd URL.

      Example:

      ```
      baseURL: https://crowd.example.com/crowd
      ```

        - **spec.crowd.clientID**
          string

          Required value

          Application ID from Atlassian Crowd (Application Name).

        - **spec.crowd.clientSecret**
          string

          Required value

          Application secret key from Atlassian Crowd (Password).

        - **spec.crowd.enableBasicAuth**
          boolean

          Enables basic authorization for the Kubernetes API server.

          The username and password of the user from the application created in Crowd are used as credentials for basic authorization (you can enable it only if there is just one provider of the OIDC/Crowd type). Works **only** if the `publishAPI` is enabled.

          Authorization and group data obtained from an IdP are stored in the cache for 10 seconds.

        - **spec.crowd.groups**
          array of strings

          A list of allowed Crowd groups (filter).

          The user token will contain a set intersection of Crowd groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

          The user token will contain all Crowd groups if the parameter is not set.

        - **spec.crowd.usernamePrompt**
          string

          Prompt for username field.

          Default: `Crowd username`

    - **spec.displayName**
      string

      Required value

      The provider name to show on the authentication provider selection page. The selection page will not be displayed if there is only one provider configured.

    - **spec.enabled**
      boolean

      When false, this provider is ignored by Dex config renderer.

      Default: `true`

    - **spec.github**
      object

      Parameters of the GitHub provider (intended for the `type: Github` case only).

        - **spec.github.clientID**
          string

          Required value

          Organization application ID from GitHub.

        - **spec.github.clientSecret**
          string

          Required value

          Organization application secret key from GitHub.

        - **spec.github.orgs**
          array of objects

Filter for user organizations. ID token will contain only organizations from this list. If the user is not in any organization from this list, an authorization will fail.

By default, all organizations allowed.

- **spec.github.orgs.name**
  string

  Required value

  Name of organization.

- **spec.github.orgs.teams**
  array of strings

  A list of allowed GitHub teams (filter).

  The user token will contain a set intersection of teams from GitHub and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

  The user token will contain all GitHub teams if the parameter is not set.

- **spec.github.teamNameField**
  string

  As an example, group claims for member of ‘Site Reliability Engineers’ in Acme organization would yield:

  - [‘acme:Site Reliability Engineers’] for ‘Name’
  - [‘acme:site-reliability-engineers’] for ‘Slug’
  - [‘acme:Site Reliability Engineers’, ‘acme:site-reliability-engineers’] for ‘Both’

  ‘name’ will be used by default.

  Default: `Name`

  Allowed values: `Name`, `Slug`, `Both`

- **spec.github.useLoginAsID**
  boolean

  Flag which will switch from using the internal GitHub id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.gitlab**
  object

  Parameters of the GitLab provider (intended for the `type: Gitlab` case only).

  - **spec.gitlab.baseURL**
    string

    Base part of GitLab URL.

    Example:

    ```
    baseURL: https://gitlab.example.com
    ```

  - **spec.gitlab.clientID**
    string

    Required value

    Application ID from GitLab.

  - **spec.gitlab.clientSecret**
    string

    Required value

    Application secret key from GitLab.

  - **spec.gitlab.groups**
    array of strings

A list (filter) of allowed GitLab groups (**group paths** and not names).

The user token will contain a set intersection of GitLab groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

The user token will contain all GitLab groups if the parameter is not set;

- **spec.gitlab.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.gitlab.useLoginAsID**
  boolean

  Flag to switch from using the internal GitLab id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.ldap**
  object

  Parameters of the LDAP.

  - **spec.ldap.bindDN**
    string

    The DN for an application service account. The connector uses these credentials to search for users and groups. Not required if the LDAP server provides access for anonymous auth.

    Example:

    ```
    bindDN: uid=serviceaccount,cn=users,dc=example,dc=com
    ```

  - **spec.ldap.bindPW**
    string

    Password for read-only service account. Please note that if the bind password contains a `$`, it has to be saved in an environment variable which should be given as the value to `bindPW`.

    Example:

    ```
    bindPW: password
    ```

  - **spec.ldap.enableBasicAuth**
    boolean

    Enables Basic Authentication for access to the Kubernetes API server.

    The credentials are the Crowd user’s username and password (from the application configured for this provider).

    Limitations:

    - works only when `publishAPI` is enabled;
    - can be enabled for only one OIDC or Crowd provider in the cluster.

    Authentication data and group membership obtained from the IdP are cached for 10 seconds.

  - **spec.ldap.groupSearch**
    object

Group search queries for groups given a user entry. Details

- **spec.ldap.groupSearch.baseDN**
  string

  Required value

  BaseDN to start the search from.

  Example:

  ```
  baseDN: cn=users,dc=example,dc=com
  ```

- **spec.ldap.groupSearch.filter**
  string

  Optional filter to apply when searching the directory.

  Example:

  ```
  filter: "(objectClass=person)"
  ```

- **spec.ldap.groupSearch.nameAttr**
  string

  Required value

  Represents group name.

  Example:

  ```
  nameAttr: name
  ```

- **spec.ldap.groupSearch.userMatchers**
  array of objects

  Required value

  Following list contains field pairs that are used to match a user to a group. It adds a requirement to the filter that an attribute in the group must match the user’s attribute value.

  - **spec.ldap.groupSearch.userMatchers.groupAttr**
    string

    Required value

    The name of the attribute that stores the group member names.

    Example:

    ```
    groupAttr: member
    ```

  - **spec.ldap.groupSearch.userMatchers.userAttr**
    string

    Required value

    The name of the attribute that stores the user name.

    Example:

    ```
    userAttr: uid
    ```

- **spec.ldap.host**
  string

  Required value

  Host and optional port of the LDAP server in the form “host:port”. If the port is not supplied, it will be guessed based on “insecureNoSSL”, and “startTLS” flags. 389 for insecure or StartTLS connections, 636 otherwise.

  Example:

```
host: ldap.example.com:636
```

- **spec.ldap.insecureNoSSL**
  boolean

  Following field is required if the LDAP host is not using TLS (port 389). This option inherently leaks passwords to anyone on the same network as Dex. Equals to false by default.

  Default: `false`

- **spec.ldap.insecureSkipVerify**
  boolean

  If a custom certificate isn’t provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn’t be used outside of explorative phases.

  Default: `false`

- **spec.ldap.kerberos**
  object

  Optional Kerberos (SPNEGO) SSO settings for LDAP.

  - **spec.ldap.kerberos.enabled**
    boolean

    Enable Kerberos SPNEGO flow for this LDAP provider.

    Default: `false`

  - **spec.ldap.kerberos.expectedRealm**
    string

    Optional realm to require (case-insensitive).

  - **spec.ldap.kerberos.fallbackToPassword**
    boolean

    If `true`, in the absence of/incorrect `Authorization: Negotiate` header, a login/password form will be displayed instead of a 401 response with `WWW-Authenticate: Negotiate`.

    Default: `false`

  - **spec.ldap.kerberos.keytabSecretName**
    string

    Name of Secret containing key ‘krb5.keytab’ to mount for Dex.

  - **spec.ldap.kerberos.krb5ConfConfigMapName**
    string

    Optional ConfigMap name containing key ‘krb5.conf’ to mount at /etc/krb5.conf.

  - **spec.ldap.kerberos.krb5ConfSecretName**
    string

    Optional Secret name containing key ‘krb5.conf’ to mount at /etc/krb5.conf.

  - **spec.ldap.kerberos.usernameFromPrincipal**
    string

    How to map Kerberos principal to LDAP username.

    Default: `Localpart`

    Allowed values: `Localpart`, `SAMAccountName`, `UserPrincipalName`

- **spec.ldap.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

```
rootCAData: |
  -----BEGIN CERTIFICATE-----
  MIIFaDC...
  -----END CERTIFICATE-----
```

- **spec.ldap.startTLS**
  boolean

  When connecting to the server, connect using the ldap:// protocol then issue a StartTLS command. If unspecified, connections will use the ldaps:// protocol

  Default: `false`

- **spec.ldap.userSearch**
  object

  Required value

  User search maps a username and password entered by a user to a LDAP entry.
  Details...

  - **spec.ldap.userSearch.baseDN**
    string

    Required value

    BaseDN to start the search from.

    Example:

    ```
    baseDN: cn=users,dc=example,dc=com
    ```

  - **spec.ldap.userSearch.emailAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user email entry. When an email address is not available, use another value unique to the user, like uid.

    Example:

    ```
    emailAttr: mail
    ```

  - **spec.ldap.userSearch.filter**
    string

    Optional filter to apply when searching the directory.

    Example:

    ```
    filter: "(objectClass=person)"
    ```

  - **spec.ldap.userSearch.idAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user id entry.

    Example:

    ```
    idAttr: uid
    ```

  - **spec.ldap.userSearch.nameAttr**
    string

    LDAP attribute that will be matched to Dex user name entry. No default value provided.

    Example:

```
nameAttr: name
```

- **spec.ldap.userSearch.username**
  string

  Required value

  Username attribute used for comparing user entries. This will be translated and combined with the other filter as “(=)".

  Example:

  ```
  username: uid
  ```

- **spec.ldap.usernamePrompt**
  string

  The attribute to display in the provided password prompt. If unset, will display “LDAP Username”.

  Default: `LDAP username`

  Example:

  ```
  usernamePrompt: SSO Username
  ```

- **spec.oidc**
  object

  Parameters of the OIDC (intended for the `type: OIDC`).

  - **spec.oidc.allowedGroups**
    array of strings

    A list of groups the user must belong to in order to authenticate successfully.

    If none of the specified groups match the user’s groups, authentication will be denied.

    If the parameter is omitted, no group-based filtering will be applied.

  - **spec.oidc.basicAuthUnsupported**
    boolean

    Use POST requests to interact with the provider instead of including the token in the Basic Authorization header. Generally, Dex automatically determines the type of request to make, while in some cases enabling this parameter can help.

    Default: `false`

  - **spec.oidc.claimMapping**
    object

    Some providers return non-standard claims (eg. mail). Claim mappings are hints for Dex how to map claims to standard OIDC claims.

    Dex can only map a non-standard claim to a standard one if it’s not included in the id_token returned by OIDC provider.

    - **spec.oidc.claimMapping.email**
      string

      The claim to use as the user email.

      Default: `email`

    - **spec.oidc.claimMapping.groups**
      string

      The claim to use as the user groups.

      Default: `groups`

    - **spec.oidc.claimMapping.preferred_username**
      string

      The claim to use as the user preferred username.

Default: `preferred_username`

- **spec.oidc.claimMappingOverride**
  boolean

  If enabled, the claim mapping will override the standard OIDC claims.

  By default, the claim mapping will be used only if the standard OIDC claims are not present, e.g., if there is no `email` claim in the id_token, the `claimMapping.email` will be used.

  Default: `false`

- **spec.oidc.clientID**
  string

  Required value

  OIDC issuer application ID.

- **spec.oidc.clientSecret**
  string

  Required value

  OIDC issuer application secret key.

- **spec.oidc.enableBasicAuth**
  boolean

  Enables basic authorization for the Kubernetes API server.

  The username and password of the user from the application created in OIDC are used as credentials for basic authorization (you can enable it only if there is just one provider of the OIDC/Crowd type). Works **only** if the publishAPI parameter is enabled.

  Authorization and group data obtained from an IdP are stored in the cache for 10 seconds.

- **spec.oidc.getUserInfo**
  boolean

  Request additional info about the authenticated user.

  Learn more here...

  Default: `false`

- **spec.oidc.insecureSkipEmailVerified**
  boolean

  Allow authentication for clients without verified email address.

  Default: `false`

- **spec.oidc.insecureSkipVerify**
  boolean

  If a custom certificate isn’t provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn’t be used outside of explorative phases.

  Default: `false`

- **spec.oidc.issuer**
  string

  Required value

  Canonical URL of the provider, also used for configuration discovery. This value MUST match the value returned in the provider config discovery.

  Example:

  ```
  issuer: https://accounts.google.com
  ```

- **spec.oidc.promptType**
  string

  Determines if the Issuer should ask for confirmation and provide hints during the

Determines if the Issuer should ask for confirmation and provide hints during the authentication process.

By default, the confirmation will be requested on the first authentication. Possible values may vary depending on the Issuer.

Default: `consent`

- **spec.oidc.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.oidc.scopes**
  array of strings

  List of additional scopes to request in token response.

  A scope is a single token and must not contain whitespace: the OAuth2 protocol passes scopes as a space-delimited list.

  Default: `["openid","profile","email","groups","offline_access"]`

  - **Element of the array**
    string

    Pattern: `^\S+$`

- **spec.oidc.userIDKey**
  string

  The claim to use as the user id.

  Default: `sub`

- **spec.oidc.userNameKey**
  string

  The claim to use as the user name.

  Default: `name`

- **spec.saml**
  object

  Parameters of a SAML provider (intended for the `type: SAML`).

  - **spec.saml.allowedGroups**
    array of strings

    If set, only members of at least one of the listed groups will be allowed to log in.

  - **spec.saml.emailAttr**
    string

    SAML attribute to map to the email claim.

    Default: `email`

  - **spec.saml.entityIssuer**
    string

    Issuer value expected in the SAML response.

    Defaults to the callback URL.

  - **spec.saml.filterGroups**
    boolean

    If `true`, the connector will filter the groups claim to only include groups from the `allowedGroups` list.

Default: `false`

- **spec.saml.groupsAttr**
  string

  SAML attribute to map to the groups claim.

- **spec.saml.groupsDelim**
  string

  Delimiter to split the groups attribute value if it is a single string.

- **spec.saml.insecureSkipSignatureValidation**
  boolean

  Skip signature validation of SAML responses. This is insecure and should only be used for testing.

  Default: `false`

- **spec.saml.nameIDPolicyFormat**
  string

  The NameIDPolicy format to request from the IdP.

  Allowed values: `persistent`, `emailAddress`, `unspecified`, `X509SubjectName`, `WindowsDomainQualifiedName`, `transient`

- **spec.saml.redirectURI**
  string

  Callback URI.

  Overrides the default callback URL. Should be set to `https://<dex-domain>/callback`.

- **spec.saml.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.saml.ssoIssuer**
  string

  Issuer value expected in the SAML response from the IdP.

- **spec.saml.ssoURL**
  string

  Required value

  SSO URL used for POST value.

  Example:

  ```
  ssoURL: https://idp.example.com/saml/sso
  ```

- **spec.saml.usernameAttr**
  string

  SAML attribute to map to the username claim.

  Default: `name`

- **spec.type**
  string

  Required value

Type of authentication provider.

Allowed values: `Github`, `Gitlab`, `BitbucketCloud`, `Crowd`, `OIDC`, `LDAP`, `SAML`

Deprecated resource. Support for the resource might be removed in a later release.

Defines the configuration for connecting a third-party provider.

With it, you can flexibly configure the integration of the account directory with Kubernetes.

Usage example...

- **spec**
  object

  Required value

  - **spec.bitbucketCloud**
    object

    Parameters of the Bitbucket Cloud (intended for the `type: BitbucketCloud`).

    - **spec.bitbucketCloud.clientID**
      string

      Required value

      Team application ID from BitbucketCloud (Key).

    - **spec.bitbucketCloud.clientSecret**
      string

      Required value

      Team application secret key from BitbucketCloud.

    - **spec.bitbucketCloud.includeTeamGroups**
      boolean

      Optional parameter to include team groups.

      If enabled, the groups claim of Dex id_token will looks like this:

      ```
      ["my_team", "my_team/administrators", "my_team/members"]
      ```

      Default: `false`

    - **spec.bitbucketCloud.teams**
      array of strings

      A list of allowed Bitbucket Cloud teams (filter).

      The user token will contain a set intersection of Bitbucket Cloud teams and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

      The user token will contain the user teams in the `groups` claim (similar to other providers).

  - **spec.crowd**
    object

    Parameters of the Crowd (intended for the `type: Crowd`).

    - **spec.crowd.baseURL**
      string

      Required value

      Base part of Attlassian Crowd URL.

      Example:

      ```
      baseURL: https://crowd.example.com/crowd
      ```

    - **spec.crowd.clientID**
      string

Required value

Application ID from Atlassian Crowd (Application Name).

- **spec.crowd.clientSecret**
  string

  Required value

  Application secret key from Atlassian Crowd (Password).

- **spec.crowd.enableBasicAuth**
  boolean

  Enables basic authorization for the Kubernetes API server.

  The username and password of the user from the application created in Crowd are used as credentials for basic authorization (you can enable it only if there is just one provider of the OIDC/Crowd type). Works **only** if the `publishAPI` is enabled.

  Authorization and group data obtained from an IdP are stored in the cache for 10 seconds.

- **spec.crowd.groups**
  array of strings

  A list of allowed Crowd groups (filter).

  The user token will contain a set intersection of Crowd groups and groups from this list. If the set is empty, the authorization will be considered unsuccessful.

  The user token will contain all Crowd groups if the parameter is not set.

- **spec.crowd.usernamePrompt**
  string

  Prompt for username field.

  Default: `Crowd username`

- **spec.displayName**
  string

  Required value

  The provider name to show on the authentication provider selection page. The selection page will not be displayed if there is only one provider configured.

- **spec.enabled**
  boolean

  When false, this provider is ignored by Dex config renderer.

  Default: `true`

- **spec.github**
  object

  Parameters of the GitHub provider (intended for the `type: Github` case only).

  - **spec.github.clientID**
    string

    Required value

    Organization application ID from GitHub.

  - **spec.github.clientSecret**
    string

    Required value

    Organization application secret key from GitHub.

  - **spec.github.orgs**
    array of objects

    Filter for user organizations. ID token will contain only organizations from this list. If the user is not in any organization from this list, an authorization will fail.

By default, all organizations allowed.

- **spec.github.orgs.name**
  string

  Required value

  Name of organization.

- **spec.github.orgs.teams**
  array of strings

  A list of allowed GitHub teams (filter).

  The user token will contain a set intersection of teams from GitHub and teams from this list. If the set is empty, the authorization will be considered unsuccessful.

  The user token will contain all GitHub teams if the parameter is not set.

- **spec.github.teamNameField**
  string

  As an example, group claims for member of ‘Site Reliability Engineers’ in Acme organization would yield:

  - [‘acme:Site Reliability Engineers’] for ‘name’
  - [‘acme:site-reliability-engineers’] for ‘slug’
  - [‘acme:Site Reliability Engineers’, ‘acme:site-reliability-engineers’] for ‘both’

  ‘name’ will be used by default.

  Default: `name`

  Allowed values: `name`, `slug`, `both`

- **spec.github.useLoginAsID**
  boolean

  Flag which will switch from using the internal GitHub id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.gitlab**
  object

  Parameters of the GitLab provider (intended for the `type: Gitlab` case only).

  - **spec.gitlab.baseURL**
    string

    Base part of GitLab URL.

    Example:

    ```
    baseURL: https://gitlab.example.com
    ```

  - **spec.gitlab.clientID**
    string

    Required value

    Application ID from GitLab.

  - **spec.gitlab.clientSecret**
    string

    Required value

    Application secret key from GitLab.

  - **spec.gitlab.groups**
    array of strings

    A list (filter) of allowed GitLab groups (**group paths** and not names).

    The user token will contain a set intersection of GitLab groups and groups from this list.

If the set is empty, the authorization will be considered unsuccessful.

The user token will contain all GitLab groups if the parameter is not set;

- **spec.gitlab.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.gitlab.useLoginAsID**
  boolean

  Flag to switch from using the internal GitLab id to the users handle (@mention) as the user id. It is possible for a user to change their own user name but it is very rare for them to do so.

  Equals to false by default.

- **spec.ldap**
  object

  Parameters of the LDAP.

  - **spec.ldap.bindDN**
    string

    The DN for an application service account. The connector uses these credentials to search for users and groups. Not required if the LDAP server provides access for anonymous auth.

    Example:

    ```
    bindDN: uid=serviceaccount,cn=users,dc=example,dc=com
    ```

  - **spec.ldap.bindPW**
    string

    Password for read-only service account. Please note that if the bind password contains a `$`, it has to be saved in an environment variable which should be given as the value to `bindPW`.

    Example:

    ```
    bindPW: password
    ```

  - **spec.ldap.enableBasicAuth**
    boolean

    Enables Basic Authentication for access to the Kubernetes API server.

    The credentials are the Crowd user’s username and password (from the application configured for this provider).

    Limitations:

    - works only when `publishAPI` is enabled;
    - can be enabled for only one OIDC or Crowd provider in the cluster.

    Authentication data and group membership obtained from the IdP are cached for 10 seconds.

  - **spec.ldap.groupSearch**
    object

    Group search queries for groups given a user entry. Details

    - **spec.ldap.groupSearch.baseDN**
      string

Required value

BaseDN to start the search from.

Example:

```
baseDN: cn=users,dc=example,dc=com
```

- **spec.ldap.groupSearch.filter**
  string

  Optional filter to apply when searching the directory.

  Example:

  ```
  filter: "(objectClass=person)"
  ```

- **spec.ldap.groupSearch.nameAttr**
  string

  Required value

  Represents group name.

  Example:

  ```
  nameAttr: name
  ```

- **spec.ldap.groupSearch.userMatchers**
  array of objects

  Required value

  Following list contains field pairs that are used to match a user to a group. It adds a requirement to the filter that an attribute in the group must match the user’s attribute value.

  - **spec.ldap.groupSearch.userMatchers.groupAttr**
    string

    Required value

    The name of the attribute that stores the group member names.

    Example:

    ```
    groupAttr: member
    ```

  - **spec.ldap.groupSearch.userMatchers.userAttr**
    string

    Required value

    The name of the attribute that stores the user name.

    Example:

    ```
    userAttr: uid
    ```

- **spec.ldap.host**
  string

  Required value

  Host and optional port of the LDAP server in the form “host:port”. If the port is not supplied, it will be guessed based on “insecureNoSSL”, and “startTLS” flags. 389 for insecure or StartTLS connections, 636 otherwise.

  Example:

  ```
  host: ldap.example.com:636
  ```

- **spec.ldap.insecureNoSSL**

boolean

Following field is required if the LDAP host is not using TLS (port 389). This option inherently leaks passwords to anyone on the same network as Dex. Equals to false by default.

Default: `false`

- **spec.ldap.insecureSkipVerify**
  boolean

  If a custom certificate isn’t provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn’t be used outside of explorative phases.

  Default: `false`

- **spec.ldap.kerberos**
  object

  Optional Kerberos (SPNEGO) SSO settings for LDAP.

  - **spec.ldap.kerberos.enabled**
    boolean

    Enable Kerberos SPNEGO flow for this LDAP provider.

    Default: `false`

  - **spec.ldap.kerberos.expectedRealm**
    string

    Optional realm to require (case-insensitive).

  - **spec.ldap.kerberos.fallbackToPassword**
    boolean

    If `true`, in the absence of/incorrect `Authorization: Negotiate` header, a login/password form will be displayed instead of a 401 response with `WWW-Authenticate: Negotiate`.

    Default: `false`

  - **spec.ldap.kerberos.keytabSecretName**
    string

    Name of Secret containing key ‘krb5.keytab’ to mount for Dex.

  - **spec.ldap.kerberos.krb5ConfConfigMapName**
    string

    Optional ConfigMap name containing key ‘krb5.conf’ to mount at /etc/krb5.conf.

  - **spec.ldap.kerberos.krb5ConfSecretName**
    string

    Optional Secret name containing key ‘krb5.conf’ to mount at /etc/krb5.conf.

  - **spec.ldap.kerberos.usernameFromPrincipal**
    string

    How to map Kerberos principal to LDAP username.

    Default: `Localpart`

    Allowed values: `Localpart`, `SAMAccountName`, `UserPrincipalName`

- **spec.ldap.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

```
rootCAData: |
  -----BEGIN CERTIFICATE-----
  MIIFaDC...
  -----END CERTIFICATE-----
```

- **spec.ldap.startTLS**
  boolean

  When connecting to the server, connect using the ldap:// protocol then issue a StartTLS command. If unspecified, connections will use the ldaps:// protocol

  Default: `false`

- **spec.ldap.userSearch**
  object

  Required value

  User search maps a username and password entered by a user to a LDAP entry.
  Details...

  - **spec.ldap.userSearch.baseDN**
    string

    Required value

    BaseDN to start the search from.

    Example:

    ```
    baseDN: cn=users,dc=example,dc=com
    ```

  - **spec.ldap.userSearch.emailAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user email entry. When an email address is not available, use another value unique to the user, like uid.

    Example:

    ```
    emailAttr: mail
    ```

  - **spec.ldap.userSearch.filter**
    string

    Optional filter to apply when searching the directory.

    Example:

    ```
    filter: "(objectClass=person)"
    ```

  - **spec.ldap.userSearch.idAttr**
    string

    Required value

    LDAP attribute that will be matched to Dex user id entry.

    Example:

    ```
    idAttr: uid
    ```

  - **spec.ldap.userSearch.nameAttr**
    string

    LDAP attribute that will be matched to Dex user name entry. No default value provided.

    Example:

    ```
    nameAttr: name
    ```

  - **spec.ldap.userSearch.username**
    string

    Required value

Username attribute used for comparing user entries. This will be translated and combined with the other filter as “(=)".

Example:

```
username: uid
```

- **spec.ldap.usernamePrompt**
  string

  The attribute to display in the provided password prompt. If unset, will display “LDAP Username”.

  Default: `LDAP username`

  Example:

  ```
  usernamePrompt: SSO Username
  ```

- **spec.oidc**
  object

  Parameters of the OIDC (intended for the `type: OIDC`).

  - **spec.oidc.allowedGroups**
    array of strings

    A list of groups the user must belong to in order to authenticate successfully.

    If none of the specified groups match the user’s groups, authentication will be denied.

    If the parameter is omitted, no group-based filtering will be applied.

  - **spec.oidc.basicAuthUnsupported**
    boolean

    Use POST requests to interact with the provider instead of including the token in the Basic Authorization header. Generally, Dex automatically determines the type of request to make, while in some cases enabling this parameter can help.

    Default: `false`

  - **spec.oidc.claimMapping**
    object

    Some providers return non-standard claims (eg. mail). Claim mappings are hints for Dex how to map claims to standard OIDC claims.

    Dex can only map a non-standard claim to a standard one if it’s not included in the id_token returned by OIDC provider.

    - **spec.oidc.claimMapping.email**
      string

      The claim to use as the user email.

      Default: `email`

    - **spec.oidc.claimMapping.groups**
      string

      The claim to use as the user groups.

      Default: `groups`

    - **spec.oidc.claimMapping.preferred_username**
      string

      The claim to use as the user preferred username.

      Default: `preferred_username`

  - **spec.oidc.claimMappingOverride**
    boolean

    If enabled, the claim mapping will override the standard OIDC claims.

By default, the claim mapping will be used only if the standard OIDC claims are not present, e.g., if there is no `email` claim in the id_token, the `claimMapping.email` will be used.

Default: `false`

- **spec.oidc.clientID**
  string

  Required value

  OIDC issuer application ID.

- **spec.oidc.clientSecret**
  string

  Required value

  OIDC issuer application secret key.

- **spec.oidc.enableBasicAuth**
  boolean

  Enables basic authorization for the Kubernetes API server.

  The username and password of the user from the application created in OIDC are used as credentials for basic authorization (you can enable it only if there is just one provider of the OIDC/Crowd type). Works **only** if the publishAPI parameter is enabled.

  Authorization and group data obtained from an IdP are stored in the cache for 10 seconds.

- **spec.oidc.getUserInfo**
  boolean

  Request additional info about the authenticated user.

  Learn more here...

  Default: `false`

- **spec.oidc.insecureSkipEmailVerified**
  boolean

  Allow authentication for clients without verified email address.

  Default: `false`

- **spec.oidc.insecureSkipVerify**
  boolean

  If a custom certificate isn’t provided, this option can be used to turn off TLS certificate checks. As noted, it is insecure and shouldn’t be used outside of explorative phases.

  Default: `false`

- **spec.oidc.issuer**
  string

  Required value

  Canonical URL of the provider, also used for configuration discovery. This value MUST match the value returned in the provider config discovery.

  Example:

  ```
  issuer: https://accounts.google.com
  ```

- **spec.oidc.promptType**
  string

  Determines if the Issuer should ask for confirmation and provide hints during the authentication process.

  By default, the confirmation will be requested on the first authentication. Possible values may vary depending on the Issuer.

  Default: `consent`

- **spec.oidc.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.oidc.scopes**
  array of strings

  List of additional scopes to request in token response.

  A scope is a single token and must not contain whitespace: the OAuth2 protocol passes scopes as a space-delimited list.

  Default: `["openid","profile","email","groups","offline_access"]`

  - **Element of the array**
    string

    Pattern: `^\S+$`

- **spec.oidc.userIDKey**
  string

  The claim to use as the user id.

  Default: `sub`

- **spec.oidc.userNameKey**
  string

  The claim to use as the user name.

  Default: `name`

- **spec.saml**
  object

  Parameters of a SAML provider (intended for the `type: SAML`).

  - **spec.saml.allowedGroups**
    array of strings

    If set, only members of at least one of the listed groups will be allowed to log in.

  - **spec.saml.emailAttr**
    string

    SAML attribute to map to the email claim.

    Default: `email`

  - **spec.saml.entityIssuer**
    string

    Issuer value expected in the SAML response.

    Defaults to the callback URL.

  - **spec.saml.filterGroups**
    boolean

    If `true`, the connector will filter the groups claim to only include groups from the `allowedGroups` list.

    Default: `false`

  - **spec.saml.groupsAttr**
    string

    SAML attribute to map to the groups claim.

- **spec.saml.groupsDelim**
  string

  Delimiter to split the groups attribute value if it is a single string.

- **spec.saml.insecureSkipSignatureValidation**
  boolean

  Skip signature validation of SAML responses. This is insecure and should only be used for testing.

  Default: `false`

- **spec.saml.nameIDPolicyFormat**
  string

  The NameIDPolicy format to request from the IdP.

  Allowed values: `persistent`, `emailAddress`, `unspecified`, `X509SubjectName`, `WindowsDomainQualifiedName`, `transient`

- **spec.saml.redirectURI**
  string

  Callback URI.

  Overrides the default callback URL. Should be set to `https://<dex-domain>/callback`.

- **spec.saml.rootCAData**
  string

  A CA chain to validate the provider in PEM format.

  Example:

  ```
  rootCAData: |
    -----BEGIN CERTIFICATE-----
    MIIFaDC...
    -----END CERTIFICATE-----
  ```

- **spec.saml.ssoIssuer**
  string

  Issuer value expected in the SAML response from the IdP.

- **spec.saml.ssoURL**
  string

  Required value

  SSO URL used for POST value.

  Example:

  ```
  ssoURL: https://idp.example.com/saml/sso
  ```

- **spec.saml.usernameAttr**
  string

  SAML attribute to map to the username claim.

  Default: `name`

- **spec.type**
  string

  Required value

  Type of authentication provider.

  Allowed values: `Github`, `Gitlab`, `BitbucketCloud`, `Crowd`, `OIDC`, `LDAP`, `SAML`

Group

Scope: Cluster
Version: v1alpha1

Contains information about a user group.

- **spec**
  object

  Required value

  - **spec.members**
    array of objects

    Required value

    List of group members.

    - **spec.members.kind**
      string

      Required value

      Type of a group member.

      Allowed values: `User`, `Group`

    - **spec.members.name**
      string

      Required value

      User or group name.

  - **spec.name**
    string

    Required value

    Unique group name.

  - **spec.status**
    object
    - **spec.status.errors**
      array of objects
      - **spec.status.errors.message**
        string
      - **spec.status.errors.objectRef**
        object
        - **spec.status.errors.objectRef.kind**
          string

          Allowed values: `User`, `Group`

        - **spec.status.errors.objectRef.name**
          string

UserOperation

Scope: Cluster

- v1
- v1alpha1

Describes an operation to be applied to a user (password reset, 2FA reset, lock/unlock).

- **spec**
  object

  Required value

  - **spec.initiatorType**
    string

    Indicates who initiated the operation. Possible values:

    - `admin`: By an administrator.
    - `system`: Automatically by the system.
    - `self`: By the user.

- **spec.lock**
  object

  Parameters for locking the user.

  - **spec.lock.for**
    string

    Lock duration. Should be specified in the following format: `30s`, `10m`, `1h`, `2h30m`.

- **spec.resetPassword**
  object

  Parameters for password reset.

  - **spec.resetPassword.newPasswordHash**
    string

    Bcrypt hash of the new password.

- **spec.type**
  string

  Required value

  Type of the user operation. Possible values:

  - `ResetPassword`: Password reset.
  - `Reset2FA`: Two-factor authentication reset.
  - `Lock`: User lock.
  - `Unlock`: User unlock.
- **spec.user**
  string

  Required value

  Name (username) of the target User resource.

  Example:

  ```
  user: jane.doe
  ```

- **status**
  object
  - **status.completedAt**
    string

    Time when the operation was completed.

  - **status.message**
    string

    Optional message about the result or failure of the operation.

  - **status.phase**
    string

    Current phase of the operation. Possible values:

    - `Succeeded`: Operation was completed successfully.
    - `Failed`: Operation failed.

    Allowed values: `Succeeded`, `Failed`

Deprecated resource. Support for the resource might be removed in a later release.

Describes an operation to be applied to a user (password reset, 2FA reset, lock/unlock).

- **spec**
  object

  Required value

  - **spec.initiatorType**
    string

    Indicates who initiated the operation. Possible values:

        - `admin`: By an administrator.
        - `system`: Automatically by the system.
        - `self`: By the user.
    - **spec.lock**
      object

      Parameters for locking the user.

        - **spec.lock.for**
          string

          Lock duration. Should be specified in the following format: `30s`, `10m`, `1h`, `2h30m`.
    - **spec.resetPassword**
      object

      Parameters for password reset.

        - **spec.resetPassword.newPasswordHash**
          string

          Bcrypt hash of the new password.
    - **spec.type**
      string

      Required value

      Type of the user operation. Possible values:

        - `ResetPassword`: Password reset.
        - `Reset2FA`: Two-factor authentication reset.
        - `Lock`: User lock.
        - `Unlock`: User unlock.
    - **spec.user**
      string

      Required value

      Name (username) of the target User resource.

      Example:

      ```
      user: jane.doe
      ```

- **status**
  object
    - **status.completedAt**
      string

      Time when the operation was completed.
    - **status.message**
      string

      Optional message about the result or failure of the operation.
    - **status.phase**
      string

      Current phase of the operation. Possible values:

        - `Succeeded`: Operation completed successfully.
        - `Failed`: Operation failed.

      Allowed values: `Succeeded`, `Failed`

User

Scope: Cluster

- v1
- v1alpha1

Contains information about the static user.

Usage example...

- **spec**
  object

  Required value

  - **spec.email**
    string

    Required value

    User email. Must be in lowercase.

    Caution! Note that if used together with the user-authz module, you must specify an `email` to grant rights to the specific user as the user name in the ClusterAuthorizationRule CR.

    Important! Email addresses are case-insensitive for uniqueness validation. Dex automatically converts emails to lowercase during authentication. For new users, uppercase letters in email addresses are not allowed. Existing users with uppercase emails can be updated without changing the email field.

    Example:

    ```
    email: user@domain.com
    ```

  - **spec.groups**
    Deprecated
    array of strings

    Static user groups.

    Since the parameter has been deprecated, use the Group resource to add users to groups.

  - **spec.password**
    string

    Required value

    User password hash in plaintext or Base64 encoded.

    Use the following command to encode the password hash in Base64: `echo -n '<PASSWORD>' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' | base64 -w0; echo`. Alternatively, you can use an online service (such as https://bcrypt-generator.com/).

    Example:

    ```
    password:
    JDJ5JDEwJGRNWGVGUVBkdUdYYVMyWDFPcGdZdk9HSy81LkdsNm5sdU9mUkhnNWlQdDhuSlh6Szh
    peS5H
    ```

  - **spec.ttl**
    string

    Static user TTL.

    It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

    You can only set the TTL once. The `expireAt` date will not be updated if you change it again.

    Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

    Example:

    ```
    ttl: 24h
    ```

  - **spec.userID**
    Deprecated
    string

    Unique issuer user ID. It equals to .metadata.name.

    Deprecated and shouldn’t be set manually.

- **status**
  object
  - **status.expireAt**
    string

    User account expiration date.

    - It is shown only of the `.spec.ttl` field is set.
    - The user account will be deleted at the specified date.
    - This parameter is synchronized every 5 minutes. There may be a time lag between the moment specified in this field and the moment of actual deletion of the user account.
  - **status.groups**
    array of strings

    Static user groups.

  - **status.lock**
    object

    Information about user account lock. If present, the user cannot authenticate until the specified time or until the lock is manually lifted by an administrator.

    Administrative actions on the account (lock, unlock, forced password reset, 2FA reset) are performed via the UserOperation resource. Self-service password reset by the user is also performed via UserOperation (`initiatorType: self`). When an administrator locks the account or initiates a forced password reset, all of the user's active sessions (Dex `OfflineSessions` and `RefreshToken` objects) are deleted, so the user is forced to re-authenticate; for a forced password reset they are presented with a password change form on the next successful login.

    - **status.lock.message**
      string

      Human-readable explanation of the lock reason.

    - **status.lock.reason**
      string

      Machine-readable reason for the account lock. Used for programmatic checks and policy enforcement.

      Allowed values: `PasswordPolicyLockout`, `LockedByAdministrator`

    - **status.lock.state**
      boolean

      Indicates whether the user account is currently locked.

      - `true` — account is locked.
      - `false` — account is active.
    - **status.lock.until**
      string

      The time until which the user is locked, in RFC3339 format. After this time, the account lock will be automatically lifted.

Deprecated resource. Support for the resource might be removed in a later release.

Contains information about the static user.

Usage example...

- **spec**
  object

  Required value

  - **spec.email**
    string

    Required value

    User email. Must be in lowercase.

    Caution! Note that if used together with the user-authz module, you must specify an `email` to grant rights to the specific user as the user name in the ClusterAuthorizationRule CR.

    Important! Email addresses are case-insensitive for uniqueness validation. Dex

automatically converts emails to lowercase during authentication. For new users, uppercase letters in email addresses are not allowed. Existing users with uppercase emails can be updated without changing the email field.

Example:

```
email: user@domain.com
```

- **spec.groups**
  Deprecated
  array of strings

  Static user groups.

  Since the parameter has been deprecated, use the Group resource to add users to groups.

- **spec.password**
  string

  Required value

  User password hash in plaintext or Base64 encoded.

  Use the following command to encode the password hash in Base64: `echo -n '<PASSWORD>' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' | base64 -w0; echo`. Alternatively, you can use an online service (such as https://bcrypt-generator.com/).

  > **i** **Caution.** If a password policy with complexity checking higher than `None` is used, the user will have to change a password set this way upon their first successful login.

  Example:

  ```
  password:
  JDJ5JDEwJGRNWGVGUVBkdUdYYVMyWDFPcGdZdk9HSy81LkdsNm5sdU9mUkhnNWlQdDhuSlh6SzhpeS5H
  ```

- **spec.ttl**
  string

  Static user TTL.

  It is specified as a string containing the time unit in hours and minutes: 30m, 1h, 2h30m, 24h.

  You can only set the TTL once. The `expireAt` date will not be updated if you change it again.

  Pattern: `^([0-9]+h([0-9]+m)?|[0-9]+m)$`

  Example:

  ```
  ttl: 24h
  ```

- **spec.userID**
  string

  Unique issuer user ID. It equals to .metadata.name by default.

  Example:

  ```
  userID: '08a8684b-db88-4b73-90a9-3cd1661f5466'
  ```

- **status**
  object
  - **status.expireAt**
    string

    User account expiration date.

    - It is shown only of the `.spec.ttl` field is set.
    - The user account will be deleted at the specified date.

        - This parameter is synchronized every 5 minutes. There may be a time lag between the moment specified in this field and the moment of actual deletion of the user account.
    - **status.groups**
      array of strings

      Static user groups.

    - **status.lock**
      object

      Information about user account lock. If present with `state: true`, the user cannot authenticate until the specified time or until the lock is manually lifted by an administrator.

      Administrative actions on the account (lock, unlock, forced password reset, 2FA reset) are performed via the UserOperation resource. Self-service password reset by the user is also performed via UserOperation (`initiatorType: self`). When an administrator locks the account or initiates a forced password reset, all of the user's active sessions (Dex `OfflineSessions` and `RefreshToken` objects) are deleted, so the user is forced to re-authenticate; for a forced password reset they are presented with a password change form on the next successful login.

        - **status.lock.message**
          string

          Human-readable explanation of the lock reason.

        - **status.lock.reason**
          string

          Machine-readable reason for the account lock. Used for programmatic checks and policy enforcement.

          Allowed values: `PasswordPolicyLockout`, `LockedByAdministrator`

        - **status.lock.state**
          boolean

          Indicates whether the user account is currently locked.

            - `true` — account is locked.
            - `false` — account is active.
        - **status.lock.until**
          string

          The time until which the user is locked, in RFC3339 format. After this time, the account lock will be automatically lifted.

Usage

> **i** The module lifecycle stage: General Availability

An example of the module configuration

The example shows the configuration of the `user-authn` module in the Deckhouse Kubernetes Platform.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 2
  enabled: true
  settings:
    kubeconfigGenerator:
    - id: direct
      masterURI: https://159.89.5.247:6443
      description: "Direct access to kubernetes API"
    publishAPI:
      enabled: true
```

Configuring a provider

Checking provider connectivity

The web UI provider details page has a **Check connection** action. It creates a DexProviderCheck resource and waits for the hook to write the result to its status.

The check verifies that:

- the referenced DexProvider exists and is enabled;
- the Dex discovery endpoint inside the cluster is reachable;
- the external provider endpoint is reachable.

For OIDC providers, the check also reads the discovery document and JWKS. For LDAP providers, it verifies TCP/TLS/StartTLS reachability and, when Kerberos is enabled, that the keytab Secret exists. The check does not perform a full login flow and does not validate a test user password.

GitHub

The example shows the provider’s settings for integration with GitHub.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: github
spec:
  type: Github
  displayName: My Company Github
  # Optional: disable the provider without deleting CR
  # enabled: false
  github:
    clientID: plainstring
    clientSecret: plainstring
```

In your GitHub organization, create a new application:

To do this, go to `Settings` -> `Developer settings` -> `OAuth Aps` -> `Register a new OAuth application` and specify the `https://dex.<modules.publicDomainTemplate>/callback` address as the `Authorization callback URL`.

Paste the generated `Client ID` and `Client Secret` into the DexProvider custom resource.

If the GitHub organization is managed by the client, go to `Settings` -> `Applications` -> `Authorized OAuth Apps` -> `<name of created OAuth App>` and request confirmation by clicking on `Send Request`. Then ask the client to confirm the request that will be sent to him by email.

GitLab

The example shows the provider’s settings for integration with GitLab.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: gitlab
spec:
  type: Gitlab
  displayName: Dedicated GitLab
  gitlab:
    baseURL: https://gitlab.example.com
    clientID: plainstring
    clientSecret: plainstring
    groups:
    - administrators
    - users
```

Create a new application in the GitLab project.

To do this, you need to:

- **self-hosted**: go to `Admin area` -> `Application` -> `New application` and specify the `https://dex.<modules.publicDomainTemplate>/callback` address as the `Redirect URI (Callback URL)` and set scopes `read_user`, `openid`;
- **cloud GitLab.com**: under the main project account, go to `User Settings` -> `Application` -> `New application` and specify the `https://dex.<modules.publicDomainTemplate>/callback` address as the `Redirect URI (Callback URL)`; also, don't forget to set scopes `read_user`, `openid`;
- (for GitLab version starting with 16) enable the `Trusted`/`Trusted applications are automatically authorized on GitLab OAuth flow` checkbox when creating an application.

Paste the generated `Application ID` and `Secret` into the DexProvider custom resource.

Atlassian Crowd

The example shows the provider's settings for integration with Atlassian Crowd.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: crowd
spec:
  type: Crowd
  displayName: Crowd
  crowd:
    baseURL: https://crowd.example.com/crowd
    clientID: plainstring
    clientSecret: plainstring
    enableBasicAuth: true
    groups:
    - administrators
    - users
```

Create a new `Generic` application in the corresponding Atlassian Crowd project.

To do this, go to `Applications` -> `Add application`.

Paste the generated `Application Name` and `Password` into the DexProvider custom resource.

CROWD groups are specified in the lowercase format for the custom resource `DexProvider`.

Bitbucket Cloud

The example shows the provider's settings for integration with Bitbucket Cloud.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: bitbucket
spec:
  type: BitbucketCloud
  displayName: Bitbucket
  bitbucketCloud:
    clientID: plainstring
    clientSecret: plainstring
    includeTeamGroups: true
    teams:
    - administrators
    - users
```

Create a new OAuth consumer in the Bitbucket's team menu.

To do this, go to `Settings` -> `OAuth consumers` -> `New application` and specify the `https://dex.<modules.publicDomainTemplate>/callback` address as the `Callback URL`. Also, allow access for `Account: Read` and `Workspace membership: Read`.

Paste the generated `Key` and `Secret` into the DexProvider custom resource.

OIDC (OpenID Connect)

Authentication through the OIDC provider requires registering a client (or "creating an application"). Please refer to the provider's documentation on how to do it (e.g., Okta, Keycloak, Gluu).

Paste the generated `clientID` and `clientSecret` into the DexProvider custom resource.

Keycloak

After selecting a `realm` to configure, adding a user in the Users section, and creating a client in the Clients section with authentication enabled, which is required to generate the `clientSecret`, you need to perform the following steps:

- Create a `scope` named `groups` in the Client scopes section and assign it the predefined mapping `groups`. ("Client scopes" → "Client scope details" → "Mappers" → "Add predefined mappers")
- In the previously created client, add this `scope` in the Client scopes tab ("Clients" → "Client details" → "Client Scopes" → "Add client scope").
- In the "Valid redirect URIs", "Valid post logout redirect URIs", and "Web origins" fields of the client configuration, specify `https://dex.<publicDomainTemplate>/*`, where `publicDomainTemplate` is a value of the parameter in the `global` module config.

The example shows the provider's settings for integration with Keycloak.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: keycloak
spec:
  type: OIDC
  displayName: My Company Keycloak
  oidc:
    issuer: https://keycloak.my-company.com/realms/myrealm # Use the name of your
realm
    clientID: plainstring
    clientSecret: plainstring
    insecureSkipEmailVerified: true
    getUserInfo: true
    scopes:
      - openid
      - profile
      - email
      - groups
```

If email verification is not enabled in Keycloak, to properly use it as an identity provider, adjust the `Client Scopes` settings in one of the following ways:

- Delete the `Email verified` mapping (“Client Scopes” → “Email” → “Mappers”). This is required for proper processing of the `insecureSkipEmailVerified` field when it’s set to `true` and for correct permission assignment to users with unverified emails.
- If you can’t modify or delete the `Email verified` mapping, create a new Client Scope named `email_dkp` (or any other name) and add two mappings:
  - `email`: “Client Scopes” → `email_dkp` → “Add mapper” → “From predefined mappers” → `email`.
  - `email verified`: “Client Scopes” → `email_dkp` → “Add mapper” → “By configuration” → “Hardcoded claim”. Specify the following fields:
    - “Name”: `email verified`
    - “Token Claim Name”: `emailVerified`
    - “Claim value”: `true`
    - “Claim JSON Type”: `boolean`

  After that, in the client registered for the DKP cluster in “Clients”, change `Client scopes` from `email` to `email_dkp`.

  In the DexProvider resource, specify `insecureSkipEmailVerified: true` and in the `.spec.oidc.scopes` field, change the Client Scope name to `email_dkp` following the example:

  ```
  scopes:
    - openid
    - profile
    - email_dkp
    - groups
  ```

Okta

The example shows the provider’s settings for integration with Okta.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: okta
spec:
  type: OIDC
  displayName: My Company Okta
  oidc:
    issuer: https://my-company.okta.com
    clientID: plainstring
    clientSecret: plainstring
    insecureSkipEmailVerified: true
    getUserInfo: true
```

Blitz Identity Provider

Note that you must specify a URL to redirect the user after authorization when registering the application with the Blitz Identity Provider. When using `DexProvider`, you must specify `https://dex.<publicDomainTemplate>/`, where `publicDomainTemplate` is the cluster's DNS name template as defined in the `global` module.

The example below shows the provider settings for integration with Blitz Identity Provider.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: blitz
spec:
  displayName: Blitz Identity Provider
  oidc:
    basicAuthUnsupported: false
    claimMapping:
      email: email
      groups: your_claim # Claim for getting user groups, configured on the Blitz
    clientID: clientID
    clientSecret: clientSecret
    getUserInfo: true
    insecureSkipEmailVerified: true # Set to true if there is no need to verify the
user's email
    insecureSkipVerify: false
    issuer: https://yourdomain.idblitz.ru/blitz
    promptType: consent
    scopes:
    - profile
    - openid
    userIDKey: sub
    userNameKey: email
  type: OIDC
```

For the application logout to work correctly (the token being revoked so that re-authorization is required), set `login` as the value of the 'promptType` parameter.

To ensure granular user access to applications, you have to:

- Add the `allowedUserGroups` parameter to the `ModuleConfig` of the target application.
- Add the user to the groups (group names should be the same for Blitz and Deckhouse).

Below is an example for prometheus:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: prometheus
spec:
  version: 2
  settings:
    auth:
      allowedUserGroups:
        - adm-grafana-access
        - grafana-access
```

LDAP

The example shows the provider's settings for integration with Active Directory.

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: active-directory
spec:
  type: LDAP
  displayName: Active Directory
  ldap:
    host: ad.example.com:636
    insecureSkipVerify: true

    bindDN: cn=Administrator,cn=users,dc=example,dc=com
    bindPW: admin0!

    usernamePrompt: Email Address

    enableBasicAuth: true

    userSearch:
      baseDN: cn=Users,dc=example,dc=com
      filter: "(objectClass=person)"
      username: userPrincipalName
      idAttr: DN
      emailAttr: userPrincipalName
      nameAttr: cn

    groupSearch:
      baseDN: cn=Users,dc=example,dc=com
      filter: "(objectClass=group)"
      userMatchers:
      - userAttr: DN
        groupAttr: member
      nameAttr: cn
```

Configuring Basic Authentication

To enable Basic Authentication for the Kubernetes API using LDAP credentials:

1. Ensure that the `publishAPI` parameter is enabled in the `user-authn` module configuration.
2. Set `enableBasicAuth: true` in your LDAP DexProvider resource.

> **Warning**. Only one provider in the cluster can have `enableBasicAuth` enabled.

After configuration, users can access the Kubernetes API via `kubectl`, using their LDAP username and

password.

Example `kubeconfig` for the user:

```
apiVersion: v1
kind: Config
clusters:
- name: my-cluster
  cluster:
    server: https://api.example.com
    # Path to CA certificate or insecure-skip-tls-verify: true
    certificate-authority: /path/to/ca.crt
users:
- name: ldap-user
  user:
    username: janedoe@example.com
    password: userpassword
contexts:
- name: default
  context:
    cluster: my-cluster
    user: ldap-user
current-context: default
```

Kerberos (SPNEGO) SSO for LDAP

Dex supports passwordless Kerberos (SPNEGO) flow for the LDAP connector. When enabled, a browser that trusts the Dex host will send `Authorization: Negotiate …` and Dex will validate the Kerberos ticket using a service keytab, skip the login form, map the Kerberos principal to an LDAP username, query groups, and complete the OIDC flow.

Minimal example extending the LDAP provider spec:

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: active-directory
spec:
  type: LDAP
  displayName: Active Directory
  ldap:
    host: ad.example.com:636
    bindDN: cn=Administrator,cn=users,dc=example,dc=com
    bindPW: admin0!
    userSearch:
      baseDN: cn=Users,dc=example,dc=com
      username: sAMAccountName
      idAttr: uid
      emailAttr: mail
      nameAttr: cn
    groupSearch:
      baseDN: cn=Users,dc=example,dc=com
      nameAttr: cn
      userMatchers:
      - userAttr: uid
        groupAttr: memberUid
    kerberos:
      enabled: true
      keytabSecretName: dex-kerberos-keytab  # Secret in d8-user-authn with key
'krb5.keytab'
      expectedRealm: EXAMPLE.COM           # optional, case-insensitive match
      usernameFromPrincipal: sAMAccountName  #
localpart|sAMAccountName|userPrincipalName
      fallbackToPassword: false            # default false; if true, render form when
header missing/invalid
```

Notes:

- The Secret `dex-kerberos-keytab` must exist in the `d8-user-authn` namespace and have a data key named exactly `krb5.keytab`.
- A single Dex Pod can serve multiple LDAP+Kerberos providers. Each provider mounts its own keytab; a shared `krb5.conf` is not required (Dex validates tickets offline using the keytab). To configure authentication, create a read-only user (service account) in LDAP.

Specify the generated user path and password in the `bindDN` and `bindPW` fields of the DexProvider custom resource. Enter the password into the `bindPW` in plain-text format (unencrypted). Strategies involving the passing of hashed passwords are not supported.

You can omit these settings if anonymous read access is configured for LDAP.

SAML

The example shows the provider’s settings for integration with a SAML 2.0 Identity Provider (e.g., AD FS, Okta, Keycloak).

```
apiVersion: deckhouse.io/v1
kind: DexProvider
metadata:
  name: saml-provider
spec:
  type: SAML
  displayName: Corporate SAML
  saml:
    ssoURL: https://saml-idp.example.com/saml/sso
    rootCAData: |
      -----BEGIN CERTIFICATE-----
      MIIFaDC...
      -----END CERTIFICATE-----
    entityIssuer: https://dex.example.com/callback
    ssoIssuer: https://saml-idp.example.com
    usernameAttr: name
    emailAttr: email
    groupsAttr: groups
    nameIDPolicyFormat: persistent
```

To configure the SAML Identity Provider:

1. Register Dex as a Service Provider (SP) with your identity provider using the following settings:
   - **ACS URL (Assertion Consumer Service)**: `https://dex.<modules.publicDomainTemplate>/callback`
   - **Entity ID**: `https://dex.<modules.publicDomainTemplate>/callback`
   - **Name identifier format**: `persistent` or `emailAddress`
2. Configure attribute mapping in the identity provider to send `email`, `name` (username), and `groups` attributes in the SAML assertion.
3. Export the identity provider signing certificate and specify it in the `rootCAData` field of the DexProvider resource.

> **i** SAML does not natively support refresh tokens. Dex caches the user identity from the initial SAML assertion and returns it on subsequent refresh requests. The session lifetime is controlled by the `expiry.refreshTokens` settings in the `user-authn` module configuration.

Configuring the OAuth2 client in Dex for connecting an application

This configuration is suitable for applications that can independently perform oauth2 authentication without using an oauth2 proxy. The `DexClient` custom resource enables applications to use dex.

```
apiVersion: deckhouse.io/v1
kind: DexClient
metadata:
  name: myname
  namespace: mynamespace
spec:
  redirectURIs:
  - https://app.example.com/callback
  - https://app.example.com/callback-reserve
  allowedGroups:
  - Everyone
  - admins
  trustedPeers:
  - opendistro-sibling
```

After the `DexClient` custom resource is created, Dex will register a client with a `dex-client-myname@mynamespace` ID (**clientID**).

The client access password (**clientSecret**) will be stored in the secret object:

```
apiVersion: v1
kind: Secret
metadata:
  name: dex-client-myname
  namespace: mynamespace
type: Opaque
data:
  clientSecret: c2VjcmV0
```

Granting an application access to the Kubernetes API

A DexClient or a DexAuthenticator can be allowed to obtain tokens that the Kubernetes API server accepts. To do that, set one of the following annotations on the resource to `"true"`:

- `dexclient.deckhouse.io/allow-access-to-kubernetes` on a DexClient.
- `dexauthenticator.deckhouse.io/allow-access-to-kubernetes` on a DexAuthenticator.

The following is a DexClient configuration example:

```
apiVersion: deckhouse.io/v1
kind: DexClient
metadata:
  name: myname
  namespace: mynamespace
  annotations:
    dexclient.deckhouse.io/allow-access-to-kubernetes: "true"
spec:
  redirectURIs:
  - https://app.example.com/callback
```

The annotation registers the client as a trusted peer of the privileged `kubernetes` OAuth2 client, allowing it to request ID tokens intended for the API server. In such a token, the username is determined by the `email` claim and groups by the `groups` claim. As a result, the application accesses the API server on behalf of the authenticated user and with the permissions granted to that user.

⚠ Access granted this way applies at the cluster level, even though DexClient and DexAuthenticator are namespaced resources. Therefore, only a subject with permissions to modify the `user-authn` module configuration can add the annotation or change its value to `"true"`. For example, this permission is granted by the `d8:manage:permission:module:user-authn:edit` role. Permissions to create DexClient or DexAuthenticator resources in an individual namespace are not sufficient.

Adding the annotation is restricted regardless of its value, including `"false"`. This is required for compatibility with DKP versions earlier than 1.78, where access is granted based on the presence of the annotation regardless of its value. If access to the Kubernetes API server is not required, do not add the annotation.

The restriction does not apply to resources that already have the annotation. A user with permissions to modify such a resource can continue to modify it, including removing the annotation or changing its value to disable access.

Local Authentication

Local authentication provides user verification and access management with support for configurable password policies, two-factor authentication (2FA), and group management.
The implementation complies with OWASP recommendations, ensuring reliable protection of access to the cluster and applications without requiring integration with external authentication systems.

Creating a user

Create a password and enter its hash encoded in base64 in the `password` field. The email address must be in lowercase.

Use the command below to calculate the password hash:

```
echo -n '3xAmpl3Pa$$wo#d' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' | base64 -w0;
echo
```

> **i** If the `htpasswd` command is not available, install the appropriate package:
>
> - `apache2-utils` — for Debian-based distributions.
> - `httpd-tools` — for CentOS-based distributions.
> - `apache2-htpasswd` — for ALT Linux.

Alternatively, you can use the online service to calculate the password hash.

Note that in the below example the `ttl` parameter is set.

```
apiVersion: deckhouse.io/v1
kind: User
metadata:
  name: admin
spec:
  email: admin@yourcompany.com
  # echo -n '3xAmpl3Pa$$wo#d' | htpasswd -BinC 10 "" | cut -d: -f2 | tr -d '\n' |
base64 -w0; echo
  password:
'JDJ5JDEwJGRNWGVGUVBkdUdYYVMyWDFPcGdZdk9HSy81LkdsNm5sdU9mUkhnNWlQdDhuSlh6SzhpeS5H'
  ttl: 24h
```

Authorization rules grant permissions to users based on the email address from the issued token. Therefore, a User resource cannot be created if its `spec.email` value matches a `User` subject in an existing AuthorizationRule or ClusterAuthorizationRule resource. This prevents permissions from being unintentionally granted to a new user.

If the match is intentional, for example, if the authorization rule was created in advance, use a different email address or add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the User resource.

Email addresses are converted to lowercase when matched, as this is how they are stored in the token. For example, `Admin@Example.com` matches the `admin@example.com` subject.

The restriction does not apply to existing users whose email addresses match subjects in authorization rules. Such users continue to work, and a warning is issued when a match is detected.

Consider this restriction when managing users and authorization rules declaratively. If a user and the corresponding rule are created at the same time, the rule may be created first, causing creation of the User resource to be rejected. To allow such a match, add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the User manifest.

Deleting a user does not automatically remove the corresponding subject from the authorization rule. As long as the subject remains in the rule, permissions continue to be granted to the specified email address, and a warning is issued that no corresponding user exists. If a user with the same email address is created later, that user receives these permissions. If this behavior is not required, remove the corresponding subject from the authorization rule.

Local user operations

Password reset, 2FA reset, and lock/unlock operations are performed via the UserOperation resource. The `initiatorType` field indicates who initiated the operation: an administrator (`admin`), the system (`system`), or the user (`self`).

Administrative operations

Use the `d8 iam user` commands for administrative actions on local users. They create a UserOperation resource with `initiatorType: admin`, wait for the operation to complete, and print the result.

The `ResetPassword`, `Reset2FA`, and `Lock` operations delete the user's Dex OfflineSessions and RefreshToken objects. This terminates the user's active offline sessions and requires re-authentication.

Interactive password reset example:

```
d8 iam user reset-password admin
```

Example of reading the new password from stdin:

```
echo "N3wPa$$wo#d" | d8 iam user reset-password admin --password-stdin
```

Example of generating a new password automatically:

```
d8 iam user reset-password admin --generate-password
```

If the password is already hashed, pass the bcrypt hash without Base64 encoding:

```
d8 iam user reset-password admin --password-hash '$2y$10$abcdef...'
```

2FA reset example:

```
d8 iam user reset2fa admin
```

Example of locking a user for 30 minutes:

```
d8 iam user lock admin 30m
```

User unlock example:

```
d8 iam user unlock admin
```

By default, commands wait for the operation to complete. To only create a UserOperation and print its name, use the `--wait=false` flag.

Self-service password reset

A local user can reset their own password in the DKP authentication interface. This creates a UserOperation resource with `type: ResetPassword` and `initiatorType: self`.

Self-service password reset is available only for local accounts (the built-in `Local` connector). Users who sign in through external authentication providers must contact the administrator of the corresponding system.

When a user resets their password, the new password must comply with the password policy, and the user’s active sessions are terminated — re-authentication is required.

Adding a user to a group

Users can be grouped to manage access rights. Example manifest of the Group resource for a group:

```
apiVersion: deckhouse.io/v1alpha1
kind: Group
metadata:
  name: admins
spec:
  name: admins
  members:
    - kind: User
      name: admin
```

Where `members` is a list of users belonging to the group.

The group name is stored in the issued token without modification. It is indistinguishable from a group name received from an external authentication provider. Therefore, a Group resource cannot be created if its `spec.name` value matches a `Group` subject in an existing AuthorizationRule or ClusterAuthorizationRule resource. This prevents permissions from being unintentionally granted to

members of a new group.

If the match is intentional, use a different group name or add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the Group resource.

Unlike email addresses, group names are not converted to lowercase when matched. Therefore, group names that differ only in letter case are considered different.

The restriction does not apply to existing groups whose names match subjects in authorization rules. Such groups continue to work, and a warning is issued when a match is detected.

Consider this restriction when managing groups and authorization rules declaratively. If a group and the corresponding rule are created at the same time, the rule may be created first, causing creation of the Group resource to be rejected. To allow such a match, add the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation to the Group manifest.

Deleting a group does not automatically remove the corresponding subject from the authorization rule. As long as the subject remains in the rule, permissions continue to be granted to a group with the specified name. If a group with the same name is created later, its members receive these permissions. If this behavior is not required, remove the corresponding subject from the authorization rule.

Password policy

Password policy settings allow controlling password complexity, rotation, and user lockout:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 2
  enabled: true
  settings:
    passwordPolicy:
      complexityLevel: Fair
      passwordHistoryLimit: 10
      lockout:
        lockDuration: 15m
        maxAttempts: 3
      rotation:
        interval: "30d"
```

Field description:

- `complexityLevel`: Password complexity level.
- `passwordHistoryLimit`: Number of previous passwords stored in the system to prevent their reuse.
- `lockout`: Lockout settings after exceeding the limit of failed login attempts:
  - `lockout.maxAttempts`: Limit of allowed failed login attempts.
  - `lockout.lockDuration`: User lockout duration.
- `rotation`: Password rotation settings:
  - `rotation.interval`: Period for mandatory password change.

Two-factor authentication (2FA)

2FA increases security by requiring a code from a `TOTP` authenticator application (for example, Google Authenticator) during login.

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authn
spec:
  version: 2
  enabled: true
  settings:
    staticUsers2FA:
      enabled: true
      issuerName: "awesome-app"
```

Field description:

- `enabled`: Enables or disables 2FA for all static users.
- `issuerName`: Name displayed in the authenticator application when adding an account.

> **i** After enabling 2FA, each user must register in the authenticator application during their first login.

Assigning permissions to a user or group

For permission configuration, parameters of the custom resource ClusterAuthorizationRule are used.

FAQ

> **i** The module lifecycle stage: General Availability

How to secure my application?

To enable Dex authentication for your application, follow these steps:

1. Create a DexAuthenticator custom resource.

   When you create a DexAuthenticator in a cluster, an instance of oauth2-proxy is created and connected to Dex. The Deployment, Service, Ingress, and Secret objects will be created in the specified namespace.

   Example of the DexAuthenticator custom resource:

```
apiVersion: deckhouse.io/v1
kind: DexAuthenticator
metadata:
  # Dex authenticator pod name prefix.
  # For example, if the name prefix is `app-name`, then Dex authenticator pods
will look like `app-name-dex-authenticator-7f698684c8-c5cjg`.
  name: app-name
  # Namespace to deploy Dex authenticator to.
  namespace: app-ns
spec:
  # Your application's domain. Requests to it will be redirected for Dex
authentication.
  applicationDomain: "app-name.kube.my-domain.com"
  # A parameter that determines whether to send the `Authorization: Bearer`
header to the application.
  # This one is useful in combination with auth_request in NGINX.
  sendAuthorizationHeader: false
  # The name of the Secret containing the SSL certificate.
  applicationIngressCertificateSecretName: "ingress-tls"
  # The name of the Ingress class to use in the Ingress resource created for the
Dex authenticator.
  applicationIngressClassName: "nginx"
  # The duration of the active user session.
  keepUsersLoggedInFor: "720h"
  # The list of groups whose users are allowed to authenticate.
  allowedGroups:
  - everyone
  - admins
  # The list of addresses and networks for which authentication is allowed.
  whitelistSourceRanges:
  - 1.1.1.1/32
  - 192.168.0.0/24
```

2. Connect your application to Dex.

   For this, add the following annotations to the application's Ingress resource:

   - `nginx.ingress.kubernetes.io/auth-signin: https://$host/dex-authenticator/sign_in`
   - `nginx.ingress.kubernetes.io/auth-response-headers: X-Auth-Request-User,X-Auth-Request-Email`
   - `nginx.ingress.kubernetes.io/auth-url: https://<SERVICE_NAME>.<NS>.svc.{{ C_DOMAIN }}/dex-authenticator/auth`, where:
     - `SERVICE_NAME`: Name of the authenticator's Service. Usually, it is `<NAME>-dex-authenticator` (`<NAME>` is the `metadata.name` of the DexAuthenticator).
     - `NS`: Value of the `metadata.namespace` parameter of the DexAuthenticator.
     - `C_DOMAIN`: Cluster domain (the clusterDomain parameter of the ClusterConfiguration resource).

> **Note:** If the DexAuthenticator `<NAME>` is too long, the Service name may be truncated. To find the correct service name, use the following command (specify the namespace name and DexAuthenticator name):
>
> ```
> d8 k get service -n <NS> -l "deckhouse.io/dex-authenticator-for=<NAME>" -o
> jsonpath='{.items[0].metadata.name}'
> ```

Example of annotations for an application's Ingress resource for connecting to Dex:

```
annotations:
  nginx.ingress.kubernetes.io/auth-signin: https://$host/dex-
authenticator/sign_in
  nginx.ingress.kubernetes.io/auth-url: https://app-name-dex-authenticator.app-
ns.svc.cluster.local/dex-authenticator/auth
  nginx.ingress.kubernetes.io/auth-response-headers: X-Auth-Request-User,X-Auth-
Request-Email
```

⚠ The application Ingress must have TLS configured. DexAuthenticator does not support HTTP-only Ingress resources.

Setting up CIDR-based restrictions

DexAuthenticator does not have a built-in system for managing authentication based on user IP address. Instead, you can use Ingress resource annotations:

- To restrict access by IP and keep Dex authentication, add the annotation with a comma-separated list of allowed CIDRs:

  ```
  nginx.ingress.kubernetes.io/whitelist-source-range: 192.168.0.0/32,1.1.1.1
  ```

- To allow access without Dex authentication for users from specified networks while requiring authentication for others, add the annotation:

  ```
  nginx.ingress.kubernetes.io/satisfy: "any"
  ```

Authentication flow with DexAuthenticator

⚠ DexAuthenticator only works with HTTPS. It does not support Ingress resources configured for HTTP only.

Authentication cookies are set with the `Secure` attribute, which means they are only sent over encrypted HTTPS connections.

Make sure your application Ingress has TLS configured before integrating with DexAuthenticator.

1. Dex redirects the user to the provider's login page in most cases and waits for the user to be redirected back to the `/callback` URL. However, some providers like LDAP or Atlassian Crowd do not support this flow. The user must enter credentials in the Dex login form instead, and Dex will validate them by making a request to the provider's API.
2. DexAuthenticator sets the cookie with the full refresh token (instead of issuing a ticket as for the ID token) because Redis does not persist data. If no ID token is found in Redis by the ticket, the user can request a new ID token by providing the refresh token from the cookie.
3. DexAuthenticator sets the `Authorization` HTTP header to the ID token value from Redis. This is not required for services like `upmeter`, as `upmeter` permissions are less granular. For the Kubernetes Dashboard, it is critical: the Dashboard passes the ID token on to access the Kubernetes API.

How to generate a kubeconfig and access Kubernetes API?

`kubeconfig` for remote access to the cluster via `kubectl` can be generated in the `kubeconfigurator` web interface.

Configure the `publishAPI` parameter:

- Open the `user-authn` module settings (create the ModuleConfig `user-authn` resource if there is none):

  ```
  d8 k edit mc user-authn
  ```

- Add the following section to the `settings` block and save:

```
publishAPI:
  enabled: true
```

The name `kubeconfig` is reserved for the kubeconfig generation web interface. The URL depends on the `publicDomainTemplate` parameter (for example, for the template that looks like `%s.kube.my`, the kubeconfig generation web interface will be available at `kubeconfig.kube.my`, and for `%s-kube.company.my` — at `kubeconfig-kube.company.my`).

Configuring kube-apiserver

Using the `control-plane-manager` module, DKP automatically configures `kube-apiserver` with the following flags so that the `dashboard` and `kubeconfig-generator` modules can work in the cluster.

kube-apiserver arguments that will be configured

- `--oidc-client-id=kubernetes`
- `--oidc-groups-claim=groups`
- `--oidc-issuer-url=https://dex.%addonsPublicDomainTemplate%/`
- `--oidc-username-claim=email`

When self-signed certificates are used for Dex, one more argument is added and the CA file is mounted in the `apiserver` pod:

- `--oidc-ca-file=/etc/kubernetes/oidc-ca.crt`

The flow of accessing Kubernetes API with generated kubeconfig

1. Before `kube-apiserver` starts, it must request the OIDC provider’s configuration endpoint (Dex in our case) to get the issuer and JWKS endpoint settings.
2. Kubeconfig generator stores the ID token and refresh token in the `kubeconfig` file.
3. After receiving a request with an ID token, `kube-apiserver` verifies that the token is signed by the provider configured in step 1 using keys from the JWKS endpoint. It then compares the token’s `iss` and `aud` claim values with the configuration.

How to rotate the secret of the kubernetes OAuth2 client?

The secret of the privileged `kubernetes` OAuth2 client is stored in the `kubernetes-dex-client-app-secret` Secret of the `d8-user-authn` namespace. The same value is used by the `kubeconfig-generator`, `kubeconfig-publish-api` and `kubeconfig-<slug>` OAuth2 clients, and is passed to basic-auth-proxy as `--ldap-client-secret`.

Deleting the Secret does not rotate the value: while it is still present in the module’s values, the owning hook renders the very same one back.

To rotate the secret, do the following:

1. If a GitOps tool controls the `d8-user-authn` namespace, exclude the `kubernetes-dex-client-app-secret` Secret from syncing. Otherwise the GitOps tool will restore the previous value.
2. Empty the `secret` field:

```
d8 k -n d8-user-authn patch secret kubernetes-dex-client-app-secret --type merge -p '{"data": {"secret":""}}'
```

3. Restart DKP so that the hook picks the empty field up and generates a new value:

```
d8 k -n d8-system rollout restart deployment/deckhouse
```

4. Verify that the secret value changed:

```
d8 k -n d8-user-authn get secret kubernetes-dex-client-app-secret -o jsonpath='{.data.secret}'
```

If it did not, repeat the steps 2 and 3. The module may have restored the previous before DKP was restarted.

One the secret has been rotated, the configuration of components that use it will be updated automatically and the corresponding pods will be restarted.

Kubeconfig files downloaded from the kubeconfig generator earlier carry the old client secret and stop refreshing tokens. Download these files again. ID tokens issued before the rotation keep working until they expire, which is configured via `settings.idTokenTTL` (10 minutes by default).

How to enable Kerberos (SPNEGO) SSO for LDAP?

If clients run in a corporate SSO environment (browser trusts the Dex host), Dex can accept Kerberos tickets via `Authorization: Negotiate` and log in without the password form.

Enabling Kerberos (SPNEGO) SSO for LDAP:

1. In AD/KDC, create/provision an SPN `HTTP/<dex-fqdn>` for a service account and generate a `keytab`.
2. In the cluster, create a Secret in the `d8-user-authn` namespace with the `krb5.keytab` data key.
3. In the LDAP DexProvider resource, enable `spec.ldap.kerberos`:
   - `enabled: true`
   - `keytabSecretName: <secret name>`
   - optional: `expectedRealm`, `usernameFromPrincipal`, `fallbackToPassword`

Dex will mount the `keytab` automatically and start accepting SPNEGO. A server-side `krb5.conf` is not required — tickets are validated using the keytab.

How to configure Basic Authentication for accessing Kubernetes API via LDAP?

1. Enable the `publishAPI` parameter in the `user-authn` module configuration.
2. Create a DexProvider resource of type `LDAP` and set `enableBasicAuth: true`.
3. Configure RBAC for groups obtained from LDAP.
4. Provide users with a `kubeconfig` configured for Basic Authentication (LDAP username and password).

⚠ Only one authentication provider in the cluster can have `enableBasicAuth` enabled.

A detailed example is described in the Usage section.

How is Dex protected against credential brute-forcing?

Each user is allowed no more than 20 login attempts. After the limit is exhausted, one additional attempt is added every 6 seconds.

The user-authz module

i Available with limitations in: **CE**

Available without limitations in: **BE, SE, SE+, EE**

i The module lifecycle stage: General Availability

The module generates role-based access model objects based on the standard Kubernetes RBAC mechanism. The module creates a set of cluster roles (`ClusterRole`) suitable for most user and group access management tasks.

⚠ Starting from Deckhouse Kubernetes Platform v1.64, the module features a experimental role-based access model. The current role-based access model will continue to operate but support for it will be discontinued in the future.

The experimental role-based access model is incompatible with the current one.

The module implements a role-based access model based on the standard RBAC Kubernetes

mechanism. It creates a set of cluster roles (`ClusterRole`) suitable for most user and group access management tasks.

Experimental role-based model

Unlike the current DKP role-based model, the new role-based one does not use `ClusterAuthorizationRule` and `AuthorizationRule` resources. All access rights are configured in the standard Kubernetes RBAC way, i.e., by creating `RoleBinding` or `ClusterRoleBinding` resources and specifying one of the roles prepared by the `user-authz` module in them.

The module creates special aggregated cluster roles (`ClusterRole`). By using these roles in `RoleBinding` or `ClusterRoleBinding`, you can do the following:

- Manage access to modules of a specific subsystem.

  For example, you can use the `d8:manage:networking:manager` role in `ClusterRoleBinding` to allow a network administrator to configure *network* modules (such as `cni-cilium`, `ingress-nginx`, `istio`, etc.).

- Manage access to *user* resources of modules within the namespace.

  For example, the `d8:use:role:manager` role in `RoleBinding` enables deleting/creating/editing the PodLoggingConfig resource in the namespace. At the same time, it does not grant access to the cluster-wide ClusterLoggingConfig and ClusterLogDestination resources of the `log-shipper` module, nor does it allow configuration of the `log-shipper` module itself.

The roles created by the module are divided into two classes:

- Use roles — for assigning rights to users (such as application developers) **in a specific namespace**.
- Manage roles — for assigning rights to administrators.

i

Specifics of combined access: using RoleBinding or ClusterRoleBinding together with ClusterAuthorizationRule (CAR) and AuthorizationRule (AR) for the same user.

If multitenancy mode is enabled in the cluster (the parameter `enableMultiTenancy: true`), the effective permissions of a user are the **union** of all grants that apply to that user:

- the CAR access level — only inside the namespaces allowed by its `limitNamespaces` or `namespaceSelector` parameters;
- the AuthorizationRule access level — inside the namespace the AuthorizationRule is created in;
- the permissions granted by ordinary RoleBinding resources — inside their namespaces;
- the permissions granted by ordinary ClusterRoleBinding resources (not generated by the `user-authz` module) — cluster-wide.

The namespace restrictions of a CAR limit only the permissions granted by that CAR. They do not cancel permissions granted via RoleBinding, ClusterRoleBinding, or AuthorizationRule in other namespaces; likewise, the CAR access level does not extend to those namespaces. For example, if a user has a CAR with `accessLevel: Editor` limited to the `ns-a` namespace and a RoleBinding with the `view` role in the `ns-b` namespace, the user gets Editor permissions in `ns-a` and read-only permissions in `ns-b`: the RoleBinding is not blocked by the CAR restrictions, and the CAR Editor level does not leak into `ns-b`.

In older DKP versions, the `user-authz` module's webhook rejected all requests to namespaces not listed in the user's CAR, even if the user had a RoleBinding for those namespaces. This limitation has been removed; RoleBinding and CAR can now be combined for the same user.

Use roles

⚠ The use role can only be used in the `RoleBinding` resource.

Use roles are intended to assign rights to a user **in a specific namespace**. Users refer to, for example, developers who use a cluster configured by an administrator to deploy their applications. Such users don't need to manage DKP modules or a cluster, but they need to be able to, for example, create their Ingress resources, configure application authentication, and collect logs from applications.

The use role defines permissions for accessing namespaced resources of modules and standard namespaced resources of Kubernetes (`Pod`, `Deployment`, `Secret`, `ConfigMap`, etc.).

The module creates the following use roles:

- `d8:use:role:viewer` — allows viewing standard Kubernetes resources in a specific namespace, except for Secrets and RBAC resources, as well as authenticating in the cluster;
- `d8:use:role:user` — in addition to the role `d8:use:role:viewer` it allows viewing secrets and RBAC resources in a specific namespace, connecting to pods, deleting pods (but not creating or modifying them), executing `kubectl port-forward` and `kubectl proxy`, as well as changing the number of replicas of controllers;
- `d8:use:role:manager` — in addition to the role `d8:use:role:user` it allows managing module resources (for example, `Certificate`, `PodLoggingConfig`, etc.) and standard namespaced Kubernetes resources (`Pod`, `ConfigMap`, `CronJob`, etc.) in a specific namespace;
- `d8:use:role:admin` — in addition to the role `d8:use:role:manager` it allows managing the resources `ResourceQuota`, `ServiceAccount`, `Role`, `RoleBinding`, `NetworkPolicy` in a specific namespace.

Manage roles

> ⚠ The manage role does not grant access to the namespace of user applications.
>
> The manage role grants access only to system namespaces (starting with `d8-` or `kube-`), and only to those system namespaces where the modules of the corresponding role subsystem are running.

Manage roles are intended for assigning rights to manage the entire platform or a part of it (the subsystem), but not the users applications themselves. Using a manage role you can enable, for example, a security administrator to manage cluster security modules. Thus, the security administrator will be able to configure authentication, authorization, security policies, and other respective parameters.

> ⚠ A manage role limits which modules and namespaces a subject can address, but it does not limit the privileges a subject can obtain through the modules it is allowed to manage. This matters most for the `security` subsystem: the right to manage authentication and authorization is equivalent to full control over the cluster.
>
> A subject that can manage the `user-authn` module can register an identity provider or reset the credentials of any local user. A subject that can manage the `user-authz` module can modify authorization rules. In both cases, they can obtain an identity with any privileges, including cluster administrator, so treat a `security` subsystem manage role as a cluster administrator role when planning access.

The manage role defines access rights:

- to cluster-wide Kubernetes resources;
- to manage DKP modules (`moduleConfig` resource) within the subsystem of the role, or to all DKP modules for the role `d8:manage:all:*`;
- to manage cluster-wide resources of DKP modules within the subsystem of the role, or to all resources of DKP modules for the role `d8:manage:all:*`;
- to system namespaces (starting with `d8-` or `kube-`) in which the modules of the subsystem of the role operate, or to all system namespaces for the role `d8:manage:all:*`.

The manage role name format is `d8:manage:<SUBSYSTEM>:<ACCESS_LEVEL>`, where:

- `SUBSYSTEM` is the role's subsystem. It can be one of the subsystem, or `all`, for access across all subsystems;
- `ACCESS_LEVEL` is the access level.

  Examples of manage roles:

  - `d8:manage:all:viewer` — access to view the configuration of all DKP modules (`moduleConfig` resource), their cluster-wide resources, their namespaced resources, and standard Kubernetes objects (except Secrets and RBAC resources) in all system namespaces (starting with `d8-` or `kube-`);
  - `d8:manage:all:manager` — similar to the role `d8:manage:all:viewer`, but with admin-level access, i.e., view/create/modify/delete the configuration of all DKP modules (`moduleConfig` resource), their cluster-wide resources, their namespaced resources, and standard Kubernetes objects in all system namespaces (starting with `d8-` or `kube-`);
  - `d8:manage:observability:viewer` — access to view the configuration of DKP modules (`moduleConfig` resource) from the `observability` area, their cluster-wide resources, their namespaced resources, and standard Kubernetes objects (except secrets and RBAC

resources) in the system namespaces `d8-log-shipper`, `d8-monitoring`, `d8-okmeter`, `d8-operator-prometheus`, `d8-upmeter`, `kube-prometheus-pushgateway`.

The module provides two access level for administrators:

- `viewer` — allows viewing standard Kubernetes resources, the configuration of modules (resources `moduleConfig`), cluster-wide resources of modules, and namespaced resources of modules in the module namespace;
- `manager` — in addition to the role `viewer` it allows managing standard Kubernetes resources, the configuration of modules (resources `moduleConfig`), cluster-wide resources of modules, and namespaced resources of modules in the module namespace;

Subsystems of the role-based model

Each DKP module belongs to a specific subsystem. For each subsystem, there is a set of roles with different levels of access. Roles are updated automatically when the module is enabled or disabled.

For example, for the `networking` subsystem, there are the following manage roles that can be used in `ClusterRoleBinding`:

- `d8:manage:networking:viewer`
- `d8:manage:networking:manager`

The scope of a role depends on which subsystem it belongs to:

- The scope of roles from the `all` subsystem is all system namespaces (starting with `d8-` or `kube-`) in the cluster.
- The scope of roles from other subsystems includes the namespaces in which the subsystem's modules operate (see the subsystem composition table), as well as all cluster-wide objects of the subsystem's modules.

Role-based model subsystems composition table.

Subsystem	Subsystem modules	Namespaces in which modules of a scope operate
all	All modules	All namespaces
deckhouse	• deckhouse • multitenancy-manager	• d8-multitenancy-manager • d8-system

Current role-based model

Features:

- Manages user and group access control using Kubernetes RBAC;
- Manages access to scaling tools (the `allowScale` parameter of the `ClusterAuthorizationRule` or AuthorizationRule Custom Resource);
- Manages access to port forwarding (the `portForwarding` parameter of the `ClusterAuthorizationRule` or AuthorizationRule Custom Resource);
- Manages the list of allowed namespaces with a labelSelector (the `namespaceSelector` parameter of the `ClusterAuthorizationRule` Custom Resource);

In addition to the RBAC, you can use a set of high-level roles in the module:

- `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
- `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
- `Editor` — is the same as `PrivilegedUser` + can create and edit all objects that are usually required for application tasks.
- `Admin` — the same as `Editor` + can delete service objects (auxiliary resources such as `ReplicaSet`, `certmanager.k8s.io/challenges` and `certmanager.k8s.io/orders`);
- `ClusterEditor` — the same as `Editor` + can manage a limited set of `cluster-wide` objects

that can be used in application tasks (`ClusterXXXMetric`, `KeepalivedInstance`, `DaemonSet`, etc.). This role is best suited for cluster operators.
- `ClusterAdmin` — the same as both `ClusterEditor` and `Admin` + can manage `cluster-wide` service objects (e.g., `MachineSets`, `Machines`, `OpenstackInstanceClasses`..., as well as `ClusterAuthorizationRule`, `ClusterRoleBindings` and `ClusterRole`). This role is best suited for cluster administrators. **Note** that since `ClusterAdmin` can edit `ClusterRoleBindings`, he can **broaden his privileges within the cluster**;
- `SuperAdmin` — can perform any actions with any objects (note that `namespaceSelector` and `limitNamespaces` restrictions remain valid).

⚠ Currently, the multi-tenancy mode (namespace-based authorization) is implemented according to a temporary scheme and **isn’t guaranteed to be entirely safe and secure**!

If a `ClusterAuthorizationRule` Custom Resource contains the `namespaceSelector` field, neither `limitNamespaces` nor `allowAccessToSystemNamespaces` are taken into consideration.

The `allowAccessToSystemNamespaces`, `namespaceSelector` and `limitNamespaces` options in the custom resource will no longer be applied if the authorization system’s webhook is unavailable for some reason. As a result, users will have access to all namespaces. After the webhook availability is restored, the options will become relevant again.

Default access list for each role

```
read:
    - rbac.authorization.k8s.io/clusterrolebindings
    - rbac.authorization.k8s.io/clusterroles
write:
    - apiextensions.k8s.io/customresourcedefinitions
    - apps/daemonsets
    - extensions/daemonsets
    - gateway.networking.k8s.io/gatewayclasses
    - storage.k8s.io/storageclasses
```

Role `ClusterAdmin` (includes all rules from the role `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`):

```
proxy:
    - nodes
read-write:
    - deckhouse.io/clusterauthorizationrules
    - namespaces
    - nodes/configz
    - nodes/healthz
    - nodes/log
    - nodes/metrics
    - nodes/pods
    - nodes/proxy
    - nodes/stats
write:
    - limitranges
    - networking.k8s.io/networkpolicies
    - rbac.authorization.k8s.io/clusterrolebindings
    - rbac.authorization.k8s.io/clusterroles
    - rbac.authorization.k8s.io/rolebindings
    - rbac.authorization.k8s.io/roles
    - resourcequotas
```

You can get additional list of access rules for module role from cluster (existing user defined rules and non-default rules from other deckhouse modules):

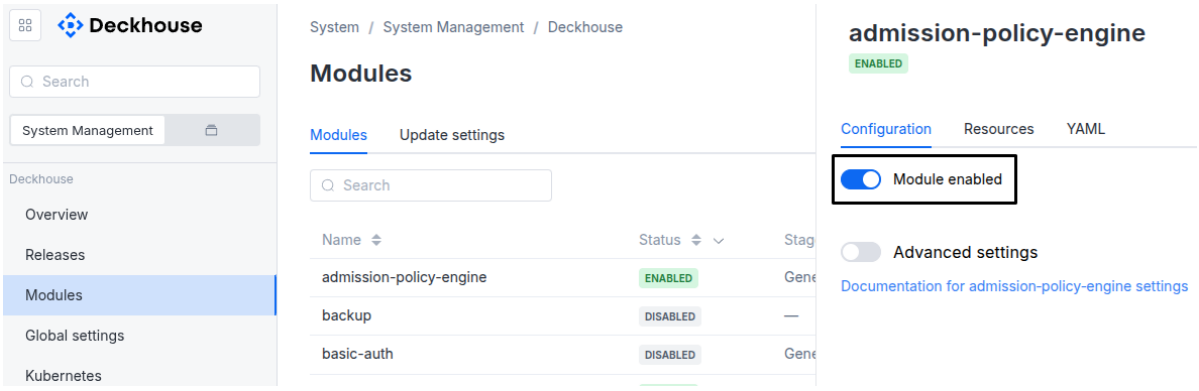
```
D8_ROLE_NAME=Editor
kubectl get clusterrole -A -o jsonpath="{range .items[?(@.metadata.annotations.user-authz\.deckhouse\.io/access-level=='$D8_ROLE_NAME')]}{.rules}{'\n'}{end}" | jq -s add
```

Configuration

> **i** Available with limitations in: **CE**
>
> Available without limitations in: **BE, SE, SE+, EE**

> **i** The module lifecycle stage: General Availability

> **i** **Caution!** We strongly do not recommend creating Pods and ReplicaSets – these objects are secondary and should be created by other controllers. Access to creating and modifying Pods and ReplicaSets is disabled.
>
> **Caution!** Currently, the multi-tenancy mode (namespace-based authorization) is implemented according to a temporary scheme and **isn't guaranteed to be entirely safe and secure**! The `allowAccessToSystemNamespaces`, `namespaceSelector` and `limitNamespaces` options in the custom resource will no longer be applied if the authorization system's webhook is unavailable for some reason. As a result, users will have access to all namespaces. After the webhook availability is restored, the options will become relevant again.



All access rights are configured using Custom Resources.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `user-authz` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

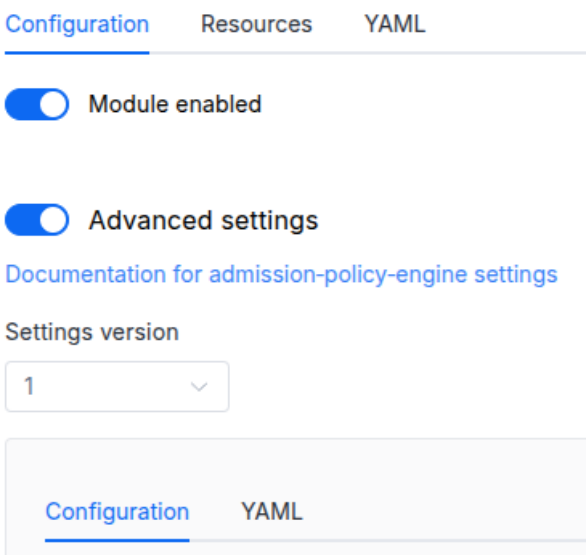
  ```
  d8 system module enable user-authz
  ```

- **Using ModuleConfig `user-authz`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `user-authz` (create it if necessary);

Example of a manifest to enable module `user-authz`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authz
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the “System” → “System Management” → “Deckhouse” → “Modules” section, open the `user-authz` module and enable the “Advanced Settings” switch. Fill in the required fields in the “Configuration” tab or specify the module settings in YAML format on the “YAML” tab, **excluding the settings section**. Save the changes.

  Example:

  You can also edit the ModuleConfig object `user-authz` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `user-authz`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `user-authz` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc user-authz
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `user-authz` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `user-authz`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: user-authz
spec:
  version: 1
  enabled: true
  settings: # Module parameters from the "Parameters" section below.
```

Parameters

Schema version: 1

- **settings**
  object
  - **settings.controlPlaneConfigurator**
    object

    Parameters of the control-plane-manager module.

    - **settings.controlPlaneConfigurator.enabled**
      boolean

      Passes parameters for configuring `authz-webhook` to the `control-plane-manager` module (see the parameters of the control-plane-manager module).

      If this parameter is disabled, the `control-plane-manager` module assumes that Webhook-based authorization is disabled by default. In this case (if no additional settings are provided), the `control-plane-manager` module will try to delete all references to the Webhook plugin from the manifest (even if you configure the manifest manually).

      Default: `true`

      Examples:

      ```
      enabled: true
      ```

      ```
      enabled: false
      ```

  - **settings.enableMultiTenancy**
    boolean

    Available in editions: BE, SE, SE+, EE

    Enable namespace-based authorization (multi-tenancy mode).

    All the `kube-apiserver` settings required for namespace-based authorization are performed automatically by the control-plane-manager module (more details).

    Default: `false`

    Examples:

    ```
    enableMultiTenancy: true
    ```

    ```
    enableMultiTenancy: false
    ```

Custom Resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability

AuthorizationRule

Scope: Namespaced
Version: v1alpha1

Manages RBAC and authorization settings within a particular namespace.

> **i** The `AuthorizationRule` resource is used in the current role-based model and isn't used in the experimental role model.

- **spec**
  object

  Required value

  - **spec.accessLevel**
    string

    Access level:

    - `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
    - `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
    - `Editor` — is the same as `PrivilegedUser` + can create and edit all objects that are usually required for application tasks;
    - `Admin` — the same as `Editor` + can delete service objects (auxiliary resources such as `ReplicaSet`, `certmanager.k8s.io/challenges` and `certmanager.k8s.io/orders`);

    Allowed values: `User`, `PrivilegedUser`, `Editor`, `Admin`

    Example:

    ```
    accessLevel: PrivilegedUser
    ```

  - **spec.allowScale**
    boolean

    Defines if scaling of Deployments and StatefulSets is allowed/not allowed.

    Default: `false`

  - **spec.portForwarding**
    boolean

    Allow/disallow the user to do `port-forwarding`.

    Default: `false`

  - **spec.subjects**
    array of objects

    Required value

    Users and/or groups to grant privileges.

    Kubernetes API reference…

    Pay attention to the following nuances if this module is used together with the user-authn module:

    - Use the user's `email` as the username to grant privileges to the specific user;
    - When specifying a group, make sure that the necessary groups are allowed to be received from the provider, i.e., they are defined in the corresponding custom resource DexProvider.
    - **spec.subjects.kind**
      string

      Required value

      Type of user identification resource.

      Allowed values: `User`, `Group`, `ServiceAccount`

Example:

```
kind: Group
```

- **spec.subjects.name**
  string

  Required value

  Resource name.

  Example:

  ```
  name: some-group-name
  ```

- **spec.subjects.namespace**
  string

  ServiceAccount namespace.

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

ClusterAuthorizationRule

Scope: Cluster

- v1
- v1alpha1

This object manages RBAC and namespace-based authorization.

The settings determine which access level is assigned to the user and/or group.

- **spec**
  object

  Required value

  - **spec.accessLevel**
    string

    Access level:

    - `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
    - `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
    - `Editor` — is the same as `PrivilegedUser` + can create and edit all objects that are usually required for application tasks;
    - `Admin` — the same as `Editor` + can delete service objects (auxiliary resources such as `ReplicaSet`, `certmanager.k8s.io/challenges` and `certmanager.k8s.io/orders`);
    - `ClusterEditor` — the same as `Editor` + can manage a limited set of `cluster-wide` objects that can be used in application tasks (`ClusterXXXMetric`, `KeepalivedInstance`, `DaemonSet`, etc.). This role is best suited for cluster operators.
    - `ClusterAdmin` — the same as both `ClusterEditor` and `Admin` + can manage `cluster-wide` service objects (e.g., `MachineSets`, `Machines`, `OpenstackInstanceClasses`..., as well as `ClusterAuthorizationRule`, `ClusterRoleBindings` and `ClusterRole`). This role is best suited for cluster administrators.

      Caution! since `ClusterAdmin` can edit `ClusterRoleBindings`, he can broader his privileges within the cluster;
    - `SuperAdmin` — can perform any actions with any objects (note that `limitNamespaces` and `namespaceSelector` (see below) restrictions remain valid).

    Allowed values: `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, `ClusterAdmin`, `SuperAdmin`

    Example:

```
accessLevel: PrivilegedUser
```

- **spec.additionalRoles**
  array of objects

  Additional roles to bind for subjects.

  This parameter is reserved for emergencies. Please, use the `accessLevel` parameter instead.

  Example:

  ```
  additionalRoles:
  - apiGroup: rbac.authorization.k8s.io
    kind: ClusterRole
    name: cluster-write-all
  - apiGroup: rbac.authorization.k8s.io
    kind: ClusterRole
    name: cluster-read-all
  ```

  - **spec.additionalRoles.apiGroup**
    string

    Required value

    apiGroup for users.

    Example:

    ```
    apiGroup: rbac.authorization.k8s.io
    ```

  - **spec.additionalRoles.kind**
    string

    Required value

    Kind of the role.

    Allowed values: `ClusterRole`

    Example:

    ```
    kind: ClusterRole
    ```

  - **spec.additionalRoles.name**
    string

    Required value

    Name of the role.

    Example:

    ```
    name: cluster-admin
    ```

- **spec.allowAccessToSystemNamespaces**
  Deprecated
  boolean

  Available in editions: BE, SE, SE+, EE

  Allow access to System namespaces (kube-*, d8-*, loghouse, default).

  Option available **only** if the enableMultiTenancy option is enabled.

  Deprecated. Use the namespaceSelector field instead.

  Default: `false`

- **spec.allowScale**
  boolean

  Defines if scaling of Deployments and StatefulSets is allowed/not allowed.

Default: `false`

- **spec.limitNamespaces**
  Deprecated
  array of strings

  Available in editions: BE, SE, SE+, EE

  List of regex-patterns that define namespaces accessible by the user.

  The decision making process:

  - If the list is defined, then only its constituents are accessible.
  - If the list is not defined, then all namespaces are accessible (except for the system ones - see `spec.allowAccessToSystemNamespaces` below).

  Option available **only** if enableMultiTenancy option is enabled.

  Deprecated. Use the namespaceSelector field instead.

  Example:

  ```
  limitNamespaces: production-.*
  ```

  - **Element of the array**
    string
- **spec.namespaceSelector**
  object

  Available in editions: BE, SE, SE+, EE

  Defines a set of namespaces accessible by the user, using the value of the `namespaceSelector.labelSelector` parameter.

  If the `namespaceSelector` parameter is specified, the values of the `limitNamespaces` and `allowAccessToSystemNamespaces` parameters are **ignored**. If the `namespaceSelector.matchAny` field is specified, then all namespaces (including system namespaces) will be accessible. Otherwise, only the namespaces with labels matching the `namespaceSelector.labelSelector` conditions will be accessible (including system namespaces).

  If the `namespaceSelector` parameter is not specified, then the set of available namespaces is determined by the value of the `limitNamespaces` and `allowAccessToSystemNamespaces` parameters. If none of the parameters `namespaceSelector`, `limitNamespaces` and `allowAccessToSystemNamespaces` are specified, then all namespaces will be available, except for the system ones (`kube-*`, `d8-*`, `loghouse`, `default`).

  Is available **only** if the enableMultiTenancy parameter is enabled.

  - **spec.namespaceSelector.labelSelector**
    object

    Defines the label selector-based filter of the namespaces.

    Cannot be used together with the `matchAny` parameter.

    If both `matchExpressions` and `matchLabels` parameters are set, their requirements are ANDed together — they must all be satisfied in order to match. If multiple `matchExpression` conditions are provided, they all must be satisfied in order to match.

    - **spec.namespaceSelector.labelSelector.matchExpressions**
      array of objects

      An array of set-based expressions.

      Example:

```
matchExpressions:
- key: tier
  operator: In
  values:
  - production
  - staging
- key: tier
  operator: NotIn
  values:
  - production
```

- **spec.namespaceSelector.labelSelector.matchExpressions.key**
  string

  A label name.

- **spec.namespaceSelector.labelSelector.matchExpressions.operator**
  string

  A comparison operator.

  Allowed values: `In`, `NotIn`, `Exists`, `DoesNotExist`

- **spec.namespaceSelector.labelSelector.matchExpressions.values**
  array of strings

  A label value.

  - **Element of the array**
    string

    Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

    Length: `1..63`

- **spec.namespaceSelector.labelSelector.matchLabels**
  object

  A set of labels a namespace must have to match.

  Example:

```
matchLabels:
  foo: bar
  baz: who
```

- **spec.namespaceSelector.matchAny**
  boolean

  Unconditionally permits access to any namespace in the cluster, including system namespaces.

  Cannot be used together with the `labelSelector` parameter.

  Since `labelSelector` provides access to a limited number of the namespaces that match it, `matchAny` is needed in cases where access to all namespaces is to be granted.

  Allowed values: `true`

- **spec.portForwarding**
  boolean

  Allow/disallow the user to do `port-forwarding`.

  Default: `false`

- **spec.subjects**
  array of objects

  Required value

  Users and/or groups to grant privileges.

Kubernetes API reference…

Pay attention to the following nuances if this module is used together with the user-authn module:

- Use the user's `email` as the username to grant privileges to the specific user;
- When specifying a group, make sure that the necessary groups are allowed to be received from the provider, i.e., they are defined in the corresponding custom resource DexProvider.
- **spec.subjects.kind**
  string

  Required value

  Type of user identification resource.

  Allowed values: `User`, `Group`, `ServiceAccount`

  Example:

  ```
  kind: Group
  ```

- **spec.subjects.name**
  string

  Required value

  Resource name.

  Example:

  ```
  name: some-group-name
  ```

- **spec.subjects.namespace**
  string

  ServiceAccount namespace.

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

Deprecated resource. Support for the resource might be removed in a later release.

This cluster-wide object manages RBAC and authorization.

> **i** The `ClusterAuthorizationRule` resource is used in the current role-based model and isn't used in the experimental role model.

- **spec**
  object

  Required value

  - **spec.accessLevel**
    string

    Access level:

    - `User` — has access to information about all objects (including viewing pod logs) but cannot exec into containers, read secrets, and perform port-forwarding;
    - `PrivilegedUser` — the same as `User` + can exec into containers, read secrets, and delete pods (and thus, restart them);
    - `Editor` — is the same as `PrivilegedUser` + can create and edit all objects that are usually required for application tasks;
    - `Admin` — the same as `Editor` + can delete service objects (auxiliary resources such as `ReplicaSet`, `certmanager.k8s.io/challenges` and `certmanager.k8s.io/orders`);
    - `ClusterEditor` — the same as `Editor` + can manage a limited set of `cluster-wide` objects that can be used in application tasks (`ClusterXXXMetric`, `KeepalivedInstance`, `DaemonSet`, etc.). This role is best suited for cluster operators.
    - `ClusterAdmin` — the same as both `ClusterEditor` and `Admin` + can manage

`cluster-wide` service objects (e.g., `MachineSets`, `Machines`, `OpenstackInstanceClasses` ..., as well as `ClusterAuthorizationRule`, `ClusterRoleBindings` and `ClusterRole`). This role is best suited for cluster administrators.

Caution! since `ClusterAdmin` can edit `ClusterRoleBindings`, he can broader his privileges within the cluster;

- `SuperAdmin` — can perform any actions with any objects (note that `limitNamespaces` (see below) restrictions remain valid).

Allowed values: `User`, `PrivilegedUser`, `Editor`, `Admin`, `ClusterEditor`, `ClusterAdmin`, `SuperAdmin`

Example:

```
accessLevel: PrivilegedUser
```

- **spec.additionalRoles**
  array of objects

  Additional roles to bind for subjects.

  This parameter is reserved for emergencies. Please, use the `accessLevel` parameter instead.

  Example:

  ```
  additionalRoles:
  - apiGroup: rbac.authorization.k8s.io
    kind: ClusterRole
    name: cluster-write-all
  - apiGroup: rbac.authorization.k8s.io
    kind: ClusterRole
    name: cluster-read-all
  ```

  - **spec.additionalRoles.apiGroup**
    string

    Required value

    apiGroup for users.

    Example:

    ```
    apiGroup: rbac.authorization.k8s.io
    ```

  - **spec.additionalRoles.kind**
    string

    Required value

    Kind of the role.

    Allowed values: `ClusterRole`

    Example:

    ```
    kind: ClusterRole
    ```

  - **spec.additionalRoles.name**
    string

    Required value

    Name of the role.

    Example:

    ```
    name: cluster-admin
    ```

- **spec.allowAccessToSystemNamespaces**

Deprecated
boolean

Available in editions: BE, SE, SE+, EE

Allow access to System namespaces (kube-*, d8-*, loghouse, default).

Option available **only** if the enableMultiTenancy option is enabled.

Deprecated. Use the namespaceSelector parameter (API version `v1` of the CR) instead.

Default: `false`

- **spec.allowScale**
  boolean

  Defines if scaling of Deployments and StatefulSets is allowed/not allowed.

  Default: `false`

- **spec.limitNamespaces**
  Deprecated
  array of strings

  Available in editions: BE, SE, SE+, EE

  List of regex-patterns that define namespaces accessible by the user.

  The decision making process:

  - If the list is defined, then only its constituents are accessible.
  - If the list is not defined, then all namespaces are accessible (except for the system ones - see `spec.allowAccessToSystemNamespaces` below).

  Option available only if enableMultiTenancy option is enabled.

  Deprecated. Use the namespaceSelector parameter (API version `v1` of the CR) instead.

  Example:

  ```
  limitNamespaces: production-.*
  ```

  - **Element of the array**
    string
- **spec.portForwarding**
  boolean

  Allow/disallow the user to do `port-forwarding`.

  Default: `false`

- **spec.subjects**
  array of objects

  Required value

  Users and/or groups to grant privileges.

  Kubernetes API reference…

  Pay attention to the following nuances if this module is used together with the user-authn module:

  - Use the user's `email` as the username to grant privileges to the specific user;
  - When specifying a group, make sure that the necessary groups are allowed to be received from the provider, i.e., they are defined in the corresponding custom resource DexProvider.
  - **spec.subjects.kind**
    string

    Required value

    Type of user identification resource.

    Allowed values: `User`, `Group`, `ServiceAccount`

    Example:

```
kind: Group
```

- **spec.subjects.name**
  string

  Required value

  Resource name.

  Example:

  ```
  name: some-group-name
  ```

- **spec.subjects.namespace**
  string

  ServiceAccount namespace.

  Pattern: `[a-z0-9]([-a-z0-9]*[a-z0-9])?`

  Length: `1..63`

Usage

> **i** The module lifecycle stage: General Availability

Example of assigning rights to a cluster administrator

> **i** The example uses the experimental role-based.

To grant access to a cluster administrator, use the role `d8:manage:all:manager` in `ClusterRoleBinding`.

Example of assigning rights to a cluster administrator (User `jane`):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: cluster-admin-jane
subjects:
- kind: User
  name: jane.doe@example.com
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:manage:all:manager
  apiGroup: rbac.authorization.k8s.io
```

The rights that the user will get

The rights that the user will get will be limited to namespaces starting with `d8-` or `kube-`.

The user will be able to:

- View, modify, delete, and create Kubernetes resources and DKP modules;
- Modify module configurations (view, modify, delete, and create `moduleConfig` resources);
- Execute the following commands on pods and services:
  - `kubectl attach`
  - `kubectl exec`
  - `kubectl port-forward`
  - `kubectl proxy`

Example of assigning rights to a network administrator

> **i** The example uses the experimental role-based.

To grant a network administrator access to manage the network subsystem of the cluster, use the role `d8:manage:networking:manager` in `ClusterRoleBinding`.

Example of assigning rights to a network administrator (User `jane`):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: network-admin-jane
subjects:
- kind: User
  name: jane.doe@example.com
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:manage:networking:manager
  apiGroup: rbac.authorization.k8s.io
```

The rights that the user will get

The rights that the user will get will be limited to the following list of DKP module namespaces from the `networking` subsystem (the actual list depends on the list of modules included in the cluster):

- `d8-cni-cilium`
- `d8-cni-flannel`
- `d8-cni-simple-bridge`
- `d8-ingress-nginx`
- `d8-istio`
- `d8-metallb`
- `d8-network-gateway`
- `d8-openvpn`
- `d8-static-routing-manager`
- `d8-system`
- `kube-system`

The user will be able to:

- View, modify, delete, and create *standard* Kubernetes resources in the module namespace from the `networking` subsystem.

  Example of resources that the user will be able to manage (the list is not exhaustive):

  - `Certificate`
  - `CertificateRequest`
  - `ConfigMap`
  - `ControllerRevision`
  - `CronJob`
  - `DaemonSet`
  - `Deployment`
  - `Event`
  - `HorizontalPodAutoscaler`
  - `Ingress`
  - `Issuer`
  - `Job`
  - `Lease`
  - `LimitRange`
  - `NetworkPolicy`
  - `PersistentVolumeClaim`
  - `Pod`
  - `PodDisruptionBudget`
  - `ReplicaSet`
  - `ReplicationController`
  - `ResourceQuota`
  - `Role`
  - `RoleBinding`
  - `Secret`
  - `Service`

    - `ServiceAccount`
    - `StatefulSet`
    - `VerticalPodAutoscaler`
    - `VolumeSnapshot`

- View, modify, delete, and create the following resources in the modules namespace from the `networking` subsystem:

  A list of resources that the user will be able to manage:

    - `EgressGateway`
    - `EgressGatewayPolicy`
    - `FlowSchema`
    - `IngressClass`
    - `IngressIstioController`
    - `IngressNginxController`
    - `IPRuleSet`
    - `IstioFederation`
    - `IstioMulticluster`
    - `RoutingTable`

- Modify the configuration of modules (view, change, delete, and create moduleConfig resources) from the `networking` subsystem.

  List of modules that the user will be able to manage:

    - `cilium-hubble`
    - `cni-cilium`
    - `cni-flannel`
    - `cni-simple-bridge`
    - `flow-schema`
    - `ingress-nginx`
    - `istio`
    - `kube-dns`
    - `kube-proxy`
    - `metallb`
    - `network-gateway`
    - `network-policy-engine`
    - `node-local-dns`
    - `openvpn`
    - `static-routing-manager`

- Execute the following commands with pods and services in the modules namespace from the `networking` subsystem:

    - `kubectl attach`
    - `kubectl exec`
    - `kubectl port-forward`
    - `kubectl proxy`

Example of assigning administrative rights to a user within a namespace

> **i** The example uses the experimental role-based.

To assign rights to a user manage application resources within a namespace, but without the ability to configure DKP modules, use the role `d8:use:role:admin` in `RoleBinding` in the corresponding namespace.

Example of assigning rights to an application developer (User `app-developer`) in namespace `myapp`:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: myapp-developer
  namespace: myapp
subjects:
- kind: User
  name: app-developer@example.com
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: d8:use:role:admin
  apiGroup: rbac.authorization.k8s.io
```

The rights that the user will get

In the `myapp` namespace, the user will be able to:

- View, modify, delete, and create Kubernetes resources. For example, the following resources (the list is not exhaustive):
  - `Certificate`
  - `CertificateRequest`
  - `ConfigMap`
  - `ControllerRevision`
  - `CronJob`
  - `DaemonSet`
  - `Deployment`
  - `Event`
  - `HorizontalPodAutoscaler`
  - `Ingress`
  - `Issuer`
  - `Job`
  - `Lease`
  - `LimitRange`
  - `NetworkPolicy`
  - `PersistentVolumeClaim`
  - `Pod`
  - `PodDisruptionBudget`
  - `ReplicaSet`
  - `ReplicationController`
  - `ResourceQuota`
  - `Role`
  - `RoleBinding`
  - `Secret`
  - `Service`
  - `ServiceAccount`
  - `StatefulSet`
  - `VerticalPodAutoscaler`
  - `VolumeSnapshot`
- View, edit, delete, and create the following DKP module resources:
  - `DexAuthenticator`
  - `DexClient`
  - `PodLogginConfig`
- Execute the following commands for pods and services:
  - `kubectl attach`
  - `kubectl exec`
  - `kubectl port-forward`
  - `kubectl proxy`

An example of `ClusterAuthorizationRule`

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: test-rule
spec:
  subjects:
  - kind: User
    name: some@example.com
  - kind: ServiceAccount
    name: gitlab-runner-deploy
    namespace: d8-service-accounts
  - kind: Group
    name: some-group-name
  accessLevel: PrivilegedUser
  portForwarding: true
  # This option is only available if the enableMultiTenancy parameter is set.
  allowAccessToSystemNamespaces: false
  # This option is only available if the enableMultiTenancy parameter is set.
  namespaceSelector:
    labelSelector:
      matchExpressions:
      - key: stage
        operator: In
        values:
        - test
        - review
      matchLabels:
        team: frontend
```

A `User` or `Group` subject is matched by name against the user identity in the token. A locally managed identity is indistinguishable from one asserted by an external authentication provider. Because of that, you can't create a User whose `spec.email` or a Group whose `spec.name` matches a subject of an existing ClusterAuthorizationRule. This prevents any unnoticed attempt to grant the identity privileges.

If the match is intentional, for example, if the ClusterAuthorizationRule has been written in advance, set the `user-authz.deckhouse.io/allow-authorization-rule-collision: "true"` annotation on the User or Group.

Write an email for the `User` subject in lowercase. It's recorded to the token in lowercase so a subject spelled `Admin@Example.com` won't match `admin@example.com`. A `Group`-type subject names are matched exactly, since group names are not lowercased anywhere.

This restriction is applied during the User and Group resource creation only and doesn't prevent adding existing users or groups to a ClusterAuthorizationRule. If a matching User or Group already exists, it receives the privileges immediately after it's added to the rule.

Example of granting access to all namespaces

> **i** The example refers to the current role-based model.

In multi-tenancy mode (`userAuthz.enableMultiTenancy`), namespace-based restrictions are configured using the ClusterAuthorizationRule resource fields.

Configuration options:

- **Allow access to all namespaces, including system namespaces** (`kube-*`, `d8-*`, `loghouse`, `default`, etc.). To allow access to all namespaces, including system namespaces, set `spec.namespaceSelector.matchAny: true`. If the `namespaceSelector` parameter is specified, the `limitNamespaces` and `allowAccessToSystemNamespaces` values are **ignored**.

  Example:

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: all-namespaces-including-system
spec:
  subjects:
  - kind: User
    name: user@example.com
  accessLevel: Editor
  namespaceSelector:
    matchAny: true
```

- **Allow access to all namespaces except system namespaces**. To grant a user access to all namespaces except system namespaces, do not specify `namespaceSelector`, `limitNamespaces`, or `allowAccessToSystemNamespaces` when creating a ClusterAuthorizationRule. For a list of system namespaces, see the CR field description.

> **i** The `SuperAdmin` access level **does not lift** the namespace restrictions specified in the `namespaceSelector` and `limitNamespaces` parameters. If you need to grant access to all namespaces, specify the scope explicitly, including via `namespaceSelector.matchAny`.

If several `ClusterAuthorizationRule` resources match the same subject, the allowed namespaces are **unioned**; the effective `accessLevel` is the **most powerful** among all matching rules. For details, refer to the FAQ.

> **⚠** Namespace restrictions from `ClusterAuthorizationRule` are enforced by the authorization webhook chain. If the webhook is unavailable, these restrictions **do not apply** until the webhook is reachable again. For more information, see the module description.

Experimental role-based model

`d8:use:role:*` roles must be bound with `RoleBinding` in a **specific** namespace — use one `RoleBinding` per namespace (or automate the process). `d8:manage:*` roles do not cover namespaces for user workloads; they only apply to system namespaces (`d8-*`, `kube-*`) within the subsystem.

Creating a user

There are two types of users in Kubernetes:

- Service accounts managed by Kubernetes via the API;
- Regular users and groups managed by some external tool that the cluster administrator configures. There are many authentication mechanisms and, accordingly, many ways to create users. Currently, two authentication methods are supported:
  - Via the `user-authn` module. The module supports the following external providers and authentication protocols: GitHub, GitLab, Atlassian Crowd, BitBucket Cloud, Crowd, LDAP, OIDC. More details — in the documentation of the `user-authn` module.
  - Via the certificates.

When issuing the authentication certificate, you need to specify the name (`CN=<name>`), the required number of groups (`O=<group>`), and sign it using the root CA of the cluster. It is this mechanism that authenticates you in the cluster when, for example, you use kubectl on a bastion node.

Creating a ServiceAccount for a machine and granting it access

You may need to create a ServiceAccount with access to the Kubernetes API when, for example, an application is deployed using a CI system.

1. Create a ServiceAccount, e.g., in the `d8-service-accounts` namespace:

```
d8 k create -f - <<EOF
apiVersion: v1
kind: ServiceAccount
metadata:
  name: gitlab-runner-deploy
  namespace: d8-service-accounts
---
apiVersion: v1
kind: Secret
metadata:
  name: gitlab-runner-deploy-token
  namespace: d8-service-accounts
  annotations:
    kubernetes.io/service-account.name: gitlab-runner-deploy
type: kubernetes.io/service-account-token
EOF
```

2. Grant it the necessary privileges (using the ClusterAuthorizationRule custom resource):

```
d8 k create -f - <<EOF
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: gitlab-runner-deploy
spec:
  subjects:
  - kind: ServiceAccount
    name: gitlab-runner-deploy
    namespace: d8-service-accounts
  accessLevel: SuperAdmin
  # This option is only available if the enableMultiTenancy parameter is set.
  allowAccessToSystemNamespaces: true
EOF
```

   If multitenancy is enabled in the Deckhouse configuration (via the `enableMultiTenancy` parameter), configure the namespaces the ServiceAccount has access to (via the `namespaceSelector` parameter).

3. Set the variable values (they will be used later) by running the following commands (**insert your own values**):

```
export CLUSTER_NAME=my-cluster
export USER_NAME=gitlab-runner-deploy.my-cluster
export CONTEXT_NAME=${CLUSTER_NAME}-${USER_NAME}
export FILE_NAME=kube.config
```

4. Generate the `cluster` section in the kubectl configuration file:

   Use one of the following options to access the cluster API server:

   - If there is direct access to the API server:

     1. Get a Kubernetes cluster CA certificate:

        ```
        d8 k get cm kube-root-ca.crt -o jsonpath='{ .data.ca\.crt }' > /tmp/ca.crt
        ```

     2. Generate the `cluster` section (the API server’s IP address is used for access):

```
d8 k config set-cluster $CLUSTER_NAME --embed-certs=true \
  --server=https://$(d8 k get ep kubernetes -o json | jq -rc '.subsets[0] | "\
(.addresses[0].ip):\(.ports[0].port)"') \
  --certificate-authority=/tmp/ca.crt \
  --kubeconfig=$FILE_NAME
```

- If there is no direct access to the API server, use one of the following options:
  - enable access to the API-server over the Ingress controller (the publishAPI parameter) and specify the addresses from which requests originate (the whitelistSourceRanges parameter);
  - specify addresses from which requests will originate in a separate Ingress controller (the acceptRequestsFrom parameter).
- If a non-public CA is used:

  1. Get the CA certificate from the Secret with the certificate that is used for the `api.%s` domain:

     ```
     d8 k -n d8-user-authn get secrets -o json \
       $(d8 k -n d8-user-authn get ing kubernetes-api -o jsonpath="
     {.spec.tls[0].secretName}") \
       | jq -rc '.data."ca.crt" // .data."tls.crt"' \
       | base64 -d > /tmp/ca.crt
     ```

  2. Generate the `cluster` section (an external domain and a CA for access are used):

     ```
     d8 k config set-cluster $CLUSTER_NAME --embed-certs=true \
       --server=https://$(d8 k -n d8-user-authn get ing kubernetes-api -ojson | jq
     '.spec.rules[].host' -r) \
       --certificate-authority=/tmp/ca.crt \
       --kubeconfig=$FILE_NAME
     ```

- If a public CA is used. Generate the `cluster` section (an external domain is used for access):

  ```
  d8 k config set-cluster $CLUSTER_NAME \
    --server=https://$(d8 k -n d8-user-authn get ing kubernetes-api -ojson | jq
  '.spec.rules[].host' -r) \
    --kubeconfig=$FILE_NAME
  ```

5. Generate the `user` section using the token from the Secret's ServiceAccount in the kubectl configuration file:

   ```
   d8 k config set-credentials $USER_NAME \
     --token=$(d8 k -n d8-service-accounts get secret gitlab-runner-deploy-token -o json |jq -r
   '.data["token"]' | base64 -d) \
     --kubeconfig=$FILE_NAME
   ```

6. Generate the context in the kubectl configuration file:

   ```
   d8 k config set-context $CONTEXT_NAME \
     --cluster=$CLUSTER_NAME --user=$USER_NAME \
     --kubeconfig=$FILE_NAME
   ```

7. Set the generated context as the default one in the kubectl configuration file:

   ```
   d8 k config use-context $CONTEXT_NAME --kubeconfig=$FILE_NAME
   ```

How to create a user using a client certificate

> **i** This method is recommended for system needs (authentication of kubelets, control plane components, etc.). If you need to create a “normal” user (e.g. with console access, `kubectl`, etc.), use kubeconfig generation.

To create a user with a client certificate, you can use either OpenSSL or the Kubernetes API (via the CertificateSigningRequest object).

> ⚠ Certificates issued by any of these methods cannot be revoked. If a certificate is compromised, you will need to remove all permissions for that user (this can be difficult if the user is added to any groups: you will also need to remove all relevant groups).

Creating a user using a certificate issued via OpenSSL

> ⚠ Consider security risks when using this method.
>
> The `ca.crt` and `ca.key` must not leave the master node: sign the CSR only on the master node.
>
> Signing CSRs outside the master node risks compromising the cluster root certificate.

The features of this method are:

- The client certificate must be signed on the master node to prevent the cluster certificate from being compromised.
- Access to the cluster CA key (`ca.key`) is required. Only the cluster administrator can sign certificates.

To create a user using a client certificate issued through OpenSSL, follow these steps:

1. Get the cluster’s root certificate (`ca.crt` and `ca.key`).
2. Generate the user key:

   ```
   openssl ecparam -name prime256v1 -genkey -out myuser.key
   ```

3. Create a CSR file and specify the username in it (`myuser`) and groups to which this user belongs (`mygroup1` and `mygroup2`):

   ```
   openssl req -new -key myuser.key -out myuser.csr -subj
   "/CN=myuser/O=mygroup1/O=mygroup2"
   ```

4. Upload the CSR created in the previous step (`myuser.csr` in this example) to the master node and sign it with the cluster root certificate. Example command to sign the CSR on the master node (make sure that the paths to `myuser.csr`, `ca.crt` and `ca.key` are correct for your case):

   ```
   openssl x509 -req -in myuser.csr -CA /etc/kubernetes/pki/ca.crt -CAkey
   /etc/kubernetes/pki/ca.key -CAcreateserial -out myuser.crt -days 10
   ```

Now the certificate can be specified in the config file:

```
cat << EOF
apiVersion: v1
clusters:
- cluster:
    certificate-authority-data: $(cat /etc/kubernetes/pki/ca.crt | base64 -w0)
    server: https://<cluster_host>:6443
  name: kubernetes
contexts:
- context:
    cluster: kubernetes
    user: myuser
  name: myuser@kubernetes
current-context: myuser@kubernetes
kind: Config
preferences: {}
users:
- name: myuser
  user:
    client-certificate-data: $(cat myuser.crt | base64 -w0)
    client-key-data: $(cat myuser.key | base64 -w0)
EOF
```

Creating a user by issuing a certificate via the Kubernetes API

This is a more secure method because a special kubernetes API is used to sign the certificate.

The features of this method are:

- API-based certificate signing: CSRs are processed through the Kubernetes API without requiring access to the CA's private key (`ca.key`).
- Not only the cluster administrator can issue client certificates. The right to create CSRs and sign them can be assigned to a specific user.

To create a user using a client certificate issued through the Kubernetes API, follow these steps:

1. Generate the user key:

   ```
   openssl ecparam -name prime256v1 -genkey -out myuser.key
   ```

2. Create a CSR file and specify in it the username (`myuser`) and groups to which this user belongs (`mygroup1` and `mygroup2`):

   ```
   openssl req -new -key myuser.key -out myuser.csr -subj
   "/CN=myuser/O=mygroup1/O=mygroup2"
   ```

3. Create a manifest for the CertificateSigningRequest object and save it to a file (`csr.yaml` in this example):

   > **i** In the `request` field, specify the contents of the CSR created in the previous step, encoded in Base64.

```
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
metadata:
name: demo-client-cert
spec:
  request: # CSR in Base64
  signerName: "kubernetes.io/kube-apiserver-client"
  expirationSeconds: 7200
  usages:
  - "digital signature"
  - "client auth"
```

4. Apply the manifest to create a certificate signing request:

   ```
   d8 k apply -f csr.yaml
   ```

5. Check that the certificate has been approved and issued:

   ```
   d8 k get csr demo-client-cert
   ```

   If the certificate is issued, it will have the value `Approved,Issued` in the `CONDITION` column. Example output:

   ```
    NAME               AGE     SIGNERNAME                              REQUESTOR
   REQUESTEDDURATION   CONDITION
    demo-client-cert   8m24s   kubernetes.io/kube-apiserver-client   kubernetes-admin   120m
   Approved,Issued
   ```

   If the certificate is not automatically verified, verify it:

   ```
   d8 k certificate approve demo-client-cert
   ```

   Then, confirm that the certificate has been successfully approved.

6. Extract the encoded certificate from the CSR named `demo-client-cert`, decode it from Base64 and save it to the file (`myuser.crt` in this example) created in step 2:

   ```
   d8 k get csr demo-client-cert -ojsonpath="{.status.certificate}" | base64 -d >
   myuser.crt
   ```

Now the certificate can be specified in the config file:

```
cat << EOF
apiVersion: v1
clusters:
- cluster:
    certificate-authority-data: $(cat /etc/kubernetes/pki/ca.crt | base64 -w0)
    server: https://<cluster_host>:6443
  name: kubernetes
contexts:
- context:
    cluster: kubernetes
    user: myuser
  name: myuser@kubernetes
current-context: myuser@kubernetes
kind: Config
preferences: {}
users:
- name: myuser
  user:
    client-certificate-data: $(cat myuser.crt | base64 -w0)
    client-key-data: $(cat myuser.key | base64 -w0)
EOF
```

Granting access to the created user

To grant access to the created user, create a `ClusterAuthorizationRule'.

Example of a `ClusterAuthorizationRule`:

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: myuser
spec:
  subjects:
  - kind: User
    name: myuser
  accessLevel: PrivilegedUser
  portForwarding: true
```

Configuring kube-apiserver for multi-tenancy mode

The multi-tenancy mode, which allows you to restrict access to namespaces, is enabled by the enableMultiTenancy module's parameter.

Working in multi-tenancy mode requires enabling the Webhook authorization plugin and configuring a `kube-apiserver`. All actions necessary for the multi-tenancy mode are performed **automatically** by the control-plane-manager module; no additional steps are required.

Changes to the `kube-apiserver` manifest that will occur after enabling multi-tenancy mode:

- The authorization chain will be configured using the structured authorization configuration (`--authorization-config=/etc/kubernetes/deckhouse/extra-files/authorization-config.yaml`) with `Node`, `Webhook`, and `RBAC` authorizers;
- The `kubeconfig` for the authorization webhook will be created at `/etc/kubernetes/deckhouse/extra-files/webhook-config.yaml`;
- The `volumeMounts` parameter will be added:

  ```
  - name: authorization-webhook-config
    mountPath: /etc/kubernetes/authorization-webhook-config.yaml
    readOnly: true
  ```

- The `volumes` parameter will be added:

```
- name: authorization-webhook-config
  hostPath:
    path: /etc/kubernetes/authorization-webhook-config.yaml
    type: FileOrCreate
```

How do I check that a user has access?

Execute the command below with the following parameters:

- `resourceAttributes` (the same as in RBAC) - target resources;
- `user` - the name of the user;
- `groups` - user groups;

> **i** You can use Dex logs to find out groups and a username if this module is used together with the `user-authn` module (`d8 k -n d8-user-authn logs -l app=dex`); logs available only if the user is authorized.

```
cat  <<EOF | 2>&1 d8 k  create --raw
/apis/authorization.k8s.io/v1/subjectaccessreviews -f - | jq .status
{
  "apiVersion": "authorization.k8s.io/v1",
  "kind": "SubjectAccessReview",
  "spec": {
    "resourceAttributes": {
      "namespace": "",
      "verb": "watch",
      "version": "v1",
      "resource": "pods"
    },
    "user": "system:kube-controller-manager",
    "groups": [
      "Admins"
    ]
  }
}
EOF
```

You will see if access is allowed and what role is used:

```
{
  "allowed": true,
  "reason": "RBAC: allowed by ClusterRoleBinding \"system:kube-controller-manager\"
of ClusterRole \"system:kube-controller-manager\" to User \"system:kube-controller-
manager\""
}
```

If the **multitenancy** mode is enabled in your cluster, you need to perform another check to be sure that the user has access to the namespace:

```
cat  <<EOF | 2>&1 d8 k --kubeconfig /etc/kubernetes/deckhouse/extra-files/webhook-
config.yaml create --raw / -f - | jq .status
{
  "apiVersion": "authorization.k8s.io/v1",
  "kind": "SubjectAccessReview",
  "spec": {
    "resourceAttributes": {
      "namespace": "",
      "verb": "watch",
      "version": "v1",
      "resource": "pods"
    },
    "user": "system:kube-controller-manager",
    "groups": [
      "Admins"
    ]
  }
}
EOF
```

```
{
  "allowed": false
}
```

The `allowed: false` message means that the webhook doesn’t block access. In case of webhook denying the request, you will see, e.g., the following message:

```
{
  "allowed": false,
  "denied": true,
  "reason": "making cluster scoped requests for namespaced resources are not
allowed"
}
```

Customizing rights of high-level roles

If you want to grant more privileges to a specific high-level role, you only need to create a ClusterRole with the `user-authz.deckhouse.io/access-level: <AccessLevel>` annotation.

An example:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  annotations:
    user-authz.deckhouse.io/access-level: Editor
  name: user-editor
rules:
- apiGroups:
  - kuma.io
  resources:
  - trafficroutes
  - trafficroutes/finalizers
  verbs:
  - get
  - list
  - watch
  - create
  - update
  - patch
  - delete
- apiGroups:
  - flagger.app
  resources:
  - canaries
  - canaries/status
  - metrictemplates
  - metrictemplates/status
  - alertproviders
  - alertproviders/status
  verbs:
  - get
  - list
  - watch
  - create
  - update
  - patch
  - delete
```

FAQ

> **i** The module lifecycle stage: General Availability

How do I create a user?

Creating a user.

How do I limit user rights to specific namespaces?

To limit a user's rights to specific namespaces in the experimental role-based model, use `RoleBinding` with the use role that has the appropriate level of access. Example....

In the current role-based model, use the `namespaceSelector` or `limitNamespaces` (deprecated) parameters in the `ClusterAuthorizationRule` CR.

What if there are two ClusterAuthorizationRules matching to a single user?

In the example, the user `jane.doe@example.com` is in the `administrators` group. There are two cluster authorization rules:

```
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: jane
spec:
  subjects:
    - kind: User
      name: jane.doe@example.com
  accessLevel: User
  namespaceSelector:
    labelSelector:
      matchLabels:
        env: review
---
apiVersion: deckhouse.io/v1
kind: ClusterAuthorizationRule
metadata:
  name: admin
spec:
  subjects:
  - kind: Group
    name: administrators
  accessLevel: ClusterAdmin
  namespaceSelector:
    labelSelector:
      matchExpressions:
      - key: env
        operator: In
        values:
        - prod
        - stage
```

1. `jane.doe@example.com` has the right to get and list any objects in the namespaces labeled `env=review`
2. `Administrators` can get, edit, list, and delete objects on the cluster level and in the namespaces labeled `env=prod` and `env=stage`.

Because `Jane Doe` matches two rules, some calculations will be made:

- `Jane Doe` will have the most powerful accessLevel across all matching rules — `ClusterAdmin`.
- The `namespaceSelector` options will be combined, so that Jane will have access to all the namespaces labeled with `env` label of the following values: `review`, `stage`, or `prod`.

> ⚠ If there is a rule without the `namespaceSelector` option and `limitNamespaces` deprecated option, it means that all namespaces are allowed excluding system namespaces, which will affect the resulting limit namespaces calculation.

How do I extend a role or create a new one?

The experimental role model is based on the aggregation principle; it compiles smaller roles into larger ones, thus providing easy ways to enhance the model with custom roles.

Creating a new role subsystem

Suppose that the current subsystems do not fit the role distribution in the company. You need to create a new subsystem that includes roles from the `deckhouse` subsystem, the `kubernetes` subsystem and the user-authn module.

To meet this need, create the following role:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: custom:manage:mycustom:manager
  labels:
    rbac.deckhouse.io/use-role: admin
    rbac.deckhouse.io/kind: manage
    rbac.deckhouse.io/level: subsystem
    rbac.deckhouse.io/subsystem: custom
    rbac.deckhouse.io/aggregate-to-all-as: manager
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-deckhouse-as: manager
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-kubernetes-as: manager
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        module: user-authn
rules: []
```

The labels for the new role listed at the top suggest that:

- The hook will use this use role:

  ```
  rbac.deckhouse.io/use-role: admin
  ```

- The role must be treated as a managed one:

  ```
  rbac.deckhouse.io/kind: manage
  ```

  > **i** Note that this label is mandatory.

- The role is a subsystem one, and it shall be handled accordingly:

  ```
  rbac.deckhouse.io/level: subsystem
  ```

- There is a subsystem for which the role is responsible:

  ```
  rbac.deckhouse.io/subsystem: custom
  ```

- The `manage:all` role can aggregate this role:

  ```
  rbac.deckhouse.io/aggregate-to-all-as: manager
  ```

Then there are selectors that implement aggregation:

- This one aggregates the manager role from the `deckhouse` subsystem:

  ```
  rbac.deckhouse.io/kind: manage
  rbac.deckhouse.io/aggregate-to-deckhouse-as: manager
  ```

- This one aggregates all the rules defined for the user-authn module:

  ```
  rbac.deckhouse.io/kind: manage
  module: user-authn
  ```

This way, your role will combine permissions of the `deckhouse` subsystem, `kubernetes` subsystem, and the user-authn module.

Notes:

- There are no restrictions on role name, but we recommend following the same pattern for the sake of readability.
- Use-roles will be created in aggregate subsystems and the module namespace, the role type is specified by the label.

Extending the custom role

Suppose a new cluster CRD object, MySuperResource, has been created in the cluster (a manage role example), and you need to extend the custom role from the example above to include the permissions to interact with this resource.

First, you have to add a new selector to the role:

```
rbac.deckhouse.io/kind: manage
rbac.deckhouse.io/aggregate-to-custom-as: manager
```

This selector would enable roles to be aggregated to a new subsystem by specifying this label. After adding the new selector, the role will look as follows:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: custom:manage:mycustom:manager
  labels:
    rbac.deckhouse.io/use-role: admin
    rbac.deckhouse.io/kind: manage
    rbac.deckhouse.io/level: subsystem
    rbac.deckhouse.io/subsystem: custom
    rbac.deckhouse.io/aggregate-to-all-as: manager
aggregationRule:
  clusterRoleSelectors:
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-deckhouse-as: manager
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-kubernetes-as: manager
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        module: user-authn
    - matchLabels:
        rbac.deckhouse.io/kind: manage
        rbac.deckhouse.io/aggregate-to-custom-as: manager
rules: []
```

Next, you need to create a new role and define permissions for the new resource, e. g., the read-only permission:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  labels:
    rbac.deckhouse.io/aggregate-to-custom-as: manager
    rbac.deckhouse.io/kind: manage
  name: custom:manage:permission:mycustom:superresource:view
rules:
- apiGroups:
  - mygroup.io
  resources:
  - mysuperresources
  verbs:
  - get
  - list
  - watch
```

The role will update the subsystem role to include its rights, so that the role bearer will be able to view the new object.

Notes:

- There are no restrictions on capability names, but we recommend following the same pattern for the sake of readability.

Extending the existing manage subsystem roles

To extend an existing role, follow the procedure outlined in the section above. Be sure to change the labels and the role name!

For example, here’s how you can extend the manager role from the `deckhouse` (`d8:manage:deckhouse:manager`) subsystem:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  labels:
    rbac.deckhouse.io/aggregate-to-deckhouse-as: manager
    rbac.deckhouse.io/kind: manage
  name: custom:manage:permission:mycustom:superresource:view
rules:
- apiGroups:
  - mygroup.io
  resources:
  - mysuperresources
  verbs:
  - get
  - list
  - watch
```

This way, the new role will extend the `d8:manage:deckhouse:manager` role.

Extending manage subsystem roles and adding a new namespace

If you need to create a new namespace (to create a use role in it by the hook), you only need to add one label:

```
"rbac.deckhouse.io/namespace": namespace
```

This label instructs the hook to create a use role in this namespace:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  labels:
    rbac.deckhouse.io/aggregate-to-deckhouse-as: manager
    rbac.deckhouse.io/kind: manage
    rbac.deckhouse.io/namespace: namespace
  name: custom:manage:permission:mycustom:superresource:view
rules:
- apiGroups:
  - mygroup.io
  resources:
  - mysuperresources
  verbs:
  - get
  - list
  - watch
```

The hook monitors `ClusterRoleBinding`, and when creating a bindings, it loops through all the manage roles to find all the aggregated roles by checking the aggregation rule. It then fetches the namespace from the `rbac.deckhouse.io/namespace` label and creates a use role in that namespace.

Extending the existing use roles

If the resource belongs to a namespace, you need to extend the use role instead of the manage role. The only difference is the labels and the name:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  labels:
    rbac.deckhouse.io/aggregate-to-kubernetes-as: user
    rbac.deckhouse.io/kind: use
  name: custom:use:capability:mycustom:superresource:view
rules:
- apiGroups:
  - mygroup.io
  resources:
  - mysuperresources
  verbs:
  - get
  - list
  - watch
```

This role will be added to the `d8:use:role:user:kubernetes` role.

The vertical-pod-autoscaler module

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

Vertical Pod Autoscaler (VPA) is an infrastructure service that allows you to avoid setting exact resource requests for a container if their values are not known in advance. VPA can automatically adjust the CPU and memory reservations (providing that the corresponding mode is enabled) based on the actual resource consumption (as shown by the Prometheus data). Also, VPA can recommend values for resource requests and limits without updating them automatically.

VPA has the following operating modes:

- `"Auto"` (default) — currently the `Auto` and `Recreate` modes do the same thing. However, when Pod in-place resource update appears in Kubernetes, this mode will do exactly that.
- `"Recreate"` — the mode allows VPA to change resources of running pods (restart them while

running). In case of one pod running (`replicas: 1`), this will lead to the service being unavailable during the restart. In this mode, VPA does not recreate pods that were created without a controller.
- `"Initial"` — VPA modifies Pod resources only when Pods are started (but not during operation).
- `"Off"` — VPA does not take any action to update the resource requests for the running containers. In this case, if VPA is running in this mode, you can see what resource values it recommends (`d8 k describe vpa <vpa-name>`).

⚠ The `Auto` mode is deprecated. It will no longer be supported in future DKP versions. Switch to one of the supported operating modes.

VPA limitations:

- Updating the resources of running Pods is currently experimental. The Pod is recreated each time VPA updates its `resource requests`. The Pod can be scheduled to another node.
- VPA **should not be used concurrently with CPU and memory-based HPA**. However, you can use VPA together with HPA for custom/external metrics.
- VPA notices almost all `out-of-memory` events, but that does not guarantee its response.
- VPA performance has not been tested for huge clusters.
- VPA recommendations may exceed the available resources in the cluster. That can lead to **Pods becoming Pending**.
- Using multiple VPAs for the same Pod can lead to undefined behavior.
- If VPA is deleted or “turned off” (the `Off` mode), the changes made by VPA earlier are not reset (the most recent value set is kept). It may lead to confusion due to the difference between resource values in Helm/controller and the actual resources of Pods (it may be perceived as if they “came from out of nowhere”).

i We highly recommend using Pod Disruption Budget with VPA.

Grafana dashboard

Displayed on dashboards:

- `Main / Namespace`, `Main / Namespace / Controller`, `Main / Namespace / Controller / Pod` — the `VPA type` column shows the value of `updatePolicy.updateMode`;
- `Main / Namespaces` — the `VPA %` column shows the percentage of VPA-enabled Pods.

Vertical Pod Autoscaler Architecture

VPA consists of 3 components:

- `Recommender` — this component monitors the current resource consumption (by making requests to the Metrics API implemented in the `prometheus-metrics-adapter` module) as well as consumption history (by making requests to Trickster caching proxy). As its name suggests, the component provides CPU and memory recommendations for containers.
- `Updater` — this component checks if the Pods have correct resources set and, if not, kills them so that they can be recreated by their controllers with the updated resource requests.
- `Admission Plugin` — this component sets the correct resource requests on new Pods (either just created or recreated by their controller due to Updater’s activity).

When the Updater component changes resource values, Pods are evicted using the Eviction API. Thus, the `Pod Disruption Budget` is taken into account for the Pods being updated.

Third-party components

List of third-party software used in the `vertical-pod-autoscaler` module:

- Kubernetes Autoscaler 1.6.0

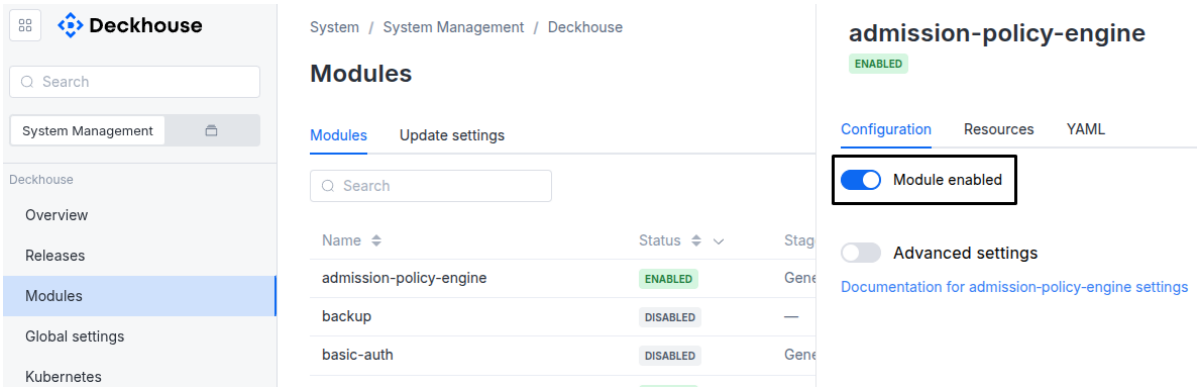
  License: Apache License 2.0

  A autoscaling-related components for Kubernetes.

The vertical-pod-autoscaler: configuration

> The module lifecycle stage: General Availability
> The module has requirements for installation

VPA works directly with the Pod (instead of the Pod controller) by measuring and changing its containers' parameters. Configuring is performed using the `VerticalPodAutoscaler` Custom Resource.



The module generally requires no configuration and only has the `nodeSelector/tolerations` settings.

The module is **enabled** by default in the following bundles: `Default`, `Managed`. The module is **disabled** by default in the `Minimal` bundle.

You may explicitly enable or disable the module in one of the following ways:

- **Via Deckhouse web UI.** In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `vertical-pod-autoscaler` module and enable (or disable) the "Module enabled" toggle. Save changes.

  Example:

- **Via Deckhouse CLI (d8).**

  Use the d8 system module enable command for enabling, or d8 system module disable command for disabling the module (you need Deckhouse CLI (d8), configured to work with the cluster).

  Example of enabling the module:

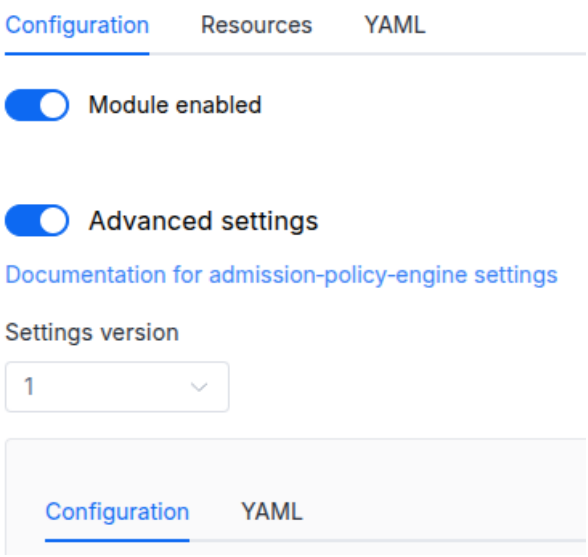
```
d8 system module enable vertical-pod-autoscaler
```

- **Using ModuleConfig `vertical-pod-autoscaler`.**

  Set `spec.enabled` to `true` or `false` in ModuleConfig `vertical-pod-autoscaler` (create it if necessary);

  Example of a manifest to enable module `vertical-pod-autoscaler`:

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: vertical-pod-autoscaler
spec:
  enabled: true
```



How to configure the module...

You can configure the module in one of the following ways:

- **Via Deckhouse web UI.**

  In the "System" → "System Management" → "Deckhouse" → "Modules" section, open the `vertical-pod-autoscaler` module and enable the "Advanced Settings" switch. Fill in the required fields in the "Configuration" tab or specify the module settings in YAML format on the "YAML" tab, **excluding the settings section**. Save the changes.

  Example:

You can also edit the ModuleConfig object `vertical-pod-autoscaler` on the “YAML” tab in the module settings window (“System” → “System Management” → “Deckhouse” → “Modules”, open the module `vertical-pod-autoscaler`) by specifying the schema version in the `spec.version` parameter and the necessary module parameters in the `spec.settings` section.

- **Via Deckhouse CLI (d8)** (requires Deckhouse CLI (d8) configured to work with the cluster).

  Edit the existing ModuleConfig `vertical-pod-autoscaler` (for more details on configuring Deckhouse, see the documentation) by executing the following command:

  ```
  d8 k edit mc vertical-pod-autoscaler
  ```

  Make the necessary changes in the `spec.settings` section. If necessary, specify the schema version in the `spec.version` parameter. Save the changes.

  You can also create a file with manifest for ModuleConfig `vertical-pod-autoscaler` using the example below. Fill in the `spec.settings` section with the required module parameters. If necessary, specify the schema version in the `spec.version` parameter.

  Apply the manifest using the following command (indicate the manifest file name):

  ```
  d8 k apply -f <FILENAME>
  ```

  Example of a manifest for ModuleConfig `vertical-pod-autoscaler`:

  ```
  apiVersion: deckhouse.io/v1alpha1
  kind: ModuleConfig
  metadata:
    name: vertical-pod-autoscaler
  spec:
    version: 1
    enabled: true
    settings: # Module parameters from the "Parameters" section below.
  ```

Requirements

To the versions of other modules:

- `prometheus`: any version.
- `prometheus-metrics-adapter`: any version.

Parameters

Schema version: 1

- **settings**
  object
  - **settings.nodeSelector**

object

The same as in the pods' `spec.nodeSelector` parameter in Kubernetes.

If the parameter is omitted or `false`, it will be determined automatically.

- **settings.tolerations**
  array of objects

  The same as in the pods' `spec.tolerations` parameter in Kubernetes;

  If the parameter is omitted or `false`, it will be determined automatically.

  - **settings.tolerations.effect**
    string
  - **settings.tolerations.key**
    string
  - **settings.tolerations.operator**
    string
  - **settings.tolerations.tolerationSeconds**
    integer
  - **settings.tolerations.value**
    string

Custom resources

> **i** The Deckhouse Kubernetes Platform installs CRDs but does not remove them when a module is disabled. If you no longer need the created CRDs, delete them.

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

VerticalPodAutoscaler

Short names: vpa

Scope: Namespaced

- v1
- v1beta2

Configuration for a vertical pod autoscaler, which automatically manages pod resources based on historical and real time resource utilization.

- **apiVersion**
  string

  Defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values.

  More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase.

  More information in the documentation.

- **metadata**
  object
- **spec**
  object

  Required value

  Specification of the behavior of the autoscaler.

  More information in the documentation.

  - **spec.recommenders**

array of objects

Recommender responsible for generating recommendation for this object. List should be empty (then the default recommender will generate the recommendation) or contain exactly one recommender.

VerticalPodAutoscalerRecommenderSelector points to a specific Vertical Pod Autoscaler recommender. In the future it might pass parameters to the recommender.

- **spec.recommenders.name**
  string

  Required value

  Name of the recommender responsible for generating recommendation for this object.

- **spec.resourcePolicy**
  object

  Controls how the autoscaler computes recommended resources. The resource policy may be used to set constraints on the recommendations for individual containers.

  If any individual containers need to be excluded from getting the VPA recommendations, then it must be disabled explicitly by setting mode to `Off` under `containerPolicies`.

  If not specified, the autoscaler computes recommended resources for all containers in the pod, without additional constraints.

  - **spec.resourcePolicy.containerPolicies**
    array of objects

    Per-container resource policies.

    Controls how autoscaler computes the recommended resources for a specific container.

    - **spec.resourcePolicy.containerPolicies.containerName**
      string

      Name of the container or `DefaultContainerResourcePolicy`, in which case the policy is used by the containers that don’t have their own policy specified.

    - **spec.resourcePolicy.containerPolicies.controlledResources**
      array of strings

      Specifies the type of recommendations that will be computed (and possibly applied) by VPA. If not specified, the default of (`ResourceCPU`, `ResourceMemory`) will be used.

      Default: `["cpu","memory"]`

      - **Element of the array**
        string

        ResourceName is the name identifying various resources in a ResourceList.

    - **spec.resourcePolicy.containerPolicies.controlledValues**
      string

      Specifies which resource values should be controlled.

      Default: `RequestsAndLimits`

      Allowed values: `RequestsAndLimits`, `RequestsOnly`

    - **spec.resourcePolicy.containerPolicies.maxAllowed**
      object

      Specifies the maximum amount of resources that will be recommended for the container. The default is no maximum.

    - **spec.resourcePolicy.containerPolicies.minAllowed**
      object

      Specifies the minimal amount of resources that will be recommended for the container. The default is no minimum.

    - **spec.resourcePolicy.containerPolicies.mode**
      string

Whether autoscaler is enabled for the container.

Default: `Auto`

Allowed values: `Auto`, `Off`

- **spec.scope**
  string

  Scope controls additional recommendation partitioning for DaemonSet targets.

  The value must be a node label key (for example: `node.kubernetes.io/instance-type`).

- **spec.targetRef**
  object

  Required value

  Points to the controller managing the set of pods for the autoscaler to control — e.g. Deployment, StatefulSet.

  VerticalPodAutoscaler can be targeted at controller implementing scale subresource (the pod set is retrieved from the controller's `ScaleStatus`) or some well known controllers (e.g. for DaemonSet the pod set is read from the controller's spec).

  If VerticalPodAutoscaler cannot use specified target it will report `ConfigUnsupported` condition. Note that VerticalPodAutoscaler does not require full implementation of scale subresource — it will not use it to modify the replica count. The only thing retrieved is a label selector matching pods grouped by the target resource.

  - **spec.targetRef.apiVersion**
    string

    API version of the referent.

  - **spec.targetRef.kind**
    string

    Required value

    Kind of the referent.

    More info.

  - **spec.targetRef.name**
    string

    Required value

    Name of the referent.

    More info.

- **spec.updatePolicy**
  object

  Describes the rules on how changes are applied to the pods. If not specified, all fields in the `PodUpdatePolicy` are set to their default values.

  - **spec.updatePolicy.evictionRequirements**
    array of objects

    EvictionRequirements is a list of EvictionRequirements that need to evaluate to true in order for a Pod to be evicted. If more than one EvictionRequirement is specified, all of them need to be fulfilled to allow eviction.

    EvictionRequirement defines a single condition which needs to be true in order to evict a Pod.

    - **spec.updatePolicy.evictionRequirements.changeRequirement**
      string

      Required value

      EvictionChangeRequirement refers to the relationship between the new target recommendation for a Pod and its current requests, what kind of change is necessary for the Pod to be evicted.

      Allowed values: `TargetHigherThanRequests`, `TargetLowerThanRequests`

        - **spec.updatePolicy.evictionRequirements.resources**
          array of strings

          Required value

          Resources is a list of one or more resources that the condition applies to. If more than one resource is given, the EvictionRequirement is fulfilled if at least one resource meets `changeRequirement`.

          - **Element of the array**
            string

            ResourceName is the name identifying various resources in a ResourceList.

      - **spec.updatePolicy.minReplicas**
        integer

        Minimal number of replicas which need to be alive for Updater to attempt pod eviction (pending other checks like PDB). Only positive values are allowed. Overrides global '–min-replicas' flag.

      - **spec.updatePolicy.updateMode**
        string

        The operation mode of the VPA controller.

        - `Auto` — currently, Auto and Recreate modes do the same thing. This mode is reserved for the Pod inplace resource update in Kubernetes.
        - `Recreate` — this mode allows VPA to modify resource requirements of the running pods (i.e., restart them during operation). This mode might result in temporary unavailability of the service (due to restart) if you have just one replica (replicas: 1). In this mode, VPA does not recreate pods that were not created by a controller.
        - `Initial` — VPA modifies pod resources only when pods are started (but not when pods are running).
        - `Off` — VPA does not take any action to update the resource requests for the running containers. Autoscaler calculates recomendations and stores them in the status field of the VPA object. You can browse VPA recommendations using the following command: `d8 k describe vpa <vpa-name>`.
        - `InPlaceOrRecreate` (GA) — supported in Kubernetes 1.33 and later. The VPA attempts to update pod resources without a restart; if that is not possible, it recreates the pod.

        Default: `InPlaceOrRecreate`

        Allowed values: `Off`, `Initial`, `Recreate`, `Auto`, `InPlaceOrRecreate`

- **status**
  object

  Current information about the autoscaler.

  - **status.conditions**
    array of objects

    Set of conditions required for this autoscaler to scale its target, and indicates whether or not those conditions are met.

    Describes the state of a VerticalPodAutoscaler at a certain point.

    - **status.conditions.lastTransitionTime**
      string

      Last time the condition transitioned from one status to another.

    - **status.conditions.message**
      string

      A human-readable explanation containing details about the transition.

    - **status.conditions.reason**
      string

      Reason for the condition's last transition.

    - **status.conditions.status**
      string

Required value

Status of the condition (`True`, `False`, Unknown).

- **status.conditions.type**
  string

  Required value

  Describes the current condition.

- **status.groups**
  array of objects

  Contains grouped recommendations by scope value when `spec.scope` is used.

  - **status.groups.containerRecommendations**
    array of objects

    Resources recommended by autoscaler for each container in this group.

    - **status.groups.containerRecommendations.containerName**
      string

      Name of the container.

    - **status.groups.containerRecommendations.lowerBound**
      object

      Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

    - **status.groups.containerRecommendations.scope**
      string

      Scope binds this recommendation to a specific scope value in form “ =".

    - **status.groups.containerRecommendations.target**
      object

      Required value

      Recommended amount of resources. Observes `ContainerResourcePolicy`.

    - **status.groups.containerRecommendations.uncappedTarget**
      object

      The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`.

      May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

    - **status.groups.containerRecommendations.upperBound**
      object

      Maximum recommended amount of resources.

      Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

  - **status.groups.scopeValue**
    string

    Required value

    Scope value of `spec.scope` label key for this recommendation group.

- **status.recommendation**
  object

  The most recently computed amount of resources recommended by the autoscaler for the

controlled pods.

- **status.recommendation.containerRecommendations**
  array of objects

  Resources recommended by the autoscaler for each container.

  Recommendation of resources computed by autoscaler for a specific container. Respects the container resource policy if present in the spec. In particular the recommendation is not produced for containers with `ContainerScalingMode` set to 'Off'.

  - **status.recommendation.containerRecommendations.containerName**
    string

    Name of the container.

  - **status.recommendation.containerRecommendations.lowerBound**
    object

    Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

  - **status.recommendation.containerRecommendations.scope**
    string

    Scope binds this recommendation to a specific scope value in form " =".

  - **status.recommendation.containerRecommendations.target**
    object

    Required value

    Recommended amount of resources. Observes `ContainerResourcePolicy`.

  - **status.recommendation.containerRecommendations.uncappedTarget**
    object

    The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`. May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

  - **status.recommendation.containerRecommendations.upperBound**
    object

    Maximum recommended amount of resources. Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

Deprecated resource. Support for the resource might be removed in a later release.

Configuration for a vertical pod autoscaler, which automatically manages pod resources based on historical and real time resource utilization.

- **apiVersion**
  string

  Defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values.

  More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase.

  More information in the documentation.

- **metadata**
  object

- **spec**
  object

  Required value

  Specification of the behavior of the autoscaler.

  More information in the documentation.

  - **spec.recommenders**
    array of objects

    Recommender responsible for generating recommendation for this object. List should be empty (then the default recommender will generate the recommendation) or contain exactly one recommender.

    VerticalPodAutoscalerRecommenderSelector points to a specific Vertical Pod Autoscaler recommender. In the future it might pass parameters to the recommender.

    - **spec.recommenders.name**
      string

      Required value

      Name of the recommender responsible for generating recommendation for this object.

  - **spec.resourcePolicy**
    object

    Controls how the autoscaler computes recommended resources. The resource policy may be used to set constraints on the recommendations for individual containers.

    If any individual containers need to be excluded from getting the VPA recommendations, then it must be disabled explicitly by setting mode to `Off` under `containerPolicies`.

    If not specified, the autoscaler computes recommended resources for all containers in the pod, without additional constraints.

    - **spec.resourcePolicy.containerPolicies**
      array of objects

      Per-container resource policies.

      Controls how autoscaler computes the recommended resources for a specific container.

      - **spec.resourcePolicy.containerPolicies.containerName**
        string

        Name of the container or `DefaultContainerResourcePolicy`, in which case the policy is used by the containers that don’t have their own policy specified.

      - **spec.resourcePolicy.containerPolicies.controlledResources**
        array of strings

        Specifies the type of recommendations that will be computed (and possibly applied) by VPA. If not specified, the default of (`ResourceCPU`, `ResourceMemory`) will be used.

        Default: `["cpu","memory"]`

        - **Element of the array**
          string

          ResourceName is the name identifying various resources in a ResourceList.

      - **spec.resourcePolicy.containerPolicies.controlledValues**
        string

        Specifies which resource values should be controlled.

        Default: `RequestsAndLimits`

        Allowed values: `RequestsAndLimits`, `RequestsOnly`

      - **spec.resourcePolicy.containerPolicies.maxAllowed**
        object

        Specifies the maximum amount of resources that will be recommended for the container. The default is no maximum.

        - **spec.resourcePolicy.containerPolicies.minAllowed**
          object

          Specifies the minimal amount of resources that will be recommended for the container. The default is no minimum.

        - **spec.resourcePolicy.containerPolicies.mode**
          string

          Whether autoscaler is enabled for the container.

          Default: `Auto`

          Allowed values: `Auto`, `Off`

    - **spec.scope**
      string

      Scope controls additional recommendation partitioning for DaemonSet targets.

      The value must be a node label key (for example: `node.kubernetes.io/instance-type`).

    - **spec.targetRef**
      object

      Required value

      Points to the controller managing the set of pods for the autoscaler to control — e.g. Deployment, StatefulSet.

      VerticalPodAutoscaler can be targeted at controller implementing scale subresource (the pod set is retrieved from the controller's `ScaleStatus`) or some well known controllers (e.g. for DaemonSet the pod set is read from the controller's spec).

      If VerticalPodAutoscaler cannot use specified target it will report `ConfigUnsupported` condition. Note that VerticalPodAutoscaler does not require full implementation of scale subresource — it will not use it to modify the replica count. The only thing retrieved is a label selector matching pods grouped by the target resource.

        - **spec.targetRef.apiVersion**
          string

          API version of the referent.

        - **spec.targetRef.kind**
          string

          Required value

          Kind of the referent.

          More info.

        - **spec.targetRef.name**
          string

          Required value

          Name of the referent.

          More info.

    - **spec.updatePolicy**
      object

      Describes the rules on how changes are applied to the pods. If not specified, all fields in the `PodUpdatePolicy` are set to their default values.

        - **spec.updatePolicy.evictionRequirements**
          array of objects

          EvictionRequirements is a list of EvictionRequirements that need to evaluate to true in order for a Pod to be evicted. If more than one EvictionRequirement is specified, all of them need to be fulfilled to allow eviction.

          EvictionRequirement defines a single condition which needs to be true in order to evict a Pod.

            - **spec.updatePolicy.evictionRequirements.changeRequirement**

string

Required value

EvictionChangeRequirement refers to the relationship between the new target recommendation for a Pod and its current requests, what kind of change is necessary for the Pod to be evicted.

Allowed values: `TargetHigherThanRequests`, `TargetLowerThanRequests`

- **spec.updatePolicy.evictionRequirements.resources**
  array of strings

  Required value

  Resources is a list of one or more resources that the condition applies to. If more than one resource is given, the EvictionRequirement is fulfilled if at least one resource meets `changeRequirement`.

  - **Element of the array**
    string

    ResourceName is the name identifying various resources in a ResourceList.

- **spec.updatePolicy.minReplicas**
  integer

  Minimal number of replicas which need to be alive for Updater to attempt pod eviction (pending other checks like PDB). Only positive values are allowed. Overrides global '–min-replicas' flag.

- **spec.updatePolicy.updateMode**
  string

  The operation mode of the VPA controller.

  - `Auto` — currently, Auto and Recreate modes do the same thing. This mode is reserved for the Pod inplace resource update in Kubernetes.
  - `Recreate` — this mode allows VPA to modify resource requirements of the running pods (i.e., restart them during operation). This mode might result in temporary unavailability of the service (due to restart) if you have just one replica (replicas: 1). In this mode, VPA does not recreate pods that were not created by a controller.
  - `Initial` — VPA modifies pod resources only when pods are started (but not when pods are running).
  - `Off` — VPA does not take any action to update the resource requests for the running containers. Autoscaler calculates recomendations and stores them in the status field of the VPA object. You can browse VPA recommendations using the following command: `d8 k describe vpa <vpa-name>`.
  - `InPlaceOrRecreate` (GA) — supported in Kubernetes 1.33 and later. The VPA attempts to update pod resources without a restart; if that is not possible, it recreates the pod.

  Default: `InPlaceOrRecreate`

  Allowed values: `Off`, `Initial`, `Recreate`, `Auto`, `InPlaceOrRecreate`

- **status**
  object

  Current information about the autoscaler.

  - **status.conditions**
    array of objects

    Set of conditions required for this autoscaler to scale its target, and indicates whether or not those conditions are met.

    Describes the state of a VerticalPodAutoscaler at a certain point.

    - **status.conditions.lastTransitionTime**
      string

      Last time the condition transitioned from one status to another.

    - **status.conditions.message**
      string

A human-readable explanation containing details about the transition.

- **status.conditions.reason**
  string

  Reason for the condition’s last transition.

- **status.conditions.status**
  string

  Required value

  Status of the condition (`True`, `False`, Unknown).

- **status.conditions.type**
  string

  Required value

  Describes the current condition.

- **status.groups**
  array of objects

  Contains grouped recommendations by scope value when `spec.scope` is used.

  - **status.groups.containerRecommendations**
    array of objects

    Resources recommended by autoscaler for each container in this group.

    - **status.groups.containerRecommendations.containerName**
      string

      Name of the container.

    - **status.groups.containerRecommendations.lowerBound**
      object

      Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

    - **status.groups.containerRecommendations.scope**
      string

      Scope binds this recommendation to a specific scope value in form “ =".

    - **status.groups.containerRecommendations.target**
      object

      Required value

      Recommended amount of resources. Observes `ContainerResourcePolicy`.

    - **status.groups.containerRecommendations.uncappedTarget**
      object

      The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`.

      May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

    - **status.groups.containerRecommendations.upperBound**
      object

      Maximum recommended amount of resources.

      Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

  - **status.groups.scopeValue**

string

Required value

Scope value of `spec.scope` label key for this recommendation group.

- **status.recommendation**
  object

  The most recently computed amount of resources recommended by the autoscaler for the controlled pods.

  - **status.recommendation.containerRecommendations**
    array of objects

    Resources recommended by the autoscaler for each container.

    Recommendation of resources computed by autoscaler for a specific container. Respects the container resource policy if present in the spec. In particular the recommendation is not produced for containers with `ContainerScalingMode` set to 'Off'.

    - **status.recommendation.containerRecommendations.containerName**
      string

      Name of the container.

    - **status.recommendation.containerRecommendations.lowerBound**
      object

      Minimum recommended amount of resources. Observes `ContainerResourcePolicy`. This amount is not guaranteed to be sufficient for the application to operate in a stable way, however running with less resources is likely to have significant impact on performance/availability.

    - **status.recommendation.containerRecommendations.scope**
      string

      Scope binds this recommendation to a specific scope value in form " =".

    - **status.recommendation.containerRecommendations.target**
      object

      Required value

      Recommended amount of resources. Observes `ContainerResourcePolicy`.

    - **status.recommendation.containerRecommendations.uncappedTarget**
      object

      The most recent recommended resources target computed by the autoscaler for the controlled pods, based only on actual resource usage, not taking into account the `ContainerResourcePolicy`. May differ from the Recommendation if the actual resource usage causes the target to violate the `ContainerResourcePolicy` (lower than MinAllowed or higher that MaxAllowed). Used only as status indication, will not affect actual resource assignment.

    - **status.recommendation.containerRecommendations.upperBound**
      object

      Maximum recommended amount of resources. Observes `ContainerResourcePolicy`. Any resources allocated beyond this value are likely wasted. This value may be larger than the maximum amount of application is actually capable of consuming.

VerticalPodAutoscalerCheckpoint

Short names: vpacheckpoint

Scope: Namespaced

- v1
- v1beta2

VerticalPodAutoscalerCheckpoint is the checkpoint of the internal state of VPA that is used for recovery after recommender's restart.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More information in the documentation.

- **metadata**
  object
- **spec**
  object

  Specification of the checkpoint. More information in the documentation.

  - **spec.containerName**
    string

    Name of the checkpointed container.

  - **spec.vpaObjectName**
    string

    Name of the VPA object that stored VerticalPodAutoscalerCheckpoint. object.

- **status**
  object

  Data of the checkpoint.

  - **status.cpuHistogram**
    object

    Checkpoint of histogram for consumption of CPU.

    - **status.cpuHistogram.bucketWeights**
      object

      Map from bucket index to bucket weight.

    - **status.cpuHistogram.referenceTimestamp**
      string

      Reference timestamp for samples collected within this histogram.

    - **status.cpuHistogram.totalWeight**
      number

      Sum of samples to be used as denominator for weights from BucketWeights.

  - **status.firstSampleStart**
    string

    Timestamp of the fist sample from the histograms.

  - **status.lastSampleStart**
    string

    Timestamp of the last sample from the histograms.

  - **status.lastUpdateTime**
    string

    The time when the status was last refreshed.

  - **status.memoryHistogram**
    object

    Checkpoint of histogram for consumption of memory.

    - **status.memoryHistogram.bucketWeights**
      object

Map from bucket index to bucket weight.

- **status.memoryHistogram.referenceTimestamp**
  string

  Reference timestamp for samples collected within this histogram.

- **status.memoryHistogram.totalWeight**
  number

  Sum of samples to be used as denominator for weights from BucketWeights.

- **status.totalSamplesCount**
  integer

  Total number of samples in the histograms.

- **status.version**
  string

  Version of the format of the stored data.

Deprecated resource. Support for the resource might be removed in a later release.

VerticalPodAutoscalerCheckpoint is the checkpoint of the internal state of VPA that is used for recovery after recommender’s restart.

- **apiVersion**
  string

  APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More information in the documentation.

- **kind**
  string

  Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More information in the documentation.

    string

    Name of the checkpointed container.

  - **spec.vpaObjectName**
    string

    Name of the VPA object that stored VerticalPodAutoscalerCheckpoint. object.

- **status**
  object

  Data of the checkpoint.

  - **status.cpuHistogram**
    object

    Checkpoint of histogram for consumption of CPU.

    - **status.cpuHistogram.bucketWeights**
      object

      Map from bucket index to bucket weight.

    - **status.cpuHistogram.referenceTimestamp**
      string

      Reference timestamp for samples collected within this histogram.

    - **status.cpuHistogram.totalWeight**

number

Sum of samples to be used as denominator for weights from BucketWeights.

- **status.firstSampleStart**
  string

  Timestamp of the fist sample from the histograms.

- **status.lastSampleStart**
  string

  Timestamp of the last sample from the histograms.

- **status.lastUpdateTime**
  string

  The time when the status was last refreshed.

- **status.memoryHistogram**
  object

  Checkpoint of histogram for consumption of memory.

  - **status.memoryHistogram.bucketWeights**
    object

    Map from bucket index to bucket weight.

  - **status.memoryHistogram.referenceTimestamp**
    string

    Reference timestamp for samples collected within this histogram.

  - **status.memoryHistogram.totalWeight**
    number

    Sum of samples to be used as denominator for weights from BucketWeights.

- **status.totalSamplesCount**
  integer

  Total number of samples in the histograms.

- **status.version**
  string

  Version of the format of the stored data.

FAQ

> **i** The module lifecycle stage: General Availability
> The module has requirements for installation

How do I view the Vertical Pod Autoscaler recommendations?

You can view the VPA recommendations after the VerticalPodAutoscaler custom resource is created using the following command:

```
d8 k describe vpa my-app-vpa
```

The `status` will have the following parameters:

- `Target` — the optimal amount of resources for the Pod (within the resourcePolicy).
- `Lower Bound` — the minimum recommended amount of resources for the regular operation of the application.
- `Upper Bound` — the maximum recommended amount of resources. Most likely, the resources above this upper bound will never be used by the application.
- `Uncapped Target` — the recommended amount of resources based on the latest metrics (the history of resource usage is ignored).

How does Vertical Pod Autoscaler handle limits?

Example No. 1

The following example shows a VPA object:

```
---
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: test2
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: test2
  updatePolicy:
    updateMode: "Initial"
```

The VPA object contains a Pod with the following resources:

```
resources:
  limits:
    cpu: 2
  requests:
    cpu: 1
```

If a container uses all the CPU, and VPA recommends 1.168 CPU for that container, then the ratio between requests and limits will be 100%. In this case, when recreating the Pod, VPA will modify it and set the following resources:

```
resources:
  limits:
    cpu: 2336m
  requests:
    cpu: 1168m
```

Example No. 2

The following example shows a VPA object:

```
---
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: test2
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: test2
  updatePolicy:
    updateMode: "Initial"
```

The VPA object contains a pod with resources:

```
resources:
  limits:
    cpu: 1
  requests:
    cpu: 750m
```

If the request-to-limit ratio is 25% and VPA recommends 1.168 CPU for the container, VPA will change

the container resources as follows:

```
resources:
  limits:
    cpu: 1557m
  requests:
    cpu: 1168m
```

If you need to limit the maximum number of resources that can be allocated to container constraints, you should use `maxAllowed` in the VPA object specification or use the Limit Range of the Kubernetes object.

Examples

> **i**
> The module lifecycle stage: General Availability
> The module has requirements for installation

The module configuration

```
apiVersion: deckhouse.io/v1alpha1
kind: ModuleConfig
metadata:
  name: vertical-pod-autoscaler
spec:
  version: 1
  enabled: true
  settings:
    nodeSelector:
      node-role/system: ""
    tolerations:
    - key: dedicated.deckhouse.io
      operator: Equal
      value: system
```

The basic `VerticalPodAutoscaler` custom resource example

```
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: my-app-vpa
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: StatefulSet
    name: my-app
```

The advanced `VerticalPodAutoscaler` custom resource example

```
apiVersion: autoscaling.k8s.io/v1
kind: VerticalPodAutoscaler
metadata:
  name: my-app-vpa
spec:
  targetRef:
    apiVersion: "apps/v1"
    kind: Deployment
    name: my-app
  updatePolicy:
    updateMode: "InPlaceOrRecreate"
  resourcePolicy:
    containerPolicies:
    - containerName: hamster
      minAllowed:
        memory: 100Mi
        cpu: 120m
      maxAllowed:
        memory: 300Mi
        cpu: 350m
      mode: Auto
```
